Red Pepper, Ground, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Rosemary - Fresh, Raw		10-14 Days	4-6 Months	To store fresh rosemary: Wrap in a damp paper towel and place in a plastic bag in the refrigerator. To freeze fresh rosemary: (1) Wash, trim and chop the rosemary; (2) Allow to dry thoroughly; (3) Once dry, place in heavy-duty freezer bags or freeze in ice cube trays with a small amount of water, then transfer to freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Rosemary Leaves, Dried, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	1-3 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Rosemary, Crushed, Dried, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	1-3 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Sage - Fresh, Raw		10-14 Days	4-6 Months	To store fresh sage: Wrap in a damp paper towel and place in a plastic bag in the refrigerator. To freeze fresh sage: (1) Wash, trim and chop the sage; (2) Allow to dry thoroughly; (3) Once dry, place in heavy-duty freezer bags or freeze in ice cube trays with a small amount of water, then transfer to freezer bags.
Salt - Table	Keeps Indefinitely			The answer to the question "How long does salt last?" is a matter of quality, not safety, assuming proper storage conditions — when properly stored, a package of salt has an indefinite shelf life, even after it has been opened. To maximize the shelf life of salt for quality purposes, store in a cool dry area away from direct heat or sunlight; keep tightly closed when not in use. Is salt safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged — commercially packaged salt may carry a "Best By," "Best if Used By," "Best Before," or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the salt will remain at peak quality. How to tell if salt has gone bad? The shelf life of salt is indefinite, but if salt develops an off flavour or appearance, it should be discarded for quality purposes.
Sea Salt	Keeps Indefinitely			Store in cool, dry area. Salt has an indefinite shelf life.
Sesame Seed, Dried, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Taco Seasoning Mix, Dry - Unopened Or Opened	2-3 Years (Best Quality)			How long does a package of taco seasoning mix last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of taco seasoning mix store in a cool, dry area. How long does taco seasoning mix last at room temperature? Properly stored, a package of taco seasoning mix will generally stay at best quality for about 2-3 years at room temperature. To maximize the shelf life of taco seasoning mix, keep the package tightly closed at all times. Is taco seasoning mix safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged taco seasoning mix will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the taco seasoning mix will remain at peak quality. Storage time shown is for best quality only - after that, the taco seasoning mix's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if taco seasoning mix is bad or spoiled? The best way is to smell and look at the taco seasoning mix: if the taco seasoning mix develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Thyme - Fresh, Raw		10-14 Days	4-6 Months	To store fresh thyme: Wrap in a damp paper towel and place in a plastic bag in the refrigerator. To freeze fresh thyme: (1) Wash, trim and chop the thyme; (2) Allow to dry thoroughly; (3) Once dry, place in heavy-duty freezer bags or freeze in ice cube trays with a small amount of water, then transfer to freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Thyme Leaves, Dried, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	1-3 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. No, commercially packaged balsamic vinegar does not spoil, but the appearance and flavour may start to deteriorate over time — the storage time shown is for best quality only. Is cloudy balsamic vinegar safe to use? Yes: over time, balsamic vinegar may become cloudy - this is not harmful; the vinegar will still be safe to consume if it has been stored properly.

9 Drinks Shelf Life

These is the shelf life of most drinks, both pre-packaged and raw.

	Pantry	Refrigerator	Freezer	Food Tips
Almond Milk, Sold Unrefrigerated - Opened	3-4 weeks after date on package (Unopened)	7-10 Days		How long does shelf-stable almond milk last once opened? The precise answer depends to a large extent on storage conditions — keep opened shelf-stable almond milk almond milk that has been sold unrefrigerated) refrigerated and tightly closed. To maximize the shelf of opened shelf-stable almond milk, do not store it on the fridge door, as the temperature is too warm - the opened shelf-stable almond milk will last longer when stored in the main body of the refrigerator, in its original package. How long does opened shelf-stable almond milk last in the refrigerator? Shelf-stable almond milk that has been continuously refrigerated will keep for about 7 to 10 days after opening. How can you tell if opened shelf-stable almond milk is bad or spoiled? The best way is to smell and look at the shelf-stable almond milk: if the shelf-stable almond milk develops an off odor, flavour or appearance it should be discarded.

Apple Juice, Commercially Canned Or Bottled, Sold Unrefrigerated - Opened	18-24 Months (Best Quality) (Unopened)	7-10 Days	8-12 Months	How long does apple juice last once opened? The precise answer depends to a large extent on storage conditions — keep opened apple juice refrigerated and tightly closed. How long does opened apple juice last in the refrigerator? Apple juice that has been continuously refrigerated will keep for about 7 to 10 days after opening. To further extend the shelf life of opened apple juice, freeze it: to freeze apple juice, store in airtight container and leave at least 1/2 inch headspace at the top, as juice will expand when frozen. How long does apple juice last in the freezer? Properly stored, it will maintain best quality for about 8 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only — apple juice that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does apple juice last after being frozen and thawed? Apple juice that has been defrosted in the fridge can be kept for an additional 3 to 5 days in the refrigerator before using; apple juice that was thawed in the microwave or in cold water should be used immediately. How can you tell if apple juice is bad? If apple juice develops an off odor, flavour or appearance, or if mould appears, it should be discarded. Discard all apple juice from cans or bottles that are leaking, rusting, bulging or severely dented.
Apple Juice, Sold In Refrigerated Container - Unopened		1 week after date on package	8-12 Months	Keep refrigerated at all times. Consume or freeze juice before the number of days shown for refrigerator storage has elapsed. To freeze, store in airtight container and leave at least 1/2 inch headspace at the top, as juice will expand when frozen. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Apple Juice, Sold In Refrigerated Container - Opened		7-10 Days	8-12 Months	Keep refrigerated at all times. Once opened, consume or freeze product within the time shown for refrigeration, even if the date on package has not yet been reached. To freeze, store in airtight container and leave at least 1/2 inch headspace at the top, as juice will expand when frozen. Freezer time shown is for best quality - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Champagne - Opened Bottle		3-5 Days		Re-cork the champagne - if a stopper is not available, cover opening with plastic wrap and place a rubber band around the bottle neck to seal plastic tightly. Depending on the champagne variety and method used to re-close the bottle, opened champagne may go flat before the time shown above, but will remain safe to drink; consuming the champagne as soon as possible after opening will result in the best taste and appearance. Keep refrigerated until ready to drink.
Coffee — Freshly Brewed		1 Day	3-4 Months	For best results, store coffee in vacuum storage bottle or thermal carafe. To refrigerate, store coffee in tightly covered container. To freeze, pour into airtight plastic containers or pour coffee into ice cube trays; once cubes are frozen, transfer to a heavy-duty freezer bag.
Coffee, Ground, Commercially Canned Or Bagged, Vacuum-Packed - Opened	1-2 Weeks 1 Year (Unopened)		1 month (best quality)	How long does ground coffee last once opened? The precise answer depends to a large extent on storage conditions - store in cool, dry area and keep package tightly sealed at all times. To maximize the shelf life of ground coffee after opening, transfer the ground coffee to a canister that blocks out light and has an airtight seal. How long does ground coffee last at room temperature? Properly stored, an opened package of ground coffee will generally stay at best quality for about 1 to 2 weeks at room temperature, assuming it has been properly stored. Should ground coffee be stored in the fridge? No, you should not refrigerate ground coffee, as the temperature fluctuations will affect the taste and flavour of the coffee. Should you freeze ground coffee? Frozen ground coffee may lose some of its flavour, so freezing is recommended only for coffee that cannot be used up within two weeks of opening the package. Freeze ground coffee in tightly sealed original package or place inside covered airtight container. How long does ground coffee last in the freezer? Properly stored, it will maintain best quality for about 1 month, but will remain safe beyond that time. The freezer time shown is for best quality only - ground coffee that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How can you tell if ground coffee is bad or spoiled? Ground coffee typically loses flavour over time and develops a stale taste - if coffee develops an off odor, flavour or appearance, it should be discarded for quality purposes; if mould appears, discard the ground coffee.
Diet Soda / Soft Drinks (Including Diet Cola, Ginger Ale, Root Beer), Commercially Canned Or Bottled — Opened	3-6 months after date on package (Unopened)	1-4 Days 3-6 months after date on package (Unopened)		How long do diet soft drinks last once opened? The precise answer depends to a large extent on storage conditions — keep opened diet soft drinks refrigerated and tightly closed. How long do diet soft drinks last in the refrigerator once opened? Diet soft drinks that have been continuously refrigerated will keep at best quality for about 1 to 4 days after opening. Are opened diet soft drinks safe to drink after the "expiration" date on the bottle? Yes, provided they are properly stored and the bottle or can is undamaged - commercially packaged diet soft drinks will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the diet soft drinks will remain at peak quality. How can you tell if opened diet soft drinks are bad or spoiled? After opening, commercially manufactured diet soft drinks will start to become flat and lose flavour; if the diet soft drinks develop an off odor, flavour or appearance they should be discarded. Discard all diet soft drinks from cans or bottles that are leaking, rusting, bulging or severely dented.
Energy Drinks, Commercially Canned Or Bottled, Sold Unrefrigerated - Opened	6-9 months after date on package (Unopened)	2-4 Days		How long do energy drinks last once opened? The precise answer depends to a large extent on storage conditions — keep opened energy drinks refrigerated and tightly closed. How long do energy drinks last in the refrigerator once opened? Energy drinks that have been continuously refrigerated will keep at best quality for about 2 to 4 days after opening. Are opened energy drinks safe to drink after the "expiration" date on the bottle? Yes, provided they are properly stored and the bottle or can is undamaged - commercially packaged energy drinks will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the energy drinks will remain at peak quality. How can you tell if opened energy drinks are bad or spoiled? If energy drinks develop an off odor, flavour or appearance they should be discarded. Discard all energy drinks from cans or bottles that are leaking, rusting, bulging or severely dented.
Iced Tea (Ice Tea), Ready To Drink, Sold Unrefrigerated, Commercially Bottled Or Canned — Unopened	18-24 Months (Best Quality)			How long does unopened iced tea last? The precise answer to the question depends to a large extent on storage conditions - store unopened bottles of iced tea in a cool, dark area. To extend the shelf life of unopened iced tea, keep unopened iced tea away from direct sources of heat or light. How long does unopened iced tea last at room temperature? Properly stored, unopened iced tea will generally stay at best quality for about 18-24 months when stored at room temperature, although it will usually remain safe to drink after that. Is unopened iced tea safe to drink after the "expiration" date on the bottle? Yes, provided it is properly stored and the bottle is undamaged - commercially packaged iced tea will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the unopened iced tea will remain at peak quality. Storage times shown are for best quality only - after that, the unopened iced tea's colour or taste may change, but in most cases, it will still be safe to consume if it has been stored properly and the bottle is not damaged. How to tell if iced tea is bad? If iced tea develops an off odor, flavour or appearance, it should be discarded.
Instant Coffee, Commercially Bottled - Opened	12-18 months (Best Quality) 18-24 months (Best Quality) (Unopened)			How long does a package of opened instant coffee last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened instant coffee store in a cool, dry area and keep tightly closed. How long does opened instant coffee last at room temperature? Properly stored, an opened package of instant coffee will generally stay at best quality for about 12 to 18 months at room temperature. Storage time shown is for best quality only - after that, the coffee's texture, colour or flavour may change, but in most cases, the opened instant coffee will still be safe to consume if it has been stored properly and shows no signs of spoilage. Is opened instant coffee safe to use after the "expiration" date on the package? Yes, if properly stored - commercially packaged coffee will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the coffee will remain at peak quality. How can you tell if instant coffee is bad or spoiled? Instant coffee typically loses flavour over time and develops a stale taste - if coffee develops an off odor, flavour or appearance or if mould appears, it should be discarded.
Juice Boxes, Drink Boxes, Sold Unrefrigerated — Opened	12-18 Months (Unopened) (Best Quality)	5-7 Days	8-12 Months	How long do juice boxes last once opened? The precise answer depends to a large extent on storage conditions — keep opened juice boxes refrigerated and tightly closed. How long do opened juice boxes last in the refrigerator? Juice boxes that have been continuously refrigerated will keep for about 5 to 7 days after opening. To further extend the shelf life of juice boxes, freeze: pour juice into an airtight container and leave at least 1/2 inch headspace at the top, as juice will expand when frozen. How long do juice boxes last in the freezer? Properly stored, the juice will maintain best quality for about 8 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only — juice boxes that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does juice last after being frozen and thawed? Juice that has been defrosted in the fridge can be kept for an additional 3 to 5 days in the refrigerator before using; juice that was thawed in the microwave or in cold water should be used immediately. How can you tell if juice boxes are bad or spoiled? The best way is to smell and look at the juice: if the juice develops an off odor, flavour or appearance, or if mould appears, it should be discarded. Discard all juice from juice boxes that are leaking, bulging or severely dented.
Lemon & Lime Juice — Freshly Squeezed		2-3 Days	3-4 Months	How long does freshly squeezed lemon juice last? The precise answer depends to a large extent on storage conditions — keep freshly squeezed lemon juice refrigerated. To maximize the shelf life of freshly squeezed lemon juice, refrigerate in a covered glass or plastic container. How long does freshly squeezed lemon juice last in the refrigerator? Freshly squeezed lemon juice that has been continuously refrigerated will keep for about 2 to 3 days. To further extend the shelf life of freshly squeezed lemon juice, freeze it: to freeze freshly squeezed lemon juice, store in airtight container and leave at least 1/2 inch headspace at the top, as juice will expand when frozen. How long does freshly squeezed lemon juice last in the freezer? Properly stored, it will maintain best quality for about 3 to 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only — freshly squeezed lemon juice that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does freshly squeezed lemon juice last after being frozen and thawed? Freshly squeezed lemon juice that has been defrosted in the fridge can be kept for an additional 2 to 3 days in the refrigerator before using; freshly squeezed lemon juice that was thawed in the microwave or in cold water should be used immediately. How can you tell if freshly squeezed lemon juice is bad or spoiled? The best way is to smell and look at the freshly squeezed lemon juice: if the freshly squeezed lemon juice develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Liquid Breakfast Drink — Canned, Unopened	6 Months			Store in cool, dry area. Discard all food from cans that are leaking, rusting, bulging or severely dented. Storage time shown is for best quality only — after that, the drink's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly. “Best By,” “Best if Used By,” and “Use By” dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the unopened drink will still be safe to consume after that date, as long as it has been stored properly and the package is not damaged.
Orange Juice — Freshly Squeezed		2-3 Days	3-4 Months	How long does freshly squeezed orange juice last? The precise answer depends to a large extent on storage conditions — keep freshly squeezed orange juice refrigerated. To maximize the shelf life of freshly squeezed orange juice, refrigerate in a covered glass or plastic container. How long does freshly squeezed orange juice last in the refrigerator? Freshly squeezed orange juice that has been continuously refrigerated will keep for about 2 to 3 days. To further extend the shelf life of freshly squeezed orange juice, freeze it: to freeze freshly squeezed orange juice, store in airtight container and leave at least 1/2 inch headspace at the top, as juice will expand when frozen. How long does freshly squeezed orange juice last in the freezer? Properly stored, it will maintain best quality for about 3 to 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only — freshly squeezed orange juice that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does freshly squeezed orange juice last after being frozen and thawed? Freshly squeezed orange juice that has been defrosted in the fridge can be kept for an additional 2 to 3 days in the refrigerator before using; freshly squeezed orange juice that was thawed in the microwave or in cold water should be used immediately. How can you tell if freshly squeezed orange juice is bad or spoiled? The best way is to smell and look at the freshly squeezed orange juice: if the freshly squeezed orange juice develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Orange Juice, Commercially Canned Or Bottled, Sold Unrefrigerated — Opened	12-18 Months (Unopened)	5-7 Days	8-12 Months	Refrigerate after opening. Once opened, consume or freeze product within the time shown for refrigeration, even if the "Best By," "Best if Used By," or "Use By" date has not yet been reached. Freeze in airtight container and leave at least 1/2 inch headspace at the top, as juice will expand when frozen. Freezer time shown is for best quality — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Orange Juice, Sold In Refrigerated Carton Or Bottle - Unopened		1 week after date on package	8-12 Months	How long does unopened orange juice last? The precise answer to that question depends to a large extent on storage conditions - to maximize the shelf life of unopened orange juice, keep it refrigerated at all times. How long does unopened orange juice last in the fridge? Unopened orange juice will generally stay at best quality for about 1 week after the date on the package, assuming it has been continuously refrigerated. To further extend the shelf life of orange juice, freeze it: to freeze orange juice, store in airtight container and leave at least 1/2 inch headspace at the top, as orange juice will expand when frozen. How long does orange juice last in the freezer? Properly stored, it will maintain best quality for about 8 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only — orange juice that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does orange juice last after being frozen and thawed? Orange juice that has been defrosted in the fridge can be kept for an additional 3 to 5 days in the refrigerator before using; orange juice that was thawed in the microwave or in cold water should be used immediately. How can you tell if opened orange juice is bad or spoiled? The best way is to smell and look at the orange juice: if the orange juice develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Orange Juice, Sold In Refrigerated Carton Or Bottle — Opened		7-10 Days	8-12 Months	How long does orange juice last once opened? The precise answer depends to a large extent on storage conditions — keep opened orange juice refrigerated and tightly closed. How long does opened orange juice last in the refrigerator? Orange juice that has been continuously refrigerated will keep for about 7 to 10 days after opening. To further extend the shelf life of opened orange juice, freeze it: to freeze orange juice, store in airtight container and leave at least 1/2 inch headspace at the top, as juice will expand when frozen. How can you tell if opened orange juice is bad or spoiled? The best way is to smell and look at the orange juice: if the orange juice develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Pineapple Juice, Commercially Canned Or Bottled, Sold Unrefrigerated — Opened	12-18 Months (Unopened)	7-10 Days	8-12 Months	How long does pineapple juice last once opened? The precise answer depends to a large extent on storage conditions — keep opened pineapple juice refrigerated and tightly closed. How long does opened pineapple juice last in the refrigerator? Pineapple juice that has been continuously refrigerated will keep for about 7 to 10 days after opening. To further extend the shelf life of opened pineapple juice, freeze it: to freeze pineapple juice, store in airtight container and leave at least 1/2 inch headspace at the top, as juice will expand when frozen. How long does pineapple juice last in the freezer? Properly stored, it will maintain best quality for about 8 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only — pineapple juice that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does pineapple juice last after being frozen and thawed? Pineapple juice that has been defrosted in the fridge can be kept for an additional 3 to 5 days in the refrigerator before using; pineapple juice that was thawed in the microwave or in cold water should be used immediately. How can you tell if pineapple juice is bad? If pineapple juice develops an off odor, flavour or appearance, or if mould appears, it should be discarded. Discard all pineapple juice from cans or bottles that are leaking, rusting, bulging or severely dented.

Regular Soda / Soft Drinks (All Flavours, Including Cola, Lemon-Lime, Ginger Ale, Root Beer) Commercially Canned Or Bottled — Opened	6-9 months after date on package (Unopened)	2-4 Days 6-9 months after date on package (Unopened)		How long do soft drinks last once opened? The precise answer depends to a large extent on storage conditions — keep opened soft drinks refrigerated and tightly closed. How long do soft drinks last in the refrigerator once opened? Soft drinks that have been continuously refrigerated will keep at best quality for about 2 to 4 days after opening. Are opened soft drinks safe to drink after the "expiration" date on the bottle? Yes, provided they are properly stored and the bottle or can is undamaged - commercially packaged soft drinks will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the soft drinks will remain at peak quality. How can you tell if opened soft drinks are bad or spoiled? After opening, commercially manufactured soft drinks will start to become flat and lose flavour; if the soft drinks develop an off odor, flavour or appearance they should be discarded. Discard all soft drinks from cans or bottles that are leaking, rusting, bulging or severely dented.
Rum, Commercially Bottled - Unopened Or Opened Bottle	Keeps Indefinitely			The answer to the question How long does rum last? is a matter of quality, not safety, assuming proper storage conditions - when properly stored, a bottle of rum has an indefinite shelf life, even after it has been opened. To maximize the shelf life of rum for quality purposes, store in a cool dry area away from direct heat or sunlight; keep tightly closed when not in use. Once a bottle of rum is opened, the contents may begin to evaporate slowly and some flavour may be lost over time, but the rum will remain safe to consume if it has been stored properly. How to tell if rum has gone bad? The shelf life of rum is indefinite, but if rum develops an off odor, flavour or appearance, it should be discarded for quality purposes.
Sparkling Water, Commercially Bottled — Opened	12-18 months (Best Quality) (Unopened)	2-3 Days		How long does sparkling water last once opened? The precise answer depends to a large extent on storage conditions — keep opened sparkling water refrigerated and tightly closed. How long does sparkling water last in the refrigerator once opened? Sparkling water that has been continuously refrigerated will keep at best quality for about 2 to 3 days after opening. Is opened sparkling water safe to drink after the "expiration" date on the bottle? Yes, provided it is properly stored and the bottle is undamaged - commercially packaged sparkling water will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the sparkling water will remain at peak quality. How can you tell if opened sparkling water is bad or spoiled? After opening, commercially manufactured sparkling water will start to become flat; if the sparkling water develops an off odor, flavour or appearance it should be discarded. Discard all sparkling water from cans or bottles that are leaking, rusting, bulging or severely dented.
Tea Bags, Commercially Packaged — Unopened Or Opened	18-14 months (best quality)			How long do tea bags last? The precise answer depends to a large extent on storage conditions — to maximize the shelf life of tea bags (including black, green, herbal and oolong), store in a cool, dark cupboard, away from direct heat or sunlight. How long do tea bags last at room temperature? Properly stored, tea bags will generally stay at best quality for about 18 to 24 months. To maximize the shelf life of tea bags, and to better retain flavour and potency, store in airtight containers. Are tea bags safe to use after the "expiration" date on the package? Yes, provided they are properly stored and the package is undamaged — commercially packaged tea bags will typically carry a "Best By," "Best if Used By," "Best Before," or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the tea bags will remain at peak quality. Do tea bags ever spoil? No, commercially packaged tea bags do not spoil, but will start to lose potency and flavour over time — the storage time shown is for best quality only. Should you store tea bags in the refrigerator or freezer? Storing tea bags in the fridge or freezer is not recommended, since condensation can result, which will harm the taste and flavour of the tea. How can you tell if tea bags are still good? To test whether tea bags are still good, brew a cup of tea for at least 3 to 5 minutes - if the aroma is weak and the flavour is not obvious, the tea bags should be replaced.
Water, Commercially Bottled — Opened	Keeps Indefinitely (Unopened)	4-6 Days		How long does bottled water last once opened? The precise answer depends to a large extent on storage conditions — keep opened bottled water refrigerated and tightly closed. How long does bottled water last in the refrigerator once opened? Bottled water that has been continuously refrigerated will keep at best quality for about 4 to 6 days after opening. Is opened bottled water safe to drink after the "expiration" date on the bottle? Yes, provided it is properly stored and the bottle is undamaged - commercially packaged bottled water will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the bottled water will remain at peak quality. How can you tell if opened bottled water is bad or spoiled? If the bottled water develops an off odor, flavour or appearance it should be discarded.
Whiskey (Whisky), Commercially Bottled - Unopened Or Opened Bottle	Keeps Indefinitely			The answer to the question ? How long does whiskey last? is a matter of quality, not safety, assuming proper storage conditions - when properly stored, a bottle of whiskey (whisky) has an indefinite shelf life, even after it has been opened. To maximize the shelf life of whiskey for quality purposes, store in a cool dry area away from direct heat or sunlight; keep tightly closed when not in use. Once a bottle of whiskey is opened, the contents may begin to evaporate slowly and some flavour may be lost over time, but the whiskey will remain safe to consume if it has been stored properly. How to tell if whiskey has gone bad? The shelf life of whiskey is indefinite, but if whiskey develops an off odor, flavour or appearance, it should be discarded for quality purposes.
Wine, Red - Opened Bottle	3 years and up, depending on vintage (Unopened)	3-5 Days	4-6 Months	How long does red wine last once opened? The precise answer to that question depends to a large extent on storage conditions - re-cork the wine as soon as finished drinking. Should an opened bottle of red wine be refrigerated? Yes, refrigerating an opened bottle of red wine will help keep it fresher than storing it at normal room temperature; take the red wine out of the fridge about an hour before serving to bring back to room temperature. How long does opened red wine last in the refrigerator? An opened bottle of red wine will usually keep for about 3 to 5 days in the refrigerator (be sure to re-cork it first). If a cork or stopper is not available for the opened bottle of red wine, cover the opening with plastic wrap and place a rubber band around the bottle neck to seal plastic tightly. In general, opened bottles of full-bodied red wines such as cabernet sauvignon, merlot and syrah will maintain their flavour longer than lighter varieties such as pinot noir. Can you freeze red wine? Yes, leftover red wine may be frozen and used later for cooking - freeze the red wine in airtight containers or pour wine into ice cube trays; once the red wine is frozen, transfer cubes to a heavy-duty freezer bag. How long does red wine last in the freezer? Properly stored, red wine will maintain best quality for about 6 months, but will remain safe beyond that time; red wine that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if an opened bottle of red wine is bad? The best way is to smell and look at the red wine: red wine that has gone bad often develops an off smell and a brownish appearance.
Wine, White - Opened Bottle	3 years and up, depending on vintage (Unopened)	3-5 Days	4-6 Months	How long does white wine last once opened? The answer to that question depends to a large extent on storage conditions - re-cork the wine as soon as finished drinking. Keep an opened bottle of white wine refrigerated until ready to drink. If a cork or stopper is not available for the opened bottle of white wine, cover the opening with plastic wrap and place a rubber band around the bottle neck to seal plastic tightly. Leftover white wine may be frozen and used later for cooking - freeze the white wine in airtight containers or pour wine into ice cube trays; once the white wine is frozen, transfer cubes to a heavy-duty freezer bag. How long does white wine last in the freezer for safety purposes? The freezer time shown is for best quality only -foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if an opened bottle of white wine is bad? The best way is to smell and look at the white wine: white wine that has gone bad often develops an off smell and a yellowish-brown appearance.

10 Condiments Shelf Life

These is the shelf life of most condiments, both pre-packaged and raw.

	Pantry	Refrigerator	Freezer	Food Tips
Barbecue Sauce (Bbq Sauce), Commercially Bottled - Opened	1 Month (Opened) 1 Year (Unopened) (Best Quality)	6-9 months (best quality)		How long does BBQ sauce last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened BBQ sauce, store in a cool, dark place and keep tightly covered at all times. How long does an opened bottle of BBQ sauce last at normal room temperature? Opened BBQ sauce will usually keep well for 1 month when stored in the pantry. To extend the shelf life of opened barbecue sauce, refrigerate it. How long does opened BBQ sauce last in the refrigerator? BBQ sauce that has been continuously refrigerated will generally stay at best quality for about 6 to 9 months. Is opened BBQ sauce safe to use after the "expiration date"? Yes, provided it has been stored properly, the bottle is undamaged, and there are no signs of spoilage - commercially bottled barbecue sauce will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the BBQ sauce will remain at peak quality. The storage time shown for opened BBQ sauce is for best quality only - after that, the BBQ sauce's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been kept continuously refrigerated, the bottle is undamaged, and there are no signs of spoilage. How can you tell if opened BBQ sauce is bad or spoiled? The best way is to smell and look at the BBQ sauce: if the BBQ sauce develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Ketchup (Tomato Sauce), Commercially Bottled - Opened	1 Month 1 Year (Unopened) (Best Quality)	9-12 months (best quality)		How long does ketchup last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened ketchup, store in a cool, dark place and keep tightly covered at all times. How long does an opened bottle of ketchup last at normal room temperature? Opened ketchup will usually keep well for 1 month when stored in the pantry. To extend the shelf life of opened ketchup, refrigerate it. How long does opened ketchup last in the refrigerator? Ketchup that has been continuously refrigerated will generally stay at best quality for about 9 to 12 months. Is opened ketchup safe to use after the "expiration date"? Yes, provided it has been stored properly, the bottle is undamaged, and there are no signs of spoilage - commercially bottled ketchup will typically carry a "Best By," "Best if Used By," " Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the ketchup will remain at peak quality. The storage time shown for opened ketchup is for best quality only - after that, the ketchup's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been kept continuously refrigerated, the bottle is undamaged, and there are no signs of spoilage. How can you tell if opened ketchup is bad or spoiled? The best way is to smell and look at the ketchup: if the ketchup develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Mayonnaise, Commercially Packaged - Opened	3-4 months after date on package (Unopened)	2-3 months after date on package		How long does mayonnaise last once opened? The precise answer depends to a large extent on storage conditions - keep opened mayonnaise refrigerated and tightly covered at all times. How long does opened mayonnaise last in the refrigerator? Mayonnaise that has been continuously refrigerated will generally stay at best quality for about 2 to 3 months after the "Best By" date on the package. How long can opened mayonnaise be left at room temperature? Bacteria grow rapidly at temperatures between 40°F and 140 °F; opened mayonnaise should be discarded if left out for more than 8 hours at room temperature. Is opened mayonnaise safe to use after the "expiration date" on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged mayonnaise will typically carry a " Best By," "Best if Used By," " Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the mayonnaise will remain at peak quality. How can you tell if mayonnaise is bad or spoiled? The best way is to smell and look at the mayonnaise: if mayonnaise develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Mustard, Commercially Bottled, All Types (Including Yellow, Dijon, Whole Grain) - Opened	1-2 Months 2 Years (Unopened) (Best Quality)	12-18 months (best quality)		How long does mustard last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened mustard, store in a cool, dark place and keep tightly covered at all times. How long does an opened bottle of mustard last at normal room temperature? Opened mustard will usually keep well for 1 to 2 months when stored in the pantry. To extend the shelf life of opened mustard, refrigerate it. How long does opened mustard last in the refrigerator? Mustard that has been continuously refrigerated will generally stay at best quality for about 12-18 months. Is opened mustard safe to use after the "expiration date"? Yes, provided it has been stored properly, the bottle is undamaged, and there are no signs of spoilage - commercially bottled mustard will typically carry a "Best By," "Best if Used By," "Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the mustard will remain at peak quality. The storage time shown for opened mustard is for best quality only - after that, the mustard's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been kept continuously refrigerated, the bottle is undamaged, and there are no signs of spoilage. How can you tell if opened mustard is bad or spoiled? The best way is to smell and look at the mustard: if the mustard develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Olive Oil, Commercially Bottled - Opened	18-24 Months 2 Years (Unopened)	18-24 Months 2 Years (Unopened)		How long does olive oil last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened olive oil, store in a cool, dark place and keep tightly covered at all times. How long does an opened bottle of olive oil last at normal room temperature? Opened olive oil will usually keep for 18 to 24 months when stored in the pantry. Should olive oil be refrigerated? An opened bottle of olive oil can be refrigerated to extend its shelf life - refrigeration is recommended in hot, humid environments. Refrigerating an opened bottle of olive oil may cause the oil to become cloudy and solidify, but this will not affect the quality or flavour - once the olive oil is brought back to room temperature, it will return to its normal consistency and colour. Is an opened bottle of olive oil safe after the Use By or Best By date? Yes: "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the opened bottle of olive oil will still be safe to consume after that date, as long as it has been stored properly. How can you tell if an opened bottle of olive oil has gone bad? To determine if oil is still suitable for use, smell and taste it: If the oil has developed an off odor, flavour or appearance, it should be discarded for quality purposes.
Pesto, Sold In Refrigerated Container — Opened		3-4 Days	1-2 Months	Keep refrigerated. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Pesto, Sold In Refrigerated Container - Unopened		3-4 Weeks or date on carton	1-2 Months	Keep refrigerated. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Relish, Commercially Jarred, All Types (Including Hotdog, Hamburger, Sweet, India, Pickle, Piccalilli) - Opened	2 Years (Best Quality) (Unopened)	1 Year (best quality)		How long does relish last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened relish (including hotdog, hamburger, sweet, India, pickle, piccalilli), keep it refrigerated and tightly covered. How long does opened relish last in the refrigerator? Relish that has been continuously refrigerated will generally stay at best quality for about 1 year. Is opened relish safe to use after the expiration date on the jar? Yes, provided it has been stored properly, the jar is undamaged, and there are no signs of spoilage - commercially jarred relish will typically carry a Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the relish will remain at peak quality. The storage time shown for opened relish is for best quality only - after that, the relish's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been kept continuously refrigerated, the jar is undamaged, and there are no signs of spoilage. How can you tell if opened relish is bad or spoiled? The best way is to smell and look at the relish: if the relish develops an off odor, flavour or appearance, or if mould appears, it should be discarded.

Condiments Shelf Life

Soup Mix, Dry, Commercially Packaged (All Types, Including Onion, Vegetable, Chicken Noodle) — Unopened Or Opened	18-24 Months (Best Quality)			
Soy (Soya) Sauce, Commercially Bottled - Opened	3 Years (Best Quality)	2 years (best quality)		How long does soy sauce last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened soy sauce (or soya sauce), refrigerate and keep tightly covered at all times. How long does opened soy sauce last in the refrigerator? Soy sauce that has been continuously refrigerated will generally stay at best quality for about 2 years. Is opened soy sauce safe to use after the "expiration date"? Yes, provided it has been stored properly, the bottle is undamaged, and there are no signs of spoilage - commercially bottled soy sauce will typically carry a "Best By," "Best if Used By," "Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the soy sauce will remain at peak quality. The storage time shown for opened soy sauce is for best quality only - after that, the soy sauce's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been kept continuously refrigerated, the bottle is undamaged, and there are no signs of spoilage. How can you tell if opened soy sauce is bad or spoiled? The best way is to smell and look at the soy sauce: if the soy sauce develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Spaghetti Sauce/ Pasta Sauce, Tomato-Based (Including Marinara Sauce), Commercially Canned Or Bottled - Opened	2-5 Years (Unopened)	7-10 Days	4-6 Months	How long does spaghetti sauce last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened spaghetti sauce, keep refrigerated and keep tightly covered at all times. How long does opened spaghetti sauce last in the refrigerator? Spaghetti sauce that has been continuously refrigerated will generally keep for about 7 to 10 days. For best quality, do not store spaghetti sauce in opened metal can - refrigerate in covered glass or plastic container after opening. To further extend the shelf life of opened spaghetti sauce, freeze in covered airtight containers or heavy-duty freezer bags. How long does spaghetti sauce last in the freezer? Properly stored, it will maintain best quality for about 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only — spaghetti sauce that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does spaghetti sauce last at room temperature? If kept at temperatures above 40 °F, spaghetti sauce will rapidly develop signs of spoilage; spaghetti sauce should be discarded if left for more than 4 hours at room temperature. How can you tell if spaghetti sauce has gone bad? If spaghetti sauce develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Spaghetti / Pasta Sauce, Tomato-Based (Including Marinara Sauce) - Homemade		3-4 Days	4-6 Months	How long does cooked, homemade pasta sauce last in the fridge or freezer? The precise answer to that question depends to a large extent on storage conditions - refrigerate pasta sauce within two hours of cooking. To maximize the shelf life of cooked pasta sauce for safety and quality, refrigerate the pasta sauce promptly in covered airtight containers. Properly stored, cooked pasta sauce will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked pasta sauce, freeze it; freeze in covered airtight containers or heavy-duty freezer bags. How long does cooked pasta sauce last in the freezer? Properly stored, it will maintain best quality for about 4 to 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked pasta sauce that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked pasta sauce last after being frozen and thawed? Cooked pasta sauce that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; pasta sauce that was thawed in the microwave or in cold water should be eaten immediately. How long can cooked pasta sauce be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked pasta sauce should be discarded if left for more than 2 hours at room temperature. How to tell if cooked pasta sauce is bad? If cooked pasta sauce develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Spaghetti Sauce / Pasta Sauce, Tomato-Based (Including Marinara Sauce), Commercially Canned Or Bottled - Unopened	12-18 Months			Store unopened spaghetti sauce in cool, dry area. Storage time shown is for best quality only - after that, the unopened spaghetti sauce's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly. If spaghetti sauce develops an off odor, flavour or appearance, it should be discarded for quality purposes. "Best By", "Best if Used By", and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the unopened spaghetti sauce will still be safe to consume after that date, as long as it has been stored properly and the package is not damaged.
Vegetable Oil Sprays, Commercially Canned — Unopened Or Opened	2 Years			Store in cool, dry area. Storage time shown is for best quality only — after that, the product's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly. If spray develops an off odor, flavour or appearance, it should be discarded for quality purposes. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the spray will still be safe to consume after that date, as long as it has been stored properly and the package is not damaged.
Worcestershire Sauce, Commercially Bottled - Opened	4-5 Years (Unopened) (Best Quality)	3 Years (Best Quality)		How long does Worcestershire sauce last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened Worcestershire sauce, refrigerate and keep tightly covered at all times. How long does opened Worcestershire sauce last in the refrigerator? Worcestershire sauce that has been continuously refrigerated will generally stay at best quality for about 3 years. Is opened Worcestershire sauce safe to use after the "expiration date"? Yes, provided it has been stored properly, the bottle is undamaged, and there are no signs of spoilage - commercially bottled Worcestershire sauce will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the Worcestershire sauce will remain at peak quality. The storage time shown for opened Worcestershire sauce is for best quality only - after that, the Worcestershire sauce's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been kept continuously refrigerated, the bottle is undamaged, and there are no signs of spoilage. How can you tell if opened Worcestershire sauce is bad or spoiled? The best way is to smell and look at the Worcestershire sauce: if the Worcestershire sauce develops an off odor, flavour or appearance, or if mould appears, it should be discarded.

Field Dressing

How to bleed, skin, gut and prepare wild game

"Confucis say: butcher who back into meat grinder get a little behind in his orders."
Unknown

Introduction

This section outlines how to butcher and prepare all types of meats caught in the wild.

Purpose	The aim of FIELD DRESSING is to provide step-by-step instructions on how to bleed, gut and skin animals you've caught in preparation for consumption. It also includes details on what animals and insects you shouldn't eat and what parts of animals to avoid.
Lost?	● For information on killing animals humanely see the HUNTING section. ● If you want a list of recipes, see the RECIPES section. ● For the cooking of food, see the COOKING section. ● If you're looking for eating all kinds of wild and foraged foods as well as the wild food edibility test, see the PLANTS section. ● If you're looking for the food groups, see the HEALTH section. ● If you want to know how to properly prepare wild game for consumption, see the FIELD DRESSING section. ● For a list of recommended foods and food storage, see the FOOD section.

Contents

1 Insects

Subheadings

1 Insects to Avoid

- Don't eat brightly coloured bugs.
- Avoid hairy bugs - they may have stingers.
- Avoid bugs with a potent smell.

2 Beetle

Some species of beetles are edible, although a large portion of them are brightly coloured and are potentially toxic. Even the edible ones have a tendency to be extremely bitter and distasteful.

Preparation
o

3 Stinkbug

Preparation
Rid them of their smell by soaking in warm water for 10 minutes then cook very well in a dry pan. They can live a week after being boiled.

4 Butterfly & Moth

5 Cricket & Grasshopper

Crickets and grasshoppers are a delicacy in many places, especially Mexico where they are often fried with chilli powder, garlic, and lime juice. They're sold as street food in many parts of Mexico and I thoroughly enjoyed them on my many trips there. They also have a high risk of parasites though, so always cook them through.

Preparation
Pull off their heads and the entrails should come with it. Entrails are edible but to reduce parasite transmission always cook before eating.

6 Scorpion

Scorpions can also be eaten so long as you are careful not to get stung. They are usually best deep fried or roasted over a fire.

Preparation
Roast over fire until well browned.

7 Spider

Tarantula's in particular are eaten all over southeast Asia as well as the Amazon basin in south America. Cambodia serves tarantulas that are gathered in rice patties and deep fried in a crunchy sweet batter. The flavour is fairly enjoyable.

Preparation
Remove hair and don't eat the fangs.

8 Worm

Earth worms in particular are very high in protein. The main concern with earthworms is parasites, so be sure to cook them before ingesting them.

Preparation
Can be eaten raw but it's better to cook them. Skewer them and cook over an open flame until crispy.

9 Grub

Grubs are usually the larva of beetles and other winged insects. They can often be found in dead/punky wood. They can be eaten raw or cooked, but are much better cooked. Most grubs have a tendency to be bitter before they're cooked.

10 Mealworm

Mealworms can be easily obtained at pet stores or from farms that sell online. The ease with which they can be obtained combined with their mild nutty flavour makes them the perfect choice for beginning insect eaters. They taste just like a nestle crunch bar when toasted in a pan and dipped in melted chocolate.

11 Caterpillar

	Preparation Cook well. May be toxic, research the type first.

12 Bee & Wasp

Bees and wasps are eaten in many parts of Asia, including China and Japan. They are usually deep fried in a sweet sauce and eaten with rice or noodles.	**Preparation** Cut off the stingers and cook well.

13 Ant

	Preparation Catch and boil for 6 minutes which neutralizes the body acids. If you eat them raw, ensure they are dead first.

14 Termite

Much like ants, termites live in huge social colonies. They may be small, but in a colony, they can provide quite a bit of food. Termites are eaten all through Africa and Australia. I think they taste fairly good and nutty when toasted in a pan.	**Preparation** Roast them in a dry pan.

15 Snail & Slug

Snails and slugs are notorious carriers of pathogens and parasites and require processing to be considered safe for consumption. First gut them, then char them over a fire until they tasted like burnt bacon. The amount of meat you get per slug isn't worth the effort. However, special snails are eaten as escargot. They are usually oven-roasted in garlic butter sauce and can be quite pleasant when done properly. Usually the snails need to be fed lettuce for a few days to make sure they haven't ingested anything harmful to humans.	**Preparation** Remove Shell and cook thoroughly. Likely they have fed on poisonous plants so keep in a container for a day until the toxins diminish.

2 Small Game

Subheadings

1. Fish	**2. Bird**	**3. Rabbits**	**4. Turkey**
5. Duck	**6. Chicken**		

1 Fish

Killing Strike the head with a heavy object separating it. Can also cut the spinal cord and head with a knife. Fish begin multiplying bacteria immediately, keep it cold.	**Gutting & Cleaning** 1. Use a knife to remove scales underwater. 2. Insert knife shallowly at the tailfin and slice to gills. 3. Remove entrails and gills. 4. Gouge out kidneys. 5. Rinse stomach cavity.	**Filleting** 1. Cut down to the backbone just behind the fish's head, then turn the knife and cut down towards the tail, repeat on other side. 2. Remove ribcage. 3. To skin, place it skin-side down, grip the tail firmly and begin cutting at an angle form the tail forward.

2 Bird

Cooking

Cooking all types of food and food preservation methods

"You are what you eat.. That's strange,
I don't think I've eaten any sexy beasts today.."
Unknown

Introduction

A section detailing the preparation of different foods, types of ovens and various cooking styles. Tips on how to preserve spoilable foods such as rice, fruit, cheese and pastas.

Purpose	The aim of COOKING is to provide a comprehensive list of ways to make food safe for consumption through the various forms of cooking techniques available today. It also includes sections on cooking safety and food preservation if you don't wish to eat it straight away.
Lost?	● If you want a list of recipes, see the RECIPES section. ● If you're looking for eating all kinds of wild and foraged foods as well as the wild food edibility test, see the PLANTS section. ● For stove and oven construction, see the CRAFTING > Kitchen Items section. ● If you're looking for the food groups, see the HEALTH section. ● If you want to know how to properly prepare wild game for consumption, see the FIELD DRESSING section. ● For a list of recommended foods and food storage, see the FOOD section.

Contents

1 Food Preparation

How to preparing food for cooking.

2 Cookware

Various materials have different strengths and weaknesses when used for cooking. This section will discuss what the benefits of each is and when to use it.

Cooking Materials

Aluminium	Aluminium is the lightest of the common materials used for backpacking cookware. It is soft, and not nearly as durable as steel or titanium. Over time, it will age, pit and feel nasty. Aluminium conducts heat much better than stainless steel, which conducts heat far better than titanium. Aluminium cookware should be able to utilize more heat generated by a stove for heating its contents than titanium.
Steel	Plain steel is used for making food packing cans. These cans tend to be made of minimal thickness material, which makes them light weight. They are prone to rusting, but can be easily replaced.
Stainless Steel	Stainless steel is a nice material for cooking with. It is durable, easy to find and generally inexpensive. It wears like iron and is a reasonable heat conductor. It also tends to be heavier than titanium and aluminium cookware.
Titanium	Titanium cookware can be very durable while still being lightweight. It tends to be pricey and more difficult to find. Titanium cookware tends to not evenly distribute the heat from your stove and may create hot spots and burn your food. Hot spots are not a real concern if you are just boiling water.
Cast Iron	Cast iron heats up evenly and retains heat. This is good for actually cook many types of foods, but cast iron cooking utensils are generally too heavy for backpacking but may be an option for car camping.
Dual Metal Clad Cookware	These pots are usually made of durable stainless steel on the side contacting your food and made of aluminium or copper on the side that doesn't. The aluminium or copper conducts heat better than steel and will distribute it much better. As these tend to be higher end cookware options, these are made to last and will be much heavier than the basic thin hiking cookware available.

Shape

Wider pots tend to maximize heat from camp stoves compared to narrower pots. Narrower pots may be easier to balance on narrow stoves, such as sideburner alcohol stoves. Short pots may be more stable than tall ones. Tall pots may be able to maximize more of the heat from a stove if a tight windscreen is used. Taller pots are also able to store taller windscreens more easily. Tall narrow pots will benefit from a tight cone shaped windscreen.

Windshield

A wind screen serves two purposes. It acts as a radiation shield, reflecting heat back at your stove and pot, and shields your stove against the wind, which can easily blow out many alcohol and gas stoves. Rocks, trees, snow walls, packs (not too close) and trekkers may be used to block some wind, but a properly designed wind screen works so much better. Commercial and DIY aluminium screens should more than make up for their extra weight in fuel savings and decreased cook times. A tight fitting windscreen around stove mounted over a gas fuel canister or petrol tank can be very dangerous. This can cause overheating and lead to an explosion.

Making a Windshield
Aluminium flashing, a disposable bake pan, heavy duty aluminium foil (folded over on itself 1-4 times for durability or not at all) and sidewalls from beverage cans can work great for a lightweight windscreen. Aluminium foil can be held together temporality with paperclips or permanently with folds. Use a hole punch and punch out holes in bottom row or cut out a square section to face away from the wind to allow air to enter the windscreen. If you want a windscreen that needs to be so close to your stove that it touches the flames, consider using titanium or stainless shim 0.003" or thinner instead of aluminium. You can also make a windscreen that's cone shaped to allow it to have enough space away from your stove at the bottom and then come in around a narrow pot at the top. This creates a skirt which concentrates stove heat around the side and bottom of your pot.

Health Concerns

Aluminium	There are a few concerns that go along with choosing the right cookware. The most popular cookware questions in the backpacking community deals with the safety of aluminium pots. Much of this concern deals with an old and out-dated theory that suggests aluminium from cookware may be the cause of Alzheimer's disease. This is based on findings in the 1970's of high concentrations of aluminium in brain tissues of patient's with Alzheimer's disease. There are also many old urban myths floating around about the hazards of aluminium cookware, most notably Rudolph Valentino's death attributed to eating food prepared in aluminium cookware. The exact role of aluminium in Alzheimer's Disease isn't clear yet, and current research suggests that aluminium cookware doesn't pose a real risk to developing Alzheimer's or dementia. Aluminium cans have a heat cured coating inside and out. There may be some health concern with using this to cook with.
Teflon	There may be a hazard with the coatings often found on them. Teflon has been know to cause Teflon Flu (AKA metal fume fever or polymer fume fever). This happens when you heat up your cookware enough that the Teflon separates from your cookware and is inhaled. There are also concerns about blood levels of Teflon and a possible risk of cancer. If you use Teflon or other coated cookware, avoid overheating it, such as melting snow without first adding some water.
Galvanized Steel	Galvanized steel containers should never be used for cooking, as it may cause heavy metal poisoning.

3 Cooking Techniques

This section contains a list of cooking techniques which covers almost any kind of food you might want to cook.

Grill: Food placed on wire grid above or below heat, cooked by thermal radiation.
Frying: Cooking of food in oil or fat using a pan.
Rotisserie: A slow cooking process where the food is skewered on a spit and rotated slowly to cook evenly.
Earth Oven: An oven pit in the ground used to trap heat and bake, smoke or steam food.
Masonry Oven: An oven consisting of a baking chamber make of brick, concrete, stone or clay. Used for heating, baking, drying or cooking foods.
Dehydrating: Removes the moisture from foods using a fan and low heat to preserve them longer.
Liquid Stove: Prime the stove by preheating the generator prior to use. Consumption is about 0.25L/h for a small family or 0.75L/h for a large family.
Sun Stove: A stove that focuses the heat of the sun in a point which cooks food.
Wood Stove: o

Subheadings

1. Baking	2. Barbecuing	3. Blanching	4. Boiling
5. Frying	6. Grilling	7. Poaching	8. Pressure Cooking

1 Baking

Baking is cooking food in an oven with dry heat applied evenly throughout the oven and is synonymous with roasting. Although it is common in some cultures to use the term baking for the so-called baked-goods, such as breads, cakes and pastries, and 'roasting' for other foods, such as meats and vegetables, the terms can also be used interchangeably. The dry heat of baking causes the outside of the food to brown or char, giving it an attractive appearance and pleasing taste. The browning is caused by caramelization of sugars and is the result of the Maillard reaction. Despite common misconceptions about the browning process, moisture is never entirely sealed into the food.

Over time an item being baked will continue to lose moisture. This can be an advantage, especially in situations where drying is the desired outcome, for example in drying herbs or in roasting certain types of vegetables. Where drying is not desired, a protective layer of butter, oil, or, in the case of breads and pastries, egg wash, can slow the loss of moisture as well as providing flavour and additional browning. Alternatively, some foods are replenished with moisture during baking by placing a small amount of liquid (such as water or broth) in the bottom of the pan and letting it steam up into or around the food.

2 Barbecuing

Barbecuing is cooking food slowly with relatively low heat and hardwood smoke. Spices, marinades or brines, and sauces may all be used in the food preparation process. Grilling as a barbecue method is hotly debated in most of the US. In places like North Carolina and Texas where barbecue is part of their history and heritage, they believe grilling is not a barbecue method. Using different select hardwoods will infuse foods with distinct smoky flavours. Gas and electric smokers allow for more temperature control than smokers using charcoal or wood. In North Carolina, pork is traditionally barbecued while in Texas it is beef. However, for the common American, barbecue means pork.

3 Blanching

Blanching is a cooking technique involving boiling food (usually vegetables and fruits) in water for a very short time. Blanching is often followed by plunging the food into ice water to stop the cooking process. Though the word means to make something white or pale, blanching certain vegetables like broccoli will make their colours more vivid. Blanching is commonly used to remove skins from tomatoes and almonds. Vegetables are often blanched prior to freezing or canning. This helps preserve the food by slowing down or halting enzyme action that causes foods to break down, losing colour, flavour, and nutritional value. Blanching is similar to parboiling, which also involves boiling food briefly in water. Certain vegetables may benefit from being blanched or parboiled before being stir-fried. One quick way to blanch vegetables is to boil fresh vegetables in water, with salt, for about 30 seconds to 1 minute, before immediately draining and freezing them.

4 Boiling

Boiling, as it applies to cooking, means cooking foods in boiling water. In most populated parts of the world, plain water boils at temperatures from about 95°C to 100°C (200°F to 212°F). This varies with the atmospheric pressure, which in turn varies with both altitude and weather. When the water is salted, the boiling temperature is slightly higher than for clean water. When the atmospheric pressure on the surface of the water is lessened, boiling takes place at a lower temperature than that mentioned, and in extremely high altitudes the boiling point is so lowered that to cook certain foods by means of boiling water is difficult. As the water heats in the process of boiling, tiny bubbles appear on the bottom of the vessel in which it is contained and rise to the surface. Then, gradually, the bubbles increase in size until large ones form, rise rapidly, and break, thus producing constant agitation of the water.

Effects
Boiling has various effects on foods. It toughens the albumin in eggs, softens the fibre and dissolves the connective tissues in meat, softens the cellulose in cereals, vegetables, and fruits, and dissolves other substances in many foods. A good point to bear in mind in preparing foods by boiling is that slowly boiling water has the same temperature as rapidly boiling water and is therefore able to do exactly the same work. However, certain recipes may specify rapid boiling or slow boiling due to other conditions (such as not wanting to disintegrate soft food, or wanting to make use of the bubbles that appear in rapid boiling).

Turning the stove on high, keeping the gas burning full heat, or running the fire hard to keep the water boiling rapidly is therefore unnecessary; besides, it wastes fuel without doing the work any faster and sometimes not so well. However, there are several factors that influence the rapidity with which water may be brought to the boiling point; namely, the kind of utensil used, the amount of surface exposed, and the quantity of heat applied.

A cover placed on a saucepan or a kettle in which food is to be boiled retains the heat, and thus causes the temperature to rise more quickly; besides, a cover so used prevents a loss of water by condensing the steam as it rises against the cover. As water boils, some of it constantly passes off in the form of steam, and for this reason syrups or sauces become thicker the longer they are cooked.

The evaporation takes place all over the surface of the water; consequently, the greater the surface exposed, the more quickly is the quantity of water decreased during boiling. Another point to observe in the boiling process is that foods boiled rapidly in water have a tendency to lose their shape and are reduced to small pieces if allowed to boil long enough. Many recipes for pork ribs call for parboiling them before cooking, but this method is not recommended, as water is a solvent and may wash away flavours.

Health Purposes
Besides serving to cook foods, boiling also renders water safe, as it kills off any germs that may be present. Boiled water, as is known, loses its good taste. However, as this change is brought about by the loss of air during boiling, the flavour can be restored and air again introduced if the water is shaken in a partly filled jar or bottle, or beaten vigorously for a short time with an egg beater or whisk.

5 Frying

Cockaigne

This technique is used for cooking chicken using a 'poaching' technique (the chicken isn't suspended from the bottom of the pan), where the chicken is cooked from the outside in over time using medium to low heat. If followed exactly, the chicken will be cooked to the safe temperature of 165°F and ready to use in any recipe.

Deep Fat Frying

Cooking Techniques | Frying

Deep frying involves fully immersing food in hot oil. It is an extremely fast cooking method, and, despite the use of liquid oil, is best classified as a dry cooking method because it does not involve liquid water. With a deep fat fryer, deep frying is reasonably safe, but hot cooking oil is intrinsically dangerous, and one should be very careful so as to avoid fires and/or severe burns.

Sautéing

Sautéing is cooking food in a small quantity of fat or oil. When sautéing, which is a type of frying, a very small amount of oil is placed in a shallow pan, and when it is sufficiently hot, the food is put into it. Foods that are to be sautéed are usually sliced thin or cut into small pieces, and they are sometimes turned frequently during the process of cooking. Sauté is French for "jumping", used to describe the action of the food in the pan. The term pan-frying is sometimes the English equivalent of sautéing (which is a French word) if only a very small amount of oil is used. Some people consider it a different technique, which uses more fat and takes longer. Stir-frying uses higher temperatures and continual stirring. With modern non-stick pans the amount of oil required can be quite small, or even omitted.

Stir-Frying

Stir-frying involves frying food quickly over very high heat in an oiled pan. While stir-frying, you generally stir continually. A special slope-sided pan called a wok is designed for stir-frying. An open flame heat source such as gas works best when using a wok. Different frying oils produce different results. A light oil such as sesame produces a slightly healthier and much more tasty result but can burn if overheated. Olive oil has a low smoking point and may heat too quickly.

Tips
- Make sure all ingredients are prepared before you begin stir-frying.
- Heat the wok on medium-high or high heat at least one minute before adding oil. Do not pre-heat the wok if it has non-stick coating, as the heat can damage the coating.
- Drizzle the oil down the sides of the wok to maximize oil coverage as well as to heat the oil more quickly.
- Cook meat on high heat in order to keep it juicy.
- Remove the meat before stir-frying the vegetables. Add the meat back into the mix once the vegetables are almost cooked.
- If you are cooking over an electric range, replace the wok with an ordinary heavy-bottomed frying pan. You will achieve better results this way since electric ranges will not properly heat the curved sides of a wok.
- If you are using an electric range, you can preheat the pan or wok in an oven set to its highest setting, and only use the electric range to maintain heat during cooking. Be careful, as the pan's handle will be very hot.

Deglazing

Deglazing is a cooking technique for removing and dissolving browned food residue from a pan to make a sauce, known as a pan sauce, that is often made to accompany sautéed meats. The browned residue is due to either the Maillard reaction or caramelization. Generally speaking, a pan sauce is made by sautéing a meat at high temperature in a skillet.

The meat is removed and the majority of the fat is poured off, leaving a small amount with the dried and browned meat juices. The pan is returned to the heat, and a liquid such as vegetable or meat stock, an alcoholic beverage, some wine, or verjuice (a highly acidic juice made by pressing unripe grapes, crab-apples or other sour fruit) is added to act as a solvent.

This allows the cook to scrape the dark spots from the bottom of the pan and dissolve them, incorporating the remaining browned material at the bottom of the pan into a basic sauce. The culinary term fond, French for "base" or "foundation", refers to this sauce, although it is also sometimes used to describe the browned food bits instead (commonly in the United States). The flavour of the pan sauce is determined chiefly by the meat, the liquid used for deglazing, and any flavouring or finishing ingredients added, such as aromatics, herbs, or butter.

This method is the cornerstone of many well known sauces and gravies. The resulting liquid can be seasoned and served on its own (sometimes called a jus), or with the addition of aromatic vegetables, such as onions or shallots, carrots and celery. The sauce can also be thickened by whisking in butter, through the addition of a starch, such as flour, cornstarch, or arrowroot, or simply simmered down with a steady heat to form a rich, concentrated reduction.

6 Grilling

Grilling is a fast, dry method of cookery which uses the intense heat radiated by an: Electrical element, Gas flame, Glowing charcoal or an open wood fire. The heat source can be either above or below the food (or both) and the heat, in the form of infra-red waves, is transferred to the surface of the food. Infra-red waves penetrate only about 1 mm into food (whereas microwave radiation penetrates about 40 mm/l½ in.) Heat is transferred from the surface to the centre of the food by conduction. (If the food comes into contact with hot grill bars, which is almost certain to happen, there is also some conduction at the surface.) It is important that the grill is preheated so that it reaches the high temperatures necessary for efficient infra-red radiation.

Grilling cooks fast because: Very high temperatures are used, the food can be positioned close to the heat source and because the energy passes from the heat source almost instantly, without having to be carried in a liquid or through much air. How much heat the food absorbs depends on the colour of its surface: darker foods tend to absorb the infra-red more easily than light ones (which reflect some of the heat). This is the same effect as a black car getting hotter in the sun than a white car (or why a person in a white shirt stays cooler in the hot sun in the summer than the same person would wearing a black shirt.)

7 Poaching

Poaching is a method of cooking that employs a liquid, usually a small amount, that is hot but not actually bubbling. The French term is frisonne – shivering. The ideal temperature is between 160F and 180F (75-80C). The cooking liquid is often water, but broth, stock, milk or juice can also be used. Delicate foods such as fish, eggs out of the shell, or fruits are commonly cooked by poaching. The cooking method is also used to partially cook certain foods such as sweetbread in order to eliminate undesirable flavours and to firm the product before final cooking. It should be noted that the term is occasionally used to describe foods that have been boiled or simmered.

Tips
- Use a thermometer to gauge the temperature of the cooking liquid or watch for bubbling and adjust the heat as necessary.
- Do not allow the food being cooked to touch the bottom of the pan or it may cook too rapidly or burn.
- When poaching eggs, add a splash of vinegar to the water. This will help quickly firm the egg white so multiple eggs can be cooked at once without all sticking together.

Hole Technique
1. Heat water to just under simmering.
2. With a pushpin, carefully pierce one end of the egg.
3. Place egg on a large spoon, and lower it gently into the water. Keep submerged for 20-30 seconds. Some egg protein may start to come out of the hole in "streamers".
4. Raise spoon, gently crack egg, and drop into water.

Pre-cooking the egg by letting some hot water inside the shell will result in a firmer egg once opened, and it will be less likely to come apart in the water while cooking.

8 Pressure Cooking

Pressure cooking is a method of cooking in which the boiling temperature of water is increased using a special vessel, causing the food to cook faster. Cooking times can be reduced by a factor of three or four. For example, shredded cabbage is cooked in one minute, fresh green beans take about five, small to medium-sized potatoes (up to 200 g) may be ready in five minutes or so and a whole chicken takes no more than twenty-five minutes.

It is often used to simulate the effects of long braising or simmering in shorter periods of time. This is accomplished using a pressure cooker, a sealed vessel that does not permit steam to escape until a preset pressure is achieved. Because water's boiling point increases as the pressure increases, the pressure built up inside the cooker allows the liquid in the pot to rise to a temperature higher than 100 °C (212 °F) before boiling.

A safety valve releases steam when the pressure exceeds the safety limit for the cooker; usually the steam pressure lifts a weighted stopper allowing excess pressure to escape. There is usually a backup pressure release mechanism, in the form of a hole in the lid blocked by a plug of low melting-point alloy, a rubber seal and pin, or a rubber ring seal. If internal temperature (and hence pressure) gets too high, the release mechanism will trigger, resulting in a release of the pressure. However, it is best not to rely on this feature.

A pressure cooker can be used at high altitude to compensate for lower atmospheric pressure. Without it, water boils off before reaching 100 °C, lengthening the cooking time for recipes. In some countries, the microwave has replaced the pressure cooker as a technical fix for faster cooking, but cannot perform the same task that programmable electronic pressure cookers, as delayed cooking and other features.

See the Preservation Section further below for more information.

9 Roasting

Roasting is high-heat baking with very little moisture. Roasted foods get drier and browned on the outside by initially exposing it to a high temperature. This keeps most of the moisture from being cooked out of the food. Temperature is then lowered to cook the meat through. The flavours of both meats and vegetables are retained and enhanced by roasting. A typical roasting temperature is 425-450 °F, with an initial temperature of over 500 °F for a period of 15 to 20 minutes. You can either roast in an oven or over an open fire.

Spit-roasting is a variation where the meat is impaled on a spit and rotated as it roasts. Once meat has been removed from the roasting environment it should be allowed to rest, this ensures that the juice inside the meat returns to the outer edges. The even distribution of juice allows each slice to retain more moisture. Un-rested meat is typically dry around the edge and over saturated in the middle, leading to a loss of moisture.

10 Rotisserie

Rotisserie, also known as spit-roasting, is a style of roasting where meat is skewered on a spit – a long solid rod used to hold food while it is being cooked over a fire in a fireplace or over a campfire, or roasted in an oven. This method is generally used for cooking large joints of meat or entire animals, such as pigs or turkeys. The rotation cooks the meat evenly in its own juices and allows easy access for continuous self-basting.

11 Simmering

Simmering, or stewing, is a modification of boiling. By this method, food is cooked in liquid at a temperature below the boiling point, or anywhere from 185-200°F (85-95°C). Water at the simmering point always moves gently--never rapidly as it does in boiling. Less heat and consequently less fuel are required to cook foods in this way, unless, of course, the time consumed in cooking the food at a low temperature is much greater than that consumed in cooking it more rapidly. Aside from permitting economy in the use of fuel, simmering, or stewing, cooks deliciously certain foods that could not be selected for the more rapid methods.

For example, tough cuts of meat and old fowl can be made tender and tasty by long cooking at a low temperature, for this method tends to soften the fibre and to develop an excellent flavour. Tough vegetables, too, can be cooked tender by the simmering process without using so much fuel as would be used if they were boiled, for whatever method is used they require long cooking. Beets, turnips, and other winter vegetables should be stewed rather than boiled, as it is somewhat difficult to cook them tender, especially in the late winter and early spring. If dry beans and peas are brought to the simmering point and then allowed to cook, they can be prepared for the table in practically the same length of time and without so much fuel as if they boiled continuously.

12 Steaming

Steaming is the cooking of food by the application of steam. In this cooking process, the food is put into a steamer, which is a cooking utensil that consists of a vessel with a perforated bottom placed over one containing water. As the water boils, steam rises and cooks the food in the upper, or perforated, vessel. Steamers are sometimes arranged with a number of perforated vessels, one on top of the other. Such a steamer permits of the cooking of several foods at the same time without the need of additional fuel, because a different food may be placed in each vessel.

Steaming is preferable to boiling in some cases, because there is no loss of mineral salts nor food substances. The flavour is not so likely to be lost as when food is boiled. Some delicate fish is best cooked by steaming as it does not break up as it might in boiling water. Vegetables prepared in this way prove very palatable, and very often variety is added to the diet by steaming bread, cake, and pudding mixtures and then, provided a crisp outside is desired, placing them in a hot oven to dry out the moist surface.

13 Stewing

In culinary terms 'stewing can best be described as slowly cooking food in its own juices with the aid of a minimum amount of moistening agent in the form of stock, wine, beer, sauce, butter etc. During cooking the liquid is flavoured by extracts from the stewed food, the result is a highly flavoured liquor or sauce which forms an integral part of the stew. Throughout this process, which is generally a lengthy one, evaporation is kept to a minimum by covering the stewing vessel with a tight fitting lid and simmering the stew on top of the stove or in the oven.

Condensation, which continually forms on the inside of the lid, acts as a self basting process keeping the food moist. If the rate of evaporation is not kept to a minimum the stew will become dry and could burn. Therefore it may be necessary to add additional liquid as needed throughout the cooking period. Once cooked the liquid and food are usually served together to form the complete dish. Tougher cuts of meat may be made tender and palatable by this method.

Cooking Tec | Stewing

Foods for stewing are cut into small pieces or cuts before cooking and may comprise of meats, fish, vegetables and fruit. The flavour and colour of stock used will be determined on the type of meat to be cooked and the colour required of the finished dish, e.g. brown beef stew using brown beef stock. When a brown colour is required the meat and vegetables are sealed and browned in oil/dripping at a high temperature to ensure correct colour and sealing of the meat. Colour is also achieved by browning the roux and by using a brown stock.

If a white coloured product is required less heat is applied to seal gently and without browning. The most suitable mediums for this process are butter and margarine. Where a roux is required it is cooked to the blond stage before being moistened with stock to effect a white colour. In some instances meats used for white stews are blanched and refreshed as a means of sealing the meat and also extracting the scum, which would otherwise discolour the resultant sauce.

4 Cooking Platforms

These are the different platforms you can cook food on, such as ovens and stoves.

Subheadings

1. Electric Cookers	2. Wild Oven	3. Wood Stove	4. Liquid Stove
5. Gas Stove	6. Candle Stove	7. Solar Stove	8. Flameless Stove
9. Calcium Carbide Stove			

1 Electric Cookers

Electric stoves are any stoves which are powered by electricity to heat an element.

Immersion Coil	These are coils which can either be plugged in or battery operated and submerged to heat water.
Induction Cooktop	Induction cooking is performed using direct induction heating of cooking vessels, rather than relying on indirect radiation, convection, or thermal conduction. Induction cooking allows high power and very rapid increases in temperature to be achieved, and changes in heat settings are instantaneous. In an induction cooktop, a coil of copper wire is placed under the cooking pot and an alternating electric current is passed through it. The resulting oscillating magnetic field induces an electrical current in the pot. For nearly all models of induction cooktops, a cooking vessel must be made of, or contain, a ferrous metal such as cast iron or some stainless steels. The iron in the pot concentrates the current to produce heat in the metal. If the metal is too thin, or does not provide enough resistance to current flow, heating will not be effective. Most induction tops will not heat copper or aluminium vessels because the magnetic field cannot produce a concentrated current; "all metal" induction tops use much higher frequencies to overcome that effect. Any vessel can be used if placed on a suitable metal disk which functions as a conventional hotplate. Induction cooking has good electrical coupling between the pan and the coil and is thus quite efficient, which means it puts less waste heat into the kitchen, can be quickly turned on and off, and has safety advantages compared to gas stoves. Cooktops are also usually easy to clean, because the cooktop itself does not get very hot.
Electric Cooktop	An electric stove or electric range is a stove with an integrated electrical heating device to cook and bake. Electric stoves became popular as replacements for solid-fuel (wood or coal) stoves which required more labour to operate and maintain. Some modern stoves come in a unit with built-in extractor hoods. Electric cooktops may have a glass covering to assist in cleaning up spills.

2 Wild Oven

Earth Oven	
Masonry Oven	
Dutch Oven	

3 Wood Stove

A wood stove is any cooking platform that uses wood as a fuel. For fuels and wood types see the FUEL or CRAFTING categories. For information on wood types and how different woods burn see the MATERIALS section.

Advantages	• Wood is easy to find	• Don't have to carry fuel			
Disadvantages	• May produce a large amount of smoke	• Blackening of pots which may get over your gear	• Variable heat output	• Fires may be banned	• Requires constant attention and feeding
	• May be heavy				

Campfire
A campfire stove is a simple fire with supports able to hold pots and pans.

Rocket Stove
A rocket stove is an efficient and hot burning stove using small-diameter wood fuel. Fuel is burned in a simple combustion chamber containing an insulated vertical chimney, which ensures almost complete combustion prior to the flames reaching the cooking surface. Rocket stove designs are most often used for portable stoves for cooking but the design is also used for large fixed stoves in institutions, and to make rocket mass heaters for heating.

Kelly Kettle
Efficient portable devices for boiling water outdoors using twigs and other small combustible materials; these devices consist of a water jacket surrounding a fire chamber which creates an upward chimney draft ensuring efficient and rapid boiling even in windy or wet weather. AKA: Storm Kettle, Ghillie Kettle, Thermette and Volcano Kettle.

4 Liquid Stove

Cooking Platforms
Liquid Stove
Alcohol

Alcohol Stove

Advantages	• Ultralight	• Fuel Availability	• Customisable	• Easily Built	• Simplicity
	• Reliable	• Quiet	• Odourless	• No Maintenance	• Safety
	• Low Cost				
Disadvantages	• Fixed Heat Output	• Reduced Output	• Invisible Flame	• Cold Sensitive	• Low Durability

Open Flame Alcohol Stove

These are the simplest of all alcohol stove designs. Since enough alcohol vaporizes at room temperature to allow for easy ignition and generally not enough to be explosive under most conditions, you can simply burn alcohol in an open shallow metal tin. Simply open up a can of tuna or cat food, empty the contents, pour in some fuel and light. More refined versions incorporate a wick made of non-flammable fibreglass insulation, perlite (volcanic rock used in insulation and horticulture) or something comparable to help vaporize fuel and prevent spilling. Open flame stoves are popular with thruhikers wanting a failsafe system.

Chimney Alcohol Stove (Updraft Stove)

These stoves incorporate ventilation similar to a Bunsen burner to facilitate mixing of oxygen with fuel as air is "sucked" into the stove by the low pressure field created by an updraft from the burning fuel. This design allows for better air fuel mixing, more controlled burning when vents are sized properly (with or without a simmer accessory) and good heat feedback to the stove (needed to keep it running). Basically, they operate better than just a simple empty can, may be set up with adjustable heat output with the proper hardware and are more dependable than pressurized stoves.

Low Pressure SideBurner Alcohol Stove

Most use a simple updraft concept to preheat the stove and fuel, but they also turn into pressurized sideburners when a pot is placed on top of them. Made with the right number, configuration of and sized holes/ventilation, and you'll have a very light weight and dependable stove that doesn't need a pot stand.

Open Jet Alcohol Stove

These stoves work by vaporizing fuel and shooting them out little jets where the fuel is burned, creating a gas range-like effect. They are beautiful little gems, but may be more difficult to construct and more finicky than other stove types listed here. They are very simple to use, just pour your fuel in the centre and light.

Hybrid SideBurner Jet Alcohol Stove

These are open jet stoves with jets on the side. Like the regular open jet stoves, alcohol is poured in an open centre fuel port and lit. Once the jets ignite, you set your pot on top of the stove and seal off the centre fuel port, creating a pressurized system. The advantage of these systems is that you don't need a separate pot stand to cook with.

Pressurized Jet Alcohol Stove

These stoves also have little jets like the open jet stoves, but lack the open centre fuel port. Instead, the fuel port is generally closed off with a screw or are nonexistent (jets double as fuel ports). This allows for the stove to build up pressure as it heats up, forcing streams of fuel vapour through its jets. These stoves generally must be preheated by burning a small amount of fuel at the base or on top of the stove. These can be very difficult to design and construct, but allow you the potential for very fast and hot cooking and possibly greater fuel efficiency.

Fuels for Alcohol Stoves
See the FUEL section.

White Gas/Petroleum

White Gas/Petroleum Stove

Advantages	• Works well in subfreezing temperatures	• Readily Available Fuel	• Fast Cooking		
Disadvantages	• Very Loud	• Heavy Setup	• Lots of maintenance to keep it operational	• Fuel smell which could leech into your pack	

Gas Stove

5 Gas Stove

There are several commercial alcohol stoves available on the market these days and a great many DIY versions. Each versions has it's own special characteristics, limitations and special little advantages over others, yet most share a few basic common features and can be categorized into six distinct designs:

Types
- Open Flame
- Chimney/Updraft
- Low Pressure SideBurner
- Open Jet
- Hybrid SideBurner Jet
- Pressurized Jet

Advantages	• Easy to Use	• Clean Burn	• Cheap		
Disadvantages	• Fuel may freeze and stop working in cold temperatures				

Open Flame	These are the simplest of all alcohol stove designs. Since enough alcohol vaporizes at room temperature to allow for easy ignition and generally not enough to be explosive under most conditions, you can simply burn alcohol in an open shallow metal tin. Simply open up a can of tuna or cat food, empty the contents, pour in some fuel and light. More refined versions incorporate a wick made of non-flammable fibreglass insulation, perlite (volcanic rock used in insulation and horticulture) or something comparable to help vaporize fuel and prevent spilling. Open flame stoves are popular with thruhikers wanting a failsafe system.
Chimney/Updraft	These stoves incorporate ventilation similar to a Bunsen burner to facilitate mixing of oxygen with fuel as air is "sucked" into the stove by the low pressure field created by an updraft from the burning fuel. This design allows for better air fuel mixing, more controlled burning when vents are sized properly (with or without a simmer accessory) and good heat feedback to the stove (needed to keep it running). Basically, they operate better than just a simple empty can, may be set up with adjustable heat output with the proper hardware and are more dependable than pressurized stoves.
Low Pressure SideBurner	Most use a simple updraft concept to preheat the stove and fuel, but they also turn into pressurized sideburners when a pot is placed on top of them. Made with the right number, configuration of and sized holes/ventilation, and you'll have a very light weight and dependable stove that doesn't need a pot stand.
Open Jet	These stoves work by vaporizing fuel and shooting them out little jets where the fuel is burned, creating a gas range-like effect. They are beautiful little gems, but may be more difficult to construct and more finicky than other stove types listed here. They are very simple to use - pour your fuel in the open centre and light.
Hybrid SideBurner Jet	These are open jet stoves with jets on the side. Like the regular open jet stoves, alcohol is poured in an open centre fuel port and lit. Once the jets ignite, you set your pot on top of the stove and seal off the centre fuel port, creating a pressurized system. The advantage of these systems is that you don't need a separate pot stand to cook with.
Pressurized Jet	These stoves also have little jets like the open jet stoves, but lack the open centre fuel port. Instead, the fuel port is generally closed off with a screw or are nonexistent (jets double as fuel ports). This allows for the stove to build up pressure as it heats up, forcing streams of fuel vapour through its jets. These stoves generally must be preheated by burning a small amount of fuel at the base or on top of the stove. These can be very difficult to design and construct, but allow you the potential for very fast and hot cooking and possibly greater fuel efficiency.

Fuel
This type of stove uses compressed canisters of Butane, Propane or a mixture of them. See the "Fuel" section for more information on fuels.

6 Candle Stove

A stove which uses one or more candles as the source of heat.

Advantages	• Lightweight and portable	• Easily made			
Disadvantages	• Low Heat Output				

Depending on the size of the flame, candle stoves may take a while to heat up food. It likely won't get hot enough to boil water, but only warm it up. The only real advantage of a candle stove is that the candle burns a long time and provides enough light to see by.

7 Solar Stove

A stove which focuses the suns heat to cook food.

Advantages	• Eco Friendly	• Virtually unlimited fuel as long as it's day and clear.			
Disadvantages	• Very slow cooking based on region	• Reduced effectiveness in colder months	• Often bulky and hard to transport		

Depending on what part of the world you're from the solar stove can be extremely effective, such as in an Australian summer to almost useless in an the arctic. Wherever you decide to set it up though it will still take some time to cook the food and is therefore only really useful for cooking lunches or early dinners with the afternoon rays.

8 Flameless Stove

A common name for "cooking" freeze-dried meals while camping using chemicals which produce heat to heat the food. This isn't really considered cooking, but more so reheating the food as freeze-dried meals are safe to eat hot or cold.

Advantages	• Very light and portable	• No Flames / Stealthy	• No harmful by-products so you can use it in your tent	• Great for small meals for 1-2 people	• Simple to use
Disadvantages	• Generates Rubbish	• Single Use Only	• For Reheating Only	• Typically only come in single serve bag sizes	• Not convenient for large groups of people

If you're looking for a quick and easy way to warm up food on a short trip then this is the most compact and lightest method for doing so. The bags are also relatively cheap coming in at about $3-5.

9 Calcium Carbide Stove

A chemical reaction between calcium carbide and water produces acetylene, calcium oxide and heat. The acetylene is then burned for light and/or heat. This very old technology is still a favourite among many cavers and newer head mounted lanterns are still produced today. These setups may not be ideal for backpacking as the hard to find fuel must be kept dry to avoid igniting while in your pack and its by-products include caustic calcium hydroxide ($Ca(OH)2$) and calcium oxide (CaO aka Lime), chemicals you don't want in your pack. This stove type is only mentioned for those seeking superfluous trivia, tinkers looking for a unique project and in the interest of being complete (at the expense of practicality).

Advantages	• Very Unique Stove				

Disadvantages	• Dangerous Chemicals	• Difficult to find chemicals			

5 Preservation

Different ways to preserve a variety of food.

Subheadings

1 Mylar Preservation

This section shows you how to preserve different kinds of food in mylar bags to greatly extend their shelf life.

Mylar Bag Basics

This is some basic information on how the Mylar bagging process works.

Oxygen Absorbers (OA's)	You can use more OA's than necessary. Most OA's will absorb 180% to 300% of their rating for a buffer of safety. OA's take about 2 hours to absorb all the oxygen. Do not use OA's with foods high in fat or which have over 10% moisture to avoid botulism. Dried food has 10-20% moisture and is bendable, whereas dehydrated food only has 2.5-5% moisture so they should snap when bent. Use OA's within 10-15 minutes of opening or reseal them in an airtight container. Mylar Bags come in 1mil-8mil thicknesses. Use 5mil+ for long-term storage. Store Dry (<10% moisture), low fat foods only. Multiple smaller OA's will absorb oxygen faster than a larger OA. Mylar bags are NOT rodent proof, so store them in an impenetrable barrier such as a sealed plastic storage crate or food grade bucket. Do not use OA's with powders or granules like salt and sugar, as they will become rock hard.
Moisture Absorbers (MA's) AKA: Silica Gel / Desiccants	Use Silica Gel in a Mylar bag to absorb trapped moisture vapour. MA's absorbs about 40% humidity of their weight. Silica Gel is most effective below 25°C (77°F) and starts losing its absorption capabilities as the temperature rises. Distributed smaller sachets will reduce moisture levels faster than one larger sachet. Silica Gel can be reused by drying it in an oven at 80-110°C (176-230°F) for 15 minutes to 2 hours depending on absorption levels. MA's absorb about 10% of their capacity per hour but slow down as they fills up.

This is a table showing the cubic centimetres of air which will likely be sealed into the Mylar bag once the food is packaged. You need to select an oxygen absorber that is equal to or more than the CC number listed in the table.

If you have a Medium (quart) bag and are packaging oats, then we need at least a 150cc oxygen absorber or more.

Mylar Bag Size	* 35% Air * Beans, Lentils, Rice, Sugar	* 50% Air * Flour, Mixes, Powders	* 75% Air * Pasta, Flakes, Oats, Wheat
Small (Pint) 16oz – 473ml	OA - 50cc	OA - 50cc	OA - 100cc
Medium (Quart) 32oz – 946ml	OA - 100cc	OA - 100cc	OA - 150cc
Large (2 Quart) 64oz – 1.89L	OA - 150cc	OA - 200cc	OA - 350cc
XLarge (1 Gal) 128oz – 3.78L	OA - 300cc	OA - 400cc	OA - 500cc
XXLarge (5 Gal) 639oz – 18.9L	OA - 1,400cc	OA - 2,000cc	OA - 2,500cc

Sealing Mylar Bags

These are the steps I developed to seal Mylar Bags with pretty much any type of food. This guide refers to Oxygen Absorbers as OA's and Moisture Absorbers (Silica Gel or Desiccants) as MA's.

Step **1**	Choose a day with low humidity (<60%) or package the food in an air-conditioned room. Ensure that any food purchased from air-conditioned shops has reached ambient room temperature before packaging it into Mylar bags, otherwise condensation will form. Try to seal newly purchased foods as much as possible, as this will give the food the longest life possible.
Step **2**	Get the equipment you need: • The Food, • Scissors, • Mylar bags • OA's, • MA's, • Permanent Marker • Heat Sealer or Hair Straightener, • Funnel or Measuring Cup • A Dry Cloth, • A Humidity Gauge (If not packing in air conditioning)
Step **3**	Visually size the food you are sealing to the correct Mylar bag. Have some smaller Mylar bag sizes handy for leftovers.
Step **4**	Write the number of: • OA's and MA's you intend to add based on the tables overleaf before you begin so you aren't working it out on the go. Try to use a whole packet of OA's at once so you do not have to store the leftovers in an airtight container. Then write the • Food Type, • Quantity (grams), • Packaged date (today), • Original expiry date of the food, • New best before date, and any other pertinent information such as the humidity level during packing or storage requirements. These will help you troubleshoot what went wrong in the case the food has spoiled once opened. You may have to measure and write the quantity (in grams/kg) after the bag has been filled if you are not sure how much you fit into the bag, so if you are unsure - leave it blank.
Step **5**	Open the Mylar Bag and extend the gusset (the base) if it has one. It is best to stand them in Tupperware containers to help prevent them falling over during the initial filling. Then Put any Moisture Absorber(s) into the bottom of the package before filling. (Do not use MA's if you are packaging sugar or powdered substances. Check the table overleaf for a complete list)

Step 6	Using a wide funnel (if required), pour the food into the Mylar bag and give it a good shake between fills to ensure the gusset is fully extended and the food has compacted down to reduce the air. Do not overfill the bag since this will cause problems when sealing the bag later, so check that you can still close the bag every so often while filling it if you are unsure. Using a measuring cup or funnel will help prevent powders sticking to the sides, which causes bubbles when sealing the bag, or may even prevent a proper seal forming. Alternatively you can add sticky tape to the sealing edge to keep it clean. Powders such as flour tend to billow up and out the top when you squeeze the air out, so be sure to remove the air and seal the zip-lock before wiping the edge or removing the sticky tape.
Step 7	Once filled and as much air as possible has been removed, seal the zip-lock if it has one and wipe any powder from the inner sealing edge with a dry cloth to ensure a proper heat seal is made, or remove the sticky tape. Then repeat steps 4-7 and fill the remaining bags. If you want, you can also pre-seal most of the bag with your heat sealer while leaving a small gap to insert the OA's later.
Step 8	When you have your Mylar bags full of food and clean sealing edges, they are ready to seal. Partially open the zip-lock on them all then cut open the OA packet and insert the amount written on the bag. From now on you have 15mins max to get them sealed.
Step 9	Again, push any remaining air out of the bags. Be careful when pushing the air out of sharper foods like pasta, since it can penetrate the bag if pushed hard enough. Do this very slowly this time, especially for powdered substances since this could re-coat the sealing surface with powder. Then seal the zip-lock (wipe again if needed) and heat-seal the top. Try to avoid ripples when sealing the bag with a hair straightener (HS). This occurs when pulling the HS across the sealing edge rather than swiping upwards off the bag. To seal properly, put the HS on the edge of the package, close it and move it upwards off the bag.
Step 10	Ensure the bags are fully labelled and haven't been damaged in any way. If you believe one of them is compromised, put it under water in a sink, press down, and check for any streams of air bubbles from the bag.
Step 11	After a few days, check that the bag is still intact and has a slightly vacuum-packed look for any solid ingredients such as rice, grains and pasta. Some ingredients don't have the vacuum packed look once sealed since they are very fine, such as flour.

Mylar Bag Food Shelf Life

This is a list of foods and their new shelf life in years after being bagged in Mylar. (Counting from the manufacture date) Always bag the freshest product you can get for the best shelf life.

Legend:
* = Don't use OA's ^ = Don't use MA's [x] = Don't use either ~ = Use MA's ° = Use OA's [2] = Use Both
[3] = OA use varies by type + = A plus before a number means to add this time to the expiry date. ₲ = Gluten Free
⊘ = Do not store this in Mylar Bags - it will either go rancid quickly, is a liquid or will be dangerous to eat if bagged.
Package the food as close to the manufacturing date as possible for the best shelf life.
When opening a Mylar bag check its appearance and smell for anything abnormal.

2 Fruit Preserves

Fruit preserves are preparations of fruits, vegetables and sugar, often stored in glass jam jars and Mason jars.

Many varieties of fruit preserves are made globally, including sweet fruit preserves, such as those made from strawberry or apricot, and savory preserves, such as those made from tomatoes or squash. The ingredients used and how they are prepared determine the type of preserves; jams, jellies, and marmalades are all examples of different styles of fruit preserves that vary based upon the fruit used. In English, the word, in plural form, "preserves" is used to describe all types of jams and jellies.

3 Canning

Canning is the process in which foods are placed in jars or cans and heated to a temperature that destroys microorganisms and inactivates enzymes. This heating and later cooling forms a vacuum seal. The vacuum seal prevents other microorganisms from decontaminating the food within the jar or can. Acid foods such as fruits and tomatoes can be processed or "canned" in boiling water (also called the "water bath method"), while low acid vegetables and meats must be processed in a pressure canner at 240°F (10 pounds pressure at sea level). See this page for why you should use a canner and how to choose one. There are a large number of unsafe canning methods that people use, from the no processing at all (just fill the jars and seal, called "open kettle" canning) to oven canning, microwave canning and even using the dishwasher.

Canning Food Equipment	**Water Bath Canner** Cans Acid food - Tomato, Pickles, Jams/Jelly Jar content must have a high acidity level.	**Pressure Canner** Cans Low Acid Food - Meats, Vegetables, Potato Dial Gauge or Pressure Gauge	**Electric Canner** o	**Oven Canning** o	**Tools** ● Canner ● Jars ● Lid Grabber ● Jar Grabber ● Bubble Remover ● Funnels
	Research Acid Foods National Centre for Home Food Preservation http://nchfp.uga.edu/	**Jar Sizes** ● 118.29ml (4oz) ● 490ml (16.56oz) ● 945ml (31.95oz)	● Separate jars from the bottom of the canner or they will crack. ● Sterilize jars prior to use by boiling for 10m. ● All American Pressure Canner is a well tried and tested canner.		

Food pH Levels

The pH and/or acidity of a food is generally used to determine the safe home canning methods and conditions. The term "pH" is a measure of acidity; the lower its value, the more acid the food. The equipment used for determining pH was generally pH meters. Canning methods are described on this page. Some liquids, like lemon juice, lime juice and vinegar, are used as acidifiers, to help lower the pH of foods to increase safety. The approximate ranges of pH values for many common fresh and processed foods are listed below. Keep in mind that considerable variation exists between varieties, condition of growing and processing methods, etc. The data presented is applicable to the edible portion of foods in their normal and natural state, unless otherwise designated. Acid foods are foods that contain enough acid to have a pH of 4.6 or lower. They include fruits, pickles, sauerkraut, jams, jellies, marmalades, and fruit butters. Acidic foods can be processed safely in a boiling water canner, usually without added acid (lemon juice, vinegar or citric acid).

This is necessary to control botulinum bacteria. Acidity may be natural, as in most fruits, or added, as in pickled food. Low-acid canned foods are not acidic enough to prevent the growth of these bacteria. Acid foods contain enough acid to block their growth, or destroy them more rapidly when heated. The acidity level in foods can usually be increased by adding lemon juice, citric acid, or vinegar, although this by itself, does not mean the recipe is safe. Low-acid foods have pH values higher than 4.6 up to 6.9. (non-acidic, or alkaline foods have pH values of 7.0 or greater) .They include red meats, seafood, poultry, milk, and all fresh vegetables except for most tomatoes. Most mixtures of low-acid and acid foods also have pH values above 4.6 unless their recipes include enough lemon juice, citric acid, or vinegar to make them acid foods. In using this table, bear in mind that considerable variation exists between varieties, condition of growing and processing methods, etc. Data is presented for the edible portion of foods in their normal and natural state, unless otherwise designated.

pH Levels Key

Very High Acidity 0-3	**High Acidity** 3-4	**Medium Acidity** 4-5	**Low Acidity** 5-6	**Neutral pH** 6-8	**Low Alkaline** 8-9	**Medium Alkaline** 9-10	**High Alkaline** 10-11	**Very High Alkaline** 11-14

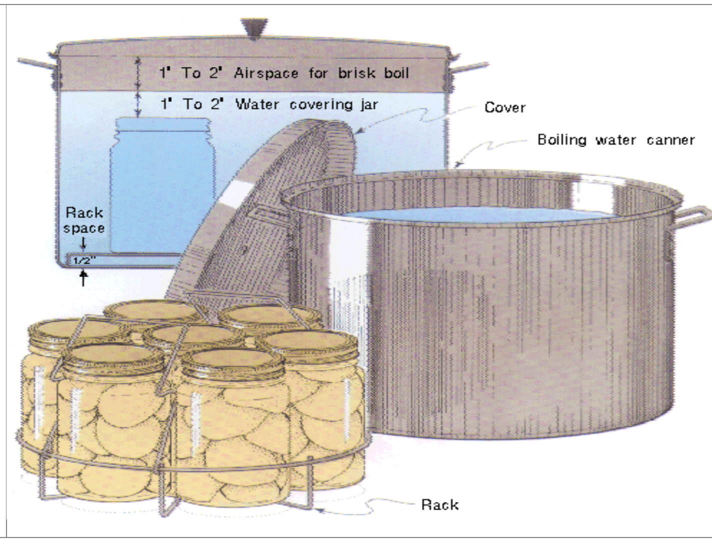
Water Bath Canning

Water bath canning is the process most people use to can fruits, vegetables, jams, jellies, and pickles at home. Unfortunately, the canners rarely come with directions, and the instructions in many canning books can be complicated and hard to follow. These boiling water bath canning directions below may serve as a guide and a reminder to the basic steps in home pressure canning food whether you have misplaced your canning books, are new to home canning or just need a refresher.

Essentially, a water bath canner is a very, very large pot, with dimensions to hold at least 7 quart jars and allow them to be submerged by 1 to 2 inches of water.   The canners usually include a rack with handles to make it easier (and safer) to put the jars in and take them out of the boiling water. Most boiling water canners are made of aluminum or porcelain-covered steel. Many boiling water canners do not have completely flat bottoms, so if you have a smooth-top stove (such as a ceramic or glass topped stove), see this page for alternatives . Gas stoves are ideal for home canning since either a flat or ridged bottom may be used on a gas burner. To ensure uniform processing of all jars with an electric range, the canner should be no more than 4 inches wider in diameter than the element on which it is heated.

(When centered on the burner or element, the canner should not be more than 2 inches wider on any side) Keep in mind that water bath canners are suitable only for acidic foods (See the pH table above for the pHs of common fruits, vegetables, grains, breads and common food products). Low acid foods must be canned in a pressure canner. You must use the type of canner called for in the recipe. Keep in mind that you can always use a pressure canner as a water bath canner (just don't seal it up, so it doesn't pressurize!) so if you can only afford one canner, get the pressure canner, and you can use it for all types of food. Pressure canners are much more expensive, though, so most people start with a water bath canner, even though it limits what they may can.



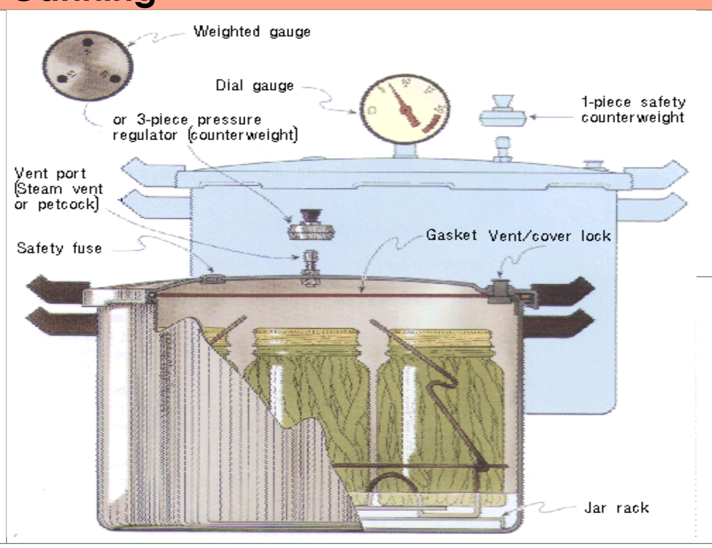
1. Sterilize jars prior to use by boiling for 10m.
2. Fill the jars and leave headspace at the top. This creates a vacuum and stops the food overflowing.
3. Remove any trapped air on the sides of the jar.
4. Using a damp coth, clean around the rim of the jar prior to putting the ring and lids on.
5. Fill up the water bath canner with hot water until it's 3 cm's over the tallest jar.
6. Place the jars in the canner on the rack and turn the heat to high. When it starts boiling the timer starts.
7. After the canning time is complete, raise the canning rack and remove the jars and place onto a towel. Make sure the room isn't cold or the jars could break.
8. Leave out for 24 hours to let the lid seal. The lid is sealed if the indentation is down.
9. Write the date canned on the lid and remove any excess drips of food from the outside of the jars.

Pressure Canning

Pressure cooking is the process of cooking food, using water or other cooking liquid, in a sealed vessel known as a pressure cooker. This simulates the effects of long braising within a shorter time. Almost any food that can be cooked in steam or water-based liquids can be cooked in a pressure cooker.

The cooker works by trapping the steam produced from boiling the cooking liquid inside the vessel. This causes internal pressure and temperature to rise quickly. After use, the steam is slowly released so that the vessel can be opened safely.

Pressure Canning and Botulinum
Unfortunately, Botulinum spores are fairly resistant to heating at boiling water temperatures. In fact, proper processing of low acid foods in a water-bath canner takes so long that doing so will significantly diminish the quality of your final product. Instead, botulism can be prevented by processing low acid food in a pressure canner. This effectively raises the maximum temperature that you can reach during processing. Instead of maxing out at 100°C, a pressure canner can heat food up to 118°C. At this high temperature, Botulinum spores are rapidly killed and the processing time is significantly reduced.



A home canner chooses their method of processing based on the pH of the food they are preserving. It all comes down to safety, and preventing the growth of C. Botulinum. This insistence on safety is what established the pH dividing line of 4.6, and provides a relatively simple way to know how to process your food.

Pressure Canning Steps
1. Sterilize jars prior to use by boiling for 10m.
2. Fill the jars and leave headspace at the top. This creates a vacuum and stops the food overflowing.
3. Remove any trapped air on the sides of the jar.
4. Using a damp coth, clean around the rim of the jar prior to putting the ring and lids on.
5. Fill up the pressure canner - usually 2 inches and then place the jars in. You can separate jar rows with separators. Add oil to the rim to prevent sticking.
6. Put the lid on and line up the arrow and then lock the lid on using the opposite toggles first until finger tight.

COOKING Preservation Canning Pressure Canning

7. Turn the stove on med-high to high and it will come up to pressure in about 30 minutes. Let the vent hiss for 10m before putting the weighted gauge on. Know your elevation to determine how long to cook the food.
8. Wait until the weight jiggles 4 times a minute and watch the pressure gauge until it's around the required PSI. Start the timer when it's up to pressure.
9. Stay nearby and monitor the pressure as it will climb slowly, reduce the pressure if necessary and lower the heat a little. Keep the pressure above the minimum pressure required for cooking.
10. After the food has cooked for the appropriate time (approx 1h 15m) turn off the heat and wait for the pressure to drop to 0. Remove the weighted gauge at 0 PSI and wait 10m before opening the lid.
11. Raise the canning rack and remove the jars and place onto a towel. Make sure the room isn't cold or the jars could break. Leave out for 24 hours to let the lid seal. The lid is sealed if the indentation is down. Write the date canned on the lid and remove any excess drips of food from the outside of the jars.

COOKING Preservation Canning Open Kettle

Open Kettle Canning (Inversion Canning)

The open-kettle method means placing hot food in jars and sealing with no further heat treatment. This is the method that many grandma's used in which granny fills a jar (sanitized or not) with hot fruit, pickles, etc., puts the lid and ring on, then turns it upside down. The jar will cool and seal, BUT it is NOT sterile, as the contents were exposed to the air (and airborne bacteria) just before sealing. From the moment the jars were filled, the contents started cooling, so airborne bacteria contacting the cooling surfaces will still be viable. They were not exposed to a heat high enough, nor long enough to destroy them. Then granny gives the jars away, playing Russian Roulette. Maybe you'll get sick, maybe not. Again, this method is NOT recommended for home canning because the amount of heat applied may not be sufficient to destroy bacteria and the product may spoil quickly or cause illness when consumed.

COOKING Preservation Canning Steam Canning

Steam Canning

The steam canner was designed as a means to process foods using steam without the aid of pressure. The manufacturer claims this process uses less water, saves time and energy, and recommends identical processing times as those required for boiling-water bath treatments.

"Steam canning is not recommended at this time for either acid or low acid foods. Processing times for use with current models have not been adequately researched. Today's steam canner looks like an upside-down boiling water canner. The base is a shallow pan with a rack that is covered with a high dome lid. After the jars of foods are placed on the canner's base, a small amount of water in the base is brought to a boil and the dome fills with steam. The jars and foods in them are heated by the steam surrounding them. However, steam canners do not heat foods in jars exactly the same as boiling water canning does. Low acid foods are potentially deadly because Clostridium botulinum bacteria could survive the steam canning and produce the poison that causes botulism. Acid foods may also be underprocessed and therefore could spoil."
National Home Food Preservation Centre

Study Conclusions
● Atmospheric steam canners result in significantly lower product temperatures at the beginning and end of the scheduled process when compared to water-bath canning.
● Use of steam canners as instructed by the manufacturer would result in under processing and considerable economic spoilage.
● Because steam canners may not heat foods in the same manner as boiling water canners, using boiling-water process times with steam canners may result in spoilage. There is no tested nor approved conversion factor.

COOKING Preservation Canning Oven Canning

Oven Canning

Oven-canning is extremely hazardous. The oven canning method involves placing jars in an oven and heating. In oven canning, product temperatures never exceed the boiling point, and uniform heat penetration cannot be assured. It is, therefore, not considered safe to use for home canning. Because this process fails to destroy the many bacteria, including the spores of Clostridium botulinum, it can cause the food to become toxic during storage. Also, canning jars are not designed for intense dry heat and may explode resulting in serious cuts or burns.

"There is not sufficient, research-based documentation to support that 'canning' any food in a dry oven as described on this web page or any page that proposes oven canning is even sufficient heating to destroy bacteria of concern, let alone enough to produce a proper seal with today's home canning lids."
USDA

COOKING Preservation Canning Other Canning Methods

Other Canning Methods

Solar Canning	The heat generated from captured sunlight is not a reliable method to process acid foods and should never be used to can low-acid foods.
Micro-Dome Food Preserver	Micro-Dome Food Preserver Recalled Washington, DC--The U.S. Consumer Product Safety Commission (CPSC) in cooperation with Micro-Dome of San Ramon, CA, has warned consumers of certain safety hazards associated with the use of the "Micro-Dome Food Preserver" manufactured by Micro-Dome and sold and distributed to consumers after August 1987. The CPSC has also urged consumers to destroy all food that has been preserved using a Micro-Dome Food Preserver.
Microwave Processing	Microwave oven cannot be used for home canning. Microwaved food reaches 100°C (212°F) but heating is not uniform. There is also a danger of explosion of the jars within the microwave oven or as food is being removed from the oven.
Dishwashing Processing	Processing canned foods in a dishwater cycle is dangerous. The temperature of the water during the cleaning and rinsing cycle is far below that required to kill harmful microorganisms. Thus the product will be underprocessed and unsafe to eat. Note that it is fine to use the dishwasher to clean and sanitize the empty jars, especially if your dishwasher has a "sanitize" setting - the empty jars will get hot enough.
Aspirin / Salicylic Acid	So-called canning powders are useless as preservatives and do not replace the need for proper heat processing. You may have heard of someone's grandmother canning corn by boiling the corn, adding aspirin or salicylic acid from the drugstore, then sealing the corn in jars with no further processing. According to the University of Illinois, a recipe circulated several years ago, using aspirin to acidify tomatoes and beans for canning. Aspirin is not recommended for canning. While it contains salicylic acid, it does not sufficiently acidify low acid foods like tomatoes or beans for safe hot water bath canning. Low acid foods (without added acids) should only be processed safely in a pressure canner. Lemon juice or vinegar is recommended to acidify tomato products for safe water bath processing. Salicylic acid, in the ways in which it is used in the preparation of food products, is not only not harmful, but is a preservative to health, inasmuch as the process of decomposition which it prevents would be far more dangerous.

Canning Tips

Canned Jar Storage

- Store the jars between 10°C-21°C (50°-70°F)
- Do not store over 35°c (95°F) at which point the seals could undo themselves.
- Store oldest at the front and the newer at the back.
- Don't store the jars stacked or the pressure could be relieved.
- Store the jars in the box that they came in for a snug fit.

Canning Food Tips

If the jar spurts upon opening it contains Botulism and must discard immediately and anything it came in contact with. The smell should be okay upon opening the jar, if it smells bad, throw it out. Check if the lid is sealed firmly when opening the jars, toss any that aren't sealed. Add a splash of white vinegar if there's a white film on the jars, this is called scaling. Canned food does not need to be cooked after opening the jar.

- Jar canned meat lasts about 2-3 years.
- Pressure can all soup
- Pressure Canning takes about 3 hours per load.

Canning Guidelines

Canning guidelines were revised in 1989 following extensive research. Canning instructions printed before 1989 may be unsafe. Here are some of the newer recommendations you should be using (these are incorporated into all of the recipes on pickyourown.org - we use only the most up-to-date directions and recommendations from the USDA, Ball and major university food science labs:

- Bottled lemon juice should be added to all canned tomatoes.
- Jellies, jams, and preserves should be processed in a boiling water bath.
- Pickles and pickled products should be processed in a boiling water bath.
- The pressure for your pressure canner and the time for processing in a boiling water bath should be adjusted according to your local altitude.

Pressure Canning Bacon

Place about 17 strips of bacon on natural parchment paper and add another strip covering the top half, flip it over and press it down. Roll it up into a cylinder, tucking excess paper under and place it in a wide mouth jar. 10lb pressure for 90m.

Pressure Canning Bread

4 Pickling

Pickling is another form of canning. Pickled products have an increased acidity that makes it difficult for most bacteria to grow. The amount of acid present is very important to the safety of the product. Pickled products are also heated in jars at boiling temperatures to destroy any other microorganisms present and form a vacuum in the jar.

5 Jams & Jellies

Jams and Jellies have a very high sugar content. The sugar binds with the liquid present making it difficult for microorganisms to grow. To prevent surface contamination after the product is made and thus possible yeast or mould growth, these are either canned, frozen, or refrigerated.

See the 'Fruit Preserves' section above for more about preserving fruit as jams.

6 Waxing

Some foods can be waxed to preserve them many years such as cheese and eggs.

Waxing Cheese	Dry cheese for 48 hours in a cool area/fridge (airtight container) at about 15°c and 90% humidity. At least 60% air in the container. Use a damp cloth for humidity. Use a double boiler to melt the wax at about 111°c which kills mould spores. Dip cheese in each half at a time for 3-4 layers holding it in for 5 seconds, letting it dry between waxes, dip cheese < 5 seconds, store it under 12°c to preserve 25 years. Using straight heat will cause thin wax layers - dip more times, ensure cheese is dry before waxing or it will crack and peel off.
Waxing Eggs	Coat eggs with cheese wax to preserve them for 10 years. Paint it on using a brush to prevent them cooking inside.

7 Salting

Salting is the preservation of food with dry edible salt. It is related to pickling in general and more specifically to brining (preparing food with brine, that is, salty water) and is one form of curing. It is one of the oldest methods of preserving food, and two historically significant salt-cured foods are salted fish (usually dried and salted cod or salted herring) and salt-cured meat (such as bacon). Vegetables such as runner beans and cabbage are also often preserved in this manner.

Salting is used because most bacteria, fungi and other potentially pathogenic organisms cannot survive in a highly salty environment, due to the hypertonic nature of salt. Any living cell in such an environment will become dehydrated through osmosis and die or become temporarily inactivated.

It was discovered in the 19th century that salt mixed with nitrates (saltpeter) would color meats red, rather than grey, and consumers at that time then strongly preferred the red-colored meat. The food hence preserved stays healthy and fresh for days avoiding bacterial decay.

8 Smoking

Smoking is the process of flavoring, browning, cooking, or preserving food by exposing it to smoke from burning or smoldering material, most often wood. Meat, fish, and lapsang souchong tea are often smoked. In Europe, alder is the traditional smoking wood, but oak is more often used now, and beech to a lesser extent. In North America, hickory, mesquite, oak, pecan, alder, maple, and fruit-tree woods, such as apple, cherry, and plum, are commonly used for smoking. Other biomass besides wood can also be employed, sometimes with the addition of flavoring ingredients. Chinese tea-smoking uses a mixture of uncooked rice, sugar, and tea, heated at the base of a wok.

Smoking can be done in four ways: cold smoking, warm smoking, hot smoking, and through the employment of "liquid smoke". However, these methods of imparting smoke only affect the food surface, and are unable to preserve food, thus, smoking is paired with other microbial hurdles, such as chilling and packaging, to extend food shelf-life.

9 Drying / Dehydrating

Drying removes most of the moisture from foods. Thus microorganisms cannot grow and enzyme action is slowed down. Dried foods should be stored in airtight containers to prevent moisture from rehydrating the products and allowing microbial growth.

10 Freezing

Freezing reduces the temperature of the food so that microorganisms cannot grow, however many will survive. Enzyme activity is slowed down, but not stopped during freezing.

11 Freeze Drying

Freeze drying, also known as lyophilisation or cryodesiccation, is a low temperature dehydration process that involves freezing the product, lowering pressure, then removing the ice by sublimation. This is in contrast to dehydration by most conventional methods that evaporate water using heat. Freeze drying results in a high quality product because of the low temperature used in processing. The original shape of the product is maintained and quality of the rehydrated product is excellent. Primary applications of freeze drying include biological (e.g., bacteria and yeasts), biomedical (e.g., surgical transplants), food processing (e.g., coffee) and preservation.

Store freeze dried food in a cool, dry place to extend life.

12 Preservation Tips

- Volume - Food Volume = Air Volume
- Air Volume x 0.21 (Air is 21% oxygen) = Oxygen absorber size
- 1g per CC
- Use powdered eggs instead of regular eggs to save space and weight.
- Ensure there's no bugs in the rice by freezing it for a week.
- Freeze grains for 7-10 days to kill weevils and the eggs.
- Store foods with oxygen absorbers equal to the amount of "Cubic Centimetres" of air in the container.
- Use mylar bags for storage of food as they protect from light, moisture and air the best.
- Use 4.5mil mylar bags or more to prevent light entering.
- Oxygen absorbers lose their absorption properties after about 4 hours
- Oxygen absorbers require slight moisture and won't work with desiccants or vacuum packing.

Oxygen Absorbers	Food Storage Variables	Mylar Bag Uses		
100cc - 15x22cm Bag 100cc - 9x13cm Bag 50cc - 6x8cm Bag 200cc - 20x30cm Bag	• Oxygen • Pests • Humidity • Heat • Light	• Oats • Rice • Flour • Beans • Lentils		

6 Cooking Safety

This section shows how to safely prepare food to avoid bacteria, cross-contamination and other contaminants in the food and to help prevent injury to the cooker.

Temperature Safety

- **-23-17°C (-10-0°F):** Best storage temperature for frozen foods.
- **-17-0°C (0-32°F):** Freezing temperatures permit slow growth of some bacteria, yeasts and moulds.
- **0-21°C (32-70°F):** Cold temperatures permit slow growth of some bacteria, yeasts and mould.
- **10-35°C (50-95°F):** Best storage temperatures for canned and dried foods.
- **21-60°C (70-140°F):** Danger Zone, These temperatures allow rapid growth of bacteria, yeast and mould.
- **35-60°C (95-140°F):** Maximum Storage temperatures for canned foods.
- **60-100°C (140-212°F):** Temperature water boils at sea level. Canning temperatures for acid fruits, tomatoes, pickles and jellied products in a boiling-water canner.
- **60-74°C (140-165°F):** Warning temperatures prevent growth but may allow survival of some microorganisms
- **82-100°C (180-212°F):** Canning temperatures are used to destroy most bacteria, yeasts and moulds in acid foods. Time required to kill these decreases as temperature increases.
- **115-121°C (240-250°F):** Canning temperatures for low acid vegetables, meat and poultry in a pressure canner.

Refrigerating Opened Cans
Storing food in an open can is normally safe for a short period, but inadvisable.

1	Cans used to be made of tin, which is toxic. Modern cans are made from either steel or aluminium. If the contents of the can are acidic, cans are lined with a polymer (plastic) inner layer. If that layer is broken -- say, by a major dent in the can or by using a knife to scrape out contents -- then the acid can get to the metal and, over time, corrode it, and some of the now-oxidized metal will dissolve into the food. As far as we know, the oxidized metal is not toxic, but it tastes horrible.
2	Contamination. Any open container of food can become contaminated when an airborne water droplet (tiny -- microns wide) containing a nasty microbe drips or settles into it. The major biological culprit here is Listeria, which can grow in any moist environment, including spaces refrigerated below 40F (5C). Also, if juices from your raw meat drips onto an upper shelf, which later gets wiped inadvertently into your container of ready-to-eat food, you are likely to get Salmonella or E coli. This risk can be mitigated if you keep your raw meats on the lowest shelf, but not eliminated. Also, it is worth noting that contamination through this pathway is a relatively rare event -- but even so, it is not worth the risk.
3	Have you ever put an ice cube in your beverage and notice your beverage tastes strange? The chemical compounds that give food their flavour tend to be volatile (meaning they will readily leave the food into the surrounding air). Also, the mustiness of a refrigerator/freezer is due to volatile compounds produced by mould and mildew. Foods that are wet and/or fatty can be molecular velcro to these compounds.

COOKING Cooking Safety Reheating

Reheating

Food which isn't consumed when cooked need to be stored correctly and then reheated when you wish to eat it. That's where this section comes in.

Simmer Reheating	
Microwave Reheating	
Heating in Cans	Cans could have an epoxy coating on the inside which when heated could melt and make its way into the food. Chromium and nickel can find their way out of steel, but the amounts would be miniscule to none. Aluminium-large amounts of which have been linked to nervous system disorders and other health problems could in theory leach out of cans into their food or drink contents. The insides of most cans on grocery shelves today are coated with food-grade epoxy. But these liners have been shown to contain Bisphenol-A (BPA) and other potentially harmful chemicals. Therefore it's recommended to tip the cans contents into another container before cooking.

Recipes

Step-by-step guides to cooking in the wild or homestead

"A joyful life is an individual creation
that cannot be copied from a recipe."
Mihaly Csikszentmihalyi

Introduction

This section contains tasty recipes divided into complexity based on food availability. For a list of what foods are likely to be common in SHTF, take a look at the "SHTF Food Rarity" section under "FOOD".

Purpose	The aim of RECIPES is to provide you with a range of foods you can cook regardless of your location or supplies. You'll find information on the staples of cooking such as bread, foraging recipes which you should be able to locally acquire from nature, homesteading recipes if you have an established farm and modern recipes which can draw from all of the ingredients available in supermarkets today.
Lost?	● For the cooking of food, see the COOKING section. ● If you're looking for eating all kinds of wild and foraged foods as well as the wild food edibility test, see the PLANTS section. ● If you're looking for the food groups, see the HEALTH section. ● If you want to know how to properly prepare wild game for consumption, see the FIELD DRESSING section. ● For a list of recommended foods and food storage, see the FOOD section.

Contents

1 Staple Recipes

These recipes are for the most basic items you can make such as bread.

Staples

Yeast

Yeasts are chemoorganotrophs, as they use organic compounds as a source of energy and do not require sunlight to grow. Carbon is obtained mostly from hexose sugars, such as glucose and fructose, or disaccharides such as sucrose and maltose. Some species can metabolize pentose sugars such as ribose, alcohols, and organic acids. Yeast species either require oxygen for aerobic cellular respiration (obligate aerobes) or are anaerobic, but also have aerobic methods of energy production (facultative anaerobes). Unlike bacteria, no known yeast species grow only anaerobically (obligate anaerobes). Most yeasts grow best in a neutral or slightly acidic pH environment.

Yeasts vary in regard to the temperature range in which they grow best. For example, Leucosporidium frigidum grows at −2 to 20 °C (28 to 68 °F), Saccharomyces telluris at 5 to 35 °C (41 to 95 °F), and Candida slooffi at 28 to 45 °C (82 to 113 °F). The cells can survive freezing under certain conditions, with viability decreasing over time.

In general, yeasts are grown in the laboratory on solid growth media or in liquid broths. Common media used for the cultivation of yeasts include potato dextrose agar or potato dextrose broth, Wallerstein Laboratories nutrient agar, yeast peptone dextrose agar, and yeast mould agar or broth. Home brewers who cultivate yeast frequently use dried malt extract and agar as a solid growth medium. The fungicide cycloheximide is sometimes added to yeast growth media to inhibit the growth of Saccharomyces yeasts and select for wild/indigenous yeast species. This will change the yeast process.

The appearance of a white, thready yeast, commonly known as kahm yeast, is often a byproduct of the lactofermentation (or pickling) of certain vegetables, usually the result of exposure to air. Although harmless, it can give pickled vegetables a bad flavor and must be removed regularly during fermentation

Ingredients	• Glass Container • Measuring Cup (1 Cup) • 1 Cup Flour • 2 Cups Warm Water
Making Yeast	1. Use a glass container with a covering that allows air in 2. Pour in 1 cup of warm water and add 1 cup of flour. 3. Stir and cover. 4. Wait 24 Hours. 5. Pour half the mixture out and add 1 cup warm water and one cup flour. Re-cover. 6. Repeat daily.
Yeast Outcomes	1. Nothing - Then move container near open window. 2. Mould develops - Smells wrong so throw it out. 3. Yeast grows - Smells good like bread or alcohol.
Proofing Yeast	Proofing ensures the yeast is alive and working. Combine yeast with a little warm water and sprinkle sugar and wait. 5-10 minutes later there should be some froth, if there's none the yeast isn't working.
Tips	• Use stored yeast to kick-start a new culture by putting it into an equal mix of water and flour. • Lactobactillus is the yeast starter for sourdough bread. • Use yeast that occurs in alcohol to leaven bread.

Bread

Ingredients	**Basic Ingredients** • Flour • Water • Yeast • Salt	**White Bread Ingredients** • 2 Tbsp Vegetable Oil • 2 Tsp Salt • 1 Cup Warm Milk • 1 Cup Warm Water • 1 Cup Warm Yeast • 1 Pk dry Yeast • 1/4 Cup Warm Water • 6 Cups White Flour		
Method	1. Proof the Yeast. 2. Combine hot milk and water and wait till cool. 3. Add Yeast. 4. Mix well. 5. Add 3/5 Flour and mix until well blended and not lumpy. 6. Add the rest of the flour until dough forms. 7. Knead Gently for 2 mins, adding remaining flour until no longer sticky. 8. Leave it for 10m under a wet cloth.		9. Knead until smooth and elastic. 10. Place in bowl with damp cloth. 11. Allow to rise, doubling in size. 12. Shape into loaves. 13. Place in loaf pans and cover with damp cloth and let it double again. 14. Bake at 218°C (425°F) for 15m. 15. Continue baking at 190°C (375°F) for 30m.	
Kneading	Folding the dough in half, pushing down and away. Rotate 90° then repeat. When ready the dough should be less sticky and won't cling to the surface.			

2 Foraging Recipes

These are very simple recipes that involve easily foraged ingredients.

Entrée

Buttered Chickweed Salad

	The freshness of chickweed combined with the healthy goodness of onions make this a great side dish to serve.			**Prep Time:** 5 Mins **Cook Time:** 5 Mins **Yields:** 2 Serves
Ingredients	• 2 cups chopped chickweed • 1 finely chopped onion • Butter (If desired) • Salt (If desired) • Pepper (If desired)			**Foraged Food in Recipe** • Chickweed

Method	**Instructions** Wash chickweed thoroughly and place in boiling salted water. Cook only for only two to three minutes, drain well. (Reserve the liquid to make a tea) Melt a small amount of butter in a frying pan. Sauté the onion until translucent then add chickweed. Add salt, pepper or any other spices. Sauté one minute.

Chickweed Salad

	A salad with the fresh, unique flavour of a tasty wild green.			**Prep Time:** 15 Mins **Cook Time:** 0 Mins **Yields:** 4 Serves
Ingredients	• 1 cup chickweed leaves • 1 bunch scallions or 1 small red onion finely sliced • 1 beet • Pinch of sea salt	• 3 tbsp. organic coconut oil • 2 tbsp. wine vinegar • 1/2 tsp. mustard of choice		**Foraged Food in Recipe** • Chickweed
Method	**Instructions** Rinse and drain chickweed. Thinly cut scallions. Grate a raw beet. Place in bowl. Combine the coconut oil, wine vinegar and mustard well then toss through salad. Sprinkle a pinch of salt over salt and enjoy.			

Nutricized Purslane

	A fresh tasting salad that is sure to please everyone.			**Prep Time:** 15 Mins **Cook Time:** 00 Mins **Yields:** 2 Serves
Ingredients	• 3 cups chopped purslane • 1 sliced hard-boiled egg • 1/2 cup pigweed (amaranth) leaves • 1/4 cup mozzarella cheese diced into small pieces	• 1 chopped onion • 1 cup chopped chickweed • 1 ripe avocado (peeled and diced) • 1 tsp garlic salt • Juice of 1/2 lemon	• Chia seeds or sunflowers seeds if desired	**Foraged Food in Recipe** • Purslane
Method	**Instructions** Place into a bowl the purslane, chickweed, pigweed and onion. Add the avocado and the egg. Mix in the cheese. Drizzle the lemon over the salad, add the garlic salt, and mix well. If desired sprinkle with seeds of your choice.			

Plantain Salad

	A refreshing and simple-to-make summertime salad that is sure to please everyone! This low-cost plantain salad packs a nutritional punch that your body will love.			**Prep Time:** 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 2 cups of plantain leaves finely chopped (Broadleaf or Narrowleaf Plantain) • ½ cup of cabbage finely chopped • 1 large can of chick peas (28 oz), drained	• 1 onion thinly chopped • 1 celery stalk finely chopped • 1 or 2 garlic gloves finely chopped • 1/8 cup olive oil • 1/8 cup wine vinegar • 1 tsp. salt		**Foraged Food in Recipe** • Broadleaf Plantain
Method	**Instructions** Mix all the above ingredients (except the oil and vinegar) in a large bowl and refrigerate. Once chilled, add the oil and vinegar. If you find the salad a bit dry, then increase the quantity of olive oil and wine vinegar equally until you have the desired moistness.			

Sesame and Wilted Green Sauté

	A quick sauté that is a powerhouse of nutrients.			**Prep Time:** 10 Mins **Cook Time:** 5 Mins **Yields:** 2 Serves
Ingredients	• 2 cloves of garlic, peeled and finely chopped • 2tbsp. sesame oil • 2 litres (8 cups) wild greens (possibilities: plantain, dandelion, lamb's quarters, mustard)	• 1 tbsp. tamari or soy sauce • 2 tbsp. orange juice • 2tbsp. toasted almonds • toasted sesame seeds for garnish		**Foraged Food in Recipe** • Broadleaf Plantain • Dandelion • Garlic Mustard • Lamb's Quarters
Method	**Instructions** In a heated skillet, sauté your choice of wild greens for two minutes with sesame oil. Add tamari (or soy sauce), orange juice and toasted almonds. Blend well. Remove from heat. Sprinkle toasted sesame seeds on top as a garnish and serve.			

Summer Salad

	A light salad with a big taste. This is a refreshing salad that has the perfect blend of flavours that's sure to please.			**Prep Time:** 15 Mins **Cook Time:** 0 Mins **Yields:** 2 Serves
Ingredients	• 1 sliced cucumber • 1/8 cup chopped purslane • 5 – 7 radishes (your choice), thinly sliced • 3/4 cup raisons	• 1/2 cup plain yogurt • 2 tsp finely chopped fresh mint • sea salt to taste		**Foraged Food in Recipe** • Purslane
Method	**Instructions** In a salad bowl combine all ingredients. Let sit in fridge 30 minutes before serving.

Mains

Baked Dandelion

	Baked dandelion leaves will have you re-thinking eating potato chips. Healthy, tasty, and so easy to make, dandelion chips are a great snack.			**Prep Time:** 5 Mins **Cook Time:** 10 Mins **Yields:** 00 Serves
Ingredients	● Fresh large dandelion leaves (washed and dried) ● 1 cup whole wheat flour ● 1 1/2 cup water ● 1 egg	● 2 tbsp. wheat germ ● 2 tbsp. spiked salt (or a variety of spices of your choosing)		**Foraged Food in Recipe** ● Dandelion
Method	**Instructions** Preheat oven to 204°C (400°F). Combine the flour, water, egg, wheat germ and spices into a bowl and mix well. Dip leaves into the batter and place onto a baking sheet lined with parchment paper. Be sure to not to overlap for best results. Bake 5 -10 minutes if the leaves used are very large. If the dandelion leaves are smaller then start watching them at about the 3-4 minute mark to ensure they do not burn. Serve warm or once cooled!			

Baked Plantain

	These plantain chips are simple to make and home grown! Loaded with nutrients, these chips are a great potato chip alternative.			**Prep Time:** 5 Mins **Cook Time:** 10 Mins **Yields:** 00 Serves
Ingredients	● Fresh large plantain leaves (washed and dried) ● 1 cup whole wheat flour ● 1 1/2 cup water ● 1 egg	● 2 tbsp. wheat germ ● 2 tbsp. spiked salt (or a variety of spices of your choosing)		**Foraged Food in Recipe** ● Broadleaf Plantain
Method	**Instructions** Preheat oven to 204°C (400°F). Combine the flour, water, egg, wheat germ and spices into a bowl and mix well. Dip leaves into the batter and place onto a baking sheet lined with parchment paper. Be sure to not to overlap for best results. Bake 5 -10 minutes if the leaves used are very large. If the plantain leaves are smaller then start watching them at about the 3-4 minute mark to ensure they do not burn. Serve warm or once cooled!			

Buffalo Style Milkweed Pods Recipe

	The vegetarian answer to buffalo style chicken wings.			**Prep Time:** 10 Mins **Cook Time:** 30 Mins **Yields:** 2 Serves
Ingredients	● 1 and 1/2 cup Panko (Japanese bread crumbs) (Or any other bread crumbs) ● 1/4 cup flour ● 1 tbsp. garlic powder ● 1 egg	● 1 tsp. of each: paprika, oregano, cayenne and turmeric ● 1/2 cup almond milk ● 1/2 cup water ● Hot wing sauce of your choice		**Foraged Food in Recipe** ● Milkweed
Method	**Instructions** Preheat oven to 176°C (350°F). Mix dry ingredients together. Mix egg, almond milk and water together then blend in dry ingredients. Mix well. Dip milkweed pods into batter and place on a baking sheet covered with parchment paper. Place in oven and cook for 15-20 minutes. When crisp take out and place in a bowl. Add in your favourite wing sauce (enough to evenly coat) and mix. Place milkweed pods back on the baking sheet and cook for an additional 10 minutes.			

Burdock Brown Rice and Mushroom

				Prep Time: 10 Mins **Cook Time:** 45 Mins **Yields:** 00 Serves
Ingredients	● 4 large mushrooms of your choice ● 1 tbsp. olive oil ● 1 medium burdock root ● Cold, salted water for soaking burdock root	● 2 cups cold water for cooking rice ● 1 cup long-grain brown rice ● 1 grated carrot ● 1/2 tsp. sea salt		**Foraged Food in Recipe** ● Burdock
Method	**Instructions** Preheat oven to 176°C (350°F). Cut mushrooms into small pieces. Scrub burdock and whittle into slivers – then place them into the cold, salted water. Soak for 5 minutes. Drain and place burdock into a pan with 2 cups water, olive oil, rice, mushrooms, carrots and salt. Bring to a boil while stirring occasionally. Remove from stove and place into a lightly greased casserole dish – cover and bake for 45 minutes. Remove from oven, uncover, fluff and let stand 5 minutes before serving.			

Cattail Rice

Cattail Rice				**Prep Time:** 5 Mins **Cook Time:** 5 Mins **Yields:** 00 Serves
Ingredients	● 1 tbsp. olive oil ● 1/2 cup peeled and chopped cattail shoots ● 1 cup chopped shallots ● 2 cloves chopped garlic	● 3 cups cooked brown rice ● 2 tbsp soy sauce ● 1/2 teaspoon cayenne pepper		**Foraged Food in Recipe** ● Cattail
Method	**Instructions** Heat the olive oil in a large skillet. Add the cattails, shallots and garlic and sauté for 5 minutes. Add the remaining ingredients and cook until the rice is hot. Stir frequently to prevent sticking.			

Chicken Weed Wrap

Chicken Weed Wrap	Fast, easy and tasty chicken wraps with fresh greens are sure to be a hit when you're tight on time.			**Prep Time:** 5 Mins **Cook Time:** 0 Mins **Yields:** 00 Serves
Ingredients	● 1 large whole wheat tortilla wrap ● 1 cooked breaded chicken finger (or 2 if they are small) ● 1 cup chopped greens	● Hot sauce and/or any other condiment you prefer ● Optional: grated cheese of your choice.		**Foraged Food in Recipe** ● Broadleaf Plantain ● Dandelion ● Garlic Mustard ● Lamb's Quarters ● Purslane
Method	**Instructions** Place one cup of chopped greens that grow in your garden such as: purslane, dandelion, garlic mustard, lamb's quarters, wild lettuce, red clover leaves, white clover leaves, plantain, etc., on your tortilla. If desired add in some fresh parsley, cilantro or any other herb. Place the cooked chicken strip on top. Add cheese if desired. Top off with your favourite hot sauce, dressing or other condiment. Wrap and enjoy!			

Dandelion Fritters

Dandelion Fritters	Enjoy the health benefits of dandelion flowers in a fritter batter with the spices you and your family love. Edible dandelion flowers are a fabulous way to add a touch of wild to your meal!			**Prep Time:** 10 Mins **Cook Time:** 10 Mins **Yields:** 4 Serves
Ingredients	● 4 cups of fresh picked (washed) dandelion flowers ● 2 cups flour ● 2 eggs ● 2 cups milk			**Foraged Food in Recipe** ● Dandelion
Method	**Instructions** Mix the milk, flour and eggs and beat until blended well. Warm some olive oil in a skillet on the stove (keep at medium heat). Holding the underneath of the flowers, dip into the batter until totally covered in the fritter batter then place into skillet, flower side down. Once they are brown, flip and brown the other side. If need be, continue flipping until the batter coating is light brown. Remove from oil and allow excess oil to soak onto a towel or paper towel. Eat plain or drizzle with maple syrup, honey, or even roll them in icing sugar while they are still warm. Be creative – add your favourite spices or herbs to the fritter batter!			

Dandy Pasta

Dandy Pasta	Pasta never tasted so good and so nutritious as well.			**Prep Time:** 15 Mins **Cook Time:** 15 Mins **Yields:** 2 Serves
Ingredients	● 2 cups of bowtie whole wheat pasta (or pasta of your choice) ● 2-3 cups of freshly picked (washed) dandelions with roots ● 1 large red onion	● 2 large cloves of garlic ● 1/4 cup butter ● 3 tbsp coconut oil ● 2 tbsp spiked salt (or 2 tbsp of spices of your choice - but go very easy on the salt!)		**Foraged Food in Recipe** ● Dandelion
Method	**Instructions** Cut dandelion roots from the leaves right at the top of the root so that the leaves stay intact (if using young shoots). Finely chop the roots. Finely chop the onion and garlic cloves. In a stove top frying pan (or wok) melt butter and coconut oil over low heat. Add spices and blend well. Add dandelion root, garlic and onions and allow to simmer 5-10 minutes. After simmering add drained pasta to the pan and stir well. Simmer 1-2 minutes. Add dandelion leaves and stir. Let simmer 1 minute and serve! (If using larger leaves you may want to increase the spices you use to help offset the bitter taste.)			

Fried / Baked Purslane

Fried / Baked Purslane				**Prep Time:** 5 Mins **Cook Time:** 15 Mins **Yields:** 00 Serves
Ingredients	● 1 cup of purslane ● Ground bread crumbs (fresh or use Panko for best flavour) ● 1/2 cup flour ● 1 egg			**Foraged Food in Recipe** ● Purslane
Method	**Instructions** Mix the purslane in a beaten egg and flour. Then cover the purslane with bread crumbs. Sauté the purslane in butter or coconut oil for about five minutes or until golden brown. Or if you prefer, bake in an oven at about 148°C (300°F) for about 15 minutes.			

RECIPES | Foraging Recipes | Mains

Grape Leaf Burritos

	Bean burritos wrapped in nutrient-dense grape vine leaves makes this meal a very healthy choice.				**Prep Time:** 20 Mins **Cook Time:** 15 Mins **Yields:** 2 Serves
Ingredients	• 10 large grapevine leaves • 1 can refried beans • 1 cup cooked quinoa • 4 onions finely chopped • garlic salt and pepper to taste	• taco seasoning to taste (homemade preferable) • spaghetti sauce • grated mozzarella and cheddar cheese			**Foraged Food in Recipe** • Wild Grape Vine
Method	**Instructions** Preheat oven at 350°F. Sauté three quarters of the chopped onions. In a bowl, mix the can of refried beans, the quinoa, sautéed onions, and taco seasoning. Cover a baking sheet with parchment paper. Place some of the burrito mixture in the centre of a grape leaf, roll and place on baking sheet with the folded side faced down. Repeat with the remaining leaves. Once arranged in two rows, spoon some spaghetti sauce over the folded leaves. Take the remaining onions and place them over the burritos. Sprinkle some grated cheese over the burritos then season with garlic salt and pepper. Bake 15 minutes.				

Lamb's Quarters Gnudi

	Gnudi is a fantastic dish that tastes incredible.				**Prep Time:** 15 Mins **Cook Time:** 35 Mins **Yields:** 4 Serves
Ingredients	• 1 cup chopped lamb's quarters • 1 cup cottage cheese • 1 egg • 1 cup flour • sea salt (to taste)	• 1/2 cup grated parmesan cheese • 4 tablespoons butter • Spice mixture – your choice			**Foraged Food in Recipe** • Lamb's Quarters
Method	**Instructions** Finely chop the lamb's quarters. Combine with the cottage cheese, egg, 3/4 cup of flour, sea salt and 1/4 cup of parmesan cheese. Mix well and form into dough. Knead and add rest of flour until it becomes a workable consistency. Don't overwork. Let sit 30 minutes. Break off small clumps of dough, roll in flour, and form into dumplings (about 2 " long and 1" wide). Boil water in a pot; add some salt and a few drops of oil. Once boiling, place the gnudi into water and let boil for about 7 minutes. Do not crowd the gnudi. Drain. Place in a fry pan with butter and brown. Sprinkle with the remainder of the parmesan cheese and spice mixture.				

Milkweed Rice

	Milkweed rice is a tasty, healthy and uniquely flavoured side dish that goes well with most meals.				**Prep Time:** 10 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 cup basmati rice • 1 cup vegetable stock (or make an herbal tea of your choice and use this) • 1/2 cup milkweed • flower buds (or flowers just as they bloom)	• 1/2 cup white wine • 3 cloves garlic (chopped finely) • 3 tbsp finely chopped yellow onions • 3 tbsp butter • 1 tbsp olive oil	• Grated Parmesan cheese (optional) • Sea salt and/or pepper to taste		**Foraged Food in Recipe** • Milkweed
Method	**Instructions** Place the vegetable (or herbal) stock and wine in a saucepan and add rice. Bring to a boil and reduce heat to simmer. Slightly cover rice and stir occasionally until all moisture is absorbed. Remove from heat, cover and let sit. As the rice is in the simmering stage, in a small skillet melt butter and the olive oil in your pan until melted, then add garlic and onions. Sauté for no more than two minutes, add flower buds (or fresh flowers) and sauté one more minute. Mix the sautéed mixture into the rice and let sit two minutes and serve. If desired add some Parmesan cheese, sea salt, and/or pepper.				

North African Style Purslane

					Prep Time: 10 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 3 cups steamed purslane • 2 chopped garlic cloves • 1/2 cup cilantro • 3/4 cup parsley • 1 tsp paprika	• 1 tsp chilli • 1 tsp cumin • Olives • Lemon juice of one lemon and its pulp • Coconut oil (about 2 tbsp)			**Foraged Food in Recipe** • Purslane
Method	**Instructions** In a frying pan melt the coconut oil. As it melts add in cilantro, parsley, chopped garlic and simmer over low heat for a few minutes stirring often. Add the purslane, paprika, lemon pulp and stir constantly for about 5 minutes. Add cumin and lemon juice. Stir well. Garnish with olives. This can be served warm or cold.				

Roasted Lambs Quarters

	Lamb's quarters stems are just as useful in the kitchen as the leaves and seeds. Roast the stems and enjoy these as a tasty treat.				**Prep Time:** 15 Mins **Cook Time:** 25 Mins **Yields:** 00 Serves
Ingredients	• 2 cups (soft) lamb's quarters stems chopped into pieces (about 6cm long) • 2 tbsp. flax seed oil (or oil of your choice) • Spices (as many as you like)	• garlic powder • black pepper • sea salt			**Foraged Food in Recipe** • Lamb's Quarters

Method	**Instructions** Wash the lamb's quarters stems and place into a bowl. Add the oil and spices and blend well. Place parchment paper on a baking sheet and evenly spread the stems on the sheet. Sprinkle with sea salt. Bake at 350°F until crispy (or to your liking). As some ovens differ in heat distribution, ten minutes may be sufficient depending on thickness of the stems. Check frequently to avoid burning them. I have suggested spices above but this is a recipe to can tailor to your taste preference. When cooked crispy, roasted lamb's quarters can be broken and added to salads for extra flavour!

Roasted Reed Rhizomes

				Prep Time: 10 Mins **Cook Time:** 25 Mins **Yields:** 00 Serves
Ingredients	● 12 phragmites rhizomes (at least 6" long) ● olive oil ● Sea salt and pepper (or other spices) to taste			
Method	**Instructions** After washing the phragmites rhizomes place them on a baking sheet. Or if you choose to, you can coat them with a tiny bit of olive oil and spices then place on a baking sheet. Bake at 350 degree Fahrenheit for 25 minutes.			

Salt and Vinegar Lambs Quarters

	This salt and vinegar recipe is a healthy alternative to regular salads. There is no going wrong when you serve lambs quarters.			**Prep Time:** 10 Mins **Cook Time:** 20 Mins **Yields:** 00 Serves
Ingredients	● 5 cups washed chopped lamb's quarter leaves ● 2 tbsp. raw apple cider vinegar ● 2 tbsp. olive oil ● 1/4 tsp. sea salt	● Optional: 2 tbsp. of any finely chopped fresh garden herb of your choice (rosemary, basil, thyme, mint, etc.)		**Foraged Food in Recipe** ● Lamb's Quarters
Method	**Instructions** Wash and chop greens and place into a bowl. Add all other ingredients and mix well. This can be eaten fresh or you can bake this for 20 minutes at 162°C (325°F). (Spread evenly on a baking sheet.)			

Stuffed Milkweed Pods

				Prep Time: 15 Mins **Cook Time:** 20 Mins **Yields:** 00 Serves
Ingredients	● 4 oz. cream cheese softened ● 1 tbsp. diced red onion ● 2 slices of cooked bacon ● 1 small jalapeno chopped fine ● Salt and pepper	● 20 milkweed pods, boiled and split ● Bread crumbs		**Foraged Food in Recipe** ● Milkweed
Method	**Instructions** Heat oven to 190°C (375°F). Place the softened cream cheese in a bowl and mix in the diced onion, jalapeno, bacon, salt and pepper. Remove the immature seeds and silk from the boiled milkweed pods, and spoon in about 2 tsp. of cream cheese filling until the pod is full. Roll the exposed seam of cream cheese in bread crumbs and place seam side up on a baking sheet covered with a sheet of parchment paper. Bake the stuffed pods for 15-20 minutes. Serve warm.			

Weed Burger

	Vegetarian burgers never tasted so good. Adding some wild greens into the mix boosts flavour and nutritional levels.			**Prep Time:** 10 Mins **Cook Time:** 10 Mins **Yields:** 8 Burgers
Ingredients	● 2 2/3 cups cooked quinoa ● 4 large eggs, beaten ● 1/2 teaspoon salt ● 3 cloves garlic finely chopped ● 1 onion finely chopped	● 3/4 cup gluten free whole grain breadcrumbs (or regular) ● 1 cup of finely chopped wild edibles of your choice ● 1 tbsp spices of your choosing		
Method	**Instructions** Combine the cooked quinoa, eggs, salt and spices in a large bowl. Stir in the onion and the garlic. Stir in the bread crumbs and wild edibles. Let the mixture sit for a few minutes so the crumbs absorb some of the moisture. Form into thick patties and cook in a frying pan 10 minutes (5 minutes each side) or a couple of extra minutes until slightly crispy on the outside. Use coconut oil (or butter) of your choice when cooking the burgers. Makes about 8 burgers. Serve as a burger or on its own with chickpea gravy.			

Wild Pizza

				Prep Time: 15 Mins **Cook Time:** 20 Mins **Yields:** 00 Serves
Ingredients	● Premade pizza shell or pita ● 8 cups of wild greens (packed tightly) ● 2 onions medium sized finely chopped ● 3 tbsp. olive oil or butter ● 1/2 cup sour cream ● 1 egg	● 1/4 teaspoon ground nutmeg ● Pinch ground cloves ● Pinch cayenne ● 1/4 cup grated parmesan cheese ● 2 cups grated mozzarella cheese		**Foraged Food in Recipe** ● Broadleaf Plantain ● Dandelion ● Garlic Mustard ● Lamb's Quarters

Method	**Instructions** (Recommended greens include: plantain, dandelion, wild lettuce, garlic mustard and lamb's quarters.) Preheat oven to 232°C (450°F). Chop greens and place in a small amount of water, boil until tender and wilted. Older greens may be boiled more than once in a change of water to lessen bitterness if desired. Drain well. Once cooled, squeeze out excess liquid. Sauté onions in oil or butter until soft. Add in greens and sauté about 5 minutes. In a bowl beat egg and sour cream. Add cloves, nutmeg, cayenne, parmesan cheese, sautéed onions and greens. Spread evenly on premade pizza shell or pita, leaving a small border around the edge. Sprinkle mozzarella cheese on top. Cook for 15 minutes or when cheese starts to bubble			

Wood Sorrel and Onion Tart

	If you like quiche then you'll love this wood sorrel, onion and wild green tart with feta cheese. This nutrient-dense quiche-like tart will have you going for seconds.			**Prep Time:** 15 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 2 tbsp. butter • 1/2 large (or one small) onion thinly sliced • 1/8 cup of dry white wine • 1/4 tsp. salt	• 1 tbsp. flour • 3/4 fresh wood sorrel leaves, flowers and pods (avoid tough stems) • 2 eggs • 1 cup heavy cream	• 6 freshly ground black pepper • 3/4 cup grated gruyere cheese • pinch of nutmeg • 1 pre-baked pie shell • pepper	**Foraged Food in Recipe** • Wood Sorrel
Method	**Instructions** Sauté onion in salt and butter slowly on medium-low heat until onions are soft. Raise the heat to medium and add the wine allowing it to evaporate. Add flour and stir well. Add sorrel and stir constantly for one minute. Remove from heat. In a large bowl whisk together the cream, eggs, pepper and nutmeg. Combine the sorrel mixture with the egg mixture and half of the cheese. Place the other half of the cheese evenly			

Yarrow Omelette

	So simple, tasty, and incredibly healthy, this yarrow omelette is easy to make. Within minutes you can be enjoying a very healthy breakfast or lunch.			**Prep Time:** 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 6 eggs • ¼ cup finely chopped yarrow • 1 small onion finely chopped • Salt and pepper to taste			**Foraged Food in Recipe** • Fern Leaf Yarrow
Method	**Instructions** In a mixing bowl beat eggs. Add in finely chopped yarrow and onion and blend well. Cook the omelette your favourite way then enjoy!			

Soups

B17 Soup

				Prep Time: 15 Mins **Cook Time:** 20 Mins **Yields:** 00 Serves
Ingredients	• 12 cups water • 2 or 3 cans of chick peas • 2 cups dried red lentils • 1 head of broccoli chopped fine (or more if desired)	• 4 cups chopped spinach • 2 large onions finely chopped • 3 tbsp (heaping) granulated garlic • 2 tbsp (heaping) turmeric • 2 tbsp (heaping) cumin	• (Optional) wildcrafted alfalfa (1/4 to 1/2 cup dried or fresh) • Salt and pepper to taste	**Foraged Food in Recipe** • Alfalfa
Method	**Instructions** Place lentils and water in a pot. Bring to a boil and immediately reduce temperature to medium. Stir often to ensure lentils do not stick to the bottom of the pot. Once the lentils are soft add all other ingredients and stir well. Let simmer 20 minutes. Add salt and pepper if desired.			

Burdock Root Soup

				Prep Time: 10 Mins **Cook Time:** 45 Mins **Yields:** 00 Serves
Ingredients	• Burdock root (8-12"), peeled and cut into 1.5 inch pieces. (Pre-soak in water 15 minutes) • 2 organic carrots, peeled and cut into thin pieces	• 6 honey dates cut up • 1/8 cup goji berries • 6 cups water • Spices of your choice		**Foraged Food in Recipe** • Burdock
Method	**Instructions** Put water and burdock root in a pot and bring to a boil. Let simmer 30 minutes. Add carrots and continue simmering for 45 minutes. Add in the dates and goji berries and simmer another 15 minutes. Season to taste with whatever spices you prefer then enjoy!			

Cattail Soup

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves

Ingredients	● 2 1/2 cups almonds ● 10 cups water ● 2 cups thinly sliced cattail shoots ● 1/4 cup fresh spearmint leaves or other mint leaves, finely chopped ● Juice of half a lemon			**Foraged Food in Recipe** ● Cattail
Method	**Instructions** Cover the almonds with water and soak overnight in the refrigerator. Puree the soaked almonds with about 3 cups of the almond/water mixture at a time in a blender until all the almonds have been pureed. Pour the puree into a colander lined with cheesecloth or thin nylon fabric over a bowl. Twist the top of the cloth and squeeze the remaining water. Discard the pulp and mix the remaining ingredients with the almond milk. Serve chilled.			

Fiddlehead Soup

	Mouth-watering soup that's easy to make and tantalizes the tastebuds.			**Prep Time:** 15 Mins **Cook Time:** 30 Mins **Yields:** 4 Serves
Ingredients	● 5 medium potatoes cubed ● 2 1/2 cups fiddleheads ● 1 cup chopped wild leeks ● 3 stalks of celery chopped ● 2 onions chopped	● 5 cups water ● 2 cups vegetable broth ● 4 cloves of fresh garlic minced ● salt and pepper to taste ● 1 to 2 cups cream (optional)	If wild leeks are not available then substitute them with a medium-large size onion. Make large batches of this and freeze so you can enjoy fiddlehead soup in the winter months!	
Method	**Instructions** Pour the water and vegetable broth into a large pot. Add the cubed potatoes, chopped celery, wild leeks, onions, garlic, salt and pepper. Bring to a boil then turn the stove down to simmer. Add fiddleheads. Simmer until the vegetables are soft. Put the soup mixture in a blender until desired consistency is reached. If you want to make this a creamy soup then return soup to the pot and slowly add cream until it is thickened.			

Lambs Quarters Soup

	A unique soup that is perfect for a warm summer's day.			**Prep Time:** 15 Mins **Cook Time:** 15 Mins **Yields:** 4-6 Serves
Ingredients	● 1 tomato cut in half ● 3 cups of water ● 2-3 cloves of garlic ● 1/2 of a juiced lime ● 1 tbsp. of olive oil	● 1 tsp. of honey or agave syrup ● 1/2 tsp. sea salt ● 2 cups freshly picked lamb's quarters (washed and chopped) ● 1/2 an avocado (chopped)	● 1 thinly sliced sautéed red pepper ● 1 chopped sautéed onion ● 2 celery stalks chopped thin and sautéed	**Foraged Food in Recipe** ● Lamb's Quarters
Method	**Instructions** Blend the first seven ingredients in blender until smooth. Pour in to a pot on the stove. Then add the last five ingredients. Simmer (do not boil) until onions celery are soft. Decorate with marigold or other edible flower petals and serve.			

Leek and Nettle Soup

	This health-nourishing nettle soup goes well with your favourite crackers or all on its own. One bowl is not enough of this easy-to-make, nutrient-rich soup.			**Prep Time:** 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	● 2 large (washed) potatoes cut up small with skin on ● 10 cups water ● 4 cups thinly sliced leeks ● 1/2 cup dried stinging nettle (or equivalent fresh)	● Handful of fresh finely chopped dandelions ● Handful of dried or fresh (washed) red clovers ● 2 tsp. of dried thyme (or equivalent fresh)	● 1 tsp. salt ● 1 tsp. pepper ● 3 tsp. garlic powder ● 3 tsp. dulce flakes (reserve one teaspoon for garnishing)	**Foraged Food in Recipe** ● Dandelion ● Red Clover ● Stinging Nettle
Method	**Instructions** In one pot bring potatoes to a boil. Once par-boiled, drain and rinse. In a large pot, pour in water, add stinging nettle. Bring to a boil. Lower temperature and add all remaining ingredients (including potatoes). Stir well. Simmer 30 minutes. Place soup mixture in a blender and turn on low for 10-20 seconds. Pour into bowls and garnish with dulce flakes. (Garnish with fresh parsley as well if you have it!)			

Stinging Nettle Soup

	A healthy soup that delivers great taste and loads of nutrients.			**Prep Time:** 15 Mins **Cook Time:** 45 Mins **Yields:** 4-6 Serves
Ingredients	● 4 cups young nettle leaves ● 4 cups spinach ● 4 cups chicken or vegetable stock ● 4 cold cooked sausages(vegetarian sausages can also be used)	● 3 tbsp. sour cream ● 3 tbsp. flour ● Salt and pepper to taste ● Cold milk		**Foraged Food in Recipe** ● Stinging Nettle
Method	**Instructions** Wash the nettle leaves after you have carefully taken them off the stems with thick protective gloves. Blanch the leaves and drain. Wash the spinach and add to the nettles in a saucepan. Pour hot stock over the nettles and spinach. Season and simmer for 45 minutes adding more stock if needed. Leave soup to cool and blend in blender. Mix the flour to a smooth paste with some cold milk. Add this to the soup and bring to a boil. Chop the sausages into small rounds and add to the soup. Swirl in the sour cream just before serving.			

Wild Leek and Potato Soup

	An aromatic soup that is simple to make and tastes fabulous.			**Prep Time:** 10 Mins **Cook Time:** 30 Mins **Yields:** 4 Serves

Ingredients	• 12 cups water • 10 cups cut up potatoes • 3 cups wild leeks • 2 tbsp granular garlic (or garlic to taste)	• Salt to taste		
Method	**Instructions** In a large pot cook the potatoes in the water until soft. Let cool. In a blender, purée in batches with the wild leeks. Return to stove and simmer 30 minutes. Add spices to taste.			

Yellow Rocket Soup

	This creamy soup provides a fresh taste to the palate and has a hint of mustard from the yellow rocket greens. A summertime soup that can be enjoyed with your favourite crackers or bread.			**Prep Time:** 10 Mins **Cook Time:** 20 Mins **Yields:** 2 Serves
Ingredients	• 2 cups yellow rocket leaves (chopped) • 3/4 cup chopped green onions • 2 cups vegetable broth • 2 cups milk • 2 tbsp coconut oil	• 2 tbsp flour • spices to taste		**Foraged Food in Recipe** • Yellow Rocket
Method	**Instructions** In a large saucepan sauté onions in coconut oil. Add flour and stir until thick. Add broth and the winter cress then let simmer for 15 minutes. Add milk and spices then simmer another 5 minutes.

Dessert & Snacks

Autumn Olive and Poppy Seed Cake

	This delicious autumn olive poppy seed cake with orange icing is moist and simple to make. It boasts a fresh orange flavour, along with the wonderful taste of autumn olive berries.			**Prep Time:** 15 Mins **Cook Time:** 60 Mins **Yields:** 1 Loaf
Ingredients	• 1 1/4 cup all-purpose flour • 1 tsp baking powder • 1/2 tsp salt • 1/2 cup sugar • Zest of 1 orange (save the juice) • 1/2 cup buttermilk	• 1/2 cup unsalted butter, room temperature • 1 tsp vanilla paste or extract • 1/2 teaspoon orange extract • 2 eggs	• 2 tbsp poppy seeds • 1/2 cup autumn olives, washed and separated from stem • 1/2 cup powdered sugar, sifted • 1 tbsp freshly squeezed orange juice	
Method	**Instructions** Heat the oven to 350°F. Grease and flour a 9"x5" loaf pan and set aside. Whisk the flour, baking powder, salt and set aside. Stir the sugar and the orange zest together until well-combined and fragrant. Using a stand mixer with a paddle attachment, cream the butter and sugar/zest mixture together until light. Add the vanilla and orange extracts. Add the eggs one at a time, mixing well until thoroughly incorporated, scraping down the sides of the bowl as needed. Add the flour mixture in two additions, alternating with the buttermilk. Add the poppy seeds. Process the batter until smooth, about 15-20 seconds. Fold in the red currants. To make the orange glaze, whisk the powdered sugar and orange juice until creamy. If needed, add more orange juice, a little at a time, until the correct consistency is achieved (thick, smooth, yet still liquid). Pour the batter into the pan and bake until the cake is firm and a tester inserted into the centre comes out clean, about 50-60 minutes. Cool for an hour and drizzle with orange glaze. Let glaze set before serving.			

Autumn Olive Cookies

	Autumn olive berries explode with flavour when used in cookies.			**Prep Time:** 15 Mins **Cook Time:** 15 Mins **Yields:** 12 Serves
Ingredients	• 1/2 cup butter • 1/4 cup organic cane sugar • 1/3 cup light or dark brown sugar • 1 egg • 1 tsp vanilla extract • 2 tbsp milk	• 1/2 tsp salt • 1/4 tsp baking soda • 1/2 tsp baking powder • 1 1/4 cups unbleached flour • 2 cups autumn olive berries		
Method	**Instructions** Preheat oven to 176°C (350°F). Line a baking sheet with parchment paper. Cream sugars with the butter. Add the egg, vanilla extract and milk then mix well. In a separate bowl combine all dry ingredients. Slowly add the wet mixture into the dry mixture and continue to stir until completely mixed. Once all ingredients are blended fold in the autumn olive berries. Drop by spoonful's onto the baking sheet leaving about 1" between cookies. Bake 12-15 minutes until thoroughly baked (test with a toothpick to ensure the centre is dry).			

Chewy Pine Granola Bars

	No need for supplements with these nutrient-dense granola bars. They are chock full of vitamins and minerals that your body needs.			**Prep Time:** 15 Mins **Cook Time:** 25 Mins **Yields:** 12 Bars
Ingredients	● 2 cups oatmeal ● 1 cup pine nuts (or almonds) crushed into small pieces ● 1 cup shredded coconut (sweetened or unsweetened) ● 3 tbsp + 1 tsp softened butter	● 1/4 cup yellow dock flour (or 1/8 cup dock flour + 1/8 cup pine needle flour) ● 1/4 cup wheat germ ● 1/8 cup hemp seeds ● 1/4 cup wild dried cranberries (or regular dried cranberries)	● 2/3 cup unpasteurized honey ● 1/4 cup brown sugar ● 2 tsp vanilla ● 1/2 cup dates ● 1/2 cup prunes ● 1/4 dried barberries (or raisins)	
Method	**Instructions** Preheat oven to 162°C (325°F). Stir the first three ingredients together then spread them over a parchment paper-lined baking sheet. Toast in the oven 5 minutes, mix around, and then toast another 5 minutes. Reduce oven heat to 300°F. Place in bowl being mindful of the heat. Add the wheat germ, yellow dock flour (and pine flour if using this) and hemp seeds. Mix well. In a small saucepan place the butter, sugar, honey and vanilla. Blend well and bring to a boil. Remove from stove and using a spatula, add to the dry mixture. Mix well. In a processor place the fruit. Process until the fruit is in small pieces. Add to the mixture and if necessary, use your hands to mix thoroughly. Place combined mixture into a parchment paper-lined glass oblong baking dish (9"x13"). Press the mixture into the dish until all corners are filled and the top is flat. Bake 25 minutes. Let cool at least 2 ½ hours until cutting into granola bar shapes. Will store in fridge 5 to 7 days.			

Coconut Pine Cookies

	Boreal forest meets tropical fruit in a shortbread cookie.			**Prep Time:** 10 Mins **Cook Time:** 12 Mins **Yields:** 60 Serves
Ingredients	● 3 cups unbleached flour ● 1 cup organic cane sugar ● 1/4 cup shredded sweetened coconut ● 10 tbsp pine powder ● 1/2 cup melted butter	● 3 eggs ● 1 tsp vanilla		
Method	**Instructions** Place all dry ingredients into a bowl. In another bowl blend together melted butter, eggs, and vanilla. Mix the wet ingredients into the dry ingredients and blend well. Roll cookie dough into balls about 3/4 the size of a golf ball and place on ungreased cookie sheet. Use a fork to flatten the cookies until they are about 1/4" thick. Bake at 176°C (350°F) for about 10-12 minutes. Makes about 5-6 dozen.			

Coltsfoot Sorbet

				Prep Time: 15 Mins **Cook Time:** 22 Mins **Yields:** 00 Serves
Ingredients	● 65 fresh coltsfoot flowers ● 1 cup organic cane sugar ● 3 1/3 cups water ● 1 tsp fresh squeezed lemon juice ● 1 egg white			**Foraged Food in Recipe** ● Coltsfoot
Method	**Instructions** Make sure you have only the yellow petals from 65 coltsfoot flowers. (Remove the petals by rubbing the flowers between your thumb and forefinger. Make sure there are no green sepals in with the petals.) Place the petals, sugar and water into a pan. Bring to a boil and cook for 2 minutes then remove from the heat and let steep for 20 minutes. Filter through a sieve and refrigerate the syrup until chilled. Add the egg white and whisk. Either place in an ice cream maker or in the freezer. As the sorbet churns, the egg white will trap air bubbles and this turns the sorbet white. If you have chosen the freezer method you will need to whisk briskly every five minutes for the first hour, then every fifteen minutes until the sorbet sets.			

Dandelion Banana Bread

				Prep Time: 15 Mins **Cook Time:** 20 Mins **Yields:** 00 Serves
Ingredients	● 3 large or 4 medium ripe bananas ● 1/2 cup organic canola oil (or a baking oil of your choice) ● 1 egg ● 1/3 cup organic cane sugar	● 1 cup buckwheat flour ● 1/3 cup fresh picked dandelion flower petals ● 1/4 cup wheat germ ● 1/2 tsp. (aluminium-free) baking soda		**Foraged Food in Recipe** ● Dandelion
Method	**Instructions** Mash the bananas then add the oil, egg and sugar, mix well. Stir in flour, wheat germ, dandelion flowers and the baking soda and mix until everything is perfectly blended. If desired, add in chopped walnuts or chocolate chips. Scoop into greased and floured muffin or loaf (bread) baking tins. Bake at 176°C (350°F) for 15-20 minutes. Check at the 15 minute mark by inserting a toothpick or knife – if it comes out clean then it is done.			

Dandy Muffin Tops

	Light, tasty, and packed with nutrients, these dandelion muffins have earned their name as being Dandy Muffin Tops. Enjoy worry-free snacking when dandelion muffins are in your kitchen.			**Prep Time:** 10 Mins **Cook Time:** 10 Mins **Yields:** 4-6 Serves

Ingredients	• 1.5 cups dandelion flowers (lightly packed) • 1 cup unbleached flour • 1 cup rolled oats • 1 cup apple sauce	• 2 eggs • 1/2 cup organic cane sugar • 1/2 cup melted coconut oil • 1 tsp vanilla extract • 1 tsp baking soda	Notes: • Dandelion flowers – when picking them, snip off the green sepal to ensure you are collecting mostly the yellow petals. Some green sepal matter is ok but keep it to a minimum as this can add a bit of a bitter taste to the muffin tops. • You can use sweetened or unsweetened apple sauce.	**Foraged Food in Recipe** • Dandelion
Method	**Instructions** Preheat oven to 350°F. In one bowl place all wet ingredients and mix with a blender for 20-30 seconds. In another bowl, place all dry ingredients and blend well. Slowly mix the wet ingredients to the dry and stir well until everything has blended thoroughly. Using a large soup spoon, scoop dough onto a parchment paper-covered baking sheet leaving about 1" between dough. Bake about 10 minutes until the middle it properly cooked - allow to cool.			

Elderflower Gelato

	Elderflower gelato is a refreshing treat to enjoy on a warm afternoon.			**Prep Time:** 5 Mins **Cook Time:** 10 Mins **Yields:** 6-8 Serves
Ingredients	• Pinch sea salt • 1/2 cup (144 g) sugar • 2 tbsp (21 g) superfine white rice flour • 2 1/2 cups (540 ml) heavy cream, divided • 1/4 cup (180 ml) elderflower cordial		Note: Regular rice flour is typically made by grinding medium- or long-grain rice into a powder. Superfine rice flour is made by grinding short-grain and/or sticky glutinous rice into a finer powder. This produces flour with higher starch content that will dissolve much easier, making it ideal for thickening liquids.	
Method	**Instructions** Prepare the ice cream machine by freezing the machine's ice cream bowl for 8 hours or overnight. To a medium saucepan, add the salt, sugar and rice flour and whisk to combine. Add 2 tablespoons (30 ml) of the cream and whisk to make an even paste. Over medium-low heat, start whisking in the rest of the cream and cook, stirring, for 3 to 5 minutes, until the mixture bubbles a little and it thickens a bit. Off the heat, whisk the cordial in and combine well. Pour the mixture into a bowl and cover it with plastic wrap so the mixture doesn't form a skin. Let this chill in the refrigerator for 8 hours or up to overnight. Pour the chilled mixture into the frozen ice cream bowl and let the mixture churn for 18 to 20 minutes or according to the manufacturer's instructions. Transfer the gelato to a freezer-proof container and let it chill for at least 4 hours.			

Gingerbread Mushrooms

	Enjoy these festive gingerbread mushrooms anytime of year when you get a hankering for wild mushrooms!			**Prep Time:** 3 Hours **Cook Time:** 36 Mins **Yields:** 16 Serves
Ingredients	• 1 cup shortening • 1 cup sugar (or organic cane sugar) • 1 cup dark molasses • 1/2 cup water • 5 cups unbleached flour	• 1 tsp. baking soda • 2 tsp. ginger • 1 tsp. allspice • 1/2 tsp. cinnamon • 1/2 tsp salt		
Method	**Instructions** Cream shortening and sugar. Blend in molasses and water. In a separate bowl blend all dry ingredients. Slowly mix the dry ingredients into the wet mixture until perfectly mixed. Cover; chill 2 hours. Heat oven to 190°C (375°F). Cut chilled dough into quarters. Roll dough onto pre-cut parchment paper (one quarter at a time – you will have to repeat this three more times) that fits onto a baking sheet. (So no flour is required during rolling, use another sheet of parchment paper and roll dough in between the two pieces.) Roll until about 1/8" thick. (This will not totally fill an average sized baking sheet.) Carefully lift the rolled dough on the parchment paper onto a baking sheet. Bake one baking sheet at a time for 9 or 10 minutes. Cool. Place pattern pieces onto cooled gingerbread and hold in place using thumbtacks. Using a sharp knife, carefully cut your pieces. Use royal icing and food colours and decorate your gingerbread mushrooms!			

Healthy Heart Vegan Hawthorn Cookies

	Enjoy a mouth-watering vegan cookie that contains wild edible hawthorn berries. Very healthy for your heart!			**Prep Time:** 15 Mins **Cook Time:** 10 Mins **Yields:** 12 Serves
Ingredients	• 1 cup gluten-free flour • 1/2 cup fresh hawthorn berries (then mash) • 1/2 cup almond butter • 1/4 cup organic cane sugar	• 3 tbsp almond milk • 1 tsp vanilla extract • 3/4 tsp baking soda • 1/4 tsp salt • Jam or jelly of your choice		**Foraged Food in Recipe** • Common Hawthorn
Method	**Instructions** Preheat the oven to 350°F and line a cookie sheet with parchment paper. In a large bowl, stir together the almond butter, coconut sugar, almond milk, vanilla extract, and optional stevia extract. In a small bowl, whisk together the flour, baking soda, and salt. Place the dry ingredients into the wet ingredients (which includes the hawthorn berry mash) and mix just until thoroughly blended. Create balls that are just slightly bigger than golf balls. Press the balls into patties and place them on a baking sheet. Use a small spoon to indent a thumbprint into the cookies. Reshape any large cracks that form on the edges of the cookie dough. Fill each thumbprint with a jam or jelly of your choice. (Cookies in the image contain autumn olive jam.) Bake for 9-11 minutes - be sure not to over bake. Cool thoroughly before enjoying!			

Honey Cattail Cookies

				Prep Time: 25 Mins **Cook Time:** 60 Mins **Yields:** 00 Serves

Ingredients	• 1 brown cattail • 2 cups coconut flakes (sweetened or unsweetened) • 2 cups oats • 1 tsp vanilla	• 3 tsp cinnamon • 1/2 cup honey • 4 tbsp coconut butter		**Foraged Food in Recipe** • Cattail
Method	**Instructions** Grind the cattail fluff with the oats to make the flour fluffy. Place in a bowl and add in the rest of the ingredients. Knead until thoroughly mixed and shape into cookies. Eat as is (raw) or dry in the oven at 150F for 1-2 hours. Bake about 1 hour at 176°C (350°F) or until a knife inserted in the centre comes out dry. Cool on a rack.			

Japanese Knotweed Bread

	Take a bite out of this invasive plant. This nutrient-dense bread is made with Japanese knotweed and it can be enjoyed as a breakfast bread or an anytime snack.			**Prep Time:** 15 Mins **Cook Time:** 60 Mins **Yields:** 1 Loaf
Ingredients	• 2 cups unbleached flour • 1/2 cup organic cane sugar • 1 1/2 tsp baking powder • 1/2 tsp salt • 1 egg	• 1/8 cup honey • 2 tbsp sunflower or safflower oil • 3/4 cup orange juice • 3/4 cup chopped walnuts • 1 cup puréed Japanese knotweed		
Method	**Instructions** Sift all dry ingredients together into a large bowl. In another bowl, beat the egg, oil, honey and orange juice. Add walnuts and purée to dry ingredients. Then add the moist ingredients. Blend only until all ingredients are moist. Spoon into a greased loaf pan.			

Lemon and Autumn Olive Tart

	An incredibly tasty and healthy lemon meringue-like pie. This is sure to become an autumn favourite.			**Prep Time:** 15 Mins **Cook Time:** 15 Mins **Yields:** 1 Pie
Ingredients	• 1 cup unbleached all purpose flour • 1/2 cup softened butter • 1/4 cup icing sugar • 2 large eggs • 1 cup organic cane sugar	• 1/2 tsp baking powder • 2 tbsp fresh squeezed lemon juice • 1 to 1 1/2 cups of autumn olive berries		
Method	**Instructions** Heat oven to 176°C (350°F). Thoroughly mix the flour, butter and icing sugar. Press in an ungreased pie plate or 8x8x2 baking pan. Build up the edges so that there is a half inch edge. Bake 15 minutes. Beat remaining ingredients except the berries. Be sure to beat minimum 3 minutes or until the mixture is light and fluffy. Fold in the berries. Pour over the cooked hot crust. Bake about 20 minutes or until no imprint remains when lightly touched. Cool thoroughly.			

No Bake Chocolate Seed Balls

	Loaded with Omega-3, fibre, calcium and magnesium, these no bake treats make a healthy anytime snack.			**Prep Time:** 5 Mins **Cook Time:** 0 Mins **Yields:** 4 Serves
Ingredients	• 1 cup pitted dates, finely chopped • 1/8 cup chia seeds • 1 tbsp hemp seed • 1 tbsp yellow dock seed (ground) • 1 tbsp cacao powder	• 2 tsp coconut oil • 2 tsp raw (or unpasteurized) honey • Shredded coconut (sweetened or unsweetened) for rolling.		
Method	**Instructions** Place dates and coconut oil in a food processor; process until you have fine, sticky crumbles. Add the cacao powder, honey and all seeds; pulse until well blended. Create small balls using the palms of your hands. Roll them in the shredded coconut. Store in the refrigerator for a maximum of 10 days.			

Nutty Plantain Snack

				Prep Time: 10 Mins **Cook Time:** 15 Mins **Yields:** 00 Serves
Ingredients	• 1 handful of plantain seed • 3 handfuls of pumpkin seeds • 3 handfuls of sesame seeds • Olive oil (enough to just cover the seeds) • Sea salt to taste			**Foraged Food in Recipe** • Broadleaf Plantain
Method	**Instructions** Place seeds into a bowl, add olive oil and salt. Be sure to coat all seeds. Either roast seeds in oven on a baking sheet at 148°C (300°F) for 10-15 minutes or roast them in a frying pan on the stove.			

Pine Cookies

	Pine needle cookies that taste great. No pine nuts are used in this recipe.			**Prep Time:** 10 Mins **Cook Time:** 12 Mins **Yields:** 60 Serves
Ingredients	• 3 cups unbleached flour • 1 1/2 cups organic cane sugar • 8 tbsp white or red pine powder • 1/2 cup melted butter • 3 eggs • 1 tsp vanilla			

Method	**Instructions** Place all dry ingredients into a bowl. In another bowl blend together melted butter, eggs, and vanilla. Combine the wet ingredients into the dry ingredients and blend well. Roll cookie dough into balls about 3/4 the size of a golf ball and place on ungreased cookie sheet. Use a fork to flatten the cookies until they are about 1/4" thick. Bake at 162°C (325°F) for about 10-12 minutes. Makes about 5-6 dozen. To make pine powder: Collect pine needles (still on the branches) and hang them in your home to dry (choose a dry area of your home). After 2-3 weeks (depending on moisture levels in your home) remove the needles from the branches (it is ok if little bits of branches get into the needles). Place the needles into a good quality coffee grinder or mixer and grind into powder!

Pine Muffins

	Pine trees provide us with great health benefits and when baked into muffins, those pine needles are simply mouth-watering.			**Prep Time:** 15 Mins **Cook Time:** 20 Mins **Yields:** 00 Serves
Ingredients	• 1 1/3 cups flour of your choice • 1 cup quick cooking rolled oats • 1/4 cup brown sugar • 1/2 cup raisins • 3 tbsp (heaping) pine powder	• 1 tbsp baking powder • 1 egg • 1 cup milk • 2 tbsp melted butter		
Method	**Instructions** Preheat oven to 375°F. Grease muffin tins. Combine the first 6 ingredients. Add egg, butter and milk then stir until the flour is moistened. Fill muffin cups 3/4 full. Bake 20 minutes or until an inserted knife comes out clean.			

Wild Chocolate Brownies

	Simple to bake, scrumptious gluten-free chocolate brownies you'll want to share. Loaded with wild goodness, you'll feel great knowing that these taste amazing and are healthy for you and your family.			**Prep Time:** 15 Mins **Cook Time:** 30 Mins **Yields:** 4-6 Serves
Ingredients	• 1 cup softened butter • 1 cup organic cane sugar • 1/2 cup gluten-free flour • 1/2 cup curly ground curly dock seed • 3/4 cup cocoa powder	• 4 eggs • 1 tsp. vanilla extract • 1/2 tsp. baking powder • autumn olive jam (or any homemade or store-bought jam if not available)		
Method	**Instructions** Preheat oven to 350°F. Line a baking pan (9x9in) with parchment or grease. Beat softened butter and sugar together until light and fluffy; then add eggs and vanilla. Blend flour, ground dock seed, cocoa and baking powder together. Slowly beat dry ingredients into the wet ingredients until well blended; about one minute. Spread mix in lined (or greased) baking pan (it will be thick). With a spoon, drop jam in various spots, carefully swirl jam with a knife across the surface mixing it just slightly into the brownie batter. Bake 25 to 30 minutes or until centre comes out clean with a knife. Sprinkle with icing sugar if desired. Cut into squares once cooled and enjoy!			

Wild Grape Chiffton

				Prep Time: 15 Mins **Cook Time:** 40 Mins **Yields:** 00 Serves
Ingredients	• 2-1/4 cups flour • 1-1/2 cups organic cane sugar • 1 tbsp baking powder • 1/2 tsp sea salt • 6 eggs, yolks and whites separated • 3/4 cup wild grape juice	• 2 tbsp crushed wild grapes (seeds removed) • 1/2 cup vegetable oil • 2 egg whites • 1/4 tsp cream of tartar		
Method	**Instructions** In large bowl, sift flour, 3/4 cup of the sugar, baking powder and salt. In separate bowl, whisk egg yolks, crushed wild grapes, wild grape juice, and oil; pour over flour mixture and whisk just until smooth. Set aside. In large bowl, beat 8 egg whites until foamy. Add cream of tartar; beat until soft peaks form. Beat in remaining sugar until stiff glossy peaks form; gently stir one-quarter into batter. Fold in remaining egg white mixture; scrape into a rectangular baking (cake) pan. Run spatula through batter to eliminate any large air bubbles; smooth top. Bake at 176°C (350°F) until a knife comes out clean when inserted (about 40 minutes).			

Wild Harvest Pie

	Go wild with a mouth-watering fruit-filled pie that's sure to have everyone asking for seconds. Served warm or cold, these healthy individual-sized fruit pies make a great grab and go snack!			**Prep Time:** 20 Mins **Cook Time:** 35 Mins **Yields:** 2 Pies
Ingredients	• 2 baked pie shells Filling: • 3 cups peeled, finely chopped apples (about 5 large) • 2 cups fresh (or frozen/thawed) finely chopped cranberries	• 2 cups elderberries (or another fruit of choice finely chopped) • 1/2 cup organic cane sugar • 1/4 cup spelt (or unbleached) flour • 2 teaspoons ground cinnamon '• 1/4 teaspoon ground nutmeg	Topping: • 1/4 cup spelt (or unbleached) flour • 1/3 cup packed brown sugar • 2 teaspoons ground cinnamon • 1/4 cup butter • 1/3 cup chopped pecans (optional)	

RECIPES | Foraging Recipies | Dessert & Snacks | Wild Harvest

Method	**Instructions** Heat oven to 190°C (375°F). In a large bowl, mix apples, cranberries and elderberries. In small bowl, mix remaining filling ingredients. Add dry ingredients to fruit and blend well. Spoon into pre-baked pie shells. In small bowl, mix all topping ingredients except butter and pecans. Soften butter then add to the mixture. Once fully blended add pecans. Carefully place the topping onto the fruit mixture. Take pieces of foil wrap and cover the crust edges of the pie so that they do not burn while baking. Bake 35 minutes or until the fruit is tender and the topping is golden brown. If desired, serve warm with whipped cream or ice cream. You can make this recipe using pre-baked tart pie shells. Topping can be optional.

Beverages

Belgium Wild Beer

RECIPES | Foraging Recipies | Beverages | Belgium Wild Beer

	A wild beer that's sure to please all beer drinkers.			**Prep Time:** 45 Mins **Cook Time:** 10 Days **Yields:** 16 Serves
Ingredients	● 1 gallon water (3.75 L) ● 0.2 ounce (2 g) wormwood ● 0.2 ounce (2 g) common yarrow ● 0.5 ounce (6 g) fresh ground ivy (creeping charlie)	● 0.3 ounces (4 g) chopped dried dandelion roots ● 3-4 crushed stems bitter dock 3 to 4 inches (7.5 to 10 cm) long or 1 to 2 lemons	● 1 1/4 pounds (680 g) brown sugar ● Yeast (wild or commercial)	**Foraged Food in Recipe** ● Bitter Dock ● Common Yarrow ● Creeping Charlie ● Dandelion
Method	**Instructions** Place the sugar, wormwood, yarrow, dandelion roots and bitter dock stems into a large pot with water (cut and squeeze the lemons if you used them). Bring to a light boil for 30 minutes. Add the fresh ground ivy after 15 minutes of boiling. Remove from heat and strain the brew into the fermenter then add the yeast. Position the airlock or cover your fermenter with a paper towel or cheesecloth. Let the beer ferment for 10 days. Start counting when the fermentation is active (may take 2 to 3 days with a wild yeast starter). Siphon into swing-top bottles (16 oz - 500ml) and prime them with ½ teaspoon (2g) brown sugar for carbonation. Close the bottles and store somewhere not too hot. The beer will be ready to drink in around 3 weeks.			

Campfire Coffee

RECIPES | Foraging Recipies | Beverages | Campfire Coffee

	Basic coffee, not much more to say.			**Prep Time:** 5 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	● Coffee ● Water			
Method	**Instructions** Fresh ground coffee Bring water to boil; add fresh ground coffee; immediately remove from fire; pour from top.			

Burdock Tonic Tea

RECIPES | Foraging Recipies | Beverages | Burdock Tonic Tea

	This nourishing brew relaxes and provides you with lots of nutrients.			**Prep Time:** 5 Mins **Cook Time:** 30 Mins **Yields:** 1 Serve
Ingredients	● 1 tsp dried burdock root ● 1 tsp dried dandelion root ● 2 dried red clover flowers ● Dried peppermint leaves to taste			**Foraged Food in Recipe** ● Burdock ● Dandelion ● Red Clover

RECIPES | Foraging Recipies | Beverages

Method	**Instructions** Combine all the above ingredients and place into a large mug. Add boiling water and steep covered for 30 minutes. Strain, and enjoy. This tea helps to stimulate the kidney and liver functions and can possibly help to treat acne and eczema.

Elderflower Cordial

	Elderflower cordial is a classic summer beverage that is easy to make and tastes refreshing. Let your taste buds come alive with this fragrant drink.			**Prep Time:** 48 Hours **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	● 1kg (2 1/4 lbs) sugar ● 1.5 litres (6 cups) boiling water ● 4 lemons ● 30 large elderflower heads ● 55g / 2 oz citric acid			
Method	**Instructions** Place the sugar into a large Pyrex bowl. Pour boiling water over the sugar and stir until all the sugar has dissolved. Allow to cool. Grate the rind of the lemons with a fine grater then add to the sugar water. Slice the lemons and add to the sugar water. Add the citric acid and stir. Add the flower heads to the water and stir again. Cover and let steep for 48 hours. After 48 hours strain through a cheesecloth into a clean bowl. Using a funnel, fill sterilized bottles. Seal and store in a cool, dark place (not the refrigerator) for two to three weeks or freeze in plastic containers.			

Fire Cider

				Prep Time: 8 Weeks **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	● 4 cups organic apple cider vinegar ● 1/2 cup grated horseradish root ● 1/8 cup chopped garlic ● 1/2 cup of chopped onion ● 1/2 cup of grated ginger ● 1 tsp. fresh grated cayenne		Fire Cider Uses: Drink straight or mixed with some water or tomato juice. Drink a shot glass a day to help fight off many ailments. Add some honey to help ease a cough. Breathe in to ease a congested chest. Place some of the mixture on sore	
Method	**Instructions** Place all ingredients in a 4 cup (1 litre) mason jar and cover with apple cider vinegar. Cover tightly. Steep for 8 weeks. Strain into clean jar. Important: do not use a metal lid because the vinegar will corrode it. Use a plastic lid if possible or put a layer of cellophane between the jar and lid, then tighten the lid. Or better still, put a piece of plastic over the mouth of the jar and hold it tight with a rubber band. (If you use unpasteurized vinegar you may get a film that forms at the top of what is called, 'the mother'. Skim it off when you decant.)			

Healthy Heart Tea

	A pleasant tasting, nutritious and healthy tea that your heart will love!			**Prep Time:** 5 Mins **Cook Time:** 20 Mins **Yields:** 00 Serves
Ingredients	● Motherwort (1 teaspoon dried or 4-6 fresh leaves) ● 1/8 cup of hawthorn berries (fresh, crushed berries or a few berries with leaves as well)	● 2 thin slices of fresh ginger root ● 2 pinches of fennel seeds		**Foraged Food in Recipe** ● Motherwort
Method	**Instructions** Add all herbs into five cups of cold water in a saucepan. Bring to a boil over low heat, reduce heat, then simmer for 20 minutes. Let steep until cool enough to drink. Add honey or lemon to taste if desired. Yields just over 4 cups.			

Highbush Cranberry Juice

	Highbush cranberries, orange juice and maple syrup makes for a tasty drink that leaves you wanting more. Gathering berries in the winter months is a great way to enjoy the fruits of winter foraging.			**Prep Time:** 5 Mins **Cook Time:** 30 Mins **Yields:** 1 Serve
Ingredients	● 3 cups water ● 2 cups highbush cranberries (they can remain on the wooden umbels so long as they look healthy)	● 2 cups orange juice ● 1 tsp (pure) maple syrup		
Method	**Instructions** Bring water to boil then turn stove off. Place the berries into the water and slightly mash. Let sit 30 minutes. After 30 minutes, thoroughly strain. Allow this cranberry liquid to thoroughly cool. Once cool, add the orange juice and maple syrup; stir. Store in fridge up to 5 days.			

Milkweed Flower Cordial

	A unique floral taste with light, citrus notes, makes this an enjoyable summertime beverage.			**Prep Time:** 10 Mins **Cook Time:** 4-5 Days **Yields:** 8 Cup Serves
Ingredients	● 8 cups water ● 2 1/2 cups flowers ● 2 cups organic cane sugar (or white sugar)	● 2 sliced lemons ● 2 tbsp. white vinegar ● Mason jars		**Foraged Food in Recipe** ● Milkweed

Method	**Instructions** Pour water and sugar into a large bowl – be sure to dissolve sugar. Add in vinegar. Evenly divide the flowers and sliced lemons into 2 (or more) mason jars. Pour into jar(s) the water mixture. Let sit four days (out of direct sunlight) at room temperature and be sure to keep the lid loose. Stir (or tighten lid to shake) once daily then be sure you loosen the lid after shaking. After four days strain flowers and lemons. Seal jars for one day to build up carbonation. Keep in a bucket with a lid in the event it may explode. Strain to remove yeast. Refrigerate then enjoy! Optional: If you choose to, you can omit the carbonation step and simply strain and refrigerate after 4 days of infusing. It still makes a unique tasting beverage.

Mullein Tea

	Nourishing mullein tea can help quell the onset of a cough and is beneficial in many other ways. It is easy to make and nourishes your body.			**Prep Time:** 20 Mins **Cook Time:** 15 Mins **Yields:** 1 Serve
Ingredients	● 1-2 tsp of dried mullein leaves and/or flowers ● 1 cup boiling water			**Foraged Food in Recipe** ● Mullein
Method	**Instructions** Pour 1 cup of boiling water over the dried mullein flowers and leaves. Steep for 10 - 15 minutes. Pour the liquid through a cheesecloth or a coffee filter to strain out the plant's tiny hairs as they may irritate the throat. Mullein leaf tea has a soothing effect on the urinary tract and facilitates urination. It also eases a nervous, irritable bladder and incontinence. Prepare mullein tea as directed above (minus the mullein flowers) and drink 3 - 4 cups daily. (Be sure to ask your health practitioner first if this is suitable for your condition.)			

Purslane Smoothie and Popsicles

	Purslane smoothies nourish your body and satisfy your craving for something different. On a hot day, purslane smoothies or purslane popsicles will have you wanting more.			**Prep Time:** 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	● 1 1/2 cups pureed purslane with lemon juice ● 1 or 2 bananas ● 1 cup organic applesauce ● 1/4 cup 100% pure maple syrup			**Foraged Food in Recipe** ● Purslane
Method	**Instructions** Blend all ingredients until smooth. Pour any leftover smoothie into popsicle moulds and freeze. If you have hens and chicks (Sempervivum tectorum) these can be used instead of purslane.			

Red Clover Ice Tea

	Harvest and store red clover flowers so that you can enjoy this tasty, healthy ice tea any time of the year.			**Prep Time:** 10 Mins **Cook Time:** 60 Mins **Yields:** 8 Serves
Ingredients	● 12 red clover flowers (with leaves is fine) ● 8 cups water ● 3/4 cup organic can sugar (or sweetener of your choice) ● one half lemon, squeezed			**Foraged Food in Recipe** ● Red Clover
Method	**Instructions** Boil water in a saucepan, then remove from stove and allow to cool 10 minutes. Place red clover flowers in water; let infuse minimum 1/2 hour. (For a stronger flavour and more nutrients allow to sit 1-2 hours.) Strain, add sweetener of your choice and the fresh squeezed lemon juice. (The amount of sweetener can be reduced or increased based on your taste buds.) Place in ridge to chill then enjoy!			

Stinging Nettle Beer

	Stinging nettle beer can be an acquired taste, but knowing how high in nutrients this is makes home brewing well worth the time.			**Prep Time:** 3-5 Days **Cook Time:** 30 Mins **Yields:** 4 Litres
Ingredients	● 5 kg young nettle leaves ● 4 litres of water + 1/2cup boiled water cooled to about 25°C ● Fresh squeezed juice from 2 lemons and 2 oranges	● 1 cup of brown sugar ● 100g cream of tartar ● 1 sachet of wine yeast ● (For a more bitter beer add a large dandelion root)	● (For a more spicy beer add a large ginger root)	**Foraged Food in Recipe** ● Stinging Nettle
Method	**Instructions** Before hops were widely used in the 17th century all sorts of plants were used to make beer including nettles. Not only is nettle beer inexpensive to make, it is believed to help alleviate rheumatic pain, gout and asthma.			
Making Wort	Making the wort: Boil nettle leaves (and dandelion root (or) ginger root) in 4 litres of water for 30 minutes. Strain off the nettles (squeeze excess liquid) and save the liquid. Add lemon and orange juice, brown sugar and cream of tartar to the liquid. Pour mixture into a sterile container (fermenter) with lid. Cool to 20-27°C (68-80°F) overnight. Brewing: Sprinkle yeast into 1/2 cup of boiled water that has cooled down and wait for it to sink. Gently stir yeast and gently pour evenly into fermenter. Place lid on fermentation pail and wait 3-5days, or until foam has collapsed. For proper fermentation keep beer at a constant temperature between 20-27°C (68-80°F).			

Wild Grape Juice

				Prep Time: 2 Hours **Cook Time:** 10 Mins **Yields:** 00 Serves
Ingredients	• 2 cups wild grapes • 8 cups water • organic cane sugar to taste			
Method	**Instructions** Place grapes in a pot with the water. Bring to a boil then turn stove off. Mash the berries and let sit two hours. Strain and pour juice into a juice container. Sweeten to taste and chill.			

Yarrow Tea

	A slightly bitter tea that aids in digestion and helps to fight colds.			**Prep Time:** 5 Mins **Cook Time:** 10 Mins **Yields:** 1 Serve
Ingredients	• 1 tsp. of dried yarrow • 1 cup boiling water • Slice of lemon			**Foraged Food in Recipe** • Fern Leaf Yarrow
Method	**Instructions** Add the dried yarrow in a mug of boiling water and allow to steep minimum 10 minutes. Strain leaves. Add honey to sweeten if desired or a slice of lemon. Alternative method: Add 2 fresh large Yarrow leaves to a cup of boiling water and let steep minimum 10 minutes. Remove leaves then if desired, add honey to sweeten or a slice of lemon.			

Frying Pan Cookies

				Prep Time: 5 Mins **Cook Time:** 10 Mins **Yields:** 36 Serves
Ingredients	• 2 Eggs, unbeaten • 1 c Sugar* • 1 1/2 c Dates, chopped • Salt			
Method	**Instructions** Cook over a low heat for 10 minutes, stirring constantly. Remove from stove and add 2 cups of Rice Krispies. Roll in balls and dip in coconut. *Would recommend from nil to 1/2 c sugar. Dates, coconut and Rice Krispies supply sufficient sweetener.			

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	**Ingredients** •			**Foraged Food in Recipe** •
Method	**Instructions** o			

3 Homestead Recipes

These recipes are more complex than the foraging recipes as they require either purchasing the ingredients or having an established homestead to make them yourself.

Entrée

Dutch Oven Bisquits

				Prep Time: 15 Mins **Cook Time:** 10 Mins **Yields:** 00 Serves
Ingredients	• 2 c Flour • 1/2 ts Salt • 3 ts Baking powder • 4 tb Solid shortening • 1 c Milk (diluted canned ok)			**Grown Food in Recipe** •

Method	**Instructions** Blend flour, salt, baking powder and mash in shortening with a fork until crumbly. Add milk and stir until the dough sags down into trough left by spoon as it moves around the bowl. Turn dough out on a floured surface, knead for 30 seconds, pat out gently until it is 1/2 inch thick. Cut with a round cutter or pinch off pieces of dough and form by hand. Put bisquits into a greased Dutch Oven, cover, and bury in bright coals for 5 or 10 minutes or until golden brown.

Egg in a Nest

(Toad in a Hole)				**Prep Time:** 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 Slice of bread • 1 Egg			**Grown Food in Recipe** •
Method	**Instructions** Make a hole in the centre of the slice of bread and place in frying pan and break egg in the centre of the hole and leave to cook.			

Camping Seasoning Mix

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1/3 c Salt • 1 tb Paprika • 1 tb Garlic Powder • 2 ts Onion Powder • 1/2 ts Cayenne or substitute Curry • 1/2 ts Pepper			**Grown Food in Recipe** •
Method	**Instructions** Mix well and store in a double zip-lock bag or a good screw-top container.			

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	**Ingredients** •			**Grown Food in Recipe** •
Method	**Instructions** o			

Mains

Nettle Ravioli in Nettle Pasta

	Nettles are a traditional springtime food wherever they grow. There is a reason for this. Despite their ferocious stingers, stinging nettles are incredibly high in vitamins C, D, iron, potassium, manganese, and calcium. Nettles are unusually high in protein for a green plant, and are usually pretty common in cool, wet weather. Many, many cultures turn to nettles to break the nutritional privations of winter, when few green things are available. This is what happened in Italy's alpine regions, among other places. This is a bit of a project. While it doesn't take that long, the process of making the pasta and then the ravioli requires a few hours — too much for a weeknight. But once you make them, you can freeze the ravioli for later in the week. To properly do this, arrange the finished, uncooked ravioli on a baking sheet that has been dusted with semolina or cornmeal. Put the baking sheet into the freezer. When the ravioli have frozen solid, about 2 hours, you can move them to a freezer bag and store that way. They will keep for about 2 months; after that, they get brittle. Serve these ravioli with simple, high-quality butter, fresh ground black pepper and some grated dry cheese. A Tocai Friulano or other big white wine would be an ideal accompaniment.			**Prep Time:** 3 Hours **Cook Time:** 10 Mins **Yields:** 35-40 Ravioli
Ingredients	• 1 batch stinging nettle pasta • 2 cooked Yukon Gold or other waxy potatoes, about 8 ounces • 4 ounces mascarpone	• 4 ounces blanched stinging nettles, about a cup • Salt and pepper		**Grown Food in Recipe** •
Method	You will want to start the process by making the pasta. Instructions for doing so are here. While the pasta dough is resting, make the filling. To make the filling, you will need two or three big tong-fulls of fresh nettles to get your 4 ounces. I say tong-fulls because you do not want to pick up fresh nettles, as they will sting you. Get a large pot of water boiling and add a handful of salt. Grab the nettles with tongs and put them into the boiling water. Stir around and boil for 1-3 minutes, depending on how old the nettles are. Fish them out with a skimmer or the tongs and immediately dump them into a big bowl with ice water in it. Once they are cool, put them in a colander to strain. Get a cloth towel, like a tea towel, and put the nettles in it. Wrap one end of the towel one way, then the other end of the towel the other and squeeze out as much moisture as you can. Chop the nettles finely — don't use a food processor or you will get a mush. In a bowl, mash the potatoes, mascarpone and nettles into a cohesive paste. Again, not a food processor! Do this by hand, as it is important for the texture. Taste it and add salt and pepper to your liking. If you want, a little nutmeg is good, too.			

RECIPES	Homestead Recipies	Mains	Nettle Ravioli in Nettle Pasta		
				Method	Roll out your pasta dough. Cut the dough ball into 4 to 6 equal pieces. Keep each piece covered in plastic or under a tea towel until you need it. Using a pasta maker, roll the dough into long sheets at least 2 inches wide. Roll them very thin: I go to No. 8, which is the second-thinnest on my Atlas. Lay the sheets down on a work surface (I use a large maple board) and place about a heaping teaspoon of filling on each one, at least 2 inches apart. Cover them with another piece of the dough. As you are laying the second piece of dough down, carefully press it to remove any trapped air. Start from one end of the sheet and work toward the other. It takes practice to do this seamlessly, and I don't always get every ravioli right. Cut each ravioli out with a circle cutter or a wineglass. Of course, you can also use a standard ravioli mould or cut them into squares with a ravioli cutter. When each ravioli is finished, lay it out on a well floured board to dry a bit. Repeat this with the rest of the dough.
				Method	You can let the ravioli sit out for a couple hours, but for more than that you should refrigerate them. Don't refrigerate for more than 8 hours, though, or the filling will destroy the ravioli. If you need to store them for any length of time, freeze them according to the instructions above. To cook the ravioli, bring a large pot of water to a boil and salt it well; it should taste of the sea. While the water is heating, melt some butter or olive oil in a large sauté pan set over medium-low heat. Add some minced garlic if you'd like. Don't let the garlic brown, though. Boil the ravioli for 2 to 3 minutes, or about 90 seconds after they start to float to the top. Move them to the sauté pan and toss to coat with the butter. Serve at once with freshly ground black pepper and grated pecorino or parmesan cheese.

Hot Dog Surprise

RECIPES | Homestead Recipies | Mains | Hot Dog Surprise

				Prep Time: 5 Mins **Cook Time:** 45 Mins **Yields:** 00 Serves
Ingredients	● 10 x Hot Dogs ● American cheese (or boutique brand Wisconsin cheddar sliced into hot dog-length fingers ● 10 sl Bacon ● Hot Dog Buns			**Grown Food in Recipe** ●
Method	**Instructions** At home or on the road, cut a deep slit in each wiener, and stuff with fingers of cheese. Then wrap on the diagonal, like an old bias-ply tire, with the bacon. Seal individually in foil. These are great for stuffing into those odd places on the engine where you can't fit a turkey or a suckling pig. Cook about 45 minutes, or until cheese is melted and bacon is somewhat crisp.			

Campers Pizza Pie

RECIPES | Homestead Recipies | Mains | Campers Pizza Pie

				Prep Time: 00 Mins **Cook Time:** 10 Mins **Yields:** 00 Serves
Ingredients	● 1 lb Wheat bread ● 1/4 lb Mozzarella cheese pizza or spaghetti sauce Pepperoni			**Grown Food in Recipe** ●
Method	**Instructions** Using a pie iron, take two slices of bread, put 1 1/2 tablespoons pizza sauce on one slice of bread. Top with Mozzarella cheese and sliced pepperoni. Place other side of bread on top and butter outer sides of bread. Put sandwich into pie iron and place in coals of fire. Cook until bread is toasted.			

Buttermilk Biscuits

RECIPES | Homestead Recipies | Mains | Buttermilk Biscuits

				Prep Time: 15 Mins **Cook Time:** 15 Mins **Yields:** 00 Serves
Ingredients	● 1/4 cup shortening ● 1/4 teaspoon baking soda ● 2 cups self-rising flour ● 3/4 cup buttermilk			**Grown Food in Recipe** ●
Method	**Instructions** Cut shortening into flour. Stir soda in milk and pour into flour and shortening. Stir until well blended. Pour out onto a floured surface and knead 12 to 15 times. Roll out and cut. Place on a baking sheet and bake at 450 degrees F. until brown.			

Gorp

RECIPES | Homestead Recipies | Mains | Gorp

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	● 1 c Corn syrup or molasses or Honey ● 3/4 c Milk powder ● 1 c Oatmeal ● 1/2 c Peanut butter ● 1/2 c Chocolate chips	● 1/2 c Wheat Germ ● 1/2 c Crushed peanuts ● 1/2 c Raisins		**Grown Food in Recipe** ●
Method	**Instructions** Mix all the ingredient thoroughly. Roll into balls and each in a small piece of wax paper, twisting ends and chill.			

Sauerkraut

		Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves

RECIPES | Homestead Recipies | Mains | Sauerkraut

Ingredients	• 1 qt Sauerkraut • 1 ea Onion, chopped • 1 t Caraway seeds • 2 T Butter • 1 ea Potato, grated			**Grown Food in Recipe** •
Method	**Instructions** Melt the butter and add the onion and cook until brown. Add the sauerkraut and cook for 8 minutes. Add the caraway seed and potato, cover with boiling water and cook for 30 minutes in an uncovered vessel over a slow fire. Cover the kettle and cook 30 minutes longer. Brown sugar or an apple may be added to give different flavour.			

Corned Beef & Cabbage

RECIPES | Homestead Recipies | Mains | Corned Beef & Cabbage

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 2 lb Well trimmed corned beef boneless brisket or round • 1 sm Head green cabbage, cut into • 6 Wedges • 6 md Carrots cut into quarters	• 1 sm Onion, quartered • 1 Clove garlic, crushed		**Grown Food in Recipe** •
Method	**Instructions** Pour enough cold water on corned beef in Dutch oven to just cover. Add onion and garlic. Heat to boiling, reduce head. Cover and simmer until beef is tender, about 2 hours. Remove beef to warm platter, keep warm. Skim fat from broth. Add cabbage and carrots, heat to boiling. Reduce heat and simmer uncovered 15 min.			

Roast Corn

RECIPES | Homestead Recipies | Mains | Roast Corn

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 2 Ears or corn • Salt and pepper • Butter • String			**Grown Food in Recipe** •
Method	**Instructions** Peel ears leaving husks on at bottom and remove corn silk. Replace husks covering ears and tie around top. Dip corn in salt water. Place corn on screen over hot coals and turn often until all side are done. When cooked remove husks and add salt and pepper and margarine.			

Onion Swiss Steak

RECIPES | Homestead Recipies | Mains | Onion Swiss Steak

				Prep Time: 00 Mins **Cook Time:** 120-180 Mins **Yields:** 00 Serves
Ingredients	• 3 lb Round steak, 3/4" thick • 1 1/2 ts Salt • 1/4 ts Pepper • 2 pk Onion soup mix • 2 cn (10 oz) tomatoes			**Grown Food in Recipe** •
Method	**Instructions** Cut steak into serving pieces, season with salt and pepper and place into Dutch oven. Sprinkle onion soup mix over top and pour tomatoes over all. Cover and cook over slow fire for 2 to 3 hours or until meet is done and tender.			

Sticky Bones

RECIPES | Homestead Recipies | Mains | Sticky Bones

				Prep Time: 00 Mins **Cook Time:** 20 Mins **Yields:** 4-5 Serves
Ingredients	• 1 c Vinegar • 1/2 c Honey • 2 T Worcestershire sauce • 1/2 c Ketchup • 1 t EACH salt, dry mustard, paprika	• 1/4 t Black pepper • 1 Clove garlic, minced • 4 lb Beef ribs		**Grown Food in Recipe** •
Method	**Instructions** In saucepan, combine vinegar, honey, Worcestershire, ketch- up, salt, mustard, paprika, pepper, and garlic. Cover, bring to boil, reduce heat and simmer 15 minutes. In baking pan, place ribs. Cover with hot marinade, then bake ribs at 325 degrees for 1 hour, turning and basting often with marinade. Or grill over medium coals, basting and turning often, until browned, about 20 minutes.			

Meat Loaf

RECIPES | Homestead Recipies | Mains | Meat Loaf

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 1/2 lb Ground beef • 3/4 c Quick oats • 1 Eggs • 1/4 ts Dry mustard • 1/4 c Bell pepper	• 1 pk Onion soup mix • 3/4 ts Salt • 1/8 ts Marjoram		**Grown Food in Recipe** •
Method	**Instructions** Mix all ingredients and put in casserole pan. Place in Dutch oven. Bake 1 hour, covered.			

Great Outdoors Potatoes

RECIPES | Homestead Recipies | Mains | Great Outdoors Potatoes

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 6 Potatoes • 1/4 c Olive oil • 2 ts Lemon juice • 1 ts Dijon mustard • 1/2 ts Coriander	• 1/2 ts Fresh ground pepper • 1 ts Minced onion • 1 Pureed garlic clove . • 1 ts Paprika		**Grown Food in Recipe** •
Method	**Instructions** Scrub potatoes and cut into quarters, keeping skins on. Boil until tender, and coat them with the dressing which you can prepare in advance. Wrap the potato quarters in tin foil, and place on coal to brown. Delicious with meat or fish.			

Foiled Burgers

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 lb Ground beef • 4 Squares heavy duty foil (16x16 inches) • 4 Carrots; chopped • 1 cn New potatoes; sliced (16oz)	• 2 sm Green peppers; chopped • Dehydrated onion flakes • Worcestershire sauce • Salt & pepper to taste		**Grown Food in Recipe** •
Method	**Instructions** Separate the meat into 4 portions. Place each portion in the centre of a aluminium foil square. Top with equal portions of chopped carrots, potatoes and bell peppers. Season with dehydrated onion flakes, Worcestershire sauce, salt and/or pepper to suit your taste. Seal the foil, check for leaks. Place on the coals for 10 to 15 minutes per side.			

Flank Steak Teriyaki

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 4 - 6 flank steaks • 1 tb Salad oil • 1/4 c Sugar • 1 ts Ginger • 1/2 ts MSG	• 4 - 6 pineapple slices • 1/2 c Soy sauce • 2 tb Sherry (optional) • 1 Clove garlic, crushed.		**Grown Food in Recipe** •
Method	**Instructions** To form marinade, combine all except steaks and pineapple. Mix well and pour over steaks. Let marinate 1 to 1-1/2 hours. Fry steaks in very hot oven or skillet brushing once with marinade. Add pineapple during last few minutes, brush with marinade and cover. Cook 3-5 min. Serve over rice.			

Venison Goulash

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 2 tb Oil • 1 1/2 lb Venison, from neck, flank, Shanks, cut into cubes 1 to 1 1/2 inches • 3 md Onions, very thinly sliced • 2 tb Paprika	• 1 ts Salt • 1 md Green Bell pepper, thinly • Sliced, seeds & pith removed • 1/2 c Water		**Grown Food in Recipe** •
Method	**Instructions** In a Dutch Oven, heat oil and brown venison, stirring often. Add the onions, sprinkle with paprika and salt while stirring, sauté over med heat until onions are soft. Put in the green pepper and water, cover the Dutch Oven but do not put coals on top. Cook 1 to 1 1/2 hours, until the venison is fork tender. Traditionally Goulash is served with broad noodles.			

Pork Chops & Garden Vegetables

				Prep Time: 15 Mins **Cook Time:** 45 Mins **Yields:** 00 Serves
Ingredients	• 6 (1" thick) pork chops • 3 Carrots, cut 1/2" slices • 3 sm Potatoes, peeled, 1/2" cubes • 1 ts Basil • 1 1/2 c Fresh green beans, cut	• 6 (1/4 oz) instant onion soup mix 2 c water • 3 tb Butter, melted		**Grown Food in Recipe** •
Method	**Instructions** Brown chops on both sides in butter in bottom of oven, drain. Place vegetables in bottom of oven and replace chops on top. Combine dry soup mix and water, mixing well. Pour over chops and bring to a boil. Cover and reduce heat, simmer 45 min or until chops are tender.			

Campfire Meatloaf

				Prep Time: 10 Mins **Cook Time:** 60 Mins **Yields:** 00 Serves
Ingredients	• 1 1/2 lb Ground beef • 3/4 c Quick oats • 1 Eggs • 1/4 ts Dry mustard • 1/4 c Bell pepper	• 1 pk Onion soup mix • 3/4 ts Salt • 1/8 ts Marjoram		**Grown Food in Recipe** •
Method	**Instructions** Mix all ingredients and put in casserole pan. Place in Dutch oven. Bake 1 hour, covered.			

Grilled Sausage & Sweet Mustard in Tortillas

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 lb Hot or sweet Italian sausage or Spanish choriza* • 1 c Hearty red wine (such as Italian Barolo or Spanish R10ia) • 9 8-inch flour or 6-inch corn tortillas • Honey mustard** or Dijon mustard			**Grown Food in Recipe** •
Method	**Instructions** Place sausage in single layer in 9-inch skillet. Pour wine over sausage. Bring to boil. Reduce heat, cover partially and simmer until sausages are cooked through, turning frequently, about 12 minutes. Remove sausage from pan and cool slightly. Discard liquid. (Can be prepared 1 day ahead. Cover tightly and refrigerate. Bring to room temperature before continuing.) Prepare barbecue (medium-high heat). Cut sausages into 1/2-inch slices. Thread slices on long metal skewers, using 3 to 4 skewers. Cut tortillas into quarters and wrap in foil. Place tortillas on side of grill to heat through. Grill sausage until heated through and charred on all sides, about 5 minutes. Remove sausage from skewers and place in serving bowl. Serve sausage with tortillas and mustard. *A fresh pork link sausage flavoured with garlic and spices, and milder than Mexican chorizo. Spanish chorizo is available at Spanish markets.			

Honey Mustard Grilled Chicken

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 2 lb Boneless chicken parts (may use bone in parts) • 2 tb Honey • 2 tb Dijon mustard • 2 tb Melted margarine	• 1 ts Basil Leaves • 1/2 ts California Style Blend Garlic Powder		**Grown Food in Recipe** •
Method	**Instructions** Preheat grill for direct-heat cooking. Place chicken on grill rack. Combine remaining ingredients. During last 3-4 minutes per side of grilling time, brush chicken with sauce.			

Pizza Baby

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• Biscuit mix • Part of can of tomato soup • Parmesan cheese • Cold meats • Chopped green pepper	• Oregano • Seasoning		**Grown Food in Recipe** •
Method	**Instructions** Mix pizza dough and shape into a shallow dish about 12 cm across. Spoon soup into dish and top with other ingredients Place in a double wrap of heavy aluminium foil. Cook in hot coals or on rack over hot coals close to the heat.			

Foiled Chicken

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 sm Green pepper; chopped • 1/2 sm Red pepper; chopped • 10 Mushrooms; chopped • 4 lg Chicken breasts • 1 cn Pineapple slices (8oz)	• Non-stick cooking spray *or* 1 tsp butter • Garlic powder, salt and/or pepper to taste . • 4 Squares heavy duty foil (16x16 inches)		**Grown Food in Recipe** •
Method	**Instructions** Divide the bell peppers and mushrooms into 4 equal parts. Coat a small area in the centre of the foil with cooking spray or a small amount of butter. Place a portion of peppers and mushrooms on the greased area of the foil. Top with a chicken breast and a pineapple slice. Season with garlic powder, salt and pepper to your taste. Fold the foil securely and check for leaks. Place on the coals for 10 to 15 minutes per side.			

One Pan Breakfast

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 3 sausage links • 3 eggs • 1/2 spud • 1/4 cup shredded cheese • 3 tablespoons milk			**Grown Food in Recipe** •
Method	**Instructions** Dice sausage links and cook until done, setting aside drippings. Dice the spud into small hash size pieces, cook in drippings until done (not crispy)and drain. Beat eggs and milk and add to spuds. Cook to a soft scramble, add cheese and sausage. Cook until cheese is melted. Serve with cold milk and toast. Serves one.			

20 Minute Hamburger Skillet Stew

RECIPES | Homestead Recipies | Mains | 20 Minute Hamburger St

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1/4 lb Lean ground beef • 1 lg Onion, sliced wafer-thin • 4 Carrots, sliced wafer-thin • 2 Potatoes, halved, sliced wafer-thin • 3 Ribs celery, sliced wafer-thin	• 1 c Boiling water • 2 t Beef extract OR bouillon • 2 Bay leaves • 1/4 t Dried thyme • Salt OR garlic salt	• Pepper 1/4 c Dry red wine OR tomato juice • 2 T All purpose flour	**Grown Food in Recipe** •
Method	**Instructions** Use melon baller and shape meat into tiny meatballs. Brown in skillet. Discard any fat. Stir onion into skillet and cook 1 min. Add boiling water or broth and extract or bouillon. Add remaining veggies, seasonings. Cover, cook over low heat, 15 mins until vegs are tender. Combine wine or water and flour in covered jar. Shake and stir into skillet. Cook and stir until sauce is thick, 4 mins.			

Campfire Pasta

RECIPES | Homestead Recipies | Mains | Campfire Pasta

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 lb Pasta; any kind • 1 pk Spaghetti sauce mix • 1 cn Tomato paste • 1 lb Lean hamburger; ground turkey or italian sausage	• 2 Pots • 2 Stirring spoons • 1 Lid • Potholders or gloves		**Grown Food in Recipe** •
Method	**Instructions** Heat water to a boil in a large pot. In a smaller pot cook the meat and add the sauce mix, water, and tomato paste according to the instructions on the sauce package. Cook the pasta in the water for 8-10 minutes. Place the lid on the pot and with gloves or pot holders drain the water from the pasta through the crack between the lid and the pot. Putting the pot on a stump or log and letting the stump or log hold the weight of the pot helps. Mix the sauce with the drained pasta and serve. Grated cheese may be used with the pasta. Pasta notes: Spaghetti is the traditional pasta, but wheels, or other forms that are more compact and larger will be much easier to drain.			

Easy Stroganoff

RECIPES | Homestead Recipies | Mains | Easy Stroganoff

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 2 ts Butter or margarine • 1 cn Cream of mushroom soup • 1 lb Round steak cut into thin stripes • 1/4 c Water • 1/2 c Sour cream	• 1/2 c Chopped onion • 1/2 ts Paprika		**Grown Food in Recipe** •
Method	**Instructions** Melt butter or margarine in skillet. Brown strips of round steak in hot fat. Add onion and brown. Stir in soup, water, sour cream and paprika. Cover and cook over low heat about 45 minutes, or until meat is tender. Stir frequently. Serve over hot noodles (wide egg noodles, etc.) or rice.			

Camp Chilli

RECIPES | Homestead Recipies | Mains | Camp Chili

				Prep Time: 00 Mins **Cook Time:** 45 Mins **Yields:** 00 Serves
Ingredients	• 1 c Lentils • 3 tb Tomato soup powder • 2 tb Masa or Corn flour • 1 tb Chilli Powder • 1 tb Onion Flakes	• 1 tb Cumin • 1 ts Oregano • 1 ts Salt • 1 Clove Garlic • 4 c Water		**Grown Food in Recipe** •
Method	**Instructions** Combine all the ingredients and simmer 30 - 45 Min.			

Campers Hobo Pie

RECIPES | Homestead Recipies | Mains | Campers Hobo Pie

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 lb Ground beef • 4 Carrots sliced • 2 Potatoes cubed • 1 md Onion, sliced in 1/4" pieces • Butter			**Grown Food in Recipe** •
Method	**Instructions** Form hamburger patties and put one patty, with individual servings of whole carrots, sliced potatoes and sliced onions, on a sheet of aluminium foil. Brush everything with butter and sprinkle with salt and pepper. Fold foil over food and place on charcoal or open fire Cook for an hour, turning every 15 minutes. Chicken can be substituted for the hamburger meat.			

Campfire Pork And Beans

RECIPES | Recipies | Mains | k And Beans

		Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves

Ingredients	• 8 Bacon slices, cut 1 1/2" • 1/2 c Chopped onion • 1/2 c Chopped green bell pepper • 53 oz Can pork and beans • 1/4 c Molasses • 1/4 ts Tabasco sauce			**Grown Food in Recipe** •
Method	**Instructions** Heat oven to 375 degrees. Fry bacon until crisp; set aside. Reserve 2 tablespoons drippings in pan. Sauté onion and green pepper in drippings until tender. Combine beans, molasses and red pepper sauce in a 2 1/2 quart casserole. Bake 40 to 45 minutes. Top with bacon.

Power Bars

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 2 c Whole wheat flour • 1/2 c Packed brown sugar • 1/4 c Skim milk powder • 1/4 c Wheat germ • 1 ts Baking powder	• 1 1/2 c Raisins or chopped dried apricots • 1/2 c Unsalted sunflower seeds • 2 Eggs • 1/2 c Vegetable oil	• 1/2 c Molasses • 1/3 c Peanut butter	**Grown Food in Recipe** •

Method	**Instructions** In bowl, combine flour, sugar, skim milk powder, wheat germ and baking powder; stir in raisins and sunflower seeds. Combine eggs, oil, molasses and peanut butter. Add to dry ingredients, blending well. Spread in greased 9 inch square cake pan. Bake in 350F oven for 35 minutes or until browned and firm to the touch. Let cool completely. Cut into 24 bars. Bars can be stored in air tight container for up to 5 days.

S'Mores

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• Marshmallows • Hershey bars • Graham crackers • Green sticks or coat hangers			**Grown Food in Recipe** •
Method	**Instructions** Get prepared by getting 1 large graham cracker and breaking it in half. Cover 1/2 of the graham cracker with Hershey bar. Put a marshmallow (or 2) on the stick and hold it over the fire until roasted. Some people like them lightly golden, others like to catch them on fire and then blow the fire out. If you do that, be careful. You have to put the fire out quickly or your marshmallow will fall on the ground. When the marshmallow's roasted, place on top of the Hershey bar, put the other graham cracker on top.			

Blazing Trail Mix

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 16 Serves
Ingredients	• 2 c Shredded miniature wheat or bran squares • 1 c Unsalted thin pretzel sticks; broken into pieces • 1/2 c Cooked lentils	• 1/2 c Quick-cooking rolled oats • 1/2 c Raisins • 1/2 c Chopped dried apples • 1/4 c Honey • 2 ts Curry powder	• 1/2 ts Ground coriander • 1/4 ts Ground cumin • 1/4 ts Paprika • 1/8 ts Ground red pepper	**Grown Food in Recipe** •
Method	**Instructions** In a 13x9-inch baking pan, combine the wheat or bran squares, pretzels, lentils, oats, raisins, and apples. In a small bowl, stir together the honey, curry powder, coriander, cumin, paprika and pepper. Drizzle the honey mixture over the cereal mixture. Toss until evenly coated. Bake at 350 degrees for 15 to 20 minutes or until crisp, stirring occasionally. Store in an airtight container or self-closing plastic bags.			

Biscuits

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 8 Biscuits
Ingredients	• 1/4 cup commercial biscuit mix • 4 teaspoons milk			**Grown Food in Recipe** •
Method	**Instructions** Combine biscuit mix and milk with a fork. Drop by half-teaspoonful's onto a well greased pan. Bake 10 minutes.			

Cherry Fudge Goodies

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 ea Box fudge brownie mix • 1 1/2 c Shredded Coconut • 1 1/2 c Chopped, Candied cherries • 2 tb Cherry flavouring oil • 1 c Chopped walnuts	• Powdered Sugar • Shortening		**Grown Food in Recipe** •
Method	**Instructions** Follow brownie mix directions/recipe on box. Add coconut, 3/4 C walnuts, flavouring oil and cherries. Blend well. Pour batter into greased Dutch Oven or covered baking pan. Add coals 5 on top 7 under (350) Bake. Its done when a knife comes out clean. Top with remaining walnuts and sprinkle with the powdered sugar. Let cool. Cut into squares.			

Camp Cobbler Delight

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 cn Sliced peaches, large • 1 cn Fruit cocktail, large • 1 cn Crushed pineapple, small • 1/2 c Instant tapioca • 1/4 lb Margarine	• 1 c Brown sugar • 1 pk Cake mix		**Grown Food in Recipe** •
Method	**Instructions** In 12 inch foil lined Dutch Oven, combine fruit and tapioca. Sprinkle cake mix evenly over top of fruit. Sprinkle brown sugar over cake mix. Dab butter all over top of brown sugar. Place lid on oven. Bake 45 minutes to 1 hour. Use 6 to 8 coals on the bottom and 14 to 16 on the top. Cake is done when top is brown and cake has absorbed juices and is no longer dry.			

Campfire Cinnamon Coffeecake

RECIPES | Homestead Recipies | Dessert & Snacks | Campfire Cinnamon Coffeec

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 2 tb Butter or margarine • 1 c Packaged biscuit mix • 1/3 c Evaporated milk, undiluted • 1 tb Prepared cinnamon-sugar			**Grown Food in Recipe** •
Method	**Instructions** Make Coffeecake: Cut butter into tiny pieces over biscuit mix in medium bowl. Toss lightly with fork until butter is coated. Make a well in centre. Pour in milk and cinnamon-sugar, stirring with fork just until mixture is moistened. Turn dough into a lightly greased and floured 8-inch shiny, heavy skillet. With floured hands, pat down evenly into the skillet. Cook, covered, over very low heat, 12 to 15 minutes, or until a cake tester or wooden pick inserted in centre comes out clean. For Topping: Spread the coffeecake with 2 Ts butter or margarine. Then sprinkle 1 ts prepared cinnamon-sugar over all of it. Cut into quarters, and serve warm.			

Camper's Cookies

RECIPES | Homestead Recipies | Dessert & Snacks | Camper's Cookies

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 2 c Flour • 1 ts Baking soda • 1/2 ts Salt • 1/2 ts Baking powder • 1 c Margarine	• 1 c White sugar • 1 c Brown sugar • 2 Eggs • 1 ts Vanilla • 2 c Oats	• 6 oz Semi-sweet chocolate chips • 1 c Nuts	**Grown Food in Recipe** •
Method	**Instructions** Sift together the flour, baking soda, salt, and baking powder. Cream the margarine and the sugars together. Add the eggs and beat. Add the flour mixture and mix well. Add the vanilla, oats, chocolate chips, and nuts. Grease a 13x9x2 pan, and press mixture in evenly. Bake in a preheated oven 15 minutes at 350 F.			

Camper's Buckwheat Pancakes

RECIPES | Homestead Recipies | Dessert & Snacks | Camper's Buckwheat

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 3/4 c Buckwheat Flour • 3/4 c Flour, All-Purpose • 1/2 ts Salt • 1/3 c Dried Whole Egg • 1/2 c Non-fat Dry Milk	• 1 1/2 ts Baking Powder • 4 tb Margarine • 1 1/2 c Water		**Grown Food in Recipe** •
Method	**Instructions** Mix all ingredients, except margarine, with water to make a creamy batter. Melt margarine and add gradually to batter while stirring. Makes about 30-40 2-inch pancakes.			

RECIPES | Homestead Recipies | Dessert & Snacks | Entree

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	**Ingredients** •			**Grown Food in Recipe** •
Method	**Instructions** o			

Beverages

Mexican Coffee

RECIPES | Homestead Recipies | Beverages | Mexican Coffee

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 qt Milk • 1 ts Ground cinnamon • 1 ts Vanilla extract • 2/3 c Instant cocoa mix • 8 c Boiling water	• 1/3 c Instant coffee granules • Whipped cream • Garnish: cinnamon sticks		**Grown Food in Recipe** •
Method	**Instructions** Combine first 3 ingredients in a Dutch oven; cook over medium heat until thoroughly heated. Stir in instant cocoa mix. Combine boiling water and coffee granules; stir into milk mixture. Serve with a dollop of whipped cream and, if desired, garnish with cinnamon stick.			

Hot Cocoa

RECIPES | Homestead Recipies | es

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves

RECIPES | Homestead Recipies | Beverages | Hot Cocoa

Ingredients	• 1/2 c Cocoa Powder • 1 t Corn Starch • 1/3 c Sugar • 1 c Water (Divided) • 1 c Milk			**Grown Food in Recipe** •
Method	**Instructions** Mix Cocoa, corn starch and sugar with 1/2 cup water. Heat on low until ingredients are dissolved. Add remaining 1/2 cup water and milk. Heat over low heat until mixture thickens. Recommended high quality cocoas are Pernigotti and De Zaan. Hershey's cocoa may require reducing corn starch to 1/2 tsp.			

Russian Tea

RECIPES | Homestead Recipies | Beverages | Russian Tea

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 3/4 c Tang (orange drink mix) • 1 pk (1/2 oz) lemonade, unsweetened • 1 c Sugar (optional) • 1 c Instant tea • 1 ts Cinnamon	• 1/2 ts Ground cloves • Dash salt		**Grown Food in Recipe** •
Method	**Instructions** Mix ingredients. Use 2 teaspoons per serving.			

Iced Tea

RECIPES | Homestead Recipies | Beverages | Iced Tea

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1/2 ts Vanilla • 1/2 ts Almond Extract • 1/4 c Lemon Juice • 1/2 c Sugar • 1 qt Tea, freshly brewed			**Grown Food in Recipe** •
Method	**Instructions** Combine all ingredients.			

Cauldron Brew

RECIPES | Homestead Recipies | Beverages | Cauldron Brew

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 qt Apple juice • 1 1/2 Cups Canned, unsweetened pineapple • 2 tb Fresh lemon juice • 3 Cinnamon Sticks			**Grown Food in Recipe** •
Method	**Instructions** Mix all ingredients together in a saucepan. Heat over low heat until ready to serve. Remove cinnamon sticks. Ladle brew into serving cups.			

Tea Punch

RECIPES | Homestead Recipies | Beverages | Tea Punch

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 3 c Tea; strong • 1 c Lemon juice • 4 c Orange juice • 2 c Raspberry syrup; or grenadine • 2 qt Club soda; chilled	• 1 Cup Pineapple, crushed • Sugar; to taste		**Grown Food in Recipe** •
Method	**Instructions** Combine all ingredients except club soda in a punch bowl with a large block of clear ice; allow to chill thoroughly. (If fresh fruit juices are used, they should be strained.) Add club soda just before serving.			

Indian Style Lemonade

RECIPES | Homestead Recipies | Beverages | Indian Style Lemonade

				Prep Time: 5 Mins **Cook Time:** 0 Mins **Yields:** 00 Serves
Ingredients	• 8 Cups Water • 1/2 Cup Fresh lime juice • 2/3 Cup Fresh lemon juice • 1 1/3 Cup Maple syrup • 1/2 tb Freshly grated ginger • 1/8 ts Cayenne, optional			**Grown Food in Recipe** •
Method	**Instructions** Combine all ingredients in a large pitcher or punch bowl. Serve at room temperature or chilled.			

Hot Cider Punch

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 4 c Water • 4 c Apple cider • 2/3 c Orange flavour Tang • 1/4 ts Cinnamon • 1/8 ts Nutmeg • 1/8 ts Ground cloves			**Grown Food in Recipe** •
Method	**Instructions** Combine ingredients in a saucepan; mix well. Heat just to boiling. Serve hot in punch cups or mugs. This makes about 2 quarts.			

Hot Buttered Cow

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 lb Brown sugar • 1/4 lb Soft butter • 1/2 ts Vanilla • 1/2 ts Cinnamon • 1/4 ts Nutmeg	• 1/4 ts Cloves • 1/4 ts Mace • 1/4 ts Allspice • 1 pn Salt		**Grown Food in Recipe** •
Method	**Instructions** Beat sugar and butter together until thoroughly creamed and fluffy. Beat in vanilla and spices. Chill. For each cup to be served, place 1+1/2 teaspoons batter in a preheated mug (Could also include: 1 1/2 ounces dark rum and 1/2 ounce gold or white rum.) Stir well. Fill with hot milk and serve.			

Lemonade Syrup

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 2 c Sugar • 1 pt Water • 6 Lemons • 1 Lemon Rind, grated			**Grown Food in Recipe** •
Method	**Instructions** Cook the sugar and water together without stirring until it is a thick syrup, adding the grated outer rind of one lemon. When this is cool, add the juice of the lemons and bottle. By diluting with ice water, you have lemonade on short notice.			

Root Beer

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1 oz Sassafras • 1 oz Allspice • 1 oz Yellowdock • 1 oz Wintergreen • 1/2 oz Wild cherry bark	• 1/2 oz Coriander seeds • 1 oz Hops • 3 qt Molasses • 1/2 pt Yeast • 4 ga Cold water		**Grown Food in Recipe** •
Method	**Instructions** Mix together the sassafras, allspice, yellow dock, wintergreen, wild cherry bark, coriander seeds, hops and molasses. Cover them with boiling water, allow to stand for 24 hours, then filter, add the yeast and cold water. The beer will be ready in twenty-four hours. Bottle and seal.			

Lemonade Stall

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 8 Lemons • 1 c Sugar • 10 Ice cubes			**Grown Food in Recipe** •
Method	**Instructions** Bring lemons to room temp. Roll; slice in half and squeeze into gallon container. Toss lemon rinds into container. Pour sugar over rinds. Let sit for one half hour. Add ice cubes and enough water to fill container. Stir and serve. Each 12 oz serving has 91 calories and 0 grams fat.			

Ice Tea (Sun Method)

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 4 Tea bags • 1 1/2 qt Cold water			**Grown Food in Recipe** •

Method	**Instructions** In a two quart clear glass container, place tea bags. Add 1 1/2 quarts of cold water. Cover. Let stand in full sun 2 to 3 hours or until desired strength. Remove tea bags, serve over ice. Store this tea in refrigerator. NOTE: You don't need the sun to brew Sun Tea. Simply prepare as directed above, except let stand at room temperature several hours or until desired strength.

Doughboys

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	• 1/2 c Flour • 1 ts Baking powder • 1 ts Shortening • pn Salt • 1/4 c Water • 1 Hot dog			**Grown Food in Recipe** •
Method	**Instructions** You can also use 3/4 cup of biscuit mix. Mix ingredients with shortening and then add water. Put hot dog on green stick and wrap dough around it. Cook holding 6 inches from coals so inside will cook and then brown nearer to the coals. Ensure the dough is not too sticky.			

				Prep Time: 00 Mins **Cook Time:** 00 Mins **Yields:** 00 Serves
Ingredients	**Ingredients** •			**Grown Food in Recipe** •
Method	**Instructions** o			

4 Modern Recipes

These are the most common recipes today which are based on the current availability of modern foods in stores. These will be very difficult to make during SHTF.

Fire

Methods for starting fires, types of tinder and firestarters

"Build a man a fire, and he'll be warm for a day.
Set a man on fire, and he'll be warm for the rest of his life."
Terry Pratchett

Introduction

Fire is an absolutely essential item to have in a survival kit, there are so many reasons to have fire on hand, from cooking to water sterilization to morale. You should be well versed in the ability to make a fire in any conditions, from the rain and snow to the dry outback. Fire is easy to start with modern inventions such as the BIC lighter, ZIPPO or matches, but can also be accomplished with a few other items around the house such as a battery.

Purpose	The aim of FIRE is to educate the reader on the uses of fire, the different types of fires and their individual uses and how to properly light fires using any number of techniques available today. It also includes information on fire resistance, fire safety and how to extinguish fires to help avoid a man-made disaster.
Lost?	• If you're looking for wildfire information, see the NATURAL DISASTERS > Wildfire section. • If you want to build a signal fire to be seen by, head to the COMMUNICATION section. • For a list of fire temperatures, see the CRAFTING > Blacksmithing section. • For cooking on different types of fires, see the COOKING section. • For a list of fire-based weapons, see the OFFENCE section. • If you want to know the best types of woods for a fire, see the FUEL section. • For burns and fire-related injuries, see the INJURY section.

Contents

1 Fire Uses

These are some of the most common uses of fire.

Cooking	The primal use of fire, to make food safe for consumption.
Warmth	A by-product of fire which is lifesaving in cold climates.
Light	Fires give off light which can be utilized to see with.
Water Purification	Purification by boiling water for 3m will kill viruses and pathogens.

Charcoal	The fire's by-product charcoal, which has many uses.
Sterilizing	Put metal objects in a flame to kill bacteria, viruses and protozoa.
Signalling	A pillar of black smoke can be seen for many miles - use young green leaves.
Discouraging Predators	Generally repels and wards off animals and predators.
Wound Disinfection	Use a flame to disinfect wounds when there's no other option, you can also cauterise wounds to stop them bleeding.
Morale	A warm fire after a cold day can make the going much easier.
Sewing	Preventing ends from fraying and unravelling.
Removing Evidence	Fire removes traces of your existence.
Cleaning	Smoke gets bacteria off you?
Crafting	Fires can help create tools and materials such as soap.
Blacksmithing	Smithing tools, armour and weapons.
Landscaping	Burning brush and altering the landscape.
Energy	The energy released from a fire can be harnessed and converted to electricity.
Save Electricity	Instead of using torches and heaters.
Drying Clothes	Leaving clothes near a fire can dry them faster.
Incinerating Rubbish	Burning rubbish is easier than holding onto it to dispose of later.
Smoking Meats	Smoke meats to preserve them for longer.
Flaming Weapons	Flaming arrows, spears etc.
Heat Treatment	Materials become more pliable when heated and can be moulted into other shapes.
Discourage Bugs	Mosquitoes and other bugs don't like staying around smoke.
Heating Stones	Heating stones for use in heating something else such as a bed or water.

2 Fire Starters

This section lists the various ways you can start fires.

Subheadings

1. Natural Occurrence	**2. Friction**	**3. Percussion**	**4. Air Compression**
5. Solar	**6. Electricity**	**7. Chemical**	**8. Spontaneous Comb.**

1 Natural Occurrence

These are the most common naturally occurring ways fire can be created.

Volcanos & Lava	Occurs naturally under the earths crust, however they may sometimes make their way to the surface.
Meteorites	Causes massive friction and force when impacting the earth creating fires in the vicinity.
Lightning Strikes	Can ignite combustible materials on the ground, it usually only lasts if it's not raining.
Spontaneous Combustion	The ignition of tinderous materials via natural heat which occurs when the temperature of an object exceeds it's combustion point.

2 Friction

Hand Drill	This repeated spinning and downward pressure causes black dust to form in the notch of the fireboard, eventually creating a hot, glowing coal.
Bow Drill	Takes a lot of practice, rub hard wood and soft woods together to generate friction and put the ember into a tinder bunch.
Pump Drill	A variant of the bow drill that uses a coiled rope around a cross-section of wooden stake spin the shaft by pumping up and down a cross-member.
Fire Plough	Consists of a stick cut to a dull point, and a long piece of wood with a groove cut down its length. The stake is pressed down hard and rubbed quickly against the groove of the second piece in a "ploughing" motion.
Fire-Saw	A method by which a piece of wood is sawed through a notch in a second piece or pieces to generate friction. The tinder may be placed between two slats of wood with the third piece or "saw" drawn over them above the tinder so as to catch a coal, but there is more than one configuration.

Fire-Thong	Uses a non-melting cord, ratan, or flexible strip of wood to 'saw' the wood creating friction. On the board, opposite side the cord, is a well with a hole through the board to gathered the charred, soon-to-smoke, wood dust.

3 Percussion

Percussion is the striking of two elements together to generate heat or sparks.

Stone & Flint

Commonly used to throw sparks onto tinder. Will work when completely wet. Flint can be found naturally and is quite common. Strike with a 90° edge of steel to throw sparks.

Quartz / Jasper / Agate Stones	Strike with steel to throw sparks onto tinder.
Firesteel (Fire Striker)	Firesteel is a manufactured rod of purified flint which can be struck with a 90° edge of steel to throw sparks.
Blast Matches	An automatic flint striker. When pushed down it throws sparks out the bottom onto tinder. It can be used one-handed as opposed to any other flint striker methods.

Matches

Matches are a modern invention to make fire creation simple. Simply strike the match on the specific strip and it will combust and slowly burn down the stick.

Safety Matches	Strike the match on the specialised box strip to create a flame.
Windproof Matches	Matches that can't go out in the wind or underwater.
Strike Anywhere Matches	Matches you can strike on any object to ignite them.

Lighters

Lighters are the most common way to produce fire in the modern day world. They will work in any conditions, provide a solid flame and are extremely easy to use. Not only this but the gas will last a very long time if used occasionally or forever if it's never used.

BIC Lighter

A disposable lighter consisting of a flint wheel with steel which lights a small jet of butane gas. Unlike Zippo lighters the fuel doesn't have to be refilled once a week as it dried out due to having a sealed fuel compartment. BIC lighters can't be refuelled yourself.

'Fluid' Lighter (Zippo Lighter)

A refillable lighter that uses liquid fuel, also referred to as a Zippo. Zippo lighters use white gas to burn but can run dry if not refuelled often. Zippo lighters aren't recommended due to the fuel drying up quickly and require replacement wicks.

White Gas
White gas is a generic term for camp stove and lantern fuel. It can also be known as Pure Gasoline and Un-dyed gasoline.

Lighter Gases
- Zippo Fluid
- Coleman Gas
- Naptha
- 100% Alcohol
- Paint Thinners

(Best to Worst)

Butane Lighter (Z-Plus)

A refillable lighter which uses butane gas instead of white gas. The most commonly bought brand is Z-Plus! Both inserts come designed to fit in a Zippo lighter case so you can choose how it looks. Or you can forego a case and shed some weight. This is the most recommended style of lighter as the gas doesn't evaporate over time and it's easier to refuel.

Candle Flame
There are two types of butane lighters, the first has a candle style red/orange flame which is lit by flint rod the same as the BIC lighters. The gas stream activates when the lid of the lighter opens.

Jet Flame
The other style has a small cone of blue flame which makes a similar sound to a jet. This lighter uses piezo ignition and is often good for a couple of thousand sparks. The gas stream activates as long as the button is held, and at the bottom of the button is the piezo ignition lever.

Flame Adjustment
Adjust the height of the flame using the lever on the bottom of the lighter.

Refilling Lighters

Butane Purity
Butane is a dirty gas that requires repeated refining to remove particles. Therefore always refill lighters with 3x-9x refined butane to prevent clogging the lighter over multiple refills. You can see the particulate floating in the liquid in non-triple refined gas sources if the bottle/container is transparent.

Refilling
Butane lighters require refilling whenever the gas level becomes low. It's best to refill them only when empty. Refill lighters by turning them upside down and pressing the gas into the hole in the bottom firmly for a few seconds. If the lighter is upright when refilled it will be filled with air instead of gas and give inconsistent ignitions.

If attempted refill exceeded the maximum, the lighter's valve opening may have been "blown" open. To check for this, place another flame to tip of lighter, click switch and check for butane emission. If a large 6 inch flame is present, adjust valve toward the minus. If no flame is present, adjust toward the plus. If attempted refill had butane canister pointed up, it is necessary to "burp" the lighter and release unwanted air. Use a pointed object to push in the lighter's pin valve. Point the bottom of lighter up, push in valve and gas will be ejected. Point away from eyes and any other flame. After burping, refill correctly.

Step 1	Clean the flint wheel and the nozzle by brushing them with a small, specially designed stiff-bristled brush.
Step 2	Push the end of a wooden match against the filler valve on the base of the lighter to purge it. You'll hear a hissing noise as the gas escapes. Repeat until the lighter is empty.
Step 3	Press the plastic nozzle extension tube attached to a can of compressed air against the lighter gas outlet valve. Hold the canister plunger down for one or two seconds. Move the extension tube back an inch or two to blow remaining residue from the lighter recess. Refill the lighter with triple-refined butane gas, and test.
Step 4	Unwind a strand from a piece of fine fishing tracer wire. Poke the end of the fine strand into the lighter nozzle if blasting with compressed air fails. Do not apply sideways pressure or work the hardened steel wire back and forth; this will ream out and deform the nozzle outlet. Apply a second blast from the compressed air canister. Retest.

4 Air Compression

Uses the compression of air to generate enough heat to cause combustion of a flammable piece of cloth.

Fire Piston	Compresses air very rapidly into a smaller space raising the temperate drastically and igniting a piece of char cloth inside.

5 Solar

Solar is any form of firelighting using the sun. These methods may take some time depending on the temperature, cloud cover and the season.

Magnifying Glass	Focuses the rays of sunlight into a single point to generate heat to start a fire.
Fresnel Lens (Overhead Projector Lens)	A fresnel lens is a flat piece of plastic with concentric grooves in the surface to focus the light to a point. Spherical aberration is a loss of definition in an image arising from the surface geometry of a spherical mirror or lens. The grooved side should face the sun if you want the maximum effect. If the flat side is facing the sun then not all the light meets at the focal point and it takes approximately 2.4 times longer to light a fire. A linear fresnel lens focuses the light into a line rather than a point. These lenses are often found in rear projection tvs. A spot fresnel lens focuses the light into a point which has better effectiveness.
Light Bulb	A broken incandescent light bulb around the curved end can focus the light into a point.
Ice Lens	Using very clear ice, you can shape it into a generic lens shape which lets you then focus the light and start a fire. It may need a lot of perfecting to get the curvature correct but it's definitely possible to achieve it. Generally it's a strong curve used to focus the light properly - so start with a sphere and slowly turn it into an oval.
Drinks/Pressurised Can	The bottom of a coke can or any other pressurised canister can be used to start a fire if the bottom is polished so that it becomes reflective. Once it's polished you can find the focal point by using some thin newspaper to focus the spot of light into a pin point.
Binoculars	Using binoculars in reverse can start a fire. Let the light enter the larger end of the binoculars and bring the eye piece end near the tinder to focus it.
Spherical Water Bag	A spherical bag of water can be used as a makeshift lens to focus the light.
Mirror / Reflector	Uses a concave mirror to reflect the suns rays back into a point where a piece of tinder is located. **Flashlight Reflector** Using the reflector from a flashlight could be used to start a fire.

6 Electricity

Electricity can be used to create sparks to light tinder if applied correctly.

Battery Sparks	Created when the terminals from a high voltage and amperage battery touch. Striking the leads of a 12v car battery together towards tinder can ignite it if aimed correctly.
Battery Heated Filament	Using a battery to rapidly heat a thin metal element. An example element would be a thin wire or steel wool, as long as the batteries voltage and amperage is high enough.
Piezo Ignition	Uses piezoelectricity to generate a small spark which jumps between metal contacts. Best used in liquid and gas fuels.
Arc Lighter (Electric Lighter)	Uses high voltage to generate a beam to ignite.

7 Chemical

These are chemical combinations that can start fires.

Calcium Hypochlorite + Automotive Brake Fluid (polyethylene glycol)	After a few seconds the reaction violently erupts into flame. Brake fluid can last indefinitely unopened but about 1 year opened. Calcium Hypochlorite lasts up to 10 years.
Potassium Permanganate + Glycerine + Room Temp above 22°C (70°F)	After a few seconds a flame erupts from the mixture. Requires a pile of about 3x3cm to generate a flame.
Potassium Permanganate + Acetone + Sulfuric Acid	
Potassium Permanganate + Antifreeze	
Sodium Chlorate + Sugar + Sulfuric Acid	
Ammonium Nitrate Powder + Finely Ground Zinc Powder + Hydrochloric Acid	
Sulfuric Acid + Zinc + Platinum	

8 Spontaneous Combustion

Spontaneous combustion or spontaneous ignition is a type of combustion which occurs by self-heating (increase in temperature due to exothermic internal reactions), followed by thermal runaway (self heating which rapidly accelerates to high temperatures) and finally, autoignition.

Cause
1. A substance with a relatively low ignition temperature (hay, straw, peat, etc.) begins to release heat. This may occur in several ways, either by oxidation in the presence of moisture and air, or bacterial fermentation, which generates heat.
2. The heat is unable to escape (hay, straw, peat, etc. are good thermal insulators), and the temperature of the material rises.
3. The temperature of the material rises above its ignition point (even though much of the bacteria are destroyed by ignition temperatures).
4. Combustion begins if sufficient oxidizer, such as oxygen, and fuel are present to maintain the reaction into thermal run-away.

Lighting (Linseed Method)
To utilize spontaneous combustion to start a fire you will need a metal can or container, air for oxidation, lots of cloth and linseed oil. Moisten the cloth with linseed oil so that they are damp but won't drip if held up. Pack them into the can tightly, then just wait.

Affected Materials

- Hay piles and compost piles may self-ignite because of heat produced by bacterial fermentation.
- Linseed oil and Danish oil in a confined space (such as a pile of oil-soaked rags left out in an uncovered container, especially if rags afterward used with anti-moisture solvent to clean up the oil) can oxidize leading to a build-up of heat and thus ignition.
- Coal can ignite spontaneously when exposed to oxygen, which causes it to react and heat up when there is insufficient ventilation for cooling.
- Pyrite oxidation is often the cause of coal spontaneous ignition in old mine tailings.
- Cotton and linen. When these materials come into contact with polyunsaturated vegetable oils (linseed, massage oils), bacteria slowly decompose the materials, producing heat. If these materials are stored in a way so the heat cannot escape, the heat build-up increases the rate of decomposition and thus the rate of heat build-up increases. Once ignition temperature is reached, combustion occurs with oxidizers present (oxygen).
- Large manure piles can spontaneously combust during conditions of extreme heat.
- Pistachio nuts are highly flammable when stored in large quantities, and are prone to self-heating and spontaneous combustion.
- Nitrate film, when improperly stored, can deteriorate into an extremely flammable condition and combust.

Hay

Hay is one of the more studied materials in spontaneous combustion. As hay varies by the type of grass and location grown utilized in its preparation, it is very hard to establish a unified theory of what occurs in hay self-heating. It is anticipated that dangerous heating will occur in hay that contains more than 25% moisture. The largest number of fires occurs within 2 to 6 weeks of storage, with the majority occurring at 4 to 5 weeks. The process may begin with microbiological activity (bacteria or mould), but at some point, the process has to become chemical. Microbiological activity will also limit the amount of oxygen available in the hay. Moisture appears to be quite important, no matter what process. At 100 °C, wet hay absorbed twice the amount of oxygen of dry hay. There has been conjecture that the complex carbohydrates present in hay break down to simpler sugars, which are more readily oxidized.

Charcoal

Charcoal, when freshly prepared, can self-heat and catch fire. This is separate from hot spots which may have developed from the preparation of charcoal. Charcoal that has been exposed to air for a period of eight days is not considered to be hazardous. There are many factors involved, two being the type of wood and the temperature at which the charcoal was prepared.

Coal

Self-heating in coal has been extensively studied. The tendency to self-heat decreases with increasing rank of the coal. Lignite coals are more active than bituminous coals, which are more active than anthracite coals. Freshly mined coal consumes oxygen more rapidly than weathered coal, and freshly mined coal self-heats to a greater extent than weathered coal. The presence of water vapour may also be important, as the rate of heat generation accompanying the absorption of water in dry coal from saturated air can be an order of magnitude or more than the same amount of dry air.

Oil Seeds and Oil-Seed Products

Oil seeds and residue from oil extraction will self-heat if too moist. Typically, storage at 9–14% moisture is satisfactory, but limits are established for each individual variety of oil seed. In the presence of excess moisture just under levels required for germinating seed, the activity of mould fungi to generate heat is a likely candidate. This has been established for flax and sunflower seeds, as well as soy beans. Many of the oil seeds generate oils that are self-heating. Palm kernels, rapeseed, and cotton seed have also been studied. Rags soaked in linseed oil can spontaneously ignite if improperly stored or discarded.

3 Tinder

Tinder is easily combustible material used to start a fire. Tinder is a finely divided, open material which will begin to glow under a shower of sparks. Air is gently wafted over the glowing tinder until it bursts into flame. The flaming tinder is used to ignite kindling, which in turn is used to ignite the bulk material, to produce a fire. Tinder can be made of any flammable substance, as long as it is finely divided and has an open structure.

Common Tinder

These are some great materials for tinder which can be found around most houses.

Cotton	Fine fibres that should ignite easily from a spark.
Cardboard	Lights well from a flame, difficult to light from a spark.
Paper	Scrunched up or shredded - paper provides a moderately easy way to start a fire from a spark, instant from a flame.
Dryer Lint	Lights from a spark easily.
Paracord	After pulling the cord out and dividing the fibres this can be lit moderately easily by a spark.
Toilet Paper	Scrunch up or shred to provide an easy way to start a fire from a spark.
Charcloth	Heat dense wood/cloth in a pot without access to oxygen until black and crumbly. Lights easily from a spark.
Create Char Cloth	Cut an 8x8cm 100% cotton piece of cloth and cook it in a metal container with a hole in the lid until smoke stops.

Manufactured Tinder

FIRE | Tinder | Manufactured Tinder

These are some manufactured tinders which often light easier and are more efficient burners than the common tinders above.

Petroleum Jelly	When mixed with other fibrous tinder it provides an easy way to light fire from sparks.
Wetfire	Extremely easy to light and remains lit in adverse conditions.
Magnesium Powder	Burns extremely hot and is fairly easy to light with a spark.
Steel Wool	Ideally lit by a 12v battery.
Mayan Dust	
Hexamine	
Trioxane	

Liquid Tinder

These are easily combustible liquid tinders which you are likely to find around your house or garage.

Isopropyl Alcohol	Easily ignited from a flame or spark.
Alcohol	Very easy to light with flint or a spark.
Nail Polish Remover	
Turpentine	
Gasoline	
Paint Thinner	
Lighter Fluid	
Aerosol Cans	
Linseed Oil	
WD-40	

Plant Tinders

Cattail

Cattails are wetland plants with a different flowering spike and flat, blade-like leaves that reach heights from 3 to 10 feet. The highly flammable cotton-like seeds are hidden within their thin brown outer shell, located at the very top of the plant. Be careful in trying to extract the seeds because they are under high pressure and will burst out and catch the wind when released. The easiest way to retrieve them with minimal loss is to merely place the brown tip in a plastic bag and tear the outer skin. Make sure you have a sufficient amount because they burn out very quickly.

Eucalyptus Leaves

The oil will take a spark and burst into flame. These are readily found in Australia.

Red Cedar Bark

This tree is unique with its shaggy red bark which is highly flammable. Take your knife or any sharp objects you can find and scrape off only the thin layer of reddish bark fibres. After you've collected a couple of handful of fibres, make a small bundle. Leave a small gap in the middle for your Ferrocerium Rod and shower them with sparks.

Birch Bark

The Birch tree is noticeable with its white bark and dark horizontal fissures. This tree is highly flammable and water resistant, which makes this tree bark useful even in wet weather conditions. Start by gliding your knife down the tree trunk and peel off sheets of barks. Do this on fallen trees as it's much easier to tear. Tear the bark into thin strips and wrap it around your finger for a few moments to make it curly making it easier to catch a spark. Create some sparks with your fire rod and it should only take a moment for the oils in the bark to catch on fire. You can also turn the birch bark into a fine flammable powder. Take one of your pieces of bark and lightly scrape the inside, creating dust. When you have about a tablespoon full of this birch bark powder, light it on fire.

Pine Cones

Pine Cones are very flammable. You can quickly locate them just below pine trees. Pine cones contain the same flammable oils and resins as the interior of pine trees. First, you need to break down the pine cones by crushing them in your hand. Remove the large chunks, so you're only left with a small, fine fire starter. Now take your fire rod and immerse the little pieces of pine cones with a flood of sparks. Be patient as this will take a bit of time to catch on fire. Another notable mention is pine resin. Pine Resin is not considered tinder, so it's not a very good fire starter but it is great as a fuel to an already existing fire. You can find pine resin secreting from trees, it's gold in colour and very sticky, but it burns very well when thrown in a small fire.

Tinder Fungus

Tinder Fungus is a familiar name that was given to a wide variety of fungal species. You can find this fungus growing on the surface of dead or alive Birch trees and on the bottom of oak trees, to name a few. They vary in colour, but one thing they all have in common is their darker spongy core. Most of these cores are rust in colour. Cut a big chunk of fungus from the tree and look on the inside. The darker coloured part is what to use as your igniter fuel. To check if you indeed have it right, cut a piece of the darker interior region and feel it; If its spongy, yet firm, you've got fuel. Now take your Ferrocerium Rod and let the sparks fall. It shouldn't be long until a bright ember forms. These embers will stay active for a significant amount of time, so it's great to carry with you to your next location, be careful not to burn yourself or your belongings. If you immediately need a fire, gently blow on the ember and place it in a pile of dry kindle and dead grass. It shouldn't take long until you have an intense fire going.

Fire Weed

If you find yourself out in the forest and in a large clearing, then you might see some fireweed. You can't miss this plant since it can grow upwards of eight feet tall. The purple flowers growing on them is also eye-catching. In both late summer and early fall, this plant will generate a cotton-like seed that you can use as combustible tinder. What is unique about this plant is that in the winter, when resources are scarce, you can still find this cotton like substance on the inside of the fireweeds. Just rub them in your hands to reveal it's flammable seeds. Bring that back to your fire pit and throw a few sparks with your Ferrocerium Rod and watch it instantly burst into flames. Another significant advantage to fireweed is that it will burn for a considerable amount of time. The denser you pack it, the longer your fire will last.

Thistle Seed

You can find unopened Thistle Seeds as early as late spring. They can easily be opened, exposing their flammable seeds. You can also find them in the summer after they have fully bloomed, completely exposing its fluffy white cotton seeds. As with fireweed, this natural tinder should be gathered in a big enough bundle. Using your Ferrocerium Rod, let the sparks fall onto them until they catch on fire. It won't take long as this is highly combustible. After its sufficiently burning, it should then be placed at the bottom of your fire pit to let the slow-burning substance create a more significant fire. Way too easy!

Punk Wood

Punk wood is commonly referred to as trees that are in the process of rotting to the point where they no longer contain any structural integrity. You can find punk wood reasonably easy on the forest floor around half standing dead trees. You'll know if you've discovered punk wood as this fallen tree will be very brittle and quickly fall apart in your hands. Due to the fact that it is such a fragile dust, it will be very susceptible to a flutter of sparks raining down upon it. As you turn your newly found punk wood into a beautiful bright ember, place it into a pile of dead grass and voila, fire!

Fat Wood

Fat Wood comes from the wood of old pine stumps left for waste after logging, it is made from splitting the stumps of pine trees that contain a high concentration of natural resin. As the stump wood hardens over time, the resin or sap concentrates to create an all-natural, chemical-free fire starter. Fat Wood can also be found on the part of branches that is the closest to the stump. The resin that was within the branch has seeped down and settled at the bottom.

Wood Shavings

Wood shavings are often the driest tinder around in perpetually wet areas. The inside portion of standing dead wood is usually dry under the bark and below the surface of the wood. Scrape fine wood shavings from dead, dry hard and soft woods with steel knives or stone scrapers. The wood needs to be dead and dry in order for the tinder to scrape and burn properly. Place something under the branch or log to catch the shavings, and always scrape away from yourself to prevent injury The shavings can be held in a bundle of coarser tinder, or packed tightly for an all-wood-shaving tinder bundle. A bird nest shape is good, unless the shavings are too small to hold together. If the shavings won't hold together, use them in some other tinder as a core, or mixed throughout the outer bundle.

Dried Grasses

Most dead grasses make excellent tinder. Use leaf blades and seed tops primarily, and stems and stalks secondarily.
Usually grass doesn't require much processing to become tinder, as long as it is dry and broken off above ground. If the grass is pulled up out of the ground, the damp roots and lower stalks should be cut or broken off. If there are seed heads, the seeds should be shaken out if possible, as seeds are not flammable. The grass must be dry and it needs to have died on its own. Live grass that is cut and then dried (like hay) retains a lot of nitrogen and moisture, both of which are flame retardants. Grass can be coiled around to form a bird nest-shaped tinder bundle, which is easily done by hand with most grasses. The finer materials should be placed in the centre to provide the best fuel for coal and spark ignition.

Leaves

Most dead leaves from trees and plants can be used as good tinder. Leaves tolerate dampness differently, but in general leaves are a much better tinder than grass. Some dead leaves remain on their trees (i.e. oak and beech) making them a great resource when the ground is damp. If the leaves are damp, place them in the sun to dry. Wind can help in the drying process as long as the humidity is low. To make dry dead leaves into useable tinder, you should crumble them. Leaves work best with open flame ignition. They often perform poorly with spark rods, as the sparks just bounce off the flat leaf surfaces.

Pine Needles

The dead needles from most pines can be used as tinder. Pine needles handle dampness very well, perhaps better than any other tinder. Because of the small amount of flammable pitch in the needles, they should burn well unless they are soaking wet or rotten. Pine needles usually need no processing other than drying, although some pounding will split and shred the needles, increasing the surface area of the longer needled species of pine. Pine needles can be collected under the protection of their trees or from sunny spots where they collect from blowing in the wind.

Inner Bark

The dry inner bark from countless dead trees and plants can be stripped and processed into excellent tinder material. Look for the dead inner bark from trunks and branches of tulip poplar, cedar, juniper, mulberry, and some oaks. Plants that are used for cordage material, such as milkweed, dogbane, stinging nettle, and fireweed, can also provide inner bark tinder.

Inner bark can be processed by pounding, tearing, twisting, scraping, or buffing. Pounding is usually the best way to fluff up barks. When processing in any of the ways listed above, catch the fine fibres in some container and use them as the core of the finished bundle. These fine fibres and dust will make the best fuel. The finer materials should be placed in the centre to provide the best fuel for coals, though that shouldn't be necessary for spark rods or open flames. The inner bark of trees are among the longest and steadiest burning tinder's.

Outer Bark

Some outer bark, such as that from cedar, juniper, and birch can also be used like inner bark. Outer bark that is fibrous can be processed in the same ways as inner bark. Birch bark should be shredded as finely as possible. Cedar and juniper tend to smoulder, without flaming up too much. This can be frustrating if you're trying to build a friction fire, but it's a great quality if you're trying to build a long match. The papery outer bark of most birch species makes a great tinder for open-flame fire starting, though it isn't very easy to light with spark rods. The best feature of birch bark is its high oil content. This acts like a waterproofing, allowing the bark to burn even when soaked with water.

Weed Tops and Seed Down

The dead tops from many plants can be used as tinder. Some tops, such as goldenrod, have several grades of tinder in their top. Seed down can also be used as tinder. When used with friction fire coals, it usually doesn't produce flame on its own, and instead just smoulders. But apply a spark rod or open flame to the seed down, and it is explosive. Collect this downy fluff from thistle, cattail, milkweed, and even certain trees, like cottonwood.

Weed tops usually need no processing. Seed down may need to be removed from pods, fluffed, and shaken to remove the seeds, which, as stated, are not flammable. It's neighbourly of you to drop or plant these seeds to renew the resource you are using. Weed tops can be mixed together into bird nest bundles, with the finer material in the centre. There may need to be some outer layer to hold loose materials together. Any dry leaves or fibrous tinder should make a fine outer layer. Seed down can mixed throughout any tinder bundle for a quarter or a third of its volume. It can also be used as an inner core for friction fire tinder bundles.

Tropical Tinder

In southern coastal areas, there are all kinds of tinder that work well for fire building. The fabric-like bark of certain palm trees can be excellent tinder when ripped apart or folded into a wad. Some coconut shells have fibre in their husk, which makes a good tinder, and the dried husks can even be used as "firewood" where fuel is scarce. Certain mosses, such as dead and dry Spanish moss, can be used as tinder when mixed with other tinder. The gumbo limbo tree has a papery bark that readily peels off the tree and resembles a red-coloured birch bark. This papery bark can be shredded and used as great tinder in tropical areas.

Dangerous Tinder

All smoke is carcinogenic, so be careful not to breathe much of it when handling and blowing on any form of tinder. However, some good looking tinder should not be used at all because of its toxicity. The inner bark of the black locust is toxic and can cause a headache if smoke from it is inhaled. Large, old poison ivy vines are covered with a fuzzy, brown fibre that appears to be a great tinder source, but even handling the fuzz will cause those who are allergic to it to break out in a rash. Burning any part of poison ivy, poison sumac, or poison oak can even more dangerous. The smoke can carry the toxic oils into the lungs, and cover exposed skin and clothing.

Good Tinders

- Cliffrose (Cowania)- Outer bark from trunk and larger limbs.
- Cottonwood (Populus)- Inner cambium layer on old dead trees.
- Sagebrush (Artemisia tridentata)- Outer bark from trunk of larger plants.
- Juniper (Juniperus)- Outer bark from trunk of mature trees.
- Yucca (Yucca)- Fibres from pounded dead leaves or ready-made at the base of dead plants.
- Nettle (Urtica)- Fibres from pounded dead stalks.
- Milkweed (Asclepias)- Fibres from pounded dead stalks; also silk from pods.
- Dogbane (Apocynum)- Fibres from pounded dead stalks.
- Thistle (Cirsium)- Down from tops.
- Cattail (Typha)- Down from seed heads.
- Various grasses: Dead leaf blades, partially decomposed, lying at base of plants.

Collecting & Processing Tinder

Bark	Dry bark can be pried from dead trees to use as tinder if fluffed up.
Sticks	Never use green or living sticks on the fire as they won't easily catch fire. If the ground is wet from rain or snow, look for twigs that aren't resting on the ground but instead still on dead branches or leaning up against things. Sticks can be feathered by using a knife or axe in downward strokes to make it easier for a spark to catch it.
Logs	Larger logs should be split prior to use on the fire unless the fire is already large. Ideally logs should be left to dry for a year in a warm, dry location after being freshly cut.
Wet Logs	Wet or damp logs should be placed near a fire to help them dry out faster. If logs are green and wet/damp you should seek alternative wood sources.

4 Types of Fires

The following lists various types of fires and how they can be made or avoided if they are wildfires.

Controlled Fires

Teepee Fire

The Teepee fire is an efficient fire. It lights easily, burns well, and is fairly easy to start and maintain. The Teepee fire gives off a great amount of heat even if it is relatively small in size. Select an area for your fire. Depending on the conditions, choose the best site for your situation.

Construction
1. Gather your tinder, kindling and wood you will use to fuel the fire. How much of all will depend on the size of the fire you are building.
2. Clear a circle for your fire, making sure the area is free of anything that could catch fire, above you as well as around you.
3. Place your tinder in the centre of the circle.
4. Use your kindling to build the frame of the Teepee fire. Lay the small diameter twigs and sticks against one another and over the tinder bundle to form a teepee shape. Leave a small opening in the frame on the upwind side. You will use this opening to light the fire.
5. Gradually start adding larger, thicker twigs as you build outwards, leaving plenty of air space between the sticks. Be careful to maintain the shape of the teepee at all times.
6. Light the fire through the small opening you left in the frame. After the small twigs begin to burn, continue to add more and more larger pieces remembering not to suffocate the fire. You want to make sure that plenty of air gets into the heart of the fire.

Criss-Cross Fire

A crisscross fire, or council fire, is one of the best fire lays for cooking. This fire produces a large, deep bed of coals and is easy to maintain for long periods. It is built with layers of fuel crisscrossed at right angles to each other. To make a crisscross fire, place two logs on the ground parallel to each other. Place you tinder in between the two logs. Lay the logs on the fire in layers, one layer crossing the other. Leave a little space between each log for air to circulate. Finish with a few small logs on top, and simply add more logs as needed.

Fire Ring

Creating a fire ring will help contain your fire. Choose an area in a clearing so that you can keep sparks away from trees or brush. Clear a spot for The circle of rocks. Remove sticks and branches or anything that may catch fire from stray sparks. Collect large, dry rocks to encircle your fire. Avoid using rocks that may be saturated with water (like those found under or near a water source).

When these rocks are heated, steam pressure will build up and the rocks can explode. Dig a circle in the centre of your clearing. If you dig about five or six inches deep this will help protect you fire from the wind. Place the large rocks firmly into the dirt around the edge of the hole all the way around. Fit the rocks tightly together to make a solid wall around the hole. Inside your fire circle you can build a number of types of fire. From a Teepee fire to an A-frame, just choose the type that will best suite your fire ring, situation and available resources.

Keyhole Firepit

A keyhole fire is made in a keyhole-shaped fire ring, and is used for cooking. The large round area is used to build a fire in order to create coals. As coals develop, they are scraped into the long thin end of the ring to cook.

Long Fire

A long fire is typically as long as your body and is perfect for ease of maintaining and keeping your whole body warm at night. The long fire is a versatile, multi-purpose fire lay. The long fire begins as a trench, the length of which is laid to take advantage of existing wind. The long fire can also be built above ground using two parallel green logs to hold the coals together. These logs should be at least six inches in diameter and situated so you can lay things like cooking pots and such upon the logs. Two, one inch thick sticks can be placed under both logs, one at each end of the long fire. This is done to allow the coals to receive more air.

V Fire

This V fire lay is a modified version of the long fire. The way the V fire is arranged allows you to either block strong winds, or take advantage of light breezes. During high wind conditions, the part of the lay where the two logs come together is placed in the direction from which the winds are coming. This will shelter the tinder (kindling) for ignition. Reversing the lay will funnel light breezes into the tinder (kindling) making it easy to ignite.

Swedish Torch

A Swedish torch (also Swedish candle, Finn candle, Swedish fire, Siberian tree torch or Russian tree torch) is a source of heat and light from a vertically set tree trunk, incised and burning in the middle. Due to its flat surface and good embers, it can also be used for cooking. Compared to a campfire, it is more compact, and therefore several small heat sources can be distributed over an area.

Trench Fire

A Trench fire is simply a fire built in the bottom of a trench. In situations where you are forced to use poor quality wood and when cooking is made more difficult because of windy weather conditions, building a trench fire is best. Start by digging or scraping a rectangular trench that's length runs in the same direction that the wind is blowing. This will help assure a proper draft. The trench should be about a foot deep, two or three feet long, and anywhere from 6 inches to a foot wide. Make the windward end deeper sloping upward to a shallow end where the wood can be fed into the fire. Line the bottom of the trench with a layer of rocks.

This will protect the fire from damp ground and radiate heat. You make your fire on this layer of rocks. You can also use rocks to bank both sides of the length of your trench leaving the ends open to take advantage of the draft. These rocks will create a support should the ground become loose and the sides fall into the hole. If the trench is wider than your cooking gear, you may have to use green sticks to create a base to cook on. Rest the (pot, pan, etc.) on the deepest end of the trench.

Parallel Fire

Sometimes a fire is build between two long logs. If the logs are the same size, the tops of the log can be used to place pots for cooking. It has the added advantage of prolonging the fire since the insides of the log are burning too, and its easy to direct the fire up or down the length of the side log, literally until the entire log eventually consumed. A similar fire is the trench fire, used almost exclusively for cooking. These work by either blocking the wind or in funnelling the wind into the fire for a more concentrated and hotter "burn". Several pots can be placed over the trench and the fire can be maintained at different levels for a variety of cooking options.

Star Fire (Indian Fire)

This is not known as one of the popular types of camp fires, but it's an interesting one if you'd like to try it. You need five thick logs to make the five points of the star. Simply arrange them so they look like the rays of the sun, with a small empty area in the epicentre. Then light the end of each log that is closest to the centre. As the fire burns up the logs, push them further into the centre.

Pyramid/Platform Fire

This fire consists of a foundation framework of large logs laid side by side to form a solid base. A slightly shorter log is laid perpendicular and on top of this first layer. Each subsequent layer is slightly shorter as the platform or pyramid rises. This solid mass of right angle firewood takes a little effort to light but it's well worth it for the huge amount of coals it produces, especially when the fire is lit on the top most layer and burns down through the layers. A lighter version of the Pyramid fire is the platform. It's similar in shape to the pyramid fire except the logs are layered only along the outside edge (like walls on a log cabin) with each level of logs slightly shorter than the ones beneath. This creates a hollow wood platform into which smaller kindling can be placed and ignited. It can provide quick warmth and be the start of any number of larger blazes.

Stump Fire

A stump makes a great fire site, especially for cooking. Since they're underground, there's no source of oxygen to sustain the flame so the part of the stump under the surface won't burn.

Construction
Carve out the centre of the stump into the rough shape of a bowl, including a channel cut on one side that allows good air access as well as a good spot to light your fire. Once You have the rough bowl shape, put in a layer of dry tinder (ground leaves, cattail, tinder bundle, etc.) Light the tinder in the stump and slowly feed the fire with twigs and such until it's burning good. Add a few larger pieces and let it burn down into the bowl making a nice bed of coals. The edges of the stump are still good and solid, this makes a great cooking platform.

Tree Torch

As an alternative to the traditional signal fire, you can create what the US Army calls a "tree torch". If you can locate a tree in a clearing which has green leaves and is a considerable distance away from other trees (thus less likely to spark a forest fire), you can use it to make a giant torch. Load all easily reachable branches with dry tinder that will light easily. When lit, the tinder will burn while the living tree creates a massive smoke plume which will be visible for miles.

Signal Fire

Choose a good strong visual point to be seen from. Any fire you build, must be in a clear location to ensure passing crafts stand the best chance of spotting you. In a clearing or on a hilltop, make three signal fires, place them in a triangular pattern (a known signal for help). Space them about 50ft. apart so that the pattern can be distinguished from overhead. You want the smoke from your signal fire to show up against your background area. In snowy conditions for example you will want dark smoke (black). You can make dark smoke by burning the tires on your car, your vehicles oil, even plastics may work. In a forest you would want white smoke. You can get this by burning dry leaves and or green boughs. For ample smoke, use green and wet wood on top of your burning fire.

Wildfires

Crown Fires

A forest fire that spreads from treetop to treetop. This type of fire generally spreads to the ground if it hasn't already as flaming debris falls. Crown fires burn trees up their entire length to the top. These are the most intense and dangerous wild fires.

Surface Fires

Surface fires burn only surface litter and duff. These are the easiest fires to put out and cause the least damage to the forest.

Ground Fires

Ground fires (sometimes called underground or subsurface fires) occur in deep accumulations of humus, peat and similar dead vegetation that become dry enough to burn. These fires move very slowly, but can become difficult to fully put out, or suppress. Occasionally, especially during prolonged drought, such fires can smoulder all winter underground and then emerge at the surface again in spring.

For more information on Wildfires, see the 'NATURAL DISASTERS > Wildfire' section.

5 Fire Lighting

This section will teach you the theory on fire lighting and how to light one quickly and effectively.

Fire Theory

Starting a Fire

Fire Triangle Require all three sides of the fire triangle to light any fire. • **Air (Oxygen)** • **Heat** • **Fuel**	Start with the finest materials in a bundle such as cotton, alcohol or wood shavings. When smouldering, wrap it in a nest of fine, dry and fibrous material such as grass. One burning better place it under a pile of twigs to start it burning. There should be a teepee of larger sticks above the twigs and large logs on the outside ready to put on.

Stick Pyramid
- **Layer 1:** If lighting with flint, have a very fine, easily combustible tinder to start with such as magnesium, lint or cotton.
- **Layer 2:** The next layer should consist of a double fist sized bundle of dried grass or other burnable material or larger. This is typically put in the shape of a birds nest with the smaller tinder in the middle.
- **Layer 3:** The third layer should be a combination of small twigs and a few more dried materials such as leaves to assist the flames in taking hold.
- **Layer 4:** Once the twigs are alight you can now move on to larger sticks and thicker branches up to a diameter of 2-3cms (1 inch).
- **Layer 5:** Large branches can then be added with sizes from 3cm to 10cm diameter.
- **Layer 6:** You can then add the large trunks with diameters anything from 10cm to 30 cm (12 inch). Once lit, these will burn for most of the night and don't require much attention.

Flame Types

With hydrocarbon flames, such as gas, the amount of oxygen supplied with the gas determines the rate of combustion, flame colour and temperature. In all but exceptional cases, like decorative gas fireplace flames, you always want a blue flame from a gas appliance burner.

Blue Flame	A blue gas stove flame indicates complete combustion, meaning you aren't wasting gas and money.
Red / Yellow Flame	Red or yellow gas flames may be the sign of incomplete combustion, wasted gas and a serious safety hazard.

Flame Temperatures

A flame colour temperature guide for fires excluding gas.

Just Visible 525°C (977°F)	**Dull** 700°C (1,292°F)	**Dull Cherry Red** 800°C (1,472°F)	**Full Cherry Red** 900°C (1,652°F)	**Clear Red** 1,000°C (1,832°F)	**Deep Orange** 1,100°C (2,012°F)
Clear Orange 1,200°C (2,192°F)	**Whiteish** 1,300°C (2,372°F)	**Bright White** 1,400°C (2,552°F)	**Dazzling White** 1,500°C (2,732°F)		

Welding Flame Types

There are three basic flame types: neutral (balanced), excess acetylene (carburizing), and excess oxygen (oxidizing).

Carburizing Flame	A carburizing flame will produce iron carbide, causing a chemical change in steel and iron. For this reason a carburizing flame is not used on metals that absorb carbon.
Neutral Flame	A neutral flame is named neutral since in most cases will have no chemical effect on the metal being welded.
Oxidizing Flame	An oxidizing flame is hotter than a neutral flame and is often used on copper and zinc.

Autoignition Temperatures

Fires start from increasing the tinder's temperature until it combusts. Tinder is a material that combusts first (as an ember or flame) and in doing so heats other material (heavier tinder, twigs, kindling, etc.) until it burns (as a flame). Fine tinder is characterized by its ability to combust from a spark, friction, or other action from the below methods. Many forms of tinder are available - charcloth is preferred by many; tinder fungus and related fungus grows in most northern areas; most friction methods using wood generate their own fine tinder; today a pile of magnesium or ferrocerium shavings is common; and a moisture-resistant DIY tinder are cotton balls impregnated with petroleum jelly. Below are the minimum temperatures required to ignite a gas or vapour in air without a spark or flame being present.

Woods Wood - 300°C (572°F) Dry Oak Wood - 482°C (900°F) Pine Wood - 427°C (800°F)	**Solids** Charcoal - 349°C (660°F) Coal - 454°C (850°F) Peat - 227°C (441°F) Cotton Fibres - 455°C (851°F) Paper - 230°C (446°F) Leather - 206°C (446°F) Carbon - 700°C (1,292°F) Phosphorus - 34°C (93°F)	**Gases** Butane - 405°C (761°F) C. Monoxide - 609°C (1,128°F) Hydrogen - 500°C (932°F) Isobutane - 462°C (864°F) Methane - 580°C (1,076°F) Propane - 455°C (851°F) Ethane - 515°C (959°F)	**Liquids** Ethanol - 365°C (689°F) Petrol - 246-280°C (475-536°F) Petroleum - 400°C (752°F) Diesel - 210°C (410°F) Glycerol - 370°C (698°F) Kerosene - 295°C (563°F) Isopropyl Alcohol - 399°C (750°F)
Metals Tin - 940°C (1,720°F) Iron - 1,315°C (2,399°F) Lead - 850°C (1,560°F) Magnesium - 473°C (883°F) Molybdenum - 780°C (1,440°F)			

Lighting Methods

These are the different methods for lighting fires.

Using a Hand Drill

Uses the hands to rapidly rotate a spindle to create embers in a fireboard.	**Components** • Fireboard with drilled holes and notches • Drill Shaft (Spindle) • Hand Piece	See the bow drill section below for setting up the Hand Drill excluding the bow.

Using a Bow Drill

FIRE | Fire Lighting | Lighting Methods | Using a Bow Drill

A version of the hand drill using a bow to spin the stick faster instead of your hands.	**Components** ● Fireboard with drilled holes and notches ● Drill Shaft (Spindle) ● Hand Piece ● Bow	The fireboard should have holes and notches in it which to put the drill shaft into and where the embers fall down into. The wood should be of medium hardness like cottonwood, willow, aspen, tamarack, cedar, sassafras, sycamore, and poplar. Preferably, for the fireboard, you should use a wood of medium-hardness, like cottonwood, willow, aspen, tamarack, cedar, sassafras, sycamore, and poplar, which are the very best. For the spindle, you should use either the same wood or harder wood. I find that an aspen fireboard and a yucca spindle work well. Remember, use a dead, very dry branch for the spindle and fireboard. Green wood is too wet and won't start well.

For the handhold, use a piece of hardwood or a rock with an indent in one side that fits in your palm comfortably. The bow should be a flexible, slightly curved piece of wood about as long as your arm. Tie a piece of paracord on the bottom with a fairly permanent knot, then tie it loosely (not too much slack, but some) to the top with an easily adjustable knot. The spindle will be the spinning piece of wood. It is about 3/4 of an inch in diameter, 8-12 inches long, and round. It should be made out of a piece of wood about the same hardness or harder as the fireboard.

On one end, the top end, it should taper down to a point, then the point ground off slightly to dull it. On the other end, the bottom, it should be pointed also, but not tapered down, more rounded. Also ground this point off. The fireboard will be medium-hard wood about 1/2 to 3/4 of an inch thick, at least twice as wide as your spindle, and as long as you want. This should be dead wood and extremely dry. On one end, make an indentation by putting the tip of your knife on the board (about one spindle away from the edge) and twisting to make a shallow hole. This is a piece of hardwood that can fit comfortably in your left hand (lefties reverse from now on).

Carve a hole in one end like in the fireboard. You can also use a stone with a depression in it. Just make sure it's big enough to keep your fingers from going under-it gets hot down there! The bow should be a stick about as long as your arm and as thick as your thumb at the base. It should be flexible and slightly curved. Tie a strong string at the bottom using a permanent knot of your choice. Now bend the bow and tie the string at the top in an easily adjustable knot, since you will be adjusting it very often. Make sure the string is slack enough for your spindle to be twisted in it, but tight enough for it not to slip around it.

In this step, you will drill the holes in the handhold and the fireboard so that the spindle won't slip out. Begin by putting your left foot to the left of the notch you carved out in your fireboard. Put your right knee down a comfortable distance behind your left foot. Now twist the spindle in this way: hold the bow under your right arm, pinned against your side, so that both hands are free. The thick end should be the one pinned under your arm, and the string should be on top, over the bow.

Put the spindle in so that the bottom end, the one that is more rounded and will be in the fireboard, is on the right. Make sure that the string is resting on the middle of the spindle. Now reverse your hands so that you're grabbing the left of the spindle with your right hand and the right with your left. Twist the spindle clockwise, pulling it up slightly, so that the string twists with it. You can release the bow with your arm, as long as the spindle stays in place.

So, to check: The spindle is twisted in the bowstring, on the outside. It should be up and down in the notch of the fireboard, and the wood part of the bow is on the right of the spindle. Put the handhold on the top of the spindle, the notch on the tip, and hold it with your left hand. Make sure to steady your wrist on your left shin. Hold the end of the bow with your right hand, and start drilling slowly, moving the bow toward you and then away from you. Don't worry about speed right now, just work on getting the motion down.

Push down with your left hand, not too hard, but just hard enough so that the spindle doesn't pop out. If it does, carve the notches deeper in the fireboard and the handhold. Now start to drill faster, and push down harder, remembering to use the entire bowstring and to keep your bowing arm straight. Keep going, until you see smoke, and even then keep going until you can't.

When it's all drilled in, take the spindle out and let it untwist. Wait for it to cool down, and then rub the tip of the top, the one that was and will be in the handhold, in some grease or oil or soap to minimize friction in the socket. If you're in the wilderness and without grease, rub it in your hair and on the sides of your nose. Just remember not to get them mixed up from now on, or else the socket in the fireboard will get grease in it, and that will get rid of valuable friction. Now, carve a triangular notch in the socket in the fireboard. This is where the coal will form. It should go almost to the middle, but not quite, and should be a little less than 1/8 of a pie. Just experiment, because if it's too small, the coal won't have enough oxygen, but if it's to big, the spindle will fly out, and believe me, it hurts.

Carve it out a little on the bottom, just for a little extra oxygen. Put bark or a thin piece of wood underneath it to catch the coal. When you find the right tinder you should put it near your body in between the first two layers of your clothes, so that it can dry out and therefore catch easier. You should fluff it out by rubbing it in between your hands so that it stays together in a clump. You should then collect the ultra fine material that then falls out and put it in the hole you make with your thumb to put the coal in.

Creating Fire
Drill it exactly like you did in step 5, only now it has a notch, so put a piece of bark or a thin piece of wood underneath to catch the coal. Proper form is imperative. Keep a straight back and bowing arm, and keep the bow flat and level. Again, start slowly, and remember that the important thing is not speed, but using the whole bowstring. Apply more and more weight on the handhold, increasing weight in relation to speed.

Keep going until your arm aches and feels like it will fall off, and then do 10 more strokes. It is better to take the spindle off itself then to let it launch out, but what happens, happens. Look at the black dust in the notch that has formed while you were bowing. If it continues to smoke, that means that you may have a coal. Poke it out with your knife tip or a toothpick sized twig.

Fan it with your hand. If it holds together in a clump and continues to smoke, keep fanning it. If it is a true coal, it will eventually start glowing red. Remove the fireboard from the bark and sprinkle extra powder, which will have built up around the notch, on the coal to keep it going. Now put your tinder bundle on the coal, and in a quick motion turn it over to get the coal in it.

Softly bunch the bundle around the coal, hold it above your head and blow it, softly at first, into flame. Remember, long, sustained breaths are better than short ones. When it bursts into flame, don't be afraid of burning your fingers. Put it in your fire lay (teepee, lean-to, etc.) and let it catch on the kindling.

Using a Pump Drill

A variation of the hand drill which uses a pumping motion on a horizontal board instead of a spinning motion.	**Components** ● Fireboard with drilled holes and notches ● Drill Shaft (Spindle) ● Crossbeam with Rope ● Counterweight	A pump drill works by pumping a cross-piece of wood up and down. This is tied to the drill in such a way that the pumping action causes the drill to rotate first one way and then the other quickly, similar to the drill in the bowdrill. A counterweight (at the bottom of the drill) is necessary to provide momentum to the drill. Without it, the drill would lose its momentum instantly because of the friction with the fireboard. It's recommended to have some components of the pump drill pre-made and located in your BOB such as the counterweight, rope and cross-piece to ease the task of building it in the wild.

Using a Fire Plough

A fireplough is operated by quickly rubbing some wood back and forth along a "V" groove in a fireboard. This builds up a pile of hot coals at the end of the groove.	**Components** ● Fireboard with a "V" groove ● Plough stick shaped to a dull point	Find a piece of soft wood. You might get it off a piece of furniture or from an abandoned building. As long as you can make a mark on it with your fingernail, it is soft enough. Make sure it's no more than two feet long, no more than six inches wide, and no more than an inch thick. Find a very hard stick, about a foot long and a half an inch thick. With this one you shouldn't be able to leave a mark on it with your fingernail, otherwise it is too soft. Kneel down over the soft wood. Rest one end of the hard stick on your thigh and the other end on the wood. It should slant either right or left (depending on whether you are right or left-handed) at about a 45-degree angle.

Get a good grip on the stick and start rubbing it up and down the soft wood, making sure the keep the path straight as it forms a groove. The "ploughing" should be hard and fast. This is where your stamina comes into play.

Ignore your burning muscles and keep at it! Soon a pile of wood shavings will form at the end of the wood. Eventually the wood will be hot enough to ignite the wood shavings into embers. Immediately place your kindling on the embers and gently blow on it until the kindling ignites.

Using a Fire-Saw

One piece of bamboo is sliced in half lengthwise then rubbed quickly back and forth in a slot cut across another similar piece of bamboo. Underneath the slot is a tinder bundle. The hot dust from the sawing action falls into the tinder and is blown into flame.	**Components** ● Fireboard with a "V" groove ● Plough stick shaped to a dull point	Start by splitting a piece of bamboo. It should be long enough to wedge between your stomach and the ground while kneeling. You'll need to pad the stomach end, unless you leave that end blunt by cutting it at a node. There should be a long, straight, sharp edge facing away from your body. This piece needs to be fairly beefy since you'll be leaning into it. For the moving piece you need another short section of split bamboo. You grip this with two hands and saw up and down, with the curved side of the hand piece against the sharp edge of the belly piece. Once you've worn a good groove in the hand piece you need to prepare the tinder. Scrapings from the inside of the bamboo work great for this.

You put the tinder inside the hand piece, then put a little bamboo shim over the tinder. To use, grab the hand piece with both hands, while lightly holding the shim with both thumbs. A coal will (hopefully) form in the tinder after you burn a hole through the hand piece. To get the sharpest edge on bamboo, don't cut it - peel little splits off the edge. Peel from the outside of the bamboo toward the centre so that the hard outer layer forms the edge.

"Fire Hole" variation:
This is another variation called the "fire hole" technique - basically a non-bamboo version of the above. Make the stomach piece out of any bowdrill wood, making sure to create a sharp knife-like edge. The hand piece is a partially split branch, held open about 1/4" with a small wood/stone wedge. Fill the split with tinder, then poke a thimble sized hole in it where the hot dust will build up.

Using a Fire-Thong

The fire thong is a fire-by-friction technique requiring a split branch for the heath board and a piece of split rattan. The rattan thong was sawed back and forth against the underside of the heath board.	**Components** ● Log cut in half with two conical holes cut out of one end ● Rope with a toggle at each end	The heath board can be prepared three different ways for a fire thong. For each method, the heath board has an overall general configuration. Imagine a piece of branch split in half. The top side is flat from the split and the other side is rounded due to the curve of the branch.

1	For one method of preparing the heath board, a V-shaped trough is carved in the centre of the top, flat side of the heath board. A punctured hole is drilled to the base of the trough on the middle of the curved side. The hole is less than 1/8 inch (.3175 cm) in diameter. A shallow slot is cut over the tiny hole to guide the split rattan.
2	For the second method of preparing the heath board, the heath board is bound about 6 to 7 inches down the end of the wood. The end is split crosswise and a wooden wedge is placed to hold the split open. The binding keeps the wood from splitting further. The thong is positioned underneath the narrow gap.
3	For the third method of preparing the heath board, a conical shaped hole is bored on the flat side of the heath board. On the middle of the curved side, a very small hole punctures the bottom of the conical crater. The pierced hole is less that 1/8 inch (.3175 cm) in diameter. A slight groove is whittled alongside the hole to hold the split rattan.

The grips for the end of the split rattan were either coiled rattan, wooden toggles or the cut ends of the rattan. When rattan was prepared and carried, it was stored in a tightly coiled configuration. When needed, the fire maker unravelled one end to the desired length and wound the rest of the end for a hand hold. The other coiled end became the other hand grip. When toggles were utilized, the rattan was cut to the required length and the ends were thinned to tie an overhand knot to secure the short wooden stick. The last method for gripping the rattan was to cut the split rattan to a suitable length and just grab the cut ends of the rattan as the hand hold.

Using a Ferrocerium Rod (Flint and Steel)

Flint and steel is the age old way of creating fire. It can spark in the rain and pretty much any other condition you will be in. A single rod will give you thousands of lights and is the most recommended way of carrying fire on you.	**Components** ● Flint Bar ● Steel Striker	Strike the flint and steel into a tinder source until it takes hold, ensure the black coating is removed from the rod before attempting to light.

Using a Fire Piston

One of the harder methods to make a fire with as you require an easily burnable tinder such as char-cloth and lubricant for the rod. Ensure the rubber gasket is fresh and doesn't have any cracks in it and that it fits into the rod snugly. Lubricate the rubber so it slides easily on the outside. Make sure there's a good amount of resistance when pressing it down. Put the fresh tinder into the end of the piston and put the rod onto the very top and place it on a hard surface. Push down the piston very quickly and pull it out from the base. This will compress the air inside to a high level and should ignite the material. Pull it out quickly, the tinder should be smouldering. If you don't pull it out fast enough the lack of oxygen will extinguish it. Quickly put the coal into a bundle of tinder and blow gently until it catches.

Using a Magnifying Glass

FIRE / Fire Lighting / Lighting Methods

The larger the magnifying glass, the easier it will be to light a fire. The ease of lighting this type of fire comes from the position of the sun and the season. Midday in summer would be the easiest. Dawn/Dusk in summer would be a challenge. Midday in winter would be a challenge and Dawn/Dusk in winter would be near impossible. Simply put your tinder on the ground and focus the light into a single point and hold it there until a flame appears. You should use sunglasses when lighting a fire with this method as the spot is incredibly bright. Reading glasses can be used instead to light the fire if they are for close-up work or reading. Long distance glasses spread out the light instead of focusing it.

Using Water and a Bag

Using the same principle as a magnifying glass by refracting light into a single point. Fill the bag with <=5 NTU water. The larger the sphere the more effective the method. Ensure there's no crinkles in the sides of the bag and that the bag is as transparent as possible. Focus it into a point until a fire starts and blow on it gently then put it into a tinder bundle.

Using a Lighter

The easiest modern method for making fire. Commonly used for lighting cigarettes, candles and gas stoves. Press down the flint cylinder swiftly with your thumb and resting it on the gas trigger button. If done correctly a spark lights the stream of gas that emits when the lever is pressed. Release the lever to extinguish the flame. Some lighters are child proof and have a metal loop around the flint to stop it being triggered easily.

Using a Concave Mirror

A concave mirror is similar to the magnifying glass however it will focus the light at a point in front of itself, therefore you will need a small stand to place the burnable material. Add the tinder to the mirrors stand, or hold a few pieces of grass in front of it until it begins to smoulder. You may need an object to hold the grass as the process could take some time to light it depending on the amount of sunlight. When alight, quickly add more flammable materials to it and place it under your twigs and logs.

Using Battery Sparks

Battery sparks from powerful batteries, when aimed at tinder can ignite readily allowing the combustion of the materials. This method can be dangerous as the sparks could fly in any direction and the contacting metal can get extremely hot if left in position. Keep one end of the metal fixed to one end of the battery and put the other end very close to the tinder and repeatedly touch the remaining ends together.

Using a Battery and Steel Wool

This combination uses the travelling electrons through the steel wool to rapidly heat it up igniting it in the process. Simply touch the battery to the steel wool and it will heat up quickly and burst into flames. The finer the wool the faster it will burn up.

Using a Coil Lighter

A plasma arc generated by electricity can be used to ignite tinder easily. Simply open the lighter end and press the button to generate the arc then place a burnable material between the contacts. The lighter will emit a high frequency tone while in use.

Using Chemicals

Chemical fires typically have volatile reaction due to the oxidation of one of the chemicals. Give them plenty of space. Large amounts of chemicals in a reaction could also explode sending burning fragments in all directions. Put the solid chemical in a small tinder bundle of grass or easily burnable material and then add the catalyst and stand back. If done correctly the burnable materials should each take light in the correct order and start a larger fire. After the chemical reaction subsides it's typically safe to walk up to the fire and nurture it.

Fire Spread

Fire Catching Difficulty (Hardest to Easiest)
The below is a table of how easily an ignition method can light various materials. It starts out with piezo ignition which can basically only ignite gasses. Sparks such as from a ferrocerium rod, can ignite everything above on the table such as butane gas and includes a few extras such as magnesium shavings. Lower down a lighter flame can begin to light more commonly found materials such as leaves and paper, but again, can also be used to light easier substances such as dryer lint or alcohol.

Ignition	Description	Can Light
Piezo Ignition	A short current of electricity jumps between two contacts. Requires material to be between contacts. An extremely difficult way to light any materials besides gas.	• Butane • Propane • LPG • Petrol • Alcohol Soaked Cloth
Ember / Light Refraction	A tiny red hot ember typically from a fire piston or bow drill. Put the ember on the material and blow. A very difficult way to light.	(Previous Plus) • Charcloth • Dried Grass • Cotton • Dryer Lint • Shredded Paper • Alcohol • Toilet Paper
Spark	A very hot spark from a ferrocerium rod. A difficult way to light larger materials.	(Previous Plus) • Magnesium Shavings • Fatwood • Paracord
Lighter Flame (2cm) (0.7in)	A small flame from a lighter about 2cm high (0.7in).	(Previous Plus) • Paper • Cardboard • Candles • Dried Leaves • Steel Wool • Matches

Small Flame (5cm) (1.9in)	A steady flame of about 5cm (1.9in).	(Previous Plus) • Twigs • Sticks • Bark
Flame (10cm) (4in)	A steady flame of about 10cm (4in). Smaller flames may be able to light branches eventually, but a 10cm flame is optimal.	(Previous Plus) • Branches
Large Flame (30cm) (1ft)	A steady flame of about 30cm (1ft).	(Previous Plus) • Planks • Dry Thick Logs
Campfire (1m) (3.2ft)	A steady flame of about 1m (3.2ft).	(Previous Plus) • Damp Branches • Green Foliage
Inferno (5m+) (16.4ft+)	A raging flame of 5m+ (16.4ft+). Generally your fires shouldn't get over 1m high unless you're using as a signal fire.	(Previous Plus) • Damp Logs

6 Extinguishing Fire

If you're planning on starting fires you should have some means of putting them out in case they accidentally spread. The below discusses methods of putting out different types of fires safely.

Fire Types

General

To extinguish fires in general you need to remove one or multiple sides of the fire triangle. By removing either the heat, fuel or oxygen the fire will go out.

Campfires

Separate the unburned wood from the burning wood and remove any burnable material from nearby. Douse the fire with water, dirt or sand, beware of water as it could spit back at you. Keep adding water until everything is damp or wet or the fire is mixed thoroughly with your physical medium. Do not just bury the fire with sand or dirt as it will retain heat even longer and keep burning underneath but instead mix them together. Ensure the ground/embers are cool to the touch.

Electrical Fires

Switch off the appliance and pull out plug if possible. Smother fire with blanket or Type C extinguisher. Never try to extinguish with water as water conducts electricity and can give you an electric shock.

Cooking Fires

Shut off stove or oven, smother pan with lid, baking soda or Type B extinguisher. Smother fire in oven by keeping door closed and/or throwing baking soda on food. Never move the Pan. It will fan the fire or splatter grease. Never turn on the exhaust fan or use water. The fan will draw the flames into a concealed space. Let fat cool in oven or else contact with air may make fire flare up again. Hot grease can spatter and ignite any paper, cloth, or wood materials nearby. Cooking oil auto-ignites at around 400-435°C (752-815°F).

Gas Fires

Shut off gas supply. Smother with rug, blanket or Type B extinguisher or cool with water. Ventilate the area to let out the gases. Call the Fire Department to have the area pipes checked for further hazards. Then call the gas company. If there is a gas fire, it may be better to let the gas burn rather than extinguish the fire, which would let the gas fill the room or house creating the potential for an explosion. Therefore, the primary key is to shut off the gas supply and call the fire department. Never enter an area with a lighted match or cigarette if you smell gas from a pipe, heater or stove. Do not turn light switches on or off.

Extinguisher Types

Choosing the correct type of fire extinguisher for the fire is critical to extinguish it as fast as possible.

Class	Description	Symbol
Class A	For ordinary combustible materials such as paper, wood, cardboard, and most plastics. The numerical rating on these types of extinguishers indicates the amount of water it holds and the amount of fire it can extinguish.	Geometric symbol (green triangle)
Class B	Involve flammable or combustible liquids such as gasoline, kerosene, grease and oil. The numerical rating for class B extinguishers indicates the approximate number of square feet of fire it can extinguish.	Geometric symbol (red square)
Class C	Involve electrical equipment, such as appliances, wiring, circuit breakers and outlets. Never use water to extinguish class C fires - the risk of electrical shock is far too great! Class C extinguishers do not have a numerical rating. The C classification means the extinguishing agent is non-conductive.	Geometric symbol (blue circle)
Class D	Commonly found in a chemical laboratory. They are for fires that involve combustible metals, such as magnesium, titanium, potassium and sodium. These types of extinguishers also have no numerical rating, nor are they given a multi-purpose rating - they are designed for class D fires only.	Geometric symbol (Yellow Decagon)
Class E	Electrical equipment: once the electrical item is removed, the fire changes class.	
Class F	For fires that involve cooking oils, trans-fats, or fats in cooking appliances and are typically found in restaurant and cafeteria kitchens.	Geometric symbol (black hexagon)

Extinguisher Chemicals

It is vital to know what type of extinguisher you are using. Using the wrong type of extinguisher for the wrong type of fire can be life-threatening.

Chemical	Description	Effectiveness	
Water **Label: Bright Red**	Water extinguishers are the most common fire extinguisher type for class A fire risk. Most premises will require either water or foam extinguishers.	**Water Uses** • Combustible Materials	**Do Not Use On** • Electrical Fires • Kitchen Fires • Flammable Gas
Foam **Label: Cream**	Foam extinguishers are most common type of fire extinguisher for Class B fires, but also work on Class A fires as they are water-based.	**Foam Uses** • Combustible Materials • Flammable Liquids	**Do Not Use On** • Electrical Fires • Kitchen Fires • Flammable Metals
Dry Powder **Label: Blue**	Standard dry powder extinguishers are also called 'ABC' extinguishers because they tackle class A, B and C fires, however they are not recommended for use in enclosed spaces. This is because the powder can be easily inhaled, and also the residue is very difficult to clean up after. ABC powder extinguishers can also be used on some electrical fires. Specialist dry powder extinguishers are used for flammable metals.	**Dry Powder Uses** • Combustible Materials • Flammable Liquids • Flammable Gases • Flammable Metals • Electrical Equipment	**Do Not Use On** • Oil Fires • Electrical Fires > 1000v
Carbon Dioxide **Label: Black**	CO2 extinguishers are predominantly used for electrical fire risks and are usually the main fire extinguisher type provided in computer server rooms. They also put out Class B fires (flammable liquids, such as paint and petroleum).	**Carbon Dioxide Uses** • Flammable Liquids • Electrical Equipment	**Do Not Use On** • Kitchen Fires • Combustible Materials • Flammable Metals
Wet Chemical **Label: Yellow**	Wet chemical extinguishers are designed for use on Class F fires, involving cooking oils and fats. They can also be used on Class A fires although it is more usual to have a foam or water extinguisher for this type of fire risk.	**Wet Chemical Uses** • Combustible Materials • Deep Fat Fryers	**Do Not Use On** • Flammable Liquids • Flammable Gas • Electrical Fires • Flammable Metals

7 Fire Resistance

Various items and whether or not they are destroyed, partially destroyed or can survive a fire.

Jewellery	Although they may endure superficial damage when they're engulfed by flames, most items of jewellery maintain their compositions amid high heat. Diamonds, which are formed below earth's surface under intense heat and pressure, melt at about 3,315°C (6,000°F). Gold melts at a much cooler temperature - about 1,093°C (2,000°F) - but that's enough to survive most house fires. Platinum jewellery is the priciest, so it's a good thing that the metal's melting point is just higher than 1,760°C (3,200°F). Sapphire and Ruby also possess extremely high melting points.	
Precious Metals	Precious metals can survive all but the most extreme fires fairly well. See the MATERIALS section for a complete listing of the melting points of metal. See Fire Safety below for a list of the temperatures of various fires.	**Metal Melting Points** Copper: 1,083°C (1,981°F) Gold (24k): 1,063°C (1,946°F) Palladium: 1,555°C (2,831°F) Platinum: 1,770°C (3,220°F) Silver (Pure): 961°C (1,762°F) Silver (Sterling): 893°C (1,640°F)
Filing Cabinets	Steel filing cabinets are built to last so that businesses won't have to deal with the loss of important files after building fires. Many people keep personal documents in filing cabinets, which are often kept in home offices. Their steel composition and usual placement within a home – often away from the kitchen or fireplace – give them a high survival rate.	
Tools	Do-it-yourselfers might not have to repurchase the tools they'll need to rebuild their homes after a fire. Steel tools are extremely durable – the melting point of carbon steel is between 1,426-1,537°C (2,600-2,800°F) and the melting point of stainless steel is roughly 1,482°C (2,700°F).	
Cookware	Cookware is built to endure extremely high temperatures. Most pots and pans are made of steel and iron; the latter of which melts at just below 1,537°C(2,800°F). Like silverware, their placement within confined spaces helps them survive the not-so-severe fires.	
Firesafe	The steel composition of a firesafe allows it endure 926°C (1,700°F) infernos.	

8 Fire Safety

This section is for any fire safety tips.

Fire Heat

This section discusses the temperatures different types of fires can reach.

Wood Fire Wood - 1,027°C (1,880°F) Campfire - 593°C (1,099°F) Bonfire - 1,100°C (2,012°F) Housefire - 585°C (1,100°F)	**Butane Gas** 1,970°C (3,578°F)	**Propane Gas** 1,970°C (3,578°F) **Propane Blowtorch** 1,200-1,700°C (2,192-3,092°F)	**Candle** 829°C (1,524°F)	**Incinerator** 870-980°C (1,598-1,796°F)
Charcoal Fire 750-1,200°C (1,382-2,192°F)	**Methane** 900-1,500°C (1,652-2,732°F)	**Bunsen Burner Flame** 900-1,600°C (1652-2912°F)	**Candle Flame** ≈1,100°C (≈2,012°F)	**Magnesium** 1,900-2,300°C (3,452-4,172°F)
Acetylene Blowtorch Up to ≈2,300°C (≈4,172°F)	**Oxyacetylene** Up to 3,300°C (5,972°F)	**Methanol** 1,200°C (2,192°F)	**Dicyanoacetylene** 4,990°C (9,010°F)	**The Sun** **Exterior:** 2,000,000°C (1,111,093°F) **Interior:** 15,000,000°C (8,333,315°F)

Shelter

Types of shelters, building survival shelters and shelter strengths

"A house is more than just a shelter;
that it is a way of improving your way of life."
William Krisel

Introduction

In harsh conditions such as adverse weather or snow you will only last about 3 hours therefore a form of shelter is essential to survival. This shelter encompasses all forms of shelter you can find and how to create some of your own.

Purpose	The aim of SHELTER is to provide detailed information on all kinds of shelters, from natural shelters like boulders and caves, to survival shelters like log cabins and even man-made structures such as houses and military bunkers.
Lost?	• For tips on establishing a home, see the HOMESTEADING section. • For tips on remaining undetected while in a shelter and stealth camping, see the SECURITY section. • For a list of commonly carried portable shelters, see the GEAR section. • For knots related to shelter building, see the KNOTS section. • For a list of the strengths and weaknesses of existing and man-man shelters, see the LOCATIONS section. • For tips on defending yourself while in a shelter, see the DEFENCE > Shelter Defence section. • For tips on wood shelter building, or furniture building see the CRAFTING > Woodworking section. • For a list of the best materials to build shelters from, see the MATERIALS section.

Contents

1 Shelter Types

The shelters in this section are divided into categories to give an idea of what they will fare against in adverse weather. Category 1 shelters should be able to withstand moderate winds and short strong gusts. Category 3 shelters should be able to withstand violent storms. Category 5 should be able to withstand explosions and fare well against nuclear explosions.

	Category 1 A shelter in this category should survive moderate winds and gusts.	**Category 2** This type of shelter should survive a storm with moderate winds, rain, light snow and small hail.	**Category 3** This type of shelter should survive an intense storm with winds, rain, moderate snow and large hail.	**Category 4** A shelter in this category should survive category 1-3 hurricane winds, heavy snow and falling branches.	**Category 5** This type of shelter should survive category 4-5 hurricane winds, bombs and nuclear blasts.

Shelters

Natural Shelters	Natural formed caves can make excellent shelters in bad weather.	**Category 4** Caves should hold up against most winds but becomes dangerous in flooding conditions.	Caves would be the most ideal shelters as long as they are structurally sound and there's no animals living inside.
Survival Shelters	Shelters you build yourself out of natural materials such as sticks, rocks and leaves.	**Category 1-2** Depending on how they are built they can survive stronger weather.	Generally these are made for staying in for a few days as they won't survive strong winds. They use leaves on the top to shed rain and are primarily used for one night stays while moving through a location. They can be easily and quickly demolished leaving no trace that you were there.
Advanced Survival Shelters	Shelters built from stacked logs and rocks to be more stable which are in the shape of modern houses but which still have gaps and no insulation.	**Category 3-4** Custom built log cabins should be able to survive harsh storms if built and grounded correctly.	They take a while to construct but can survive much stronger winds. Not easily disassembled and it would take time to make it look like it's part of the environment again.
Portable Shelters	Any form of lightweight modern shelter that can be pitched and moved with ease such as a tent, and can withstand moderate weather events.	**Category 2** Tents, bivys and hammocks can't survive for long in heavy hail	Canvas swags are made with heavy duty materials which can resist large hail and falling branches therefore they may be able to survive longer than polyester tents.
Public Shelters	Any form of man-made object that isn't designed as a permanent shelter such as a bridge, park shelter, bus shelter etc.	**Category 2** Shelters which will stand up to strong winds but not protect against rain or hail much.	These types of shelters aren't often thought of but will provide a level of protection if required and they can often be built up.
Transport Shelters	Any form of erect modern shelter that can be transported by a vehicle such as a caravan, trailer etc.	**Category 3** Transportable shelters become very dangerous in hurricane strength winds and shouldn't be used.	
Buildings	Any building with four walls and a roof which is made for habitation and is generally waterproof, windproof and inspect proof.	**Category 4** Modern houses (in first world countries) can generally take category 1-3 hurricane force winds well with minimal damage.	
Reinforced Buildings	Buildings with a primary use of concrete such as banks, casinos, vaults etc.	**Category 4** Reinforced buildings can take category 1-3 hurricane force winds well with little to no damage.	
Missile Silos	An extremely heavy duty military grade shelter built underground and designed to shield from nuclear bombs.	**Category 5** Designed to take fire from missiles and explosives and will stand up easily in adverse weather.	
Bunkers	An extremely heavy duty military grade shelter built underground and designed to shield from nuclear bombs.	**Category 5** Will fare extremely well in all types of weather and nuclear wars.	Bunkers are the ultimate prepper's fortress which can help you survive any disaster.

2 Natural Shelters

These are naturally occurring shelters such as caves, valleys and large boulders.

Subheadings

1. Caves	**2. Valleys**	**3. Ledges & Cliffs**	**4. Boulders & Rocks**
5. Standing Trees	**6. Fallen Trees**	**7. Thick Forest**	

1 Caves

Caves are a common choice for sheltering against the elements and for turning into established shelters. For their advantages of an extremely sturdy natural shelter, there's certainly a lot of dangers that come with them, so be sure the one you pick is safe.

Advantages	• All-Weather Protection • Cyclone/Hurricane Resistant
Disadvantages	• Little to no light the deeper you go
Hazards	• Animals Living in the Cave System (Bears, Bats, Weasels, Salamander, Owl) • Poisonous Insects and Creatures (Spiders, Snakes, Scorpions, Remipedes) • Cave-ins • Cave Floor Collapsing • Flooding • Lack of Oxygen • Getting Lost • Cave Flooding at High Tide

2 Valleys

Valleys can reduce the wind factor by quite a degree depending on how steep the valley is. They will unfortunately gather water in downpours which can be life-threatening in certain situations.

Advantages	• Some wind protection
Disadvantages	• May increase the wind in certain circumstances
Hazards	• Flooding

3 Ledges & Cliffs

These can provide a single wall of protection from the elements such as wind and rain, however they may not be so useful if weather is coming from the other direction.

Advantages	• Provides a single wall of protection from the elements
Disadvantages	• May be quite muddy in the rainy season if the cliffs aren't covered by plants
Hazards	• Falling Off • Falling Rocks

4 Boulders & Rocks

Rocks and boulders are useful for shielding you from the elements, however they may be difficult to attach a tarp to since you won't be able to hammer pegs into them.

Advantages	• Resistant to all forms of weather and threats • Won't attract lightning like a tree would
Disadvantages	• Their round shape may be difficult to utilize effectively
Hazards	• Be careful of boulders and rocks which may be close to falling over as they will easily be able to crush you.

5 Standing Trees

Trees make a decent shelter if they provide enough leaf coverage and are rooted deeply enough. Never camp under Eucalyptus trees or any trees with questionable limbs as they can drop whole branches onto you.

Advantages	• Still growing and getting stronger • Provides shelter from rain and hail
Disadvantages	• May not have leaves in Autumn/Fall • May shed its leaves all over your shelter
Hazards	• Potential target for lightning • May drop branches

6 Fallen Trees

A large fallen tree can be a useful shelter if it's tall enough. It will protect you from the wind and provides a solid backing which you can connect a tarp to.

Advantages	• Protection from falling trees if you sleep as close as you can to it • You can use the fallen branches to make a lean-to shelter without having to look for wood
Disadvantages	• Slowly decomposing, weakening the tree • May have lots of branches you have to clear out of the way
Hazards	• Concealed Animal Hazards (Snakes) • Insect Hazards (Ants, Termites, Spiders, Scorpions) • The chance of it rolling over and crushing you

7 Thick Forest

SHELTER | Natural Shelters | Thick Forest

A forest full of trees can be a useful shelter from the elements if you're deep enough inside. You'll have plenty of trees to hang your hammock from and generally a bare forest floor since most of the sunlight will be blocked from any small shrubs.

Advantages	• Reduces the speed of the wind • Keeps you dry fairly easily
Disadvantages	• Chance of getting lost • Little Sunlight
Hazards	• Falling Branches • Falling Trees

3 Survival Shelters

These are shelters you build yourself out of natural materials such as sticks, logs, rocks and leaves. It's assumed you will have a few materials to assist in the construction of the shelter such as a tarp, ground sheet and some form of rope or fishing line. These forms of shelters will rarely stand up to any strong wind.

Materials
- **Natural Elements:** It's ideal to start the shelter using a natural feature of the land such as a (stable) fallen log or large boulder.
- **Logs & Sticks:** For the framework of the structure.
- **Leaves:** Used for the roofing and shedding water.
- **Rocks:** Rocks could be used to secure the frame to or to hold down the sides.
- **Healthy Trees:** These can be used as a strong tie off point for your shelter, or you could build the shelter around it.

Ground Shelters

These are shelters that are built on the ground.

Round Lodge

The round lodge is a hybrid from many cultures. Part tipi, part wicki-up, and influenced by many architectural styles, a round lodge can block wind, rain, cold, and sun. It is structured like a tipi, with the addition of a solid doorway. These typically have a smoke hole through the roof, and can accommodate a tiny fire for heat and light.

This shelter can be thatched with grass or mats; or it can be buried with a thick coat of leaf litter. Lodge styles like this abounded in the historic and prehistoric American west. This architecture worked equally well in wetter climates, and was used in pre-Roman Britain.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials	**Construction**	**Warnings / Hazards**
• Sticks • Logs • Rope	o	o

Debris Shelter

Debris survival shelters come in a variety of structural designs, but the most common is an A-frame. Natural debris, such as tree foliage and dead leaves, can be utilized to insulate your shelter and protect you from the elements.

Keep in mind that your debris won't hold your shelter together nor withhold its strength against strong wind. Incorporate mud (or clay if available) into your structure to make it sturdier. When you're in the forest, look for materials that require little to no alterations (especially when you don't have tools) to build your structures.

Category 1
The leaves will blow away with a moderate wind reducing the waterproofing of the shelter.

Materials	**Construction**	**Warnings / Hazards**
• Sticks • Logs • Rope • Leaves	o	o

Ramada

A ramada is a type of outdoor shelter characterized by a solid roof supported by posts, but typically lacking full walls or being only partially enclosed. Ramadas can be temporary structures made from natural materials for survival or quick shade, but are more commonly permanent, robust constructions made from wood, concrete, or steel.

They are designed primarily to provide shade from the sun and offer protection from other elements like light rain or wind, while still allowing for air circulation. They are often used as extensions of outdoor living spaces, such as covers for patios, decks, outdoor kitchens, or poolside areas, and can be free-standing or attached to an existing building.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Ramada	**Materials** ● Tarp ● Logs ● Rope	**Construction** Ensure the chosen area is clear of debris and as level as possible. Precisely mark the exact spots for your support posts, ensuring they form a true square or rectangle. Dig holes for your posts to the required depth (often below the frost line in cooler climates). Pour Concrete (Optional: Place concrete footings in the holes. Set your main support posts (e.g., 4x4 or 6x6 timber) into the wet concrete, using a level to ensure they are perfectly vertical (plumb) and bracing them until the concrete cures. Alternatively, use post anchors bolted to cured concrete. Measure and cut your horizontal beams (larger timber, e.g., 2x8 or 2x10) to span between the tops of your posts. Lift and attach the beams to the tops of the posts. This can be done by notching the posts, using metal connectors, or through-bolting. Ensure they are level. Use appropriate fasteners (e.g., lag screws, carriage bolts) for strong connections. Measure and cut the roof joists (smaller timber, e.g., 2x6) to span across the beams. For a flat roof, they will be uniform. For a pitched roof, they will be cut at an angle to meet at a ridge. Lay out the joists evenly across the beams according to your design. Secure them to the beams using joist hangers, nails, or screws.	**Warnings / Hazards** ○

Quinzhee

Quinzhee		a quinzhee is an effective emergency shelter built from a large, consolidated pile of loose snow. Unlike an igloo, which uses cut blocks of hard snow, a quinzhee relies on the "sintering" process, where disturbed snow crystals bond together and harden after being piled and left to settle for a few hours. Once the mound is firm, an entrance tunnel is excavated, leading into a larger, dome-shaped inner chamber. A critical step involves creating an elevated sleeping platform within the cave to separate occupants from the coldest air, which naturally sinks. Finally, a small ventilation hole is poked through the roof to ensure air circulation and prevent carbon dioxide buildup, vital for safety in a confined snow shelter.	**Category 2-3** It can survive moderate winds but likely won't survive a storm well.
Quinzhee	**Materials** ● Snow ● Sticks	**Construction** Start by piling up some moveable gear under a tarp. Backpacks are commonly used for this. Then pile snow over the tarp and gear. Pack the snow down, estimating when it is two feet thick all the way around. Next, insert 12 inch long sticks around the dome. Use 3 or 4 dozen of these guide sticks. Burrow into the side of the quinzhee, and retrieve the tarp and gear. Excavate snow inside the mound until you reach the base of every stick. This will ensure uniform thickness of the dome. Make a fist sized ventilation hole in the roof of the quinzhee.	**Warnings / Hazards** All snow shelters eventually collapse or melt.

Quinzhee

Warnings / Hazards Continued
Quinzhees can collapse from poor snow conditions, warm weather, blowing rain, construction problems (hitting a supporting wall), failure to let the snow sinter long enough, or from people climbing on them. Collapse poses a danger of suffocation for occupants. Quinzhees should not be used when temperatures are warmer than −4 °C (25 °F) due to risk of collapse. The greatest risk of collapse occurs during the excavation process. Longer sintering time generally reduces risk of excavation collapse. To reduce undue loading on the roof of the quinzhee, the interior ceiling should be excavated first, then the interior walls and floor. One person should be outside the quinzhee while another is digging inside. Place a shovel, branch, hiking pole, or such near the head of a sleeping person for roof support, to break a falling roof to create an air gap, and/or as a tool to dig out. One shovel should be left outside to mark the door and aid rescuers in digging occupants out. Some users prefer a marker to be left outside the quinzhee nearest the heads of sleeping occupants to indicate where rescuers should start digging.

Quinzhee are typically built on a flat area where snow is in abundance, on a day colder than −4 °C (25 °F). Builders break up layers of naturally fallen snow into powder and thoroughly mix bottom and top layers of snow to increase sintering, thus strengthening the eventual structure. Snow is typically piled 1.5 to 2 meters (6 to 10 feet) high in a dome 3 to 4 meters (10 to 12 feet) in diameter. It is then left for at least 2 hours to sinter, allowing both temperature and moisture in the snow to homogenize and the snow crystals to bond with each other. Packing can speed the bonding process and strengthen the structure. Small sticks, approximately 30 to 35 cm (12–14 inches) are pushed into the structure to act as thickness guides when the interior is hollowed out. According to Halfpenny and Ozane, the wall at the base should be at least 30 cm (12 inches) wide and at the top about 20 cm (8 inches) thick, though wall-base thicknesses of >60 cm (2 ft) are possible.

Excavation may be accomplished more quickly if large blocks of interior snow are carved and slid out through a large, temporary "excavation door". Strength increases when all interior wall and ceiling surfaces follow an arched curve, with no flat sections. Once excavation is complete the excavation door can be permanently blocked using previously excavated blocks, and a smaller permanent door can be cut in the most desirable spot. Time and effort are required to hollow out the centre of a Quinzhee, though these can be reduced by piling snow around a hollow structure, such as a pile of packs or a makeshift tent or dome.

Allowing the interior temperature to rise above freezing point risks weakening the shelter significantly, especially if the outside air temperature is near freezing. A small hole for air circulation should be poked through the ceiling. To avoid dripping melt-water, irregular or bumpy surfaces are often smoothed to direct the flow of water down the walls to gather around the edges. A non-airtight fabric door cover will minimize the amount of cold air coming into the quinzhee. An empty, well built snow structure, 16 or more hours old, in weather below −12 °C (10 °F) may be strong enough to support a group of adults standing on top of it.

Snow Cave

Snow Cave		A snow cave is an emergency shelter constructed by digging into a deep, stable snowdrift. Its primary purpose is to provide immediate protection from extreme cold, wind, and precipitation. The thick snow walls act as excellent insulation, trapping body heat and maintaining an interior temperature significantly warmer than the outside air, often around freezing even when external temperatures are well below zero. A snow cave's design typically includes an entrance tunnel that slopes upwards into the main chamber, effectively creating a "cold sink" where the densest, coldest air settles, leaving warmer air for the occupants on an elevated sleeping platform. A small ventilation hole poked through the roof is vital for safety, ensuring adequate airflow and preventing the dangerous buildup of carbon dioxide or carbon monoxide from any heat sources.	**Category 1-2** This won't survive long in very strong winds before being torn apart.

SHELTER | Survival Shelters | Ground Shelters | Snow Cave

Materials	Construction	Warnings / Hazards
Materials ● Snow ● Shovel (Helps)	**Construction** First, locate a deep, stable snowdrift, ideally on a gentle slope or the leeward side of a hill. Begin by digging a small entrance tunnel, ideally sloping slightly upwards into the snow bank. This upward slope helps trap warmer air inside the cave. Continue to hollow out the interior, expanding it into a dome or igloo-like shape. The curved ceiling is crucial for structural integrity and to prevent drips from melting snow. Aim for walls and a ceiling at least 12-18 inches thick for insulation and stability. Once the main chamber is excavated, create an elevated sleeping platform inside, higher than the entrance, to keep you above the coldest air. Smooth the interior walls and ceiling to minimize dripping. Finally, poke a small ventilation hole (about 2 inches in diameter) through the roof, preferably at the highest point, using a ski pole or stick to ensure constant airflow and prevent carbon dioxide buildup. The entrance can be blocked with a snow block or backpack for added warmth, but always ensure the ventilation hole remains clear.	**Warnings / Hazards** o

Wedge Tarp

SHELTER | Survival Shelters | Ground Shelters | Wedge Tarp

A wedge tarp shelter is a simple yet effective emergency shelter created using a single tarp. It provides protection from wind, rain, and snow. The basic setup involves securing one long edge or corner of the tarp low to the ground, often by pegging it directly into the earth or weighing it down with logs or rocks. The opposite edge or corner is then elevated, typically by tying it to a tree or using a trekking pole or sturdy stick as a prop, creating a sloped, wedge-like shape. This design funnels precipitation away and offers a degree of windbreak, with the low side facing into the prevailing wind for maximum protection. The open side allows for ventilation and can accommodate a small fire if safe to do so.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Arrowhead Tarp Shelter

SHELTER | Survival Shelters | Ground Shelters | Arrowhead Tarp Shelter

An arrowhead tarp shelter is a highly versatile and protective configuration that maximizes a tarp's coverage to create a relatively enclosed space. It's often favored for its ability to offer significant protection from wind and rain, and can even provide some insulation in colder conditions. This setup typically involves using a ridgeline (rope) strung between two anchor points, like trees. The tarp is then draped over this ridgeline, with a portion of it extended to the ground to form a floor and one or more walls, while the remaining sections are pulled taut and staked out to create a triangular, tent-like structure with a pointed arrowhead shape at one end. This design allows for a relatively compact and wind-resistant shelter, often with a single opening that can be partially or fully closed, making it efficient for retaining heat from body warmth or a small, carefully managed internal fire.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials	Construction	Warnings / Hazards
Materials ● Tarp ● Rope ● Tent Pegs or Rocks	**Construction** o	**Warnings / Hazards** o

Basic Fly Shelter

SHELTER | Survival Shelters | Ground Shelters | Basic Fly Shelter

A simple, often quickly erected tarp configuration primarily designed for overhead protection from rain or sun. It typically involves suspending a tarp horizontally or with a slight pitch over a ridgeline, which is a rope strung between two trees or elevated points. The corners of the tarp are then pulled out and secured to the ground using stakes or weighted objects, creating a minimalist roof. While offering essential protection from precipitation and direct sun, a basic fly provides limited defense against wind, cold, or insects, making it most suitable for milder conditions or as a quick temporary cover. Its simplicity and speed of deployment are its key advantages when immediate overhead shelter is needed.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials	Construction	Warnings / Hazards
Materials ● Tarp ● Rope ● Tent Pegs or Rocks	**Construction** o	**Warnings / Hazards** o

Body Bag

SHELTER | Survival Shelters | Ground Shelters | Body Bag

A specific and highly protective tarp configuration designed to provide maximum enclosure and weather resistance, often in colder or more exposed conditions. It's named for its ability to envelop the user much like a sleeping bag or a bodybag, offering significant protection from wind, rain, and even some insulation from cold. This setup typically involves creating a completely enclosed or nearly enclosed space by carefully folding and staking a tarp. It often utilizes a ridgeline for overhead support, with the tarp's edges brought down to the ground and overlapping to form a fully sealed, tube-like, or wedge-shaped shelter. This maximizes trapped air for warmth and minimizes exposure to the elements, making it an excellent choice when prioritizing thermal retention and full-body protection from severe weather.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials ● Tarp ● Rope ● Tent Pegs or Rocks	**Construction** o	**Warnings / Hazards** o

Envelope

This is a specific tarp configuration designed to maximize ground protection and offer a degree of enclosure, making it particularly useful in damp or windy conditions. It's constructed by utilizing a portion of the tarp as a ground sheet, which then folds upwards to form a low wall or the base of one side of the shelter. The remaining part of the tarp is then extended over a ridgeline or supported by poles, creating a sloped roof. This "envelope" effectively separates the user from the cold or wet ground, a critical factor in preventing heat loss through conduction, while the low profile and enclosed design provide a good windbreak and shed precipitation effectively. It prioritizes a dry sleeping area and modest overhead protection over expansive internal space.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials ● Tarp ● Rope ● Tent Pegs or Rocks	**Construction** o	**Warnings / Hazards** o

Forest Tent

A robust and relatively enclosed tarp configuration that leverages natural features, primarily trees, to create a secure and protective space, often resembling a small tent. This setup usually involves a ridgeline strung between two trees, over which the tarp is draped. The key characteristic is that the sides of the tarp are then pulled down and secured to the ground, often forming walls that meet the ground or even extend slightly inward to create a small "bathtub" floor. This design maximizes protection from wind, rain, and snow, as it significantly reduces exposure to the elements compared to more open tarp setups. It's an excellent choice for extended stays or harsh conditions, as it provides a more enclosed and thermally efficient environment, allowing for better heat retention from body warmth or a carefully managed internal fire.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials ● Tarp ● Rope ● Tent Pegs or Rocks	**Construction** o	**Warnings / Hazards** o

Rain Fly

A tarp setup specifically focused on providing maximum protection from precipitation. While any tarp can be used as a rain fly, this configuration emphasizes creating a waterproof overhead barrier for a primary shelter, whether it's a sleeping bag, a bivy sack, or even another, less waterproof structure like a mesh tent. The tarp is typically pitched with a good slope to effectively shed water, often in an A-frame, diamond, or lean-to style, and is secured tautly to prevent water from pooling or wind from flapping it excessively. The main goal is to keep the occupant and their gear completely dry, which is critical for preventing hypothermia and maintaining morale in wet, cold conditions, especially in regions prone to sudden downpours.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials ● Tarp ● Rope ● Tent Pegs or Rocks	**Construction** o	**Warnings / Hazards** o

Square Arch

A tarp configuration designed for quick setup and moderate protection, particularly useful when overhead clearance is desired. It's characterized by its nearly square or rectangular footprint and an arching roofline. Typically, this is achieved by running two parallel ridgelines or poles at a similar height, over which the tarp is draped. The long ends of the tarp are then pulled outwards and staked down, creating a central, relatively open space with a rounded or arched roof, and potentially low walls on two sides. This design offers good head height, sheds rain effectively, and provides a decent windbreak from two directions, making it a good balance between openness and protection for a variety of conditions where direct overhead cover and some interior space are priorities.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials ● Tarp ● Rope ● Tent Pegs or Rocks	**Construction** o	**Warnings / Hazards** o

SHELTER | Survival Shelters | Ground Shelters

Trekking Pole

Trekking Pole		
	A "trekking pole shelter" leverages a backpacker's existing equipment to create a lightweight and adaptable emergency shelter. This type of shelter uses one or two trekking poles as the primary vertical supports for a tarp, eliminating the need for finding suitable trees or carrying dedicated tent poles. Common configurations include an A-frame, where the tarp is draped over a ridgeline supported by two trekking poles at either end, or a lean-to, where one side of the tarp is elevated by a pole while the other is staked to the ground. The versatility of trekking poles allows for pitching the tarp in various shapes to best combat wind, rain, or sun, making it a highly efficient and weight-saving option for minimalist survival or unexpected overnight stays where speed and portability are crucial.	**Category 1-2** This won't survive long in very strong winds before being torn apart.
Materials ● Tarp ● Rope ● Tent Pegs or Rocks	**Construction** o	**Warnings / Hazards** o

Windshed Wedge

Windshed Wedge		
	A tarp configuration specifically designed to offer superior protection from strong winds and driving rain or snow, making it ideal for exposed environments. It's characterized by its low-profile, wedge-like shape, with one long edge of the tarp secured very close to the ground, facing directly into the prevailing wind. The opposite side is then elevated to create the roof, which slopes sharply down towards the windward side. This steep angle and minimal exposed surface area act to "cut" through the wind rather than catching it like a sail, significantly reducing flapping and structural stress. While it offers limited interior space and may require crawling to enter, its primary strength lies in its ability to withstand severe weather, providing a crucial refuge where other tarp setups might fail.	**Category 1-2** This won't survive long in very strong winds before being torn apart.
Materials ● Tarp ● Rope ● Tent Pegs or Rocks	**Construction** o	**Warnings / Hazards** o

Tarp Wing

Tarp Wing		
	A tarp wing shelter is a simple and quick-to-deploy tarp configuration designed primarily to offer overhead protection from rain or sun, often sacrificing significant wind protection for ease of setup and ventilation. It's typically created by elevating two opposite corners of the tarp relatively high (e.g., tied to trees or supported by poles), while the other two opposite corners are anchored low to the ground. This creates a large, open "wing" or diamond shape that effectively sheds precipitation and provides shade over a wider area. While it's excellent for keeping a campsite or fire dry in wet, mild conditions, its open nature makes it less suitable for strong winds, extreme cold, or situations requiring full enclosure against the elements.	**Category 1-2** This won't survive long in very strong winds before being torn apart.
Materials ● Tarp ● Rope ● Tent Pegs or Rocks	**Construction** o	**Warnings / Hazards** o

Tarp Burrito

Tarp Burrito		
	A highly effective, minimalist configuration focused on maximizing insulation and protection against cold, wind, and wet conditions, particularly when external temperatures are low. As the name suggests, it involves wrapping oneself tightly within the tarp, much like a burrito. This is often achieved by laying the tarp flat, placing an insulating layer (like leaves, pine needles, or a sleeping pad) on one half, lying down, and then folding the remaining half of the tarp over the body. The ends are then secured or tucked to minimize drafts, creating a fully or nearly fully enclosed personal cocoon. While it offers very little headroom or space for movement, its strength lies in creating a highly efficient micro-climate that traps body heat, making it an excellent choice for an emergency bivy or when lightweight, immediate thermal protection is the priority.	**Category 1-2** This won't survive long in very strong winds before being torn apart.
Materials ● Tarp	**Construction** o	**Warnings / Hazards** Be careful not to suffocate yourself during the night due to lack of oxygen.

Tarp Tipi

A robust and highly protective tarp configuration that mimics the conical shape of a traditional Native American tipi, offering excellent wind resistance and heat retention. It's typically built around a central pole (a sturdy branch or trekking pole) or by stringing a ridgeline between trees to create the peak. The tarp is then wrapped around this central support and staked out in a circular or hexagonal pattern at the base, creating enclosed walls that shed rain and block wind from all directions. This design maximizes interior volume and allows for an efficient centralized heat source (like a small, contained fire or hot rocks, with proper ventilation), making it a superior choice for colder, windier, or more prolonged survival situations where a more substantial and insulated shelter is required.

A-Frame Tarp Shelter

The A-frame is a tarp design that gives great coverage against rain and wind, when built close to the ground. When suspended higher, it still provides coverage from rain, but it allows more airflow underneath. A-frames go up fast. Once you pick your shelter site, you should have your tarp hung up in 10 minutes or less, leaving plenty of time in the day to accomplish other survival tasks. To get started, suspend a line of cordage between two trees or similar supports. Lay your tarp over the line and tie down all four corners of your tarp. This shelter is a great addition to a tarp hammock or strung up over a springy bough bed. You can even use a poncho as an A-frame tarp shelter.

o

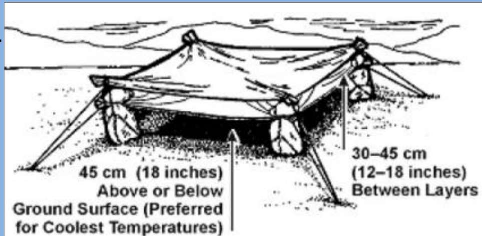
Desert Tarp



If you have material such as a poncho, canvas, or a tarp, use it along with terrain features like rock outcroppings, mounds of sand, or depressions between dunes or rocks to make your shelter. The objective is to create a covering while keeping all sides open to air current and circulation.

Category 1-2
This won't survive long in very strong winds before being torn apart.

In all methods below, if you have enough tarp material, fold it in half and form a 30- to 45-centimeter (12- to 18-inch) airspace between the two halves. This airspace will provide insulation and reduce the temperature under the shelter by as much as 25 degrees. This double-roofed shelter dates back centuries and is used in many desert survival scenarios. In addition, digging a depression in the ground can reduce the midday heat as much as 15-25 degrees. However, digging may expend too much energy to be practical. If possible, dig before or after the hottest part of the day (you may build the shelter coverage first, then dig a depression later).

Materials
- Tarp
- Rope
- Rocks

Construction (Rocky Outcrops)
1. Anchor one end of your poncho (canvas, tarp, or other material) on the edge of the outcrop using rocks or other weights.
2. Extend and anchor the other end of the poncho so it provides the best possible shade.

Construction (Sandy Area)
1. Build a mound of sand or use the side of a sand dune for one side of the shelter.
2. Anchor one end of the material on top of the mound using sand or other weights.
3. Extend and anchor the other end of the material so it provides the best possible shade.

Warnings / Hazards
o

Construction (Poles & Sticks Available for Use)
1. Dig a low spot on the ground.
2. Lay the tarp over the low spot and drive the stakes through the corners of the tarp.
3. Tie the tarp to the stake.
4. Drive the stakes into the ground leaving enough space between the ground and the tarp to provide adequate coverage.
5. If possible, drive additional anchors into the ground about 1-2 feet from each stake. Tie from the top of the stake to the anchor to provide additional support.

Tarp Hammock

Tarp Hammock

A tarp hammock combines the benefits of a suspended sleeping system with overhead protection from the elements. This setup involves hanging a hammock between two sturdy anchor points, typically trees, to get the user off the cold, wet, or uneven ground – a crucial advantage in preventing heat loss through conduction and avoiding ground-dwelling insects or creatures. Crucially, a separate tarp is then suspended above the hammock, pitched in a rain-shedding configuration (like an A-frame or diamond fly) to provide a waterproof roof. This dual-component system offers superior comfort, ventilation, and protection from rain, wind, and sun compared to purely ground-based shelters, making it ideal for forested environments or any situation where suitable hanging points are available.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials
- Tarp
- Climbing Rope

Construction
o

Warnings / Hazards
Ensure you use quality climbing rope or it may snap dropping you onto potentially sharp objects.

Bough Bed

A bough bed is a form of improvised insulation and comfort, built directly on the ground to separate a person from the cold, damp earth. Constructed from a thick layer of evergreen boughs (branches with needles, such as pine, fir, or spruce), it works by creating an insulating air pocket between the ground and the user, significantly reducing heat loss through conduction. The boughs are typically laid in an overlapping, shingle-like pattern with the cut ends facing the feet, forming a resilient, springy mattress that can be several inches to over a foot thick. This simple yet effective bed is vital for maintaining core body temperature, preventing hypothermia, and ensuring restorative rest in wilderness survival scenarios.

Warnings / Hazards
o

Wickiup

a wickiup is a traditional, dome-shaped or conical shelter, historically used by various Indigenous peoples, particularly in the southwestern and western United States. It's built by creating a framework of flexible poles (often saplings) bent and tied together to form a sturdy, somewhat open structure. This frame is then covered with available natural materials like brush, bark, reeds, grass, or even animal hides, creating an insulated and weatherproof shell. Wickiups are valued in survival scenarios for their ability to be constructed relatively quickly using readily available forest materials, offering excellent protection from wind, rain, and snow. They often incorporate a central fire pit for warmth, with a smoke hole at the top for ventilation, making them efficient at retaining heat in cold environments.

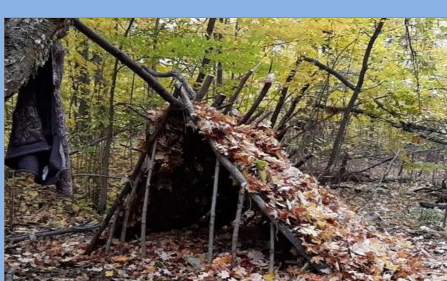
Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials
- Logs
- Brush
- Vegetation

Construction
1. Cut about 30 pine tree saplings -- nice long slender ones. They have to be green and flexible. Preferably 8-10 feet tall.
2. Trim all the little branches off of them and sort the little branches from the trunks. Put the little branches aside for later.
3. Mark a circle and also mark where you want 14 pine poles to go.
4. Dig holes where you marked the pine poles to go. You may have to wet the ground to soften it.
5. Put the poles into the holes and pack the dirt around the poles to keep them sturdy.
6. Bend all the poles over two at a time and tie the ends up at the top.
7. Wrap 3 poles around at different levels and fasten them with rope.
8. Tie the boughs onto the frame, covering it except for a doorway. You will need at least more than one.

Warnings / Hazards
o

Leaf Hut



A leaf hut is a simple, highly insulated shelter constructed primarily from natural, readily available materials, designed to offer superior protection against cold. It is essentially a small, dome-shaped or conical framework of branches, often resembling a small lean-to or A-frame, which is then covered with an extremely thick layer of dry, loose organic matter, predominantly leaves, but also grass, pine needles, or moss. The effectiveness of a leaf hut lies in the significant insulating properties of the packed organic material, which traps air and prevents heat loss from the occupant's body through convection and conduction. The thicker the layer of leaves (ideally several feet), the better the insulation, making it an excellent choice for a survival scenario in a cold environment where maintaining core body temperature is paramount.

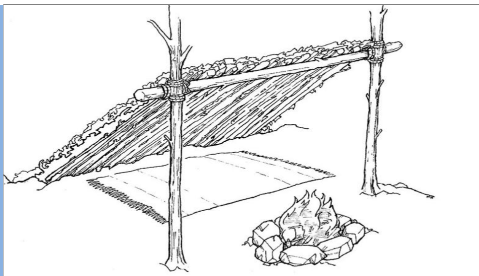
Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials
- Logs
- Sticks
- Leaves

Construction
o

Warnings / Hazards
The leaves may blow off easily leaving you vulnerable to rain.

Lean-To



A lean-to is one of the most fundamental and quickly constructed shelters, designed for immediate protection primarily from precipitation and wind coming from one direction. It consists of a simple framework, typically a horizontal support pole or branch lashed between two trees or propped up by vertical stakes, with other branches or a tarp leaned against it at an angle. The sloped side, facing the prevailing wind and rain, is then covered with available materials like evergreen boughs, bark, large leaves, or a tarp to create a roof that sheds water. While easy to build and offering decent overhead cover, a lean-to is open on one or more sides, providing limited insulation and less protection from cold or insects, making it best suited for milder conditions or as a temporary emergency solution.

Igloo

An igloo, also known as a snow house or snow hut, is a type of shelter built of snow, typically built when the snow is easy to compact. Snow is used because the air pockets trapped in it make it an insulator. On the outside, temperatures may be as low as −45°C (−49°F), but on the inside the temperature may range from −7 to 16°C (19 to 61°F) when warmed by body heat alone.

Category 1-2
This won't survive long in very strong winds before being torn apart.

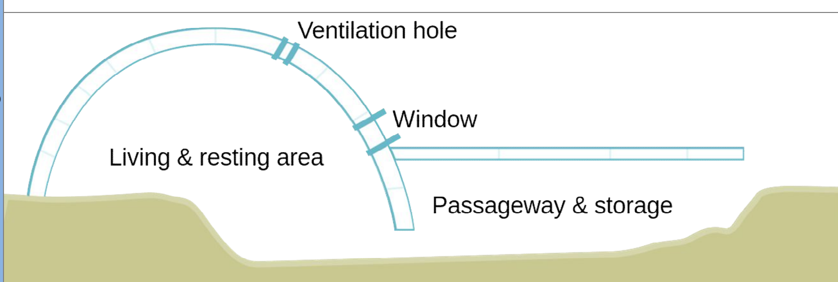
There are three traditional types of igloos, all of different sizes and used for different purposes.
- The smallest were constructed as temporary shelters, usually only used for one or two nights so they were easier to build. These were built and used during hunting trips, often on open sea ice.
- Intermediate-sized igloos were for semi-permanent, family dwelling. This was usually a single room dwelling that housed one or two families. Often there were several of these in a small area, which formed an Inuit village.
- The largest igloos were normally built in groups of two. One of the buildings was a temporary structure built for special occasions, the other built nearby for living. These might have had up to five rooms and housed up to 20 people. A large igloo might have been constructed from several smaller igloos attached by their tunnels, giving common access to the outside. These were used to hold community feasts and traditional dances.

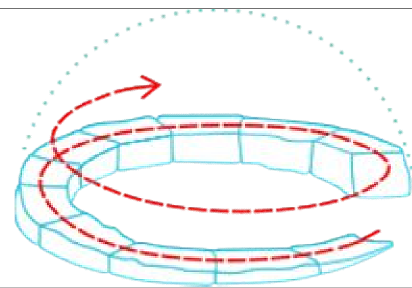
Materials
- Snow
- Sticks
- Shovel (Helps)

Construction
Snow igloos are not spherical, but are built in a catenary curve, a shape more closely resembling a paraboloid. Using this shape, the stresses of snow as it ages and compresses are less likely to cause it to buckle because in an inverted paraboloid or catenoid the pressures are nearer to being exclusively compressive. Since stress is a force per unit area, if the walls are of uniform thickness the compressive stress is independent of wall thickness; thicker walls provide better insulation but do not strengthen the structure because of added weight. The individual snow bricks start out 4-sided and being cut out of the ground with saws and machete-like blades, but are then often cut into 5 or 6-sided shapes to increase structural interlocking, similar to the stones used in the Inca Empire. Igloos gradually become shorter with time due to the compressive creep of the snow.

Warnings / Hazards
Be careful you don't pile too much snow on top or it may collapse on top of you.

The snow used to build an igloo must have enough structural strength to be cut and stacked appropriately. The best snow to use for this purpose is snow which has been blown by wind, which can serve to compact and interlock the ice crystals. The hole left in the snow where the blocks are cut is usually used as the lower half of the shelter. Sometimes, a short tunnel is constructed at the entrance to reduce wind and heat loss when the door is opened. Snow's effective insulating properties enable the inside of the igloo to remain relatively warm. In some cases, a single block of clear ice is inserted to allow light into the igloo. Animal skins were used as door flaps to keep warm air in. Igloos used as winter shelters had beds made of ice and caribou furs. These 'ice beds' are unique to the region and Inuit culture.





Architecturally, the igloo is unique in that it is a dome that can be raised out of independent blocks leaning on each other and polished to fit without an additional supporting structure during construction. An igloo that is built correctly will support the weight of a person standing on the roof. In the traditional Inuit igloo, the heat from the kudlik (qulliq, stone lamp) causes the interior to melt slightly. This melting and refreezing builds up a layer of ice that contributes to the strength of the igloo. The sleeping platform is a raised area. Because warmer air rises and cooler air settles, the entrance area acts as a cold trap whereas the sleeping area will hold whatever heat is generated by a stove, lamp, body heat, or other device. The Central Inuit, especially those around the Davis Strait, lined the living area with skin, which could increase the temperature within from around 2 °C (36 °F) to 10–20 °C (50–68 °F).

Air Shelters

Treehouse

A treehouse, in a survival context, is an elevated shelter built within the branches or trunk of a large, sturdy tree, designed primarily to escape ground-level threats. Its key advantage is providing protection from predators, flash floods, or other ground-based dangers common in certain environments. While more complex and time-consuming to construct than ground shelters, a well-built treehouse can offer a secure, dry, and observation-friendly refuge. It typically involves creating a stable platform within the tree and then building a rudimentary enclosed structure, often from salvaged materials or natural branches and leaves. Access usually requires climbing or a makeshift ladder, adding to its defensive capabilities, though its complexity limits its practicality to scenarios where an extended stay or persistent ground threat justifies the effort.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials
- Logs
- Rope

Construction
o

Warnings / Hazards
If it breaks you have quite a way to fall.

Log Suspended Shelter

Unlike the image, this type of shelter is made of a hatched square or triangle log base with strong ropes connected to a strong tree or very thick branch above. This shelter keeps you off the ground and away from the potentially dangerous cold and predators, while letting you swing gently in the breeze. You could suspend this shelter to one, two, or multiple different points to distribute the weight between multiple trees. The more points you're attached to, the less it will swing in the breeze and the more secure it will be.

Category 2
This won't survive long in very strong winds before becoming dangerous.

Materials
- Logs
- Climbing Rope

Construction
o

Warnings / Hazards
Do not use this in a storm due to the chance of lightning striking the tree.

Water Shelters

Wooden Raft

A custom made wooden raft for sheltering on. This can be used when the land is too dangerous to sleep on such as there being predators at night. There are quite a lot of risks involved in this but it would be fun to try.

Category 1-2
This won't survive long in very strong winds before being torn apart.

Materials
- Wooden Logs
- Rope

Construction
o

Warnings / Hazards
You would have to do excessive testing prior to actually sleeping on a raft and ensure there's no threats such as crocodiles.

4 Advanced Survival Shelters

Shelters built from logs and rocks to be more stable which are in the shape of modern houses but which still have gaps and limited insulation.

Log Shelter

A log shelter is a more substantial and long-term shelter built using fallen trees or logs as the primary structural material. Unlike temporary tarp or debris shelters, a log shelter offers significant protection from extreme weather elements like severe cold, heavy snow, and strong winds, due to the mass and insulating properties of the timber. Construction typically involves stacking logs horizontally, often with interlocking notches at the corners, to form solid walls. A roof, often made from smaller logs, branches, and a thick layer of natural insulation like leaves or sod, is then added. While requiring considerable effort, time, and potentially tools like an axe, a well-built log shelter provides a highly durable and thermally efficient refuge for prolonged stays in the wilderness, offering a greater sense of security and a more comfortable interior than most other improvised shelters.

Category ?

Rock Shelter

	A shelter made primarily from rocks is a more robust and permanent structure than simply using a natural rock overhang. This type of shelter is constructed by intentionally stacking rocks to form walls, or by utilizing existing large boulders as anchors and building up from there. The main advantage is the creation of a strong, durable barrier against severe wind and, if properly roofed, precipitation. The thermal mass of the rocks can also help to absorb and radiate heat, moderating internal temperatures. While labor-intensive and requiring careful selection of stable rocks to prevent collapse, a purpose-built rock shelter offers superior long-term protection in exposed, rocky environments where other building materials like timber are scarce, providing a secure and resilient refuge.	**Category ?**

Log Wall

	How to create a log wall to create a perimeter around a house.	**Category N/A** Not used as a shelter

5 Portable Shelters

Any form of lightweight modern shelter that can be pitched and moved with ease such as a tent. An easier description would be any complete shelter that you can purchase.

Tent

A tent is a shelter consisting of sheets of fabric or other material draped over, attached to a frame of poles or attached to a supporting rope. While smaller tents may be free-standing or attached to the ground, large tents are usually anchored using guy ropes tied to stakes or tent pegs. First used as portable homes by nomads, tents are now more often used for recreational camping and as temporary shelters.

Tent Types

These are the different variants of tents you can purchase today. These days you can get tents that are suspended above the ground, tents that pop out from a vehicle and tents that even float, so this is your first decision when looking at one.

Suspended Tent	A tent that is suspended in the air by 3 or more points.
Hanging Tents	A tent that hangs from a tree by a single point instead of two like a hammock.
Floating Tent	A floating tent is about the size of a large canoe which also doubles as a canoe. Ensure there's no risk to popping it from sticks, creatures or keys.
Floating Tent Raft	A floating tent raft is a larger version of a floating tent in a squarer form factor rather than a pod shape. Ensure there's no risk to popping it from sticks, creatures or keys.
Car Roof Tent	A shelter that is designed to be set up on a cars roof racks. A tent that is supported by your vehicle's roof racks. Every car tent may have a unique way to set it up so it's best to consult the information manual.
Floating Tent Raft	A floating tent raft is a larger version of a floating tent in a squarer form factor rather than a pod shape. Ensure there's no risk to popping it from sticks, creatures or keys.
Extendable Car Shelter	A tent which uses the car as a fixation point to pitch it from, giving easy access.
Pickup Truck / Ute Tent	These fit into the back of a ute and is pitched from there.
Trailer Tent	A tent that's based on a flat trailer towed by a car.

Tent Shapes

This is a list of the different types of shapes that tents can come in.

Ridge Tent	They had a pole at each end and sometimes a cross pole called a ridge holding up a tent-shaped roof: Hence the name 'ridge tent'. Ridge tents are remarkably stable and range from tiny one-person tents right up to large marquees. They are easy to pitch and still make excellent shelters today.
Dome Tent	Dome tents are the most common design today and are shaped like a dome. They have two poles that cross each other in the centre and bend down to reach the corners of the tent. A rainfly rests on top of the poles for added protection from the elements. This style of tent is easy to set up and a has a relatively high centre point giving you a decent amount of room and headspace. The rounded edges allow the tent to shed water and rain, preventing build up on the top. Some dome tents have a vestibule in front of the door that acts as a makeshift mudroom to keep dirt and muddy gear dry and out.
Geodesic Tent	A geodesic tent was created from the geodesic dome structure. For a tent, it is when we add crisscrossing poles which creates either triangles, pentagons, or hexagons. Since these shapes are known to have a higher capacity for strength, this design was made. The geodesic tent is able to withstand heavy winds, snow, and even bad rain storms.

Teepee Tent	These are cone shaped tents with a central support, material draped around the centre, and guy lines for support. The teepee tents of today are similar in design, however, they are made of modern materials. With a central pole acting as the main support, guy lines and stakes play a critical role in giving this structure its form. The taller they are the less stable they become.
Instant Tent (Pop-Up Tents)	Pop up tents are relatively new to the tent game and have grown in popularity in recent years. These tents are designed with spring loaded poles that "pop" into shape in just a few seconds. They are made to be lightweight, super convenient, and quick to set up. Pop up tents are super convenient and great to use in a pinch or on a whim, however, for more serious camping a dome or geodesic tent are more practical options.
Inflatable Tent	Inflatable tents are another newcomer to the camping game and the inflatable poles are a radical design shift from standard tent poles. Rather than having aluminium or plastic tent poles that hold the tent up, they have air beams that you inflate to support the tent structure. They require an air pump or someone with an insane lung capacity to inflate. They are still in the relatively early stages of product design and depending on the manufacturer their durability and ability to handle extreme weather varies greatly.
Tunnel Tent	Tunnel tents are similar in style to a dome tent, however, they are extended in the middle section and end up resembling a tunnel. They are held up with a series of poles that wrap from one side of the tent to the other giving them a rounded shape. Their stability comes from the tent stakes, guy lines, and pole structure. These tents are almost never freestanding and rely on a large number of attachment points, mainly because of their large size. They have high ceilings and more room than a standard tent, making them a great fit for larger groups of people.
POD Tent	Modular camping system that allows tents to be connected together using a tunnel to create interconnected tents. The perfect social camping tent for large groups or families.
A-Frame Tent	An A-Frame tent is the classic, triangular tent that looks like an 'A' with a rectangular floor, hence the 'A-Frame'. Frame tents that you buy in stores are usually double-skin tents. There is one skin that goes over the frame and protects the tent from the elements.

Tent Materials

This is a list of the materials tents are commonly made out of. Each material has its advantages and disadvantages so choose carefully when you buy one.

Cotton	Cotton tents are highly breathable, which significantly reduces condensation inside and helps regulate temperature, keeping the tent cooler in warm weather and warmer in cool weather. They are also durable, naturally insulating, quieter in wind, and offer a more traditional aesthetic. However, they are heavy, bulky, slower to dry, and require "weathering" (pre-wetting to swell fibers) to become fully waterproof. They can also be prone to mold and mildew if packed away wet.
PVC Coated	PVC (Polyvinyl Chloride) coated fabrics are excellent for waterproofness and durability. The coating creates a strong barrier against water, making tents inherently waterproof without needing a weathering process. They are very resistant to abrasion, chemicals, and UV degradation, leading to a long lifespan. PVC-coated fabrics are often used in larger, heavy-duty tents and offer a smooth finish, but can be less breathable, potentially leading to more condensation.
Polycotton Canvas	Polycotton is a blend of polyester and cotton, aiming to combine the best attributes of both. It offers good breathability (reducing condensation) and temperature regulation from the cotton, with enhanced durability, UV resistance, and faster drying times from the polyester. Polycotton tents are generally quieter in wind than pure synthetics and more robust than lightweight polyester, making them ideal for longer trips or varied climates. However, they are heavier and bulkier than pure synthetics and may still require some initial weathering.
Polyester	Polyester is a popular synthetic fabric for tents due to its affordability, lightweight nature, and good water resistance (often with a polyurethane coating). It dries quickly, resists mold and mildew, and has good UV resistance compared to nylon. Polyester tents are generally durable against abrasion and tears, and they pack down relatively small, making them a common choice for backpacking and general camping. However, they can be less breathable than cotton blends, leading to condensation, and can be noisy in strong winds.
Nylon	Nylon is known for its excellent strength-to-weight ratio, making it a top choice for ultralight tents and backpacking. It's highly durable, particularly ripstop nylon which resists tears, and is often treated with silicone or PU coatings for water resistance. Nylon tents are very lightweight and compact, allowing for quick setup and easy portability. A potential downside is that nylon can stretch and sag when wet, requiring re-tensioning, and it is more susceptible to UV degradation over long-term exposure than polyester.
Tarpaulin	A general term for a heavy-duty, waterproof sheet, in the context of tents, it often refers to materials like reinforced polyethylene (PE) or heavy-duty PVC-coated fabrics. Tarpaulins are primarily valued for their exceptional waterproofness, durability, and resistance to wear and tear. They are highly versatile for creating temporary shelters, groundsheets, or protective covers, and are generally very cost-effective. However, they are typically less breathable and can be very bulky and heavy depending on the material and thickness.
Gore-Tex	Gore-Tex is a highly advanced, patented membrane primarily known for its exceptional waterproofness, windproofness, and breathability. Its unique microporous structure allows water vapor (perspiration) to escape while preventing liquid water (rain) from entering, keeping the user dry and comfortable. While not commonly used for the entire main body of large tents due to cost, it's often found in high-performance bivy sacks, specialized expedition tents, or as a component in waterproof/breathable sleeping bags.

Tent Pegs

Tent pegs are often needed to secure a tent when you aren't inside it. This section will assist in providing information on choosing some pegs for your tent which best fit your scenario. In some situations tent pegs won't even be necessary such as in ultralight tents when you only set them up when you're going to sleep.

Types

There are a lot of different styles of tent pegs which are designed for a specific soils and situations.

Hard Ground Pegs	These are designed for tough ground and ground with small rocks.
Sand Pegs	Pegs that are designed to hold well in sand and usually have spirals or a large surface area.
Rock Peg	Pegs which are designed to penetrate well in rocky ground provided there's enough force. These usually require a mallet or hammer.

Materials

Tent pegs are made from various materials which can affect their life span and bendability.

Steel	The strongest metal but very heavy and can rust over time.

SHELTER | Portable Shelters | Tent | Tent Pegs

Stainless Steel	Similar to above but a different alloy to prevent rusting when exposed to the weather.
Galvanised Steel	Steel with a coating of zinc to prevent it from rusting.
Plastic	Not terribly strong and not designed for driving into hard soil. Preferably used for sand.
Aluminium	A lightweight metal which works well as a tent peg.
Titanium	Another lightweight metal which is commonly used for pegs although at a higher cost.
Biodegradable	A tent peg made of potato starch that degrades naturally in the earth if you've left it behind.

Sizes

The size of tent pegs varies quite dramatically and it can have a big effect on holding power and weight.

15cm	Tiny tent pegs which can secure something minimally.
20cm	A good medium size for a tent peg to save on weight and to secure a tent well.
25cm	An average size for fixing a tent securely to the ground.
30cm	A long tent peg for additional fixing power.
35cm	This length will provide a lot of staying power in windy conditions.
40cm	A very long tent peg to secure the tent from the most insane winds.

Shapes

Tent pegs come in a lot of various shapes and sizes to achieve various outcomes. The following should assist you choosing the correct tent peg for the situation.

Roundwire Peg	Supplied with most tents the round wire peg comes in a variety of lengths and is good for medium firm ground such as grass but easily bent on buried stones.
Skewer Peg	Similar to the wire peg, the skewer peg also comes in different lengths and the twisted design gives extra grip on the ground.
Ripple Peg	Great for guy lines on sand and gravel surfaces, ripple pegs provide a greater surface area and more drag resistance than a standard wire peg.
Ground Anchor	Widely regarded as the greatest innovation to hit the peg bag for many years, many campers now swear by the Delta Peg as the saviour of many a tent in extreme conditions. Designed to bury deeper into the ground when under strain.
Groundsheet Peg	A lightweight, small peg designed to hold your footprint groundsheet in the ground without a raised profile on the peg. The groundsheet peg is low strength peg good for its intended purpose.
Halfround U Peg	A high strength steel peg designed to give maximum resistance and be used in a wide variety of ground conditions.
Screw Type Rock Peg	These are a variation of the rock peg with an added screw thread on the peg for increased stability and grip. Designed to turn if they hit a stone, the Screw Type Rock Peg can sometimes be inserted with a cordless drill depending if they come with a compatible head.
Screw Peg	For the lazy camper, screw pegs simply screw into the ground with a cordless drill adaptor or hand wheel attachment. Available in various sizes, screw pegs offer exceptional hold in firm to soft ground, although they cannot be used in concrete, tarmac or rock ground as they will break.
Tent Stake	A variety of degradable pegs are now available which degrade naturally over time if accidentally left in the ground. Great for festival camping, the process takes quite a while so there is no loss to your security whilst camping.
Harpoon Peg	A new design, the harpoon peg gives excellent grip on both medium and soft ground, giving a large surface area to prevent drag and extra grip at the base for a tenacity not round on standard wire pegs. Great for sand, gravel and grass.

Thickness

The thickness of the metal of a tent peg determines how well it can be driven into solid ground. It applies to all different shapes of pegs.

1-2mm	Very thin and light pegs which may be easily bent on insertion.
3mm	A good moderation between lightweight and strength but still may be bent easily.
4mm	Another good size to look for when buying tent pegs, but may be starting to get on the heavy side.
5mm	A very strong tent peg which should make easy work of anything you are putting it in.
6mm+	Generally the thickest pegs you can find which can be driven into almost anything with enough force.

Number of Pegs

The number of tent pegs you need is determined on your tent, for a single person tent it's typically 6-8 but can be more or less depending on the size.

0 Pegs	You don't need any tent pegs if you are only sleeping inside it and there's no wind around, this works best for tiny tents and small bivvies.
3 Pegs	Probably the minimum you should carry on you if you are using tent pegs, two in the corners where the wind is coming from and the other on the opposite side.
4 Pegs	A good stable amount for securing a tent from all sides.
6 Pegs	The optimal amount of pegs to secure the corners of a tent and the middle at two points.
8 Pegs	8 pegs is used for securing the tent well while using 2 or so on the ropes to hold flaps up.

SHELTER | Portable Shelters | Tent | Tent Pegs

10 Pegs	The absolute most you should carry for any tent if you're concerned about weight. 10 pegs works best when they are all under 3 grams as it's better to have more light pegs then fewer heavier.

Weight

Weight is a vital factor when bugging out so choosing a lightweight peg is essential.

1-5g	Ultralight tent pegs which are perfect for backpacking or bugging out weight wise but are generally poor for holding a tent and are bent easily. ● Gram Counter Titanium Pin Pegs - 2g
5-10g	Very light pegs which provide a fair amount of holding power. ● MSR Carbon Core Tent Stakes - 6g
10-15g	An average weight for tent pegs today with a good compromise between strength and weight. ● MSR Groundhog - 11g
15-20g	Still a fairly average weight for tent pegs but getting on the heavier side but they have greater holding power. ● Gram-Counter Gear Titanium Nail Pegs - 15g
20-25g	Quite heavy tent pegs but they rarely bend and generally hold tents very well. ● Heavy Duty Tent Pegs
25-30g	Heavy tent pegs used for securing a tent in strong winds. ● Steel Tent Pegs
30-50g	Very heavy tent pegs which are generally made of thick steel and can be driven into rocky soil easily. ● MSR Blizzard Sand Stake Tent Peg - 33g
50g+	Ultra heavy tent pegs for only the windiest scenarios or the rockiest areas. ● Steel Tent Pegs

Other Factors

Peg Tip Shape	The tip of a peg can be flat, cone shaped, or twisted and many other variants so choose carefully.
Hollow Peg	Some tent pegs are hollow on the inside to reduce weight, these are typically easier to bend then regular pegs.
Colour	Most tent pegs come in a multitude of colours but if you're trying to be stealthy go for one which is brown or green and non reflective.
Plastic Tops	Some pegs have plastic tops to hold the ropes. This style may break easier than full metal pegs when hammered hard.
Mallet	Generally you need a mallet when hammering tent pegs unless you can "stomp" them in or use a rock. This could add a lot of wasted weight if you need to carry one.

Retrieval

Pulling out tent pegs can be a nightmare sometimes but this row will discuss factors to consider.

Puller Tool	Some pegs are difficult to retrieve and may require a pulling tool or another tent peg to get them out.
Camouflage	If your pegs are driven in too far or are painted in camo colours (and the guy lines have detached), they may be difficult to find.
Speed	Sometimes you may have to pack up camp fast and flee, so take note of how fast you can pull out the pegs.

Weather Rating

2 Season	A 2 season tent will likely only be designed for camping in relatively good weather in the sunnier parts of the year. It'll cope with mild rain and wind, but anything really heavy could push it beyond its design. It may have permanent ventilation flaps you can't close to keep you cool that will let wind through but stop mild rain.
3 Season	A 3 season tent will be able to stand up to heavier rain and winds, and hence while it'll often have ventilation flaps you'll often be able to close them on a 3 season tent to stop heavier rain and winds driving though. It'll also probably have more / stronger guy ropes, and the material may be stronger too.
4 Season	A 4 season tent will be designed for use in winter / snowy climates so it will be able to survive snow being driven at the tent, heavy constant winds, etc. Ventilation flaps probably won't be a feature - otherwise even when closed, fine snow could blow into the tent. This will often be replaced with a panel at the top of the inside tent that can be opened to provide some ventilation in warmer climates. But the main purpose of the tent is to protect against harsh elements rather than provide features for warmer climates.

Tent Assembly

Assembling a tent can at times be a tough chore, it may be raining, snowing or there may be no logical way to set it up. This section is aimed at providing tips on setting them up if you aren't sure what order to do it in or

Setting Up There are many ways to set up the multitude of tents out today, but the following should provide an outline on what to do.	1. Lay out the structure ensuring the door is the correct way you want it to face. 2. Put the flexible beams through the loops and into the eyelets on the base so the frame stands up by itself. 3. When the tent is standing up hammer in the tent pegs where necessary. 4. If the tent has guy lines (ropes) stretch them out, ensuring they have a bit of slack and hammer them into the ground. Finish by pulling them taught. 5. Secure tarps with a quick release knot such as a bowknot to allow the shelter to be dropped quickly in the event of any contact, so that its detection does not betray the position.

Tent Repairs

There's endless ways your tent could become damaged, so here's a table detailing each one and how to rectify it.

Damage

These are any forms of damage that can befall your tent.

	Description	Affected Components	Cause	Damage Resistance	Results (of occurrence)	Fix	Notes
Break (Solid Materials)	A component breaks in half such as a fibreglass beam.	● Fibreglass Beams ● Tent Poles ● Hiking Pole	● Over-bending the fibreglass ● Heavy Falling Weight ● Old Age	● Use stronger poles (at the expense of added weight) ● Try not to over-bend	● Lack of tent support	Replacement fibreglass rods would be very difficult to find in SHTF. Use a repair sleeve or something else rigid to repair the pole.	Duct tape the new component to the tent to keep it in position, but this may use a lot of tape over time.
Snap (Rope and Elastic)	The snapping of a cord or rope.	● Fibreglass Stretch Cord ● Outriggers	● Overstretching ● Old Age	● Try not to pull ropes and elastics too tight	● Less Stability ● Stretching	Use paracord instead of rope. Broken elastic can be worked around but it just takes a little longer to set up the tent.	Snaps are probably the easiest to fix due to being non critical components. They can easily be replaced using paracord.
Bend	The bending of a component out of its original shape.	● Tent Pegs ● Tent Poles	● Hammering Incorrectly ● Heavy Weight on Top	● Hammer tent pegs correctly and with proper hammering utensils	● Less Effective ● Harder to Use ● May Break ● Becomes Useless	Hammering tent pegs back into their correct shape can make them useful again.	Try to find alternate tent poles if they broke, such as a stick.
Puncture	A small hole caused by a sharp object in any surface of your tent.	● Tent Walls ● Tent Floor	● Sharp Object Contact ● Some Insects	● Look for a canvas tent or one made from thicker materials	● Rain Leakage ● Groundwater Leakage	Use a patch to cover the puncture to prevent it spreading and seal it with super glue.	A puncture can spread if not dealt with swiftly and can cause the entire tent to come apart over time.
Tear	A surface of the tent is torn by force or sliced open by a sharp object.	● Tent Walls ● Tent Floor	● Slicing motion of sharp object ● Stretching of a puncture	● Look for a canvas tent or one made from thicker materials	● Rain Leakage ● Groundwater Leakage	Sew the tear back together and apply water sealant to the hole, or sew and superglue it back together.	Tears can spread if not dealt with swiftly and can cause the entire tent to come apart over time.
Unstitching	A stitched part of the tent is unfastening slowly with use.	● Any Sewn Edges	● Overstretching ● Old Age ● Bad Construction	● Use a heavy duty fabric and look for special stitching to prevent unravelling	● Sides can't be fixed down as well ● Slow tear progression	Manually restitching where it's coming apart.	Unstitching usually occurs at points where the poles come in contact with the base of the tent due to bad stitching.
Stuck Zip	A zip that won't move along it's path or becomes stuck on parts of the tent.	● Zips	● Untrimmed threads ● Overlapping tent sections	● Tents with larger higher quality zips don't get stuck as often. ● Trim away any loose material from around zips	● Unable to seal the tent ● Unable to enter or exit the tent (possibly)	Wiggle the zip until it's unstuck and then trim the loose material or lubricate it.	You may have to try and trim the material from the tent before attempting to move the zip.
Broken Zip	A zip which has come off the tent entirely and is unable to be re-attached.	● Zips	● Excessive Force ● A stuck zip which broke ● Cheaply Made Zip	● Being careful using the zips ● Purchasing quality tents	● Unable to seal the tent ● Entry by bugs, and inquisitive mammals	Lots of safety pins around the fabric to seal up what you can or use a tarp as an entry flap.	This is a difficult one to fix due to needing to seal it at multiple points while trying to keep out the tiniest insects.
Water Leakage (Non Polymer Tents)	Water leaks into the tent through fabric pores which grow in size over time.	● Canvas Tents	● Lack of Initial Waterproofing ● Old Age	● Waterproofing the tent prior to use by dousing it 3 times after it dries	● Damp Roof ● Wet Clothes ● Dripping Roof	Adding an extra flysheet above the tent or replacing the tent.	This typically can't be fixed and only happens when the tent is exceptionally old and has had lots of use.
Grommet Tear	A grommet which has either been torn off or has torn the material extensively.	● All Tents	● Excessive Pull ● Poor Material Quality	● Stronger Material ● Reinforced Grommets ● Reinforced Corners	● Can't tie down the tent / tarp as well	Sew a reinforcing patch over the top to hold it or create a new hole in the material and secure it from there.	You could always just secure it less if that will suffice for your purposes.

Repair Kit

If possible you should take a small tent repair kit with you. Try to keep a repairs kit as light as possible because you may never need to use it.

Kit Items
- 8cm (3" inch) wall fabric squares
- 8cm (3" inch) floor fabric squares
- Spare Elastic
- Spare Cord
- Pole Repair Sleeve
- Super Glue

Other Kit Items
(You should already have)
- Scissors or Knife
- Needle and Thread

Swag

A smaller and often heavier shelter than a tent, generally being made of canvas and commonly uses hoops as supports. They typically have a top section that opens the full length or half the length of a body which is used to step into the swag. The canvas offers superior protection against animals, falling sticks etc and will probably be the most durable portable shelter for longer term bugging out.

Weathering (Seasoning)	New swags need to be weathered prior to use to bind the fibres closer together and prepare it for rain. To weather a swag firstly set it up then either wait for heavy rain or use a garden nozzle on the shower mode to completely soak every side of it. Let it dry completely after the first soaking and then repeat the soaking and drying loop two more times. After wetting for the final time, inspect the inside of the canvas to see if it's watertight. If there is still water coming through, you may need to apply a seam sealing product. Note: Never pack the swag away when wet or it can develop mould.
Setting Up	Easier to set up than a tent as it only uses between 1 and 3 poles. Tent pegs are recommended but not necessary in calm conditions. Roll out the swag and put in any hoops that are included then add the mattress if you have one. Finally peg out the corners of it followed by any guy lines.

Bivy

A small sleeping bag style shelter used for protection against the elements and insects overnight. They generally don't have hoops or poles to keep the bag from touching your face. The best option for stealth camping and they can be commonly found in camo colours. Bivys are the fastest to set up and dismantle as they only require unrolling and rolling back up again. Some come with additional features such as a fly net and pockets to store valuables but generally they are simple bags.

Setting Up	Bivys don't require any more setup than laying it on the ground and possibly adding pegs if windy weather is expected. Generally you will only set it up when you're ready to go to sleep and the weight of your body will keep it to the ground.

Hammock

A form of shelter hung between trees to suspend you off the ground. Very useful in areas where there's a chance of ground water and wild animals on the ground at night. They can come with tree straps to prevent damage to the tree.

Setting Up	Look for sturdy trees 3.6-4.6m apart. Attach webbing straps around trees at 1.8m and attach to hammock at about a 30 degree angle to the start of the hammock. Keep the hammock 30-46cm above the ground. Sleep in a hammock at a slight angle to stay mostly flat. Hang the hammock evenly between trees and at the same height on slopes.
Trailer Pop-Up Shelter	

6 Public Shelters

Any form of man-made object that isn't designed as a permanent shelter such as a bridge, park shelter, bus shelter etc.

Possible Public Shelters	● Street ● Abandoned Building ● Bus Shelters ● Under Bridges ● On Bridges	● Park Benches ● Park Shelters ● Tunnels ● Train Stations ● Stadium / Arena	● Parking Garage		
Trailer Pop-Up Shelter					

Street

How you can shelter from a disaster when you're in a street with no accessible buildings nearby.

● Hard-Topped, Fully Enclosed Vehicles: If a building isn't immediately accessible, a hard-topped, fully enclosed vehicle (like a car or truck, not a convertible or motorcycle) can offer some protection, especially from lightning. The metal frame of the vehicle acts as a Faraday cage, diverting the lightning around the occupants. Pull over safely away from trees, power lines, and low-lying areas prone to flooding, turn off the engine, close windows and vents, and stay inside until the storm passes.

● Underground or Below-Ground Areas (Last Resort for Tornadoes/Extreme Wind): In the event of a tornado or extremely severe winds, if no other options are available, a ditch, culvert, or the lowest possible depression in the ground can offer minimal protection from flying debris. Lie flat on the ground and cover your head with your arms or a backpack. This is a very last resort and still carries significant risk. Never shelter under a bridge or overpass during a tornado, as they can create a wind tunnel effect and offer no real protection from debris.

Avoid
● Trees and Utility Poles: These are lightning magnets and can fall.
● Lightweight or Flammable Structures: Sheds, carports, and flimsy kiosks offer no real protection.
● Large, Unreinforced Metal Buildings: These can be very vulnerable to collapse in strong winds.
● Underpasses/Overpasses: As mentioned, these are extremely dangerous during tornadoes.
● Water: Stay away from flooded streets, creeks, and low-lying areas.

Abandoned Building

Sheltering in an abandoned building carries significant risks, and it should generally be a last resort. However, if circumstances necessitate it, these are some crucial precautions to take.

Prioritize Safety & Assess Risks
● Structural Integrity: This is the paramount concern. Avoid any building showing obvious signs of collapse, such as severe cracks in walls, sagging roofs, leaning structures, or shifted foundations. Even if it looks intact, years of neglect, weather exposure, fire damage, or vandalism can severely compromise its stability, making it prone to collapse during strong winds or heavy rain.
● Falling Debris: Be acutely aware of loose roof tiles, crumbling masonry, broken glass, or unstable chimneys that could fall during the storm. Stay away from windows and exterior walls.
● Entry and Egress: Ensure there are clear and safe ways to enter and, more importantly, exit the building. Blocked or unstable doorways, stairs, or collapsed floors can trap you inside.

Hazard Awareness
● Hazardous Materials: Assume the presence of hazardous materials like asbestos, lead paint, mold (black mold can be very dangerous, triggering respiratory issues), and potentially discarded chemicals or drug paraphernalia. Avoid disturbing any suspicious materials and consider wearing a respirator or mask if available.
● Electrical Hazards: Live wires, outdated wiring, or overloaded circuits are common in abandoned buildings and can become extremely dangerous, especially when wet from a storm. Avoid touching any exposed wires, metal components, or anything that could be electrically charged.
● Pest Infestations: Abandoned buildings are often home to rodents (rats, mice), insects (cockroaches, bed bugs), bats, and other animals. These can carry diseases, bite, or cause contamination. Be alert for their presence and avoid disturbing them.
● Human Threats: Be aware of the potential for squatters, criminals, or other individuals who may view your presence as an intrusion. If you encounter anyone, prioritize de-escalation and your safety.

During the Storm
● Seek Interior Space: Once inside, move to an interior room away from windows and exterior walls. Smaller rooms, especially those with no or few windows, generally offer more structural integrity.
● Elevate Yourself: If there's any risk of flooding, try to move to a higher level within the building, assuming the upper floors are structurally sound.
● Listen & Monitor: Pay attention to the sounds of the storm and the building. Any creaking, groaning, or shifting noises should prompt immediate re-evaluation of your location.
● Prepare for Collapse: As a last resort, if the building begins to break up, shelter under a sturdy table, bench, or even a mattress in the strongest part of the structure (e.g., a small interior room, hallway, or cellar if accessible and safe).

General Survival Principles
● Don't Go Alone: If possible, do not enter an abandoned building alone.
● Communicate: Let someone know where you are going and when you expect to return. Mobile signal may be unreliable during a storm.
● Be Prepared: Carry a flashlight (with extra batteries), a first-aid kit, water, and any necessary personal protective equipment (e.g., N95 mask, gloves).
● Have an Exit Strategy: Always be aware of your escape routes.

Bus Shelter

Sheltering in a bus shelter during a storm, particularly a severe one, offers minimal protection and should generally be considered a last resort. They are designed for passive weather protection (sun, light rain), not for severe weather events like thunderstorms with lightning, strong winds, or hail.

SHELTER Public Shelters Bus Shelter

Assess the Storm's Severity
If it's a light rain shower, a bus shelter is fine. If it involves lightning, strong winds, or hail, seek a more substantial shelter immediately (a large building, or a hard-topped, enclosed vehicle). Bus shelters offer no protection from lightning and can be dangerous due to flying debris in high winds.

Position Yourself Safely
● Stay in the most enclosed part: If the shelter has any solid walls, position yourself against the most protected side, ideally with your back to the wind and rain.
● Avoid glass panels: If the shelter has glass or thin plastic panels, stay as far away from them as possible. They can shatter and create dangerous projectiles in strong winds or hail.
● Stay away from the edges: Don't stand directly at the opening.
● Elevate if possible: If there's a bench, sit on it to get slightly off the ground, especially if there's any risk of puddling or minor flooding.

Minimize Exposure
● Crouch low: In severe wind, crouching can reduce your profile and make you less susceptible to being hit by debris.
● Cover your head: Use your arms, a backpack, or any available item to protect your head and neck from falling or flying debris.
● Stay dry: While limited, try to stay as dry as possible under the roof. Wet clothing increases the risk of hypothermia in cold conditions.

Be Aware of Surroundings
● Watch for falling objects: Keep an eye out for falling branches, power lines, or other street furniture that could be dislodged by wind or lightning.
● Monitor flooding: Be alert for rising water levels on the street or around the shelter. If water starts to accumulate rapidly, abandon the shelter for higher ground if it's safe to do so.
● Look for a better option: Continuously assess if the storm's intensity decreases or if a safer, more substantial shelter (like an open business or large building) becomes accessible nearby.

Bridges

Shelting in and under bridges.

On Bridges

Prioritize Evacuation from the Bridge
The first and most critical step is to leave the bridge entirely if humanly possible. Bridges are extremely dangerous during storms due to:
● Extreme Wind Exposure: They are often much higher and more exposed than surrounding terrain, acting as wind tunnels. This drastically increases the risk of the bus shelter being destroyed, and of you being struck by large, fast-moving debris.
● Lightning Risk: Metal components in bridges make them highly susceptible to lightning strikes, and the open nature of bus shelters offers no protection.
● Structural Integrity: While modern bridges are robust, extreme weather can still stress them, and the shelter itself could detach.
● Flash Flooding (underneath): If the bridge spans a waterway, there's a risk of rapid water rise or debris flow underneath.
● Slippery Surfaces: The bridge deck can become extremely slippery, making it hard to move safely.

If Trapped on the Bridge
● Crouch as low as possible: Reduce your profile to minimize exposure to wind and flying debris.
● Get away from glass: If the shelter has glass or thin plastic panels, position yourself away from them, ideally against any solid back wall. These panels can shatter violently.
● Protect your head and neck: Use your arms, a backpack, or anything available to shield yourself from impacts.
● Face away from the strongest wind: Position yourself with your back to the direction of the strongest wind and driving rain/hail.
● Be aware of water accumulation: Even on a bridge, water can pool. Stay as dry as possible to prevent hypothermia.
● Continuously seek better options: Constantly scan for any opportunity to move off the bridge to a substantial, enclosed building or a hard-topped, enclosed vehicle as soon as conditions allow.

Under Bridges

Sheltering in a bus shelter under a bridge during a storm is an extremely dangerous proposition and should be avoided at all costs. While the bridge might offer some overhead cover, it introduces severe hazards that far outweigh any perceived benefit.

Why it's Dangerous
● Wind Tunnel Effect: Bridges, especially underpasses, act as natural wind tunnels during storms. This accelerates wind speeds significantly, turning even small debris into dangerous projectiles. A bus shelter's flimsy construction will be no match for these intensified winds, and you'll be at extreme risk of being hit by flying glass, metal, or other large debris.
● Flash Flooding: Areas under bridges are often low-lying and prone to rapid and deep flash flooding. You can be quickly trapped or swept away by rising water.
● Lightning Risk (Still Present): While the bridge might offer some shielding from direct strikes, lightning can still strike the bridge structure itself and conduct through metal components. You're still not safe from indirect strikes or ground currents.
● Structural Integrity of the Shelter: The bus shelter itself might not be anchored to withstand the forces under a bridge in a storm.
● Visibility and Emergency Access: Being under a bridge can make you less visible to emergency services and hinder their ability to reach you.

Alternatives
● Your absolute safest bet is a sturdy, fully enclosed building. Get out from under the bridge immediately and seek refuge in a substantial structure like a shop, public building, or even a solid house.
● If a building is not an option, a hard-topped, fully enclosed vehicle (like a car or truck) is far safer than a bus shelter under a bridge, especially for lightning. Pull over safely away from the bridge and other hazards, stay in the vehicle, and crouch below window level.
● As a true last resort in a tornado or extreme wind event, if no other option exists, get as low as possible in a ditch or depression away from the bridge, lying flat and covering your head. This is still highly risky but generally preferable to being under an overpass.

Park Bench

Park Shelter

Sheltering in a park shelter during a storm, while offering some overhead cover, provides limited protection and should be considered a temporary or last-resort option, especially during severe weather. These shelters are typically open-sided structures like gazebos, picnic shelters, or open pavilions, offering minimal defense against strong winds, driving rain/hail, or lightning.

Assess the Storm's Severity
● Light Rain/Sun: A park shelter is generally adequate for mild conditions, providing a dry spot and shade.
● Thunderstorms (Lightning, High Winds, Hail): If lightning is present (you can hear thunder, see flashes), do not use a park shelter. These open structures, especially those with metal roofs or poles, offer no protection from lightning and can attract strikes or conduct electricity. Similarly, their open design makes them highly vulnerable to being damaged or having debris blow through in strong winds. Seek a sturdy, fully enclosed building (like a visitor center, public restroom, or a nearby business) or a hard-topped, fully enclosed vehicle immediately.

If a Park Shelter is Your Only Option (Last Resort for Severe Weather)
● Position Yourself Safely: Move to the most protected side of the shelter, ideally the side facing away from the wind and driving rain/hail. Get as far into the interior as possible.
● Avoid Exposed Areas: Stay away from the open edges of the shelter.
● Crouch Low: In high winds, crouching down can reduce your profile and make you less susceptible to being hit by flying debris.
● Protect Your Head and Neck: Use your arms, a backpack, or any available item to shield your head and neck from falling branches or flying debris.
● Stay Dry: Do your best to remain dry under the shelter's roof. Wet clothing increases the risk of hypothermia.
● Watch for Falling Debris: Be acutely aware of any trees, branches, or other park furniture that could be dislodged by strong winds and fall onto or near the shelter.
● Monitor for Flooding: If the park shelter is in a low-lying area, be aware of rapidly rising water levels.

Tunnel

Sheltering in a tunnel during a storm can be extremely risky and should be carefully considered, as tunnels pose unique and severe hazards. While they offer overhead cover, the dangers can often outweigh the benefits, especially if you're unfamiliar with the specific tunnel.

● Prioritize Flash Flood Risk: This is the most significant danger in a tunnel during a storm. Tunnels, by design, often collect water, and in a heavy downpour, they can flash flood extremely rapidly and deeply, turning into dangerous waterways. Water can rise to life-threatening levels within minutes, sweeping you away or drowning you. Never enter a tunnel if there's any risk of flash flooding or if water is already accumulating. If you see water beginning to rise, exit immediately to higher ground, even if it means exposing yourself to the storm above.

Assess Tunnel Type and Stability
● Pedestrian/Utility Tunnels: Some tunnels are for pedestrians or utilities, while others are for vehicles. A tunnel not designed for human traffic might have poor lighting, ventilation, and unpredictable hazards.
● Structural Integrity: Similar to abandoned buildings, tunnels can suffer from structural weaknesses due to age, earthquakes, or poor maintenance. ● Listen for creaking, cracking, or dripping sounds that might indicate instability.

● Lightning Risk (Still Present): While a deep tunnel offers some protection from a direct lightning strike, lightning can still strike the ground near the tunnel entrance or even the tunnel structure itself, with currents potentially traveling through the ground or metal components. Deeper, fully enclosed tunnels offer more protection, but open-ended or short tunnels are still vulnerable.

● Vehicle Tunnels: If it's a vehicle tunnel, especially without active ventilation, exhaust fumes can build up rapidly, posing a serious health risk. Avoid these unless absolutely necessary and for a very short duration.
General Ventilation: Even non-vehicle tunnels might have limited airflow, leading to stagnant air or the accumulation of other gasses.

Traffic and Other Hazards
● Active Tunnels: If it's an active road or rail tunnel, the danger from vehicles or trains is immense. Never enter an active traffic tunnel for shelter.
● Debris: Storms can cause landslides, rockfalls, or send debris into tunnel entrances.
● Visibility: Tunnels can be very dark. A reliable light source (flashlight, headlamp) is essential.

If a Tunnel is Your Absolute Last Resort and Appears Dry and Stable
● Enter Carefully: Be extremely cautious of your footing, as surfaces can be slippery.
● Stay near an entrance (but not too close): Position yourself just inside an entrance, allowing for a quick exit if flooding or other hazards emerge. Don't go deep into an unknown tunnel.
● Stay Elevated: If there's any slight elevation, use it.
● Monitor Conditions: Continuously observe for any signs of water inflow, unusual noises, or changes in air quality.
● Have an Exit Strategy: Be prepared to abandon the tunnel at the first sign of danger.

Train Station

Stadium / Arena

Parking Garage

7 Transport Shelters

Any form of modern shelter that can be transported by a vehicle such as a caravan, trailer etc. They may be completely set up already or partially set up such as a top that requires popping up.

Trailer Pop-Up Shelter	A low pop up shelter that's generally only used for sleeping in and contains a few storage areas.
Trailer Fixed Shelter	A full height shelter that's generally only used for sleeping in and contains a few storage areas.
Towed Caravan	A towed caravan separate from the vehicle which can be lived in.

Campervan	A compact home within the back of a vehicle with the engine on the same section.
Motor Home	A larger form of a campervan to house more people.
Tiny House	A complete house including furnishings that can be towed. Generally they are 5m+ in length and a maximum of 2.4m wide.

8 Buildings

Any building with four walls and a roof which is designed for habitation and is generally waterproof, windproof and inspect proof.

Modern House	
Military Urban Shelter	Select the site carefully as many buildings may have suffered structural damage. Falling masonry, exposed reinforcing rods or other jagged surfaces and exposed electrical wiring are clear hazards. Keep out of occupied buildings. Sleep or rest towards the centre of the building. Always maintain security, as buildings offer multi-level, three dimensional considerations and many areas for infiltration and ambush from concealed locations.

Reinforced Buildings

Any building which has extra strong walls, floors and roof to protect it against bullets, bombs or nukes.

Banks	Many banks have extra thick walls to help prevent thieves. The vaults can typically withstand a bomb blast or even a nuclear blast.
Bunker	An extremely heavy duty military grade shelter designed to shield from nuclear bombs.
Missile Silo	
Mountain Base	

9 Shelter Components

These are the components that make up each part of a shelter such as the tarpaulin to the groundsheet and the sleeping bag.

Shelter Components
- **Tarp / Sheeting:** For creating the general structure of the shelter to keep you dry.
- **Rigid Materials:** For creating the frame of the shelter if there's no objects around.
- **Rope/Cord:** For fixing the sheeting to an object.
- **Ground Pad:** To keep you warm and dry by lifting you off the ground while you sleep.
- **Padding:** Used below the bed to soften the ground and acting like insulation.

Subheadings

1. Tarpaulin	**2. Groundsheet**	**3. Sleeping Pad**	**4. Sleeping Bag**
5. Pillow	**6. Blanket**	**7. Temperature Regulation**	

1 Tarpaulin

A tarpaulin, often simply called a tarp, is a versatile sheet of strong, flexible, waterproof, or water-resistant material, typically made from plastics like polyethylene (PE) or canvas coated with PVC. Its primary function is to provide protection from the elements, whether it's rain, sun, wind, or dust. Tarpaulins come in various sizes, colors, and thicknesses, often featuring reinforced grommets (eyelets) along the edges to allow for tying, staking, or securing the sheet over objects or to form temporary structures. Due to their durability and protective qualities, tarpaulins are widely used in construction, agriculture, camping, and disaster relief, serving as groundsheets, temporary roofs, equipment covers, or components in improvised shelters like those discussed in a survival context.

Tarpaulin Types

These are the different types of tarpaulins available today. Some make great shelter building materials where others fail miserably.

Poly Tarps	Poly tarps are a plastic based material. Poly is short for polyethylene (pòllee éth? leen). Polyethylene is a synthetic polymer: a plastic polymer of ethylene. Most poly material is used for manufacture of containers, packaging, and electrical insulation or in this case poly tarps. Polyethylene tarps a.k.a. Poly tarps are made with polyethylene, nylon tarp threading inside the material with a rope reinforcement around the perimeter of the poly tarp material. Polyethylene (PE) resins are milky white, translucent substances derived from ethylene (CH29CH2).
Canvas Tarps	Canvas tarps have been a wide use item for many years. Canvas, closely woven, plain weave fabric made of natural or synthetic fibres. The firm cloth is used in making awnings, soft luggage and tarpaulins. In this case canvas tarpaulin a.k.a. canvas tarps. Although canvas is also known as sailcloth, modern sails are constructed of fabric, made to select specifications, which may bear little resemblance to fabrics generally marketed as sailcloth or canvas.
Heavy Duty Tarps	The heavy duty tarps are highly recommended for agricultural, industrial and commercial sectors. These tarps are manufactured with strength and resistance to demanding work and severe weather conditions. So for jobs that need tougher tarps, choose from our line of heavy-duty tarps.
Fire Retardant Tarps	Fire or flame retardant tarps are canvas materials that are used for protecting people and properties from exposure or damage caused by fire. When exposed to fire they will not easily burn or fuel any combustion.
Vinyl Tarps	Compared to the other kind of tarps, Vinyl tarps are thicker and have a higher abrasion resistance. This means they can resist acid, oil, mildew and grease. Their tough nature allows them to be used for heavy-duty purposes.

SHELTER Shelter Components Tarpaulin Tarpaulin Types

Mesh Tarps	Mesh tarps are built with a nylon tarp threading that weaves a material that is screen like. Nylon mesh tarps are used for purposes for water or wind to go through. A mesh tarp is a great way to prevent hard winds on the applied area. When building a shade screen tent, mesh tarp covers and sides weaken winds that hit the canopy tent. Hard winds enter one side of the mesh tarp and blows through slowly on the other side so the wind gets defused by the mesh material. This is a great way to secure a tent or canopy.
Truck Tarps	Truck tarpaulins are made with a super strong heavy duty poly coating. Truck Tarps are heavy duty tarp covers made for secure fitting coverage over trucks that need to travel long distances. Truck covers can be comprised of rubberized tarps and heavy duty polyethylene material. The truck tarp has double reinforced fabric around the hems. Truck Tarps hems are reinforced with 1/4" triple braided roping, double stitched in hems, corners and reinforced seams. All Truck Tarps have heat sealed interior seams. Truck tarps are equipped with D Rings - One stainless steel plated on nylon webbing every 2 feet, triangular reinforced fabric at each D Ring. This assures a secure fit around the perimeter of the truck tarp cover. Solid brass grommets surround the perimeter and in each corner for additional secure fitting.
Hay Tarps	These tarps offer good protection while minimising field transportation. These UV treated hay tarps will help prevent the formation of rot and moisture and are designed for long-term coverage. With resistance to ultraviolet rays, the tarp can prevent the heat from decreasing the nutrients of hay. Since it is also resistant to acid, all the damaging agents of the rain cannot damage this tarp. This tarp also has arctic flexibility, which means the tarp will not stiffen in freezing temperatures.
Boat Tarps	The poly boat tarps provide protection from sun and rain. They can also be used during the winter season.

2 Groundsheet

SHELTER Shelter Components Groundsheet

A groundsheet is important for keeping your ground based shelter hole free and to extend its life. It's placed under the tent in the position you will most likely find yourself sleeping to prevent sharp objects such as sticks, rocks and glass puncturing your shelter. Try to match your groundsheet up with your tent to save on space - unless you want a bigger size to use as a door mat. Tarps have multiple purposes and one of these is as a groundsheet. In a pinch you can convert a tarp to a tent and back as required. Unfortunately they are very heavy, particularly the more durable ones such as canvas.

Materials
- Tarp (Heavy)
- Cuben Fibre (Light)
- Tyvek (Light)

3 Sleeping Pad

SHELTER Shelter Components Sleeping Pad

A sleeping pad shields you from the ground and is below the sleeping bag and above the ground protector. Essential for cold environments as the ground will sap all your warmth overnight.

Types

- **Air Pad:** Air pads are inflated with your breath and offer a fair amount of comfort.
- **Self Inflating:** Pads that have foam inside which adds additional spring and lets it inflate itself.
- **Closed Cell / Foam:** Typically made to fold and comprises of dense foam filled with tiny closed air cells.

Types

Air Pad	Don't blow up a sleeping pad in freezing conditions as the condensation from your breath will freeze in the night.
Self Inflating	These pads generally come in at a slightly larger size due to the foam core which helps it expand by itself. If you're determined to get the smallest and lightest pad possible, don't buy a self inflating pad.
Closed Cell / Foam	Pads that come primarily made out of foam and can't be inflated with air. These can provide the comfiest sleep if there's a mix of more solid foam on the bottom and soft foam on the top. They can be bought in an 'egg shell' style of foam which helps to equally distribute your weight all over the mattress.

Weight

Depending on what you're doing, whether car camping, or backpacking you will want to look at weight more closely. For the absolute lightest pad, the Therm-a-Rest NeoAir UberLite comes in at 170g (6 oz). The weight can range all the way up to many kilograms for the very thick non-air mattresses.

Length

There's quite a range of lengths you can purchase today, from pads made for children to pads made for the tall people - up to 2m (79 in).

Width

The width of pads can range from about 50cm to 90cm. You should choose one based on who will be using it, basing it off the width of their shoulders.

R Value

The R-value of a mattress indicates its level of thermal resistance. In short, the higher the R-value the better the product will be for use in cold temperatures.

Rails

Some pads have larger side baffles, often called "rails," to cradle you and help keep you from rolling off as you turn during sleep. Keep in mind that, on average, women and children tend to sleep colder than men, but also that everyone is unique.

4 Sleeping Bag

SHELTER Shelter Components Sleeping Bag

A sleeping bag is an insulated covering for a person, essentially a lightweight quilt that can be closed with a zipper or similar means to form a tube, which functions as lightweight, portable bedding in situations where a person is sleeping outdoors (e.g. when camping, hiking, hill walking or climbing). Its primary purpose is to provide warmth and thermal insulation through its synthetic or down insulation. It also typically has a water-resistant or water-repellent cover that protects, to some extent, against wind chill and light precipitation, but a tent is usually used in addition to a sleeping bag, as it performs those functions better. The bottom surface also provides some cushioning, but a sleeping pad or camp cot is usually used in addition for that purpose. The bottom surface of a sleeping bag may be moderately water repellent, but a plastic tarp or groundsheet is often used to protect against moist ground.

Shape

Rectangular	Offers maximum room to stretch out and move around, providing a comfortable, bed-like feel ideal for warmer weather and car camping.

Semi-Rectangular	Balances warmth and roominess, providing more wiggle room than a mummy bag while still offering good thermal efficiency, suitable for cooler weather and side sleepers.
Mummy	Designed for maximum thermal efficiency by minimizing internal air space, making it the warmest, lightest, and most packable option for cold weather and backpacking.
Double Wide	Provides ample space for two people to share body heat, offering enhanced comfort and warmth for couples or families while camping.

Material

Synthetic Insulation	● Insulates when Wet: This is its primary and most significant advantage. Unlike down, synthetic fibers retain most of their insulating properties even when damp or wet, which is crucial for safety in humid, rainy, or snowy conditions where down would lose its loft and warmth. ● Faster Drying: Synthetic insulation dries much more quickly than down, making it more practical for trips where exposure to moisture is likely. ● Less Expensive: Generally, synthetic sleeping bags are more affordable than comparable down bags, offering a good value for the performance. ● Hypoallergenic: For individuals with allergies to down feathers, synthetic insulation is an excellent, non-irritating alternative. ● Easier Care: Synthetic bags are typically easier to clean and maintain than down bags.
Goose-Down Insulation	● Superior Warmth-to-Weight Ratio: Ounce for ounce, goose down provides more warmth than synthetic insulation, making down bags incredibly lightweight for their temperature rating. This is a huge benefit for backpacking and mountaineering where every gram counts. ● Excellent Compressibility: Down compresses into a very small packed size, taking up minimal space in a backpack. This is also highly valued by ultralight enthusiasts. ● Exceptional Durability and Longevity: With proper care, a high-quality down sleeping bag can last for decades, maintaining its loft and insulating power over many years of use. ● Breathability: Down is naturally breathable, which helps to manage moisture and reduce condensation inside the bag. ● Softness and Comfort: Down offers a plush, soft feel that many find exceptionally comfortable.
Water-Resistant Down Insulation	● Improved Wet-Weather Performance: This type of down is treated with a durable water-repellent (DWR) polymer that coats individual down plumes. This significantly reduces down's tendency to absorb moisture, allowing it to retain more loft and insulate better in damp or humid conditions compared to untreated down. ● Faster Drying When Wet: While still not as fast as synthetic, water-resistant down dries considerably faster than untreated down if it does get wet. ● Enhanced Durability: The treatment can also improve the integrity and longevity of the down clusters. ● Combines Benefits: It aims to bridge the gap between traditional down and synthetic, offering much of down's superior warmth-to-weight and compressibility while mitigating its main weakness against moisture, making it a versatile choice for varied conditions.

Weather Rating

Comfort Rating (T-Comfort)	This is the lowest temperature at which an "average woman" (defined by standard parameters) is expected to sleep comfortably in a relaxed position. If you tend to sleep cold, this is the most important rating to consider for a good night's rest.
Limit Rating (T-Limit or Lower Limit)	This is the lowest temperature at which an "average man" (defined by standard parameters) can sleep without feeling uncomfortably cold. They might need to curl up to stay warm, but should not be shivering significantly or at risk of hypothermia. If you tend to sleep warm, this rating might be more relevant for you.
Extreme Rating (T-Extreme)	This is a survival rating only. It represents the minimum temperature at which the bag is expected to prevent a "standard woman" from dying of hypothermia for about six hours. You will be very cold, uncomfortable, and likely won't sleep. This rating is not for comfortable camping and should only be considered for absolute emergency situations where survival is the sole goal.

Other Features

These are any sleeping bag accessories that may be of use.

Sleeping Bag Hood	You'll lose a lot of heat through your head. Consider a semi-rectangular bag with a built-in hood. When cinched with a drawcord, the hood prevents heat from radiating away.
Stash Pocket	This keeps small items, such as an MP3 player, watch or glasses, close at hand.
Sleeping Pad Sleeve	On some bags, the underside insulation has been replaced with a sleeve to fit a sleeping pad. The result: no more rolling off the sleep pad in the middle of the night!
Pillow Pocket	Allows you to stuff your clothes inside to create a pillow.
Stuff Sack	Many bags come with a stuff sack to easily transport your bag.
Storage Sack	You can prolong the life of any sleeping bag by hanging it in your garage or storing it loosely in a cotton storage sack—and not rolled up tight in a stuff sack. This long-term storage prevents the insulation from getting permanently compressed, which reduces its insulating properties.
Sleeping Bag Liner	Slip a soft sleeping bag liner inside your bag to minimize wear and keep the bag clean.

5 Pillow

A pillow is a support of the body at rest for comfort, therapy, or decoration. Below are the different type of pillows.

Typical Pillow	A pillow stuffed with soft materials such as down or cotton to provide the softest pillow possible.
Inflatable Pillow	A pillow which can be inflated with air. These aren't as comfortable as a regular pillow.
Self-Inflating Pillow	A pillow that inflates itself if left outside its compression bag. Usually these have breath toggles to allow a bit more air inside.

6 Blanket

These will keep you warm during the cold months. Each material has different properties as shown below.

Down (Lightweight)	A down blanket or down throw is thinner and lighter than a down comforter. The spaces between the down clusters in a blanket trap warm air, keeping you warm without added weight.

Bamboo (Lightweight)	Luxuriously soft and lightweight, bamboo fabric is similar to modal, with its smooth hand and flowing drape. Called rayon from bamboo, these fabrics are known for their soft, comfortable, and highly absorbent properties.
Silk (Midweight)	Known for its strength, softness and warmth, silk blankets offer the ultimate in luxury. Silk also has natural anti-fungal and anti-microbial properties. Silk blankets should be dry cleaned.
Wool / Cashmere (Midweight - Heavyweight)	Wool blankets tend to be heavier and warmer than other fabrics. Wool fibres come from the fleece of lambs, sheep, goats, camels, llamas, alpacas and vicunas. Wool from sheep is the most common. Softer, more luxurious wool comes from Cashmere goats, Angora goats and Merino sheep. The spaces between the fibres in a fuzzy or napped blanket trap warm air, keeping you warmer.
Synthetic (Lightweight - Midweight)	Synthetic fibres such as polyester, nylon, and acrylic tend to be ultra-soft. Electric blankets are usually made with synthetic materials.
Linen (Midweight)	Linen is hypoallergenic, moisture-wicking and adjusts to your body temperature to stay cool in the summer and warm in the winter. Linen becomes softer with every wash.
Cotton (Lightweight - Midweight)	Cotton blankets can vary in weight and texture, making them a year-round bedding staple. Unlike synthetic fibres, cotton fibres breathe naturally and are absorbent. Cotton will wick moisture away from the skin and leave a layer of warm, dry air. If allergies are a concern, cotton is an excellent choice since it can be washed in hot water.

7 Temperature Regulation

Keeping Warm	● Light a fire and use the warmth. ● Layer up clothes and go for thicker layers. ● Use thermal blankets to retain your body heat. ● Stuff newspapers and clothing between layers to insulate. ● Move around and keep active to generate more body heat and refuel by eating lots of fats.	**Gain Heat** ● Thermogenesis / Food ● External Heat ● Shivering ● Exercise
Keeping Cool	● Stay in the shade, the darker the shade the better. ● Don't expend energy which heats up the body, rest during the hottest part of the day. ● Find a breeze if possible and remain in it, or use a fan. ● Wrap a wet shemagh around your neck or head to cool it down. ● If avoiding the sunlight isn't possible, wear white clothes to reflect the rays and heat. ● Wear loose-fitting moisture wicking clothes made of cotton. ● Hydrate often to replace the water you lose sweating. ● Find the lowest point in the terrain near water and dig down for a temporary shelter.	**Thermogenesis** ● Radiation ● Conduction ● Convection ● Evaporation

10 Shelter Location

Choosing the correct location to set up your portable shelter is one of the most important factors to consider. A good choice can keep you dry, safe and secure and a bad choice could leave you dead.

Location Tips

Positioning	● **Water Positioning:** Make sure you're at least 100m (328ft) from any water source. ● **Food Positioning:** You should be at least 60m (196ft) from your kitchen/bear bag/food processing location. ● **Bathroom Positioning:** You should also be at least 100m (328ft) from your bathroom and human waste location. ● **Position Triangulation:** Overall the previous three locations should be at least 100m (328ft) from any other one of them. ● **Avoid Trails:** Camp at least 50m (164ft) from any walking trail or game trail.
Tree Integrity	● **Healthy Trees:** Ensure all surrounding trees are healthy with strong roots. ● **Avoid Weak Trees:** Make sure there's no trees that are prone to falling in wind such as Gum Trees like Eucalyptus. ● **Fallen Branches:** A bad sign for trees is seeing a lot of fallen branches nearby. ● **Dead Branches:** Check for dead trees and branches lodged in trees which have been caught by other trees. ● **Snowed Trees:** Don't camp under trees in heavy snow as the weight can snap the branches. ● **Tree Diseases:** Check for tree diseases and leaking sap. If anything looks wrong, find another spot. ● **Avoid All Trees:** Try not to camp directly under tall trees if it can be helped.
Water	● **Elevated Position:** Place your shelter on a slight elevation in relatively flat ground to keep the bottom from getting soaked. ● **Avoid Ditches:** Avoid all small ditches where water can pool under you. ● **Avoid Floodplains:** Be sure you aren't in a floodplain or low valley which can collect water. ● **Water Diversion:** If you're at the base of a mountain redirect water by piling up mud into a "V" shape further up the slope.
Ground	● **Ground Clearing:** Clear the ground of leaves, snow, rocks, sticks and other items that may puncture the shelter. ● **Flat Ground:** Try to find the flattest ground possible when setting up. ● **Insects:** Check for in-ground insect nests, holes and other spots creatures could hide.
Natural Disasters	● **Minimise Wind:** Reduce the effect of strong winds by choosing a location with a natural wind break like boulders or fallen logs. ● **Avoid Cyclones:** Avoid Cyclone and Hurricane winds entirely by leaving the area prior to arrival, or seek a very sturdy shelter. ● **Flash Flood Signs:** Check for any signs of flash floods like consistent debris around rivers.
Insect / Animal Threats	● **Insects:** Check for in-ground insect nests, holes and other spots creatures could hide. ● **Trails:** Avoid game trails whenever you see them as they may be regularly used by fauna. ● **Other Insects:** Make sure there's no other nests nearby such as wasps, spider webs etc. ● **Avoid Faeces:** If you see any animal faeces avoid that area. ● **Nesting Birds:** Stay away from nesting birds, particularly those that swoop.
Stealth Shelters	For tips on stealth camping, see the SECURITY section.

11 Construction

Information on building or repairing a modern house.

Standards

Building Classes

These are the different classes of buildings.

Class 1 (A-B)	A - A single dwelling being a detached house, or one or more attached dwellings, each being a building, separated by a fire-resisting wall, including a row house, terrace house, town house or villa unit. B - A boarding house, guest house, hostel or the like with a total area of all floors not exceeding 300m2, and where not more than 12 reside, and is not located above or below another dwelling or another Class of building other than a private garage.
Class 2	A building containing 2 or more sole-occupancy units each being a separate dwelling.
Class 3	A residential building, other than a Class 1 or 2 building, which is a common place of long term or transient living for a number of unrelated persons. Example: boarding-house, hostel, backpackers accommodation or residential part of a hotel, motel, school or detention centre.
Class 4	A dwelling in a building that is Class 5, 6, 7, 8 or 9 if it is the only dwelling in the building.
Class 5	An office building used for professional or commercial purposes, excluding buildings of Class 6, 7, 8 or 9.
Class 6	A shop or other building for the sale of goods by retail or the supply of services direct to the public. Example: café, restaurant, kiosk, hairdressers, showroom or service station.
Class 7 (A-B)	A - A building which is a car park. B - A building which is for storage or display of goods or produce for sale by wholesale.
Class 8	A laboratory, or a building in which a handicraft or process for the production, assembling, altering, repairing, packing, finishing or cleaning of goods or produce is carried on for trade, sale or gain.
Class 9 (A-C)	A building of a public nature A - A health care building, including those parts of the building set aside as a laboratory. B - An assembly building, including a trade workshop, laboratory or the like, in a primary or secondary school, but excluding any other parts of the building that are of another class. C - An aged care building.
Class 10 (A-C)	A non-habitable building or structure. A - A private garage, carport, shed or the like. B - A structure being a fence, mast, antenna, retaining or free standing wall, swimming pool or the like. C - A private bushfire shelter.

Staircase Construction

Staircases (For Building Class 1-10)
General Requirements – Staircase used in habitable rooms or used externally must comply with the Building Code of Australia Part 3.9.1. All areas not specified in Building Code of Australia should be referenced in the Australian Standard AS1657 Section 4.

Staircases to storage areas or un-habitable rooms such as attics can be constructed outside the Building Code of Australia though must comply to the Australian Standards AS 1657. Your staircase must have no less than 2 risers or have no more than 18 risers without a 750mm2 landing or rest area.
Each tread and riser must be of the same measurement within a single flight. The riser opening if your staircase is of Open Rise Construction must not allow a 125mm sphere to pass through. All treads and top nosing must have a slip-resistant finish or a non-slip strip system near the edge of each tread nosing.

A flight must not have more than 3 winders in a quarter landing section or 6 winders in a half landing section.
If a door in your home opens onto a staircase a landing is required unless the floor to floor dimension is less than 570mm. If the floor to floor is less than 570mm all that is required is a zero tread.

Width and Angle	Stairways shall be not less than 600 mm wide measured between the inside edges of the handrails. The angle of pitch of a staircase shall be not less than 26.5 degrees and not greater than 45 degrees.
Straight Flights	Your staircase must have no more than 18 risers without a 750mm2 landing or rest area. The staircase should have no more than 36 rises without a change of direction.
Minimum Vertical Clearance	Unless otherwise approved by the regulatory authority, the head clearance shall be not less than 2000 mm measured vertically from the nosing line.
Riser and Going Dimensions	Riser Max: 190 Riser Min: 115 Going Max: 355 Going Min: 240 Slope Relationship Max: 700 Slope Relationship Min: 550 125mm sphere must not pass between treads.
Balustrades	A continuous handrail must be provided along the side of any stairway or ramp. A balustrade is required to any staircase A balustrade is required to any staircase, balcony, ramp, hallway, veranda, mezzanine or bridge were the potential to fall from the above mentioned area is 1000mm or greater to the surface below. The height of the balustrade on the pitch of the staircase must be not less than 865mm form the nosing line. This dimension is taken plump from the nosing line with the rail or balustrade running parallel up the pitch of the staircase. The height of the balustrade on a finished floor, balcony, landing or path must me above 1000mm. Openings in the balustrades must be constructed so that any opening does not permit a 125mm sphere to pass through it. This space is tested above the nosing line only. With floors or balconies were potential to fall more than 4000mm to the surface below, all horizontal elements between 150mm and 760mm above the floor or balcony must not facilitate climbing.

Staircases to Un-Habitable rooms	Any staircase or balustrade to a storage area or un-habitable rooms must comply to all other regulations above apart from NCC Part 3.9.1.2. The Staircase rise and goings for an un-habitable room must be constructed in accordance with AS 1657 – 4.2.1. Each rise shall be >= 130 mm and <= 225 mm. Each going shall be >= 215 mm and <= 335 mm. The product of the going, measured in millimetres, and the rise, measured in millimetres, shall be >= 45,000 and <= 48,000. The tread width shall be not less than the going and there shall be a minimum overlap of 10 mm.

House Construction

The Frame

The overall frame is composed from a number of individual wall panels, which when fixed to the base and fastened together form a rigid box like structure.

Structural Loads	The frame carries several main structural loads: It takes the load of the roof, and any upper floors, down to the foundation. It resists the wind trying to push the building over. Provides lateral support for the brick walls. Holds the windows in place. It gives a secure fixing point for the internal wall and ceiling lining boards. In the case of weatherboard or lightweight render construction it supports the outer skin of the building.
Additional Functions	Provides a route and fixing points for cables and pipes. Retains insulation. Supports cupboards and shelves. Fixing of building wrap.

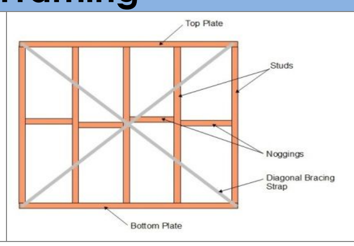
Framing Materials

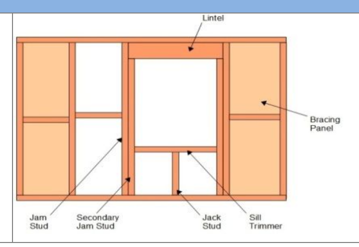
These are the different materials you can use for framing.

Wood	- Termites a Possibility - Natural Weaknesses + Cheap
Brick	+ Termite Proof + Cooler - Heavy - Takes More Space
Metal	+ Termite Proof - Thermal Expansion Noise - Heat Conductive

Timber Framing

These are the definitions of the timber framing components of a wall segment.





Components	● Top Plate ● Studs ● Noggings ● Bottom Plate ● Diagonal Bracing Strap
Minimum Timber Size	95x35mm Additional Insulation = depth of 125mm. More strength = 45mm thick instead of 35mm.
Studs	Main structural component supporting the main vertical load of the roof. Normal spacing is 450mm for external walls and 600mm for internal walls.
Top Plate	Fixes the stud in position and acts as a mounting point. Can not support major loads such as roof trusses and upper beams. Can add a second beam for strength.
Bottom Plate	The bottom plate holds the frame to the base and fixes the bottom of the studs in position. Needs to be firmly fixed to the base.
Noggings	Individual short pieces of timer between studs. They prevent studs bowing under load. They must fit perfectly. Max spacing is 135cm. One or more nogging per 2.74m required.
Diagonal Bracing Strap	The straps are galvanised steel nailed to each strut. The bracing resists any sideways deformation such as wind loading. Vital to overall strength.

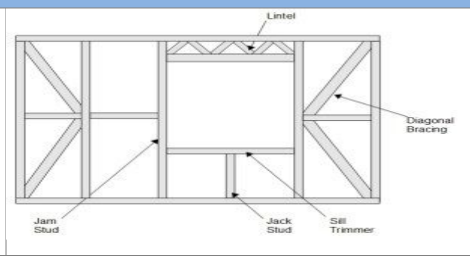
Timber Framing Openings

Components	● Bracing Panels ● Lintel ● Jam Stud ● Secondary Jam Stud ● Sill Trimmer ● Jack Stud

Bracing Panels	The bracing panels replace the bracing straps to keep the frame square and ensure the panel resists sideways forces. They are a sheet material that is nailed to the studs top plate, bottom plate, and noggins. Usually the panels are ply although I have seen other materials such as particle board.
Lintel	The lintel carries loads from above to the studs either side of the opening. The size of the lintel will depend on the width of the opening.
Jam Stud	The jam stud in normally the last full height stud before the opening.
Secondary Jam Stud	As well as assisting the jam stud to carry the lintel load the Secondary Jam Stud also provides extra stiffness to counteract the fact that there is only one noggin.
Sill Trimmer	This forms a fixing point for a window frame, and also the top fixing point for any Jack Studs. For a small window a Head Trimmer may be used between the lintel and the top of the opening.
Jack Stud	The jack stud is a short vertical stud. It can be between: ● The Bottom Plate and the Sill Trimmer. ● The Lintel and a Head Trimmer.

Steel Framing

Steel framing is relatively thin and doesn't require heavy duty cutting tools.



Components	● Diagonal Brace ● Lintel
Diagonal Brace	The diagonal braces are used instead of a panel of sheet material in the timber frame to resist sideways forces on the frame.
Steel Lintel	Rather than a solid beam, a truss structure is formed to carry loads over the opening.
Masonry Veneer	Requires a solid frame to be completed consisting of either wood or steel. The frame is usually wrapped prior to bricks being added. Appears solid however it only supports itself and relies on ties to the frame to keep it stable. It provides a weatherproof skin to the building. Easy to insulate.
Joists	
Sheathing	Sheathing is a process whereby we apply sheets of structural timber such as plywood to the outside of the timber wall and roof framing to add an additional layer of strength and bracing and also to create an additional air and water barrier for increased insulation.
Bracing	Bracing is where use galvanised steel strapping that we tension to create extra structural support.
Plasterboard	**Types** Reduced Noise Transmittance Improved Noise Absorption Increased Impact Resistance Better Water Resistance Higher Fire Resistance Flexible Boards
Windows	Building code requires at least 10% of the floor area as windows. Windows that go to the floor restrict where you can put furniture. 20-25% Glazing in South facing rooms and 40% in North facing rooms. Single Glaze or Double Glaze

Roofing

Metal Roofing	- Noisier in Rain + Fairly Light + Resistance to wind & hail - Possible dent with hail + Less likely to leak + Can lay at lower pitch + Minimal Rusting + Reflects Sunlight & Heat + More Expensive + Fitting Solar is Cheaper
Tiled Roofing	- Can be expensive + Better Insulation - Heavier - Brittle + Very Strong - Screwed down in high wind + Wide Colour Range + Looks Better
Solar Roof Direction	East-West

SHELTER Construction

Roof Slope	10°

Utilities

SHELTER Construction Utilities

Plumbing	**Valves:** Check Valve
Gas	

House Features

SHELTER Construction House Features

Doors
Sort the doors out prior to designing the electrical plan for placement of the switches.

Swing Direction	The direction the door swings, either into the next room or away from it.
Hinge Side	Typically hinged on the side nearest to a wall.

Buffer Zones
Buffer Zones are enclosed rooms which can be sealed off from others. These zones assist in heating and cooling spaces with maximum efficiency to avoid altering un-used areas. Buffer zones can come at the expense of impeding natural airflow throughout the house.

Electricity

Power generation, schematics and battery types

"With great power comes an even greater electricity bill."
Unknown

Introduction

A category for all things electronic such as batteries, renewable energy, schematics and generators. It includes sections on repairing electronics, componentry and schematics for electronics.

Purpose	The aim of ELECTRICITY is to educate the reader on all forms of preparedness related electricity usage and electrical devices. There are sections devoted to the basics of electronics, electricity generation, electrical storage, schematics and repairing electronics.
Lost?	● For information on using electricity to start a fire, see the FIRE section. ● For information on lightning, see the METEOROLOGY section. ● For using electricity to generate light, see the LIGHT section. ● For a list of recommended electrically based gear such as solar panels, see the GEAR section. ● For electronic games, see the ENTERTAINMENT section.

Contents

1 Electricity Introduction

Electricity Basics

Nucleus is made up of protons and neutrons, and the number of protons and neutrons are balanced. Neutrons have no electric charge, protons have positive charges (+) and electrons have negative charges (-). A positive charge of proton equals a negative charge of electron. Electrons are bound in their orbit by attraction of protons, but electrons in the outer band can become free of their orbit by some external forces. These are referred to as free electrons, which move from one atom to the next, electron flows are produced. These are the basis of electricity. Materials that allow many electrons to move freely are called conductors and materials that allow few free electrons to move are called insulators.

All matters are made up of atoms that have electric charges. Therefore, they have electric charges. For the matter that has a balanced the number of protons and electrons, positive charge force and negative charge force are balanced. It is called neutral state of an atom. (The number of protons and electrons remains equal) Static electricity represents a situation that all things are made up of electric charges. For example, the rubbing of material against another can cause the static electricity. Free electrons of one material move forcefully till they are freed of their orbits around nucleus and move to another. Electrons of one material decrease, it presents positive charges. At the same time, electrons of another increase, it has negative charges.

Current	An electrical phenomenon is caused by flow of free electrons from one atom to another. The characteristics of current electricity are opposite to those of static electricity. Wires are made up of conductors such as copper or aluminium. Atoms of metal are made up of free electrons, which freely move from one atom to the next. If an electron is added in wire, a free electron is attracted to a proton to be neutral. Forcing electrons out of their orbits can cause a lack of electrons. Electrons, which continuously move in wire, are called Electric Current. For solid conductors, electric current refers to directional negative-to-positive electrons from one atom to the next. Liquid conductors and gas conductors, electric current refers to electrons and protons flow in the opposite direction. Current is flow of electrons, but current and electron flow in the opposite direction. Current flows from positive to negative and electron flows from negative to positive. Current is determined by the number of electrons passing through a cross-section of a conductor in one second. Current is measured in amperes, which is abbreviated "amps". The symbol for amps is a letter "A". A current of one amp means that current pass through a cross-section of two conductors, which are placed in parallel 1 meter apart with 2x10-7 Newton per meter force occur in each conductor. It can also mean charges of one coulomb (or 6.24x1018 electrons) passing through a cross-section of a conductor in one second.
Voltage	Electric current is flow of electrons in a conductor. The force required to make current flow through a conductor is called voltage and potential is the other term of voltage. For example, the first element has more positive charges, so it has higher potential. On the other hand, the second element has charges that are more negative so it has lower potential. The difference between two points is called potential difference. Electromotive force means the force which makes current continuously flows through a conductor. This force can be generated from power generator, battery, flashlight battery and fuel cell, etc. Volt, abbreviated "V", is the unit of measurement used interchangeably for voltage, potential, and electromotive force. One volt means a force which makes current of one amp move through a resistance of one ohm.
Resistance	Electrons move through a conductor when electric current flows. All materials impede flow of electric current to some extent. This characteristic is called resistance. Resistance increases with an increase of length or decrease of cross-section of a material. The unit of measurement for resistance is ohms and its symbol is the Greek letter omega (Ω). The resistance of one ohm means a conductor allows a current of one amp to flow with a voltage of one volt. All materials are difference in allowing electrons flow. Materials that allow many electrons to flow freely are called conductors such as copper, silver, aluminium, hydrochloric solution, sulphuric acid and saltwater. In contrast, materials which allow few electrons to flow are called insulators such as plastic, rubber, glass and dry paper. Another type of materials, semiconductors have characteristics of both conductors and insulators. They allow electrons to move while being able to control flow of electrons and examples are carbon, silicon and germanium, etc. The resistance of conductor depends on two main factors as the followings: 1. Types of material 2. Temperature of material

Electrical Functions

Electric current is the ability to do work. Electric current can be converted to heat, power and magnetism, to name a few.	**Electrical Functions** 1. Heat and power 2. Electrochemistry 3. Magnetism

Heat and Power	• For example, current-carrying nichrome wire that nichrome wire has a high resistance and creates heat. This is applied to be component of electric ovens, toasters, electric irons and light bulbs, etc.
Electrochemistry	• For example, when current is passed through sodium chloride (NaCl) solution, a chemical reaction called electrolysis occurs. This is applied to produce electrolysis, galvanizing and battery, etc.
Magnetism	• The example of this electric work is a current-carrying wire, magnetic lines of flux occur. This is applied to produce electric motors, electric transformers and tape recorders, etc.

Electrical Measurement

Measuring Current	The instrument used to measure current is called ampere meter or ammeter. • Connect a small light bulb to a dry cell. Measure current that passes through light bulb by connecting positive terminal (+) of ammeter to negative terminal (-) of a dry cell.
Measuring Voltage	The instrument used to measure voltage, difference potential or electromotive force is called voltmeter. • Connect a small light bulb to a dry cell. A voltmeter is wired in parallel with the light bulb to measure voltage across the light bulb. Connect positive terminal (+) of voltmeter to positive terminal (+) of a dry cell and connect negative terminal (-) of voltmeter to negative terminal (-) of a dry cell.
Measuring Resistance	The instrument used to measure resistance is called test meter or multimeter. • The multimeter or test meter is used to make various electrical measurements such as current, voltage and resistance. It combines the functions of ammeter, voltmeter and ohmmeter. Turn the face dial to a position for required measuring, resistance, then touch both of terminals of multimeter and adjust the meter range to 0 Ω. Touch both of terminals of meter to a resistance and take the reading.

2 Power Usage

Provides information on the power draw of appliances and how to conserve power.

Power Consumption Percentages

This are the general details about how we use power in our everyday lives. For other alternatives to common household items see the 'HOMESTEADING > Alternatives' section.

Usage Percentages An ordered list of the most electrically consuming household categories.	**Space Cooling:** 17.5% **Water Heating:** 9.6% **Lighting:** 9.1% **Refrigeration:** 7.3%	**Space Heating:** 6.9% **Entertainment:** 5.8% **Computer:** 5% **Clothes Drying:** 4.4%	**Small Electronics:** 3% **Cooking:** 2.3% **Dishwashers:** 1.9% **Clothes Washing:** 0.6%

Space Cooling	• Air Conditioner • Peltier Cooler • Evaporative Cooler • Fan • Mister	**Alternatives** • Live somewhere cold • Airflow • Water Evaporation
Water Heating	• Sink Water • Shower Water • Kettle	**Alternatives** • Solar Heating • Gas Heating
Lighting	• Lights • Spotlights • Floodlights	**Alternatives** • Sunlight • Torch / Headlamp • Fairy Lights • Candles • Fireplace
Refrigeration	• Fridge • Freezer	**Alternatives** • Snow/Ice • Dehydrated / Freeze Dried Food
Space Heating	• Heater	**Alternatives** • Gas Heater (CO2)
Entertainment	• Tv • Speakers • Console	**Alternatives** • None • Board Games
Computer	• Computer • Monitors • Speakers	**Alternatives** • Mobile Phone • Laptop
Clothes Drying	• Dryer	**Alternatives** • Air Drying
Small Electronics	• Laptop • Mobile Phone • Battery Charger • Vacuum Cleaner • Iron	**Alternatives** • None
Cooking	• Oven • Grill • Microwave • Stove	**Alternatives** • Gas Stove • Sun Cooker
Dishwashers	• Dishwasher	**Alternatives** • Hand Washing • Disposable Plates
Clothes Washing	• Washing Machine	**Alternatives** • Hand Washing

Appliance Power Consumption

These are the average power consumptions of household devices, sorted by AC and DC appliances.

AC Appliances

Appliance	Minimum	Maximum	Standby	Appliance	Minimum	Maximum	Standby
100W light bulb (Incandescent)	100W	100W	0W	**Hand Wash Oversink Water Heater**	3000W	3000W	N/A
22 Inch LED TV	17W	17W	0.5W	**Heated Bathroom Mirror**	50W	100W	N/A
25" Colour TV	150W	150W	N/A	**Heated Hair Rollers**	400W	400W	N/A
3" belt sander	1000W	1000W	N/A	**Home Air Conditioner**	1000W	4000W	N/A
32 Inch LED TV	20W	60W	1W	**Home Internet Router**	5W	15W	N/A
42 Inch LED TV	58W	60W	0.3W	**Home Phone**	3W	5W	2W
46 Inch LED TV	60W	70W	1W	**Home Sound System**	95W	95W	1W
49 Inch LED TV	85W	85W	1W	**Hot Water Dispenser**	1200W	1300W	N/A
60W light bulb (Incandescent)	60W	60W	0W	**Hot Water Immersion Heater**	3000W	3000W	N/A
65 Inch LED TV	120W	130W	1W	**Humidifier**	35W	40W	N/A
82 Inch LED TV	228W	295W	0.5W	**iMac**	60W	240W	1W
9" disc sander	1200W	1200W	N/A	**Induction Hob (per hob)**	1400W	1800W	N/A
Air Cooler	65W	80W	N/A	**Inkjet Printer**	20W	30W	N/A
Air Fryer	1500W	1500W	N/A	**Inverter Air conditioner**	1300W	1800W	N/A
Air Purifier	25W	30W	N/A	**Iron**	1000W	1000W	N/A
Amazon Echo	3W	3W	2W	**Kitchen Extractor Fan**	200W	200W	N/A
American-style Fridge Freezer	40W	80W	N/A	**Laptop Computer**	50W	100W	N/A
Apple TV	3W	6W	0.3W	**Laser Printer**	600W	800W	N/A
Aquarium Pump	20W	50W	N/A	**Lawnmower**	1000W	1400W	N/A
AV Receiver	450W	450W	N/A	**LED Christmas Lights**	5W	5W	N/A

Bathroom Towel Heater	60W	150W	N/A	**LED Light Bulb**	7W	10W	0W
Ceiling Fan	60W	70W	0W	**Mi Box**	5W	7W	3W
Chromebook	45W	45W	N/A	**Microwave**	600W	1700W	3W
Chromecast	2W	2W	N/A	**Night Light**	1W	1W	0W
Clock radio	1W	2W	N/A	**Nintendo Switch AC Adapter**	7W	40W	N/A
Clothes Dryer	1000W	4000W	N/A	**Outdoor Hot Tub**	60W	500W	N/A
Coffee Maker	800W	1400W	N/A	**Oven**	2150W	2150W	N/A
Computer Monitor	25W	30W	N/A	**Paper Shredder**	200W	220W	N/A
Cooker Hood	20W	30W	0W	**Pedestal Fan**	50W	60W	N/A
Corded Drill	600W	850W	N/A	**Percolator**	800W	1100W	N/A
Corded Handheld Leaf Blower	2500W	2500W	N/A	**Philips Hue Smart Bulb**	8W	9W	0.4W
Cordless Drill Charger	70W	150W	N/A	**Phone Charger**	4W	7W	N/A
Curling Iron	25W	35W	0W	**Playstation 4**	85W	90W	N/A
DAB Mains Radio	5W	9W	N/A	**Power Shower**	7500W	10500W	0W
Deep Freezer	19W	19W	N/A	**Pressure Cooker**	700W	700W	N/A
Dehumidifier	240W	240W	N/A	**Projector**	220W	270W	1W
Desktop Computer	100W	450W	N/A	**Refrigerator**	100W	200W	N/A
Dishwasher	1200W	1500W	N/A	**Rice Cooker**	200W	800W	N/A
Domestic Water Pump	200W	300W	0W	**Sandwich Maker**	700W	1000W	N/A
DVD Player	26W	60W	N/A	**Scanner**	10W	18W	N/A
Electric Blanket	200W	200W	N/A	**Set Top Box**	27W	30W	N/A
Electric Boiler	4000W	14000W	N/A	**Sewing Machine**	70W	80W	N/A
Electric Doorbell Transformer	2W	2W	N/A	**Singer Sewing Machine**	100W	100W	N/A
Electric Heater Fan	2000W	3000W	N/A	**Sky Q 2TB Box**	40W	40W	N/A
Electric Kettle	1200W	3000W	0W	**Slow Cooker**	160W	180W	N/A
Electric Mower	1500W	1500W	N/A	**Space Heater**	2000W	5000W	N/A
Electric Pressure Cooker	1000W	1000W	N/A	**Steam Iron**	2200W	2500W	N/A
Electric Shaver	15W	20W	N/A	**Steriliser**	650W	650W	N/A
Electric stove	2000W	2000W	N/A	**Straightening Iron**	75W	300W	N/A
Electric Tankless Water Heater	6600W	8800W	N/A	**Strimmer**	300W	500W	N/A
Electric Thermal Radiator	500W	500W	N/A	**Submersible Water Pump**	200W	400W	N/A
Espresso Coffee Machine	1300W	1500W	N/A	**Table Fan**	10W	25W	N/A
EV Car Charger	2000W	7000W	N/A	**Tablet Charger**	10W	15W	N/A
EV Home Charger	1600W	3400W	N/A	**Tablet Computer**	5W	10W	N/A
Evaporative Air Conditioner	2600W	2600W	N/A	**Toaster**	800W	1800W	0W
Extractor Fan	12W	12W	N/A	**Tower Fan**	60W	60W	N/A
Fluorescent Lamp	28W	45W	N/A	**Treadmill**	280W	900W	N/A
Food Blender	300W	400W	N/A	**Tube Light (1500mm)**	22W	22W	N/A
Food Dehydrator	800W	800W	N/A	**TV (19" colour)**	40W	100W	1W
Freezer	30W	50W	N/A	**Vacuum Cleaner**	450W	900W	0W
Fridge	100W	220W	N/A	**Wall Fan**	45W	60W	0W
Fridge / Freezer	150W	400W	N/A	**Washing Machine**	500W	500W	1W
Fryer	1000W	1000W	N/A	**Water Dispenser**	100W	100W	N/A
Game Console	120W	200W	N/A	**Water Feature**	35W	35W	N/A
Gaming PC	300W	700W	1W	**Water Filter and Cooler**	70W	100W	N/A
Garage Door Opener	300W	400W	N/A	**WiFi Booster**	1W	2W	N/A
Google Home Mini	15W	15W	2W	**WiFi Router**	4W	10W	4W
Guitar Amplifier	20W	30W	N/A	**Wine cooler (18 bottles)**	83W	83W	0W
Hair Blow Dryer	1800W	2500W	N/A	**Xbox One**	50W	110W	14W

DC Appliances

These are the draw rates for 12v DC appliances. To convert KWH to Ah, Multiply by 1000 then divide by the voltage. (E.g. 0.15 @ 12v)(0.15x1000=150, 150/12 = 12.5Ah) For alternatives to power drawing devices see the 'HOMESTEADING > Minimalism' section.

Appliance	Minimum	Maximum	Standby	Appliance	Minimum	Maximum	Standby
15L Fridge - 24h Run Time - 12.5Ah				12v Pc Fan - 7h - 3.5Ah			
35L Fridge - 24h Run Time - 20.4Ah				12v Tv - 4h - 12Ah			
47L Fridge - 24h Run Time - 20.9Ah				12v LED Light - 4h - 2Ah			
60L Fridge - 24h Run Time - 21.4Ah				12v Kettle -			
78L Fridge - 24h Run Time - 25.7Ah				12v Air Pump -			
12v Floodlight - 5h - 8.35Ah				12v Grill -			
12v 8" Fan - 6.5h - 4Ah				12v Hot Water -			

Conserving Power

Tips on conserving power around the house.

Heating and Cooling

- Install a programmable thermostat
- Use window blinds effectively
- Have your HVAC system checked yearly
- Find and seal air leaks
- Install storm windows or plastic sheeting
- Insulate the room

Water Heating	● Turn down your water heater thermostat ● Insulate your water heater ● Wash clothes with cold water ● Take shorter showers
Cooking	● Use the appropriate pot size for cooking ● Use lids on pots ● Use a toaster oven when possible
Lighting	● Replace older incandescent light bulbs ● Turn lights of when not needed
Miscellaneous	● Choose Energy Star rated appliances ● Upgrade old refrigerators ● Use power strips to reduce phantom loads ● Minimize clothes dryer use
Mobile Phone	● Disable "High Performance Mode" if your phone has that option ● Enable power saving mode or extreme power saving mode and select all the lowest options. ● Lower the brightness to the minimum setting ● Lower the screen resolution ● Limit CPU power ● Disable the always on display ● Turn off sound and vibrate ● Close all unnecessary apps ● Try not to use your phone unless absolutely necessary, which includes using it to see the time ● Turn off: WiFi, Bluetooth, Mobile Data, GPS, NFC

Conservation
- Keep electricity use to a minimum and only when necessary or electricity is ample
- LED Bulbs use much less power and give off more light then regular bulbs
- Use natural alternatives where possible such as sunlight instead of bulbs and drying clothes outside
- Insulate the house to make heating and cooling easier
- Unplug devices when not in use as they continue to use electricity in standby mode

Power Tips

Air Conditioner	**Air Conditioner Power** 100-150sqft = 5K BTU = 1.5 KWh 150-200sqft = 6K BTU = 1.75 KWh 250-300sqft = 7K BTU = 2 KWh 300-350sqft = 8K BTU = 2.3 KWh
	Adjustments to Power ● Room heavily shaded - 10% ● Room Very Sunny + 10% ● Add 600 BTU pp over 2 ● Add 4K BTU if in Kitchen
Fridge/Freezer	● A freezer will stay cold for 2 days after a power cut, extend this time with blankets on the top. ● Keep the freezer full of food/water to keep everything colder longer if the power is lost.

3 Breakers & Fuses

House Breaker & Fuses

Service Panel
A service panel is a steel box with a hinged door or lift-up panel on the front. With the door open, you can access all the circuit breakers in the panel. Typically, one panel feeds the entire house, but there can also be another, smaller panel, called a subpanel, which may be used to serve a specific area, such as an addition, a large kitchen, or a detached garage. A subpanel works just like a main service panel but is supplied by the home's main panel rather than by the utility lines. Each circuit breaker is controlled with a lever that can be set manually to an ON or OFF position. If a circuit breaker trips, usually due to an overload or other problem with the circuit, the lever will automatically move to a third position between ON and OFF. Breakers should be labelled to identify the main area or appliance served by the breaker's circuit. Labels may be stickers or hand-written words next to breakers or on a sheet adhered to the inside of the panel door. Note: Older homes that have not had their electrical services upgraded may have service panels with fuses rather than circuit breakers, which have been standard since the 1960s.

Inside
When you open it, the panel door gives you access to the circuit breaker switches, but that's all. And that's as far as most homeowners need to go. However, to get inside the panel to install or replace a circuit breaker, you have to remove the protective cover around the breaker switches, known as the dead front cover. The dead front cover is typically held in place with a screw in each corner. Removing the cover provides access to all components of the panel. Some panels have a separate door and cover; others have a door and cover as parts of the same unit. Warning: Always shut off the main circuit breaker (see next slide) before removing the dead front cover. This shuts off the power to all of the circuit breakers and household circuits but does not shut off the power from the utility. The utility service lines and the terminals they connect to inside the panel remain live (carrying deadly electrical current) unless the utility company shuts off the service to the home.

Main Circuit Breaker
The main circuit breaker is a large breaker usually located at the top of the panel but sometimes near the bottom or along one side. It controls all the power of the branch circuit breakers (the breakers controlling individual circuits) in the panel. Power comes from the utility service lines, flows through the electrical meter on the outside of your house, and continues into the service panel. The main circuit breaker is often called a double-pole service disconnect and is what controls the live power energizing the circuits in the electrical panel. It's easily recognizable by the two thick black wires feeding it from the electrical meter and consists of two circuit breaker handles joined together. The main is used to turn power to all the branch circuits ON or OFF at the same time. The main circuit breaker also identifies the total amperage capacity of the service panel and will have a number on it identifying its amp capacity, such as 100, 150, or 200. The standard for new panels today is 200 amps, but panels can have higher capacity. Warning: The main circuit breaker shuts off the power to all of the branch circuits but does not shut off the power from the utility. The utility service lines and the terminals they connect to inside the panel remain live (carrying deadly electrical current) unless the utility company shuts off the service to the home.

Hot Bus Bars
The two thick, black service wires feeding the main circuit breaker each carry 120 volts from the electric meter and feed the two "hot" bus bars in the panel. Circuit breakers snap into place onto one or both of the bus bars to provide power to the circuits. Single-pole circuit breakers provide 120 volts and connect to just one hot bus bar. Double-pole circuit breakers provide 240 volts to a circuit and snap into both hot bus bars. The electrical current leaves the service panel through the hot wires that are connected to the circuit breakers. Single-pole breakers have one hot wire (usually black), while double-pole breakers have two hot wires, which may be black, red, white, or another colour.

Circuit Breakers
The circuit breaker is the weak link in each electrical circuit. But that's a good thing, as it's designed to fail safely. When a circuit draws more current than it is designed to handle, the wiring gets hot and becomes a fire hazard. Excessive current in a circuit is prevented by the use of over current safety devices, such as circuit breakers (or, in older system, fuses). Circuit breakers connect to the hot bus bars and come in a variety of types and capacities:
● Single-pole breakers provide 120 volts and typically come with ratings of 15 amps or 20 amps. These breakers make up most of the breakers in your home.
● Double-pole breakers provide 240 volts and come in ratings from 15 amps to 50 amps. These breakers usually serve dedicated circuits for large appliances, such as electric dryers, stoves, and air conditioners.
● Ground-fault circuit-interrupter (GFCI) breakers protect an entire circuit from ground faults.
● Arc-fault circuit-interrupter (AFCI) breakers protect an entire circuit from arc faults. Some dual-function breakers may provide both GFCI and AFCI protection simultaneously.

Neutral Bus Bar
Once the power leaves the electrical service panel through the hot wire(s) of a circuit and does its work through the electrical devices (light bulbs, outlets, etc.), the electrical current returns back to the service panel through the neutral (usually white) circuit wire, which is connected to the neutral bus bar. The bar connects to the main service neutral and returns the current back to the electric utility grid. In many service panels, the neutral bus bar also serves as the grounding bus bar and is where the individual bare copper circuit ground wires are terminated. In this case, it is often referred to as a neutral/ground bus bar.

Blown Fuse
The most common sign of a blown fuse is a power outage in one or more areas of your home. Fuses, unlike breakers, do not have on-off switches. Instead, most fuses have a small glass window that allows you to examine the fuse itself. Look for the blown fuse and unscrew the unit. Be sure to replace your fuse with the correct size. Most fuse boxes don't have a safeguard against installing the wrong fuse. Installing an under-powered fuse will result in constant overloading. Likewise, an overpowered fuse will allow too much current to flow through a particular circuit. In extreme cases, this can damage your wiring and even cause fires.

Fuse Types

These are the common types of household fuses. The size of the fuse is determined by its voltage or amperage. Be sure you know which size works for your fuse box before installing a new fuse.

Edison Base (Type-T) Fuses	Type-T fuses are designed to handle no more than 125 volts and have an ampere rating of no more than 30 amps. Edison Base fuses are only suitable for installations in which there is no sign of tampering or over fusing. Over fusing means installing a fuse that accepts a higher amount of electricity than the circuit can handle.
Type-S Fuses	Type-S fuses consist of two components: an adapter and the fuse itself. Each level of amperage has a matching socket adapter with a different threading to prevent mismatching fuses.
Main Fuses	Many fuse boxes have a main fuse. These are usually located above the individual fuses and housed in plastic casings. Pulling this fuse will interrupt power to your entire house. Main fuses are self-contained and hold two canister-style fuses.

Replacing a Fuse

Swapping out a blown fuse isn't as easy as flipping a breaker, but it's still a simple fix.

Step 1	Turn off your power. Pull the main fuse in your fuse box to cut power to the box. Some fuse boxes have two main fuses: Pull all the main fuses if you have more than one.
Step 2	Locate the blown fuse. Older homes weren't designed to handle modern electrical loads, so most fuse boxes house several fuses. All fuses have a glass top that allows you to see the fuse itself. Use a flashlight to locate the blown fuse. Similar to a light bulb, a blown fuse will have a broken and charred filament or circuit.
Step 3	Remove the fuse. Unscrew the blown fuse and install the replacement.
Step 4	Turn on the power. Replace the main fuses to restore power to your home.

Car Fuse Box

Fuse Location
Check your owner's manual for the location of your fuse box. It's often under the hood. Vehicles today have 40 or more auto fuses grouped in two or more places. Usually located in or around the instrument panel near the dash, fuses can also be found under the hood and even under the rear seat. Next time your radio, lights or other device stops working, chances are a blown fuse is the culprit. Look under "Fuses" in your owner's manual for help finding your fuse panels. Most manuals have a diagram showing you where each fuse box is. Each fuse panel cover should have a diagram listing each device and the corresponding fuse. Never replace a blown fuse with a higher-amp fuse. Always replace the fuse with one with the specified amp rating. You may install the next-smaller-rated fuse to get you by in a pinch until you can purchase a replacement.

Fuse Check
Clamp the grounding lead of your test light to a metal component. Turn the ignition key to the "run" position. Then probe both of the tiny test ports in the face of each fuse. The light should illuminate at each port. If it doesn't, the fuse is blown. Turn the key to the "run" position and press the tester prongs into the test ports. The LED will light up if the fuse is good. There are at least seven different styles, so you'll need the blown fuse to match it up with the right replacement. Here are the three most common sizes of car fuses.

Replacing the Fuse
Remove the fuse that's labelled for the device that's not working, for example, the fan, radio, lighter or marker lights. Use a needle-nose pliers or a fuse puller (available at auto parts stores). Hold the fuse up to the light to see if it's burned out. You'll see a fine wire connecting the two sides if the fuse is good. If a section of that wire has burned away, the fuse is bad. The picture on the left shows what a blown fuse looks like. In a good fuse, the wire between the two sides is still whole. Most fuses used in vehicles today are one of three types: mini, standard or maxi. The mini and standard are fast-acting fuses that protect the majority of your vehicle's circuits, including those for lights and radios. The maxi car fuses are slow-acting fuses that protect circuits with a large current draw such as those for anti-lock brakes, rear window defogger and traction control. Car fuses are colour coded by amp rating. For example, a standard blue fuse has a 15-amp rating, yellow is 20 amps and green is 30. Before you buy car fuses, keep in mind that the fuse panel cover often contains spare fuses and even a fuse puller. Just be sure to replace the spares so they'll be there the next time you need them. You can buy them at any auto parts store and at well-stocked service stations. Note: If your new fuse blows soon after installing it, you could have problems in that circuit. Schedule an appointment with your service station or dealer for an expert diagnosis to repair the problem.

In-Line Fuses
Some accessories that aren't factory installed may have a remote in-line fuse. These fuses can be located under the dash, under the hood or even in the trunk depending on the circuit they protect. They most likely protect an aftermarket accessory like fog lights or a CD changer. The best way to find an in-line fuse is to trace the wire from the accessory to the fuse panel. Along the way, you'll notice a fuse container that looks like one of these shown. Open the housing to pull out the fuse and examine it. Replace it with one of the same size and amperage and snap the housing back together.

4 Power Types

Renewable Power

A list of renewable power forms you could utilize.

Solar Photovoltaic	Converts the sun's rays into electricity. Works: 8/24 hrs Pros: Doesn't need much maintenance. Cons: Only works during daylight hours.
Hydroelectric	Converts water movement into electricity as long as there's a flow. Works: 24/24 Hours Pros: Constant electricity generation, lots produced. Cons: Requires waterfall or dam, long cables to house.
Dynamo	Converts human work into electricity. Works: When wound. Pros: Doubles as exercise. Cons: Takes a lot of effort.
Thermoelectric	Uses a temperature difference to generate electricity. Works: When there's a temperature difference. Pros: Synergises with Steam Energy. Cons: Little electricity production.
Wind	Uses the wind to spin a turbine. Works: When windy. Pros: No maintenance. Cons: Little electricity production.

Non-Renewable Power

A list of non-renewable power forms you could utilize.

Steam Pressure	Uses pressure to spin a turbine. Works: When burning things. Pros: Can be used to heat the home. Cons: Requires lots of wood stockpiled and constant attention.
Fuel Generator	Spins an alternator by burning fuel. Works: When fuel is available.
Chemical Energy	Combines chemicals to generate electricity. Works: Until reaction is complete. Pros: Simple to use and ready to go. Cons: Often one-time use.
The Grid	"Magic" power. Works: As long as society is functioning. Pros: AC Power, no need to worry about source. Cons: Controlled externally, may fail anytime.
Wood Gasifier	Converts wood into Gas

5 Renewable

Forms of renewable energy you can use around your homestead.

Solar

How to generate electricity from the sun.

- 80w Panels = 4-5a a day
- 120w Panels = 6-7.5a a day

Solar/Wind/Hydro MPPT

Amp Requirements
- Solar Array Wattage
- Battery Bank Voltage
- Watts / Volts = Amps

Solar Tips

Various tips on using solar panels.

- Sunlight is most useful between 10am and 4pm. (6h)
- Solar panels only put out about 70% of stated wattage.
- 1m2 of solar panels returns about 100-150w of power in direct sunlight based on 15-20% efficiency.
- Require 3x the electrical capacity of batteries to avoid a short battery life.
- Add a fuse between the panels and the regulator rated at the maximum amperage of the regulator.
- Choose an amp rating higher then the solar panels combined.
- Slight loss of performance above 25°C (77°F) of -0.3% per °C.
- Pulse Width Modulation (PWM) (70% Efficiency) vs Maximum Power Point Tracking (MPPT) (96% Efficiency)

Water

If you have a running water source with constant flow there's the possibility of performing some civil engineering work to create a miniature dam on your land or BOL. Power outputs typically range from 500W to 60kW depending on the size and number of generators.

Wind

The environment must have significant duration of wind speed at more then 4m/s for wind to be a viable generation option. The maximum wind speed during a climatic event - such as a cyclone or hurricane needs to be lower then 43m/s (150km/h) otherwise you will need to shut down the generator. The set-up site shouldn't be close to houses as it could produce quite a lot of noise and vibrations. You need to ensure you have voltage protection if high winds occasionally blow.

Gravity

Gravity can be used to generate power via a dynamo. A setup with a bucket of rocks attached to the dynamo can be designed so that light is generated as the rocks are pulled down. When the rocks reach the ground, simply reset the device and lift the rocks back into the bucket.

Dynamo

Dynamo power is the generation of electricity from a rotating turbine. The electricity can then either be stored or used straight away.

These are the different types of dynamo electricity generation.

Winding, Pedal or Pull Cord	Wind a crank or pedal a bike to generate power.
Squeeze	Squeeze a lever to generate power.
Shake	Shake a magnet through a coil to generate power.

6 Non-Renewable

Coal

Coal is a fossil fuel which is burnt to produce electricity. There's only a limited amount available and will eventually run out.

Oil

Oils are refined to produce fuels for transportation but it's non renewable.

Natural Gas

Nuclear Power

A dangerous form of power and highly unlikely you will be using this on your property, but it's included anyway.

7 Batteries

Batteries are the primary source of power in electronics today and we rely on them heavily.

General Information

This section covers the general information about batteries such as types, storage and safety.

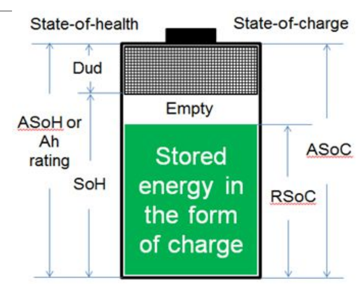
Battery Types

NiMH	Nickel Metal Hydride. Nickel-metal-hydride batteries are closely connected to Nickel Cadmium batteries, with the hydrogen being used as the active element rather than cadmium. Unlike the NiCd, this battery does NOT contain toxic metals, and is usually used in mobile phones and laptops. This type of battery are now a common consumer and industrial type battery. It has practically taken over the NiCd battery in applications. The cell voltage for these types of batteries is 1.2 volts, with the electrolyte being alkaline potassium hydroxide. The energy density of NiMH batteries is around double that of lead acid batteries, and around 40% higher than NiCd batteries. Unlike the NiCd battery, the NiMH battery is not susceptible to the “memory effect”. This type of battery is not suitable when the battery is not being used frequently (within around 30 days) or for devices which are low energy drawing, such as clocks, TV remotes and smoke alarms. NiMH batteries are around half the cost of Lithium ion batteries and are becoming more in line price-wise with NiCd batteries.
NiCd (Nickel Cadmium)	This type of battery is used when price, a high discharge rate and battery life are important. This type of battery has quite a low energy density and uses nickel oxide hydroxide and metallic cadmium as electrodes. NiCd batteries are also susceptible to a “memory effect.” The NiCd (chemicals symbols of nickel and cadmium) battery has a terminal voltage of around 1.2 volts during discharge. They are made in various sizes and capacities and have a distinct advantage over other rechargeable batteries in their ability to deliver at high discharge rates. Nickel Cadmium batteries use an alkaline chemistry and have an energy density approximately twice that of lead acid batteries. Although once the preferred battery choice for applications regarding low power portable products, they have since been overtaken by the newer Nickel-Metal Hydride (NiMH) and Lithium batteries.
Li-Ion (Lithium Ion)	The Lithium Ion battery is used where light weight and high energy density are important factors. Lithium Ions move from the negative to the positive electrode during discharge and back when charging. The electrodes in these type of batteries are made up of lightweight lithium and carbon. These batteries require a protection circuit due to the fragile technology used. The Li-ion battery loses charge very slowly when not in use. Lithium Ion batteries are safe as long as particular precautions are taken when charging and discharging. They are slightly lower in energy density than Lithium Metal batteries and around double that of Nickel Cadmium. The Lithium Ion is a low maintenance battery, which is an added advantage. They have no memory and do not require scheduling to prolong battery life. The self-discharge of Lithium Ion batteries is less than half that of Nickel Cadmium. As well as its fragile nature, another disadvantage of the Lithium Ion battery is ageing. This may also be an issue whether the battery is in use or not, and these types of battery can be known to fail after only two or three years. Nickel-Metal Hydride batteries can also have ageing as a concern if exposed to high ambient temperatures. However, Lithium Ion is progressively being improved with new, enhanced chemical combinations being introduced on a regular basis, which may improve the ageing issue. Storing in a cool place also improves the ageing process of Lithium Ion.
Lithium Ion Polymer (Li-ion Polymer)	The Lithium Ion Polymer battery offers similar elements to the Li-ion battery in an ultra-slim and simplified packaging form. It is of lithium-ion technology in a pouch format. This makes them lighter, but less rigid. The Li-polymer is different from other batteries in the type of electrolyte used, a dry solid polymer electrolyte. Rather than conducting electricity, this electrolyte allows an exchange of ions (electrically charged atoms or groups of atoms). The Lithium Polymer has an advantage over the Lithium Ion battery in regard to cost, durability and flexibility. They can be shaped to fit various devices and in virtually any way manufacturers please. They offer a slightly higher specific energy to the Lithium Ion battery, can be made thinner and in various shapes and sizes, but generally have a high manufacturing cost by around 10% to 30%. The technology used in both Lithium Ion Polymer and Lithium Ion batteries vary quite significantly to that used in NiCd and NiMH batteries. Another advantage of lithium polymer cells over NiCd and NiMH is their much lower rate of self-discharge. Lithium cells have the highest energy density as well as qualities which require particular safety considerations. Because there is no liquid or gelled electrolyte used, there is no danger of flammability. The main reason to switch to the Lithium Polymer from the Lithium Ion is form factor, they can be formed to almost any shape and size. As with Lithium Ion batteries, Lithium Polymer have a nominal voltage of 3.6 volts.
Lead Acid / SLA (Sealed Lead Acid)	Sealed Lead Acid Battery. The lead acid battery is the oldest type of rechargeable battery, invented in 1859. These type of batteries have changed little since this time and are still widely used today. The lead acid battery is an economical option for larger power applications, and where weight is of little or no importance. They are robust, tried and tested. Lead acid batteries comprise of flat lead plates immersed in electrolyte, and most types of lead acid batteries require regular water addition. Lead acid batteries are toxic due to heavy metal elements of lead-dioxide cathode, a sulphuric acid solution electrolyte, and a sponge metallic lead anode. Lead acid batteries are able to supply high surge currents, despite having low energy to weight and energy to volume ratios. Therefore, the cells have quite a large power to weight ratio, which, combined with their low cost, makes them popular for use in motor vehicles. The correct voltage must be observed when charging lead acid batteries, and although simple to charge, they are slow charging. These types of batteries are not “memory affected”. Lead acid batteries work well in cold temperatures and are better performers than Lithium-Ion batteries in subzero conditions.
Saltwater Battery (No Longer Made)	A salt water battery employs a concentrated saline solution as its electrolyte. They are non-flammable and more easily recycled than batteries that employ toxic or flammable materials. They’re inherently safe due to their chemistry, and they boast a 100% depth-of-discharge capability, with a life cycle of around 3,000 cycles. Aquion’s S30 batteries were optimized for long-duration daily cycling, which means 4 to 20+ hour charge and discharge cycles, which is ideal for solar. They were supposedly abuse tolerant and did not degrade from partial state of charge cycling, which is typical of solar applications. The main drawbacks were the slightly lower life cycle compared to lithium-ion and a 5-year warranty (as opposed to Tesla’s 10-year warranty for the Powerwall). They also have a low power output per stack – about 0.68kW of steady power – which means that you need to buy at least 5 stacks (0.68kW x 5 = 3.4 kW steady power) to get enough power output to power an average home.

Battery Terms

Batteries are specified by three main characteristics: chemistry, voltage and specific energy (capacity). A starter battery also provides cold cranking amps (CCA), which relates to the ability to provide high current at cold temperatures.

Primary Batteries	Primary batteries are non-rechargeable batteries. Primaries play an important role, especially when charging is impractical or impossible, such as in military combat, rescue missions and forest-fire services. High specific energy, long storage times and instant readiness give primary batteries a unique advantage over other power sources. They can be carried to remote locations and used instantly, even after long storage. The most popular primary battery is alkaline. It has a high specific energy and is cost effective, environmentally friendly and leak-proof even when fully discharged. Alkaline can be stored for up to 10 years, has a good safety record and can be carried on an aircraft without being subject to UN Transport and other regulations. The negative is low load currents, limiting its use to light loads such as remote controls, flashlights and portable entertainment devices.
Rechargeable Batteries	A rechargeable battery, storage battery, or secondary cell is a type of electrical battery which can be charged, discharged into a load, and recharged many times, as opposed to a disposable or primary battery, which is supplied fully charged and discarded after use. It is composed of one or more electrochemical cells. The term "accumulator" is used as it accumulates and stores energy through a reversible electrochemical reaction. Rechargeable batteries are produced in many different shapes and sizes, ranging from button cells to megawatt systems connected to stabilize an electrical distribution network. Several different combinations of electrode materials and electrolytes are used, including lead–acid, nickel–cadmium (NiCd), nickel–metal hydride (NiMH), lithium-ion (Li-ion), and lithium-ion polymer (Li-ion polymer).
Chemistry	The most common battery chemistries are lead, nickel and lithium, and each system needs a designated charger. Charging a battery on a charger designed for a different chemistry may appear to work at first but might fail to terminate the charge correctly. Observe the chemistry when shipping and disposing of batteries as each chemistry has a different regulatory requirement.
Voltage	Batteries are marked with nominal voltage; however, the open circuit voltage (OCV) on a fully charged battery is 5–7 percent higher. Chemistry and the number of cells connected in series provide the OCV. The closed circuit voltage (CCV) is the operating voltage. Always check for the correct nominal voltage before connecting a battery.
Capacity	Capacity represents specific energy in ampere-hours (Ah). Ah is the discharge current a battery can deliver over time. You can install a battery with a higher Ah than specified and get a longer runtime; you can also use a slightly smaller pack and expect a shorter runtime. Chargers have some tolerance as to Ah rating (with same voltage and chemistry); a larger battery will simply take longer to charge than a smaller pack, but the Ah discrepancy should not exceed 25 percent. European starter batteries are marked in Ah; North America uses Reserve Capacity (RC). RC reflects the discharge time in minutes at a 25A discharge.
Cold Cranking Amps (CCA)	Starter batteries, also known as SLI (starter light ignition) are marked with CCA. The number indicates the current in ampere that the battery can deliver at –18°C (0°F).
Specific Energy, Energy Density	Specific energy, or gravimetric energy density, defines battery capacity in weight (Wh/kg); energy density, or volumetric energy density, reflects volume in litres (Wh/l). Products requiring long runtimes at moderate load are optimized for high specific energy; the ability to deliver high current loads can be ignored.
Specific Power	Specific power, or gravimetric power density, indicates loading capability. Batteries for power tools are made for high specific power and come with reduced specific energy (capacity).
C-Rates	The C-rate specifies the speed a battery is charged or discharged. At 1C, the battery charges and discharges at a current that is on par with the marked Ah rating. At 0.5C, the current is half and the time is doubled, and at 0.1C the current is one-tenth and the time is 10-fold.
Load	A load defines the current that is drawn from the battery. Internal battery resistance and depleting state-of-charge (SoC) cause the voltage to drop under load, triggering end of discharge. Power relates to current delivery measured in watts (W); energy is the physical work over time measured in watt-hours (Wh).
State-of-Health (SoH)	The three main state-of-health indicators of a battery are: ● Capacity, the ability to store energy ● Internal resistance, the capability to deliver current, and ● Self-discharge, reflecting mechanical integrity and stress-related conditions Li-ion reveals SoH in capacity. Internals resistance and self-discharge stay low under normal circumstances. SoH is commonly hidden form the user in consumer products; only state-of-charge (SoC) is provided.
State-of-Charge (SoC)	SoC reflects the battery charge level; a reading battery user is most familiar with. The SoC fuel gauge can create a false sense of security as a good and faded battery show 100 percent when fully charged. SoC is sometimes divided into: ● Absolute state-of-charge (ASoC), the ability to take the specified charge when the battery is new ● Relative state-of-health (RSoC), available charge level taking capacity fade into account.
State-of-Function (SoF)	SoF reflects battery readiness in terms of usable energy by observing state-of-charge in relation to the available capacity. This can be shown with the tri-state fuel gauge in which the usable capacity is reflected as stored energy in the form of charge (RSoH); the part that can be filled as empty and the unusable part that cannot be restored as dud. SoF can also be presented with the fishbowl icon for a battery evaluation at a glance. Tri-state fuel gauges are seldom used in fear of elevated warranty claims.



● ASoH Absolute state-of-health of a new battery.
● **SoH** State-of-health. Generic term for battery health. Capacity is leading health indicator.
● **RSoC** Relative state-of-charge; charge level with capacity fade.
● **ASoC** Absolute state-of-charge of a new battery
● **RSoH** Relative state-of-health relating to available capacity
● **SoC** State-of-charge. Generic term for charge level

Priming Batteries

Not all rechargeable batteries deliver the rated capacity when new, and they require formatting. While this applies to most battery systems, manufacturers of lithium-ion batteries disagree. They say that Li-ion is ready at birth and does not need priming. Although this may be true, users have reported some capacity gains by cycling after a long storage.

Formatting vs Priming
Both address capacities that are not optimized and can be improved with cycling. Formatting completes the fabrication process that occurs naturally during use when the battery is being cycled. A typical example is lead- and nickel-based batteries that improve with usage until fully formatted. Priming, on the other hand, is a conditioning cycle that is applied as a service to improve battery performance during usage or after prolonged storage. Priming relates mainly to nickel-based batteries.

Lead Acid	Formatting a lead acid battery occurs by applying a charge, followed by a discharge and recharge. This is done at the factory and is completed in the field as part of regular use. Experts advise not to strain a new battery by giving it heavy duty discharges at first but gradually working it in with moderate discharges, like an athlete trains for weight lifting or long-distance running. This, however, may not be possible with a starter battery in a vehicle and other uses. Lead acid typically reaches the full capacity potential after 50 to 100 cycles. Deep-cycle batteries are at about 85 percent when new and will increase to 100 percent, or close to full capacity, when fully formatted. There are some outliers that are as low as 65 percent when tested with a battery analyser. The question is asked, "Will these low-performers recover and stand up to their stronger brothers when formatted?" A seasoned battery expert said that "these batteries will improve somewhat but they are the first to fail." The function of a starter battery lies in delivering high load currents to crank the engine, and this attribute is present from the beginning without the need to format and prime. To the surprise of many motorists, the capacity of a starter battery can fade to 30 percent and still crank the engine; however, a further drop may get the driver stranded one morning.
Nickel-Based	Manufacturers advise to trickle charge a nickel-based battery for 16–24 hours when new and after a long storage. This allows the cells to adjust to each other and to bring them to an equal charge level. A slow charge also helps to redistribute the electrolyte to eliminate dry spots on the separator that might have developed by gravitation. Nickel-based batteries are not always fully formatted when leaving the factory. Applying several charge/discharge cycles through normal use or with a battery analyser completes the formatting process. The number of cycles required to attain full capacity differs between cell manufacturers. Quality cells perform to specification after 5–7 cycles, while lower-cost alternatives may need 50 or more cycles to reach acceptable capacity levels. Cycling also restores lost capacity when a nickel-based battery has been stored for a few months. Storage time, state-of-charge and temperature under which the battery is stored govern the ease of recovery. The longer the storage and the warmer the temperature, the more cycles will be required to regain full capacity. Battery analysers help in the priming functions and assure that the desired capacity has been achieved.
Lithium-ion	Some battery users insist that a passivation layer develops on the cathode of a lithium-ion cell after storage. Also known as interfacial protective film (IPF), this layer is said to restrict ion flow, cause an increase in internal resistance and in the worst case, lead to lithium plating. Charging, and more effectively cycling, is known to dissolve the layer and some battery users claim to have gained extra runtime after the second or third cycle on a smartphone, albeit by a small amount. Whatever the outcome on the passivation of Li-ion may be, there is no parallel to the "memory" effect with NiCd batteries that require periodic cycling to prevent capacity loss. The symptoms may appear similar but the mechanics are different. Nor can the effect be compared to sulfation of lead acid batteries. Lithium-ion is a very clean system that does not need additional priming once it leaves the factory, nor does it require the level of maintenance that nickel-based batteries do. Additional formatting makes little difference because the maximum capacity is available right from the beginning, (the exception may be a small capacity gain after a long storage). A full discharge does not improve the capacity once the battery has faded — a low capacity signals the end of life. A discharge/charge may calibrate a "smart" battery but this does little to improve the chemical battery. Instructions recommending charging a new Li-ion for 8 hours are written off as "old school," a left-over from the old nickel battery days.
Non-Rechargeable Lithium	Primary lithium batteries, such as lithium-thionyl chloride (LTC), benefit from passivation in storage. Passivation is a thin layer that forms as part of a reaction between the electrolyte, the lithium anode and the carbon-based cathode. (Note that the anode of a primary lithium battery is lithium and the cathode is graphite, the reverse of Li-ion.) Without this layer, most lithium batteries could not function because the lithium would cause a rapid self-discharge and degrade the battery quickly. Battery scientists even say that the battery would explode without the formation of lithium chloride layers and that the passivation layer is responsible for the battery's existence and the ability to store for 10 years. Temperature and state-of-charge promote the build-up of the passivation layer. A fully charged LTC is harder to depassivate after long storage than one that was kept at a low charge. While LTC should be stored at cool temperatures, depassivation works better when warm as the increased thermal conductivity and mobility of the ions helps in the process.

Storing Batteries

How to store batteries properly to extend their life. The recommended storage temperature for most batteries is 15°C (59°F); the extreme allowable temperature is –40°C to 50°C (–40°C to 122°F) for most chemistries. If you're storing batters for an extended time, say 2 months or more, it's recommended you take the battery out in case it leaks and corrodes the device internals.

Lead Acid	You can store a sealed lead acid battery for up to 2 years. Since all batteries gradually self-discharge over time, it is important to check the voltage and/or specific gravity, and then apply a charge when the battery falls to 70 percent state-of-charge, which reflects 2.07V/cell open circuit or 12.42V for a 12V pack. (The specific gravity at 70 percent charge is roughly 1.218.) Lead acid batteries may have different readings, and it is best to check the manufacturer's instruction manual. Some battery manufacturer may further let a lead acid to drop to 60 percent before recharge. Low charge induces sulfation, an oxidation layer on the negative plate that inhibits current flow. Topping charge and/or cycling may restore some of the capacity losses in the early stages of sulfation. Sulfation may prevent charging small sealed lead acid cells after prolonged storage. These batteries can often be reactivated by applying an elevated voltage. At first, the cell voltage under charge may go up to 5V and draw very little current. Within 2 hours or so, the charging current converts the large sulphate crystals into active material, the cell resistance drops and the charge voltage gradually normalizes. At between 2.10V and 2.40V the cell is able to accept a normal charge. To prevent damage, set the current limit to a very low level. Do not attempt to perform this service if the power supply does not have current limiting.
Nickel-Based	Recommended storage is around 40 percent state-of-charge (SoC). This minimizes age-related capacity loss while keeping the battery operational and allowing for some self-discharge. Nickel-based batteries can be stored in a fully discharged state with no apparent side effect. Measuring SoC by voltage is difficult on nickel-based batteries. A flat discharge curve, agitation after charge and discharge and temperature affects the voltage. The good news is that the charge level for storage is not critical for this chemistry, so simply apply some charge if the battery is empty and store it in a cool and dry place. With some charge, priming should be quicker than if stored in a totally discharged state. Nickel-metal-hydride can be stored for 3–5 years. The capacity drop that occurs during storage is partially reversible with priming. Nickel-cadmium stores well. The US Air Force was able to deploy NiCd batteries that had been in storage for 5 years with good recovered capacities after priming. It is believed that priming becomes necessary if the voltage drops below 1V/cell. Primary alkaline and lithium batteries can be stored for up to 10 years with only moderate capacity loss.
Lithium-Based	There is virtually no self-discharge below about 4.0V at 20°C (68°F); storing at 3.7V yields amazing longevity for most Li-ion systems. Finding the exact 40–50 percent SoC level to store Li-ion is not that important. At 40 percent charge, most Li-ion has an OCV of 3.82V/cell at room temperature. To get the correct reading after a charge or discharge, rest the battery for 90 minutes before taking the reading. If this is not practical, overshoot the discharge voltage by 50mV or go 50mV higher on charge. This means discharging to 3.77V/cell or charging to 3.87V/cell at a C-rate of 1C or less. The rubber band effect will settle the voltage at roughly 3.82V. Figure 1 shows the typical discharge voltage of a Li-ion battery.

Alkaline	Alkaline and other primary batteries are easy to store. For best results, keep the cells at cool room temperature and at a relative humidity of about 50 percent. Do not freeze alkaline cells, or any battery, as this may change the molecular structure. Some lithium-based primary batteries need special care.

Capacity Loss During Storage

Storage induces two forms of losses: Self-discharge that can be refilled with charging before use, and non-recoverable losses that permanently lower the capacity. The table below illustrates the remaining capacities of lithium- and nickel-based batteries after one year of storage at various temperatures. Li-ion has higher losses if stored fully charged rather than at a SoC of 40 percent.

Temperature	**Lead Acid** (at full charge) (After 6 Months)	**Nickel-Based** (at any charge)	**Lithium-Ion (Li-Cobalt)** (40% Charge)	**Lithium-Ion (Li-Cobalt)** (100% Charge) (After 3 Months)	
0°C	97%	99%	98%	94%	
25°C	90%	97%	96%	80%	
40°C	62%	95%	85%	65%	
60°C	38%	70%	75%	60%	

Batteries are often exposed to unfavourable temperatures, and leaving a mobile phone or camera on the dashboard of a car or in the hot sun are such examples. Laptops get warm when in use and this increases the battery temperature. Sitting at full charge while plugged into the mains shortens battery life. Elevated temperature also stresses lead- and nickel-based batteries.

Nickel-metal-hydride can be stored for 3–5 years. The capacity drop that occurs during storage is partially reversible with priming. Nickel-cadmium stores well. The US Air Force was able to deploy NiCd batteries that had been in storage for 5 years with good recovered capacities after priming. It is believed that priming becomes necessary if the voltage drops below 1V/cell. Primary alkaline and lithium batteries can be stored for up to 10 years with only moderate capacity loss.

You can store a sealed lead acid battery for up to 2 years. Since all batteries gradually self-discharge over time, it is important to check the voltage and/or specific gravity, and then apply a charge when the battery falls to 70 percent state-of-charge, which reflects 2.07V/cell open circuit or 12.42V for a 12V pack. (The specific gravity at 70 percent charge is roughly 1.218.) Lead acid batteries may have different readings, and it is best to check the manufacturer's instruction manual. Some battery manufacturer may further let a lead acid to drop to 60 percent before recharge. Low charge induces sulfation, an oxidation layer on the negative plate that inhibits current flow. Topping charge and/or cycling may restore some of the capacity losses in the early stages of sulfation.

Sulfation may prevent charging small sealed lead acid cells, such as the Cyclone by Hawker, after prolonged storage. These batteries can often be reactivated by applying an elevated voltage. At first, the cell voltage under charge may go up to 5V and draw very little current. Within 2 hours or so, the charging current converts the large sulphate crystals into active material, the cell resistance drops and the charge voltage gradually normalizes. At between 2.10V and 2.40V the cell is able to accept a normal charge. To prevent damage, set the current limit to a very low level. Do not attempt to perform this service if the power supply does not have current limiting.

Alkaline batteries are easy to store. For best results, keep the cells at cool room temperature and at a relative humidity of about 50 percent. Do not freeze alkaline cells, or any battery, as this may change the molecular structure.

- Primary batteries store well. Alkaline and primary lithium batteries can be stored for 10 years with moderate loss capacity.
- When storing, remove the battery from the equipment and place in a dry and cool place.
- Avoid freezing. Batteries freeze more easily if kept in discharged state.
- Charge lead acid before storing and monitor the voltage or specific gravity frequently; apply a charge if below 2.07V/cell or if SG is below 1.225 (most starter batteries).
- Nickel-based batteries can be stored for 3–5years, even at zero voltage; prime before use.
- Lithium-ion must be stored in a charged state, ideally at 40 percent. This prevents the battery from dropping below 2.50V/cell, triggering sleep mode.
- Discard Li-ion if kept below 2.00/V/cell for more than a week. Also discard if the voltage does not recover normally after storage.

Self Discharge

Self-discharge is a phenomenon in batteries in which internal chemical reactions reduce the stored charge of the battery without any connection between the electrodes or any external circuit. Self-discharge decreases the shelf life of batteries and causes them to initially have less than a full charge when actually put to use. How fast self-discharge in a battery occurs is dependent on the type of battery, state of charge, charging current, ambient temperature and other factors. Primary batteries aren't designed for recharging between manufacturing and use, thus have battery chemistry that has to have a much lower self-discharge rate than older types of Secondary cells, but they have lost that advantage with the development of rechargeable Secondary Cells with very low self discharge rates like Low Self Discharge NiMH cells.

Self-discharge is a chemical reaction, just as closed-circuit discharge is, and tends to occur more quickly at higher temperatures. Storing batteries at lower temperatures thus reduces the rate of self-discharge and preserves the initial energy stored in the battery. Self-discharge increases with age, cycling and elevated temperature. Discard a battery if the self-discharge reaches 30 percent in 24 hours.

Battery Chemistry	Rechargeable	Typical Self-Discharge or Shelf Life
Lithium Metal	No	10 years shelf life (10% reduction in 5 years)
Alkaline	No	5 years shelf life (2-3% per year reduction)
Zinc–Carbon	No	2–3 years shelf life
Lithium-Ion	Yes	5% in 24h, 1–3% per month; (plus 3% for safety circuit) (ca. 4% p.m.)
Lithium-Polymer	Yes	~5% per month
Low Self-Discharge NiMH	Yes	As low as 0.25% per month
Lead–Acid	Yes	4–6% per month
Nickel–Cadmium	Yes	10–15% in 24h, then 15–20% per month
Nickel–Metal Hydride (NiMH)	Yes	30% per month

Specific Energy

This is the specific energy comparison of secondary and primary batteries showing that non-rechargeable batteries can store much more charge than their rechargeable counterparts.

Specific energy only indicates the capacity a battery can hold and does not include power

Battery Type	Rechargeable?	Wh/Kg	Self-Discharge Rate/mth
Lead Acid	Yes	30-40	3-20%
NiCd	Yes	30	10%
NiMH	Yes	100	30%
Li-Cobalt	Yes	195	~4.5%
Li-Phosphate	Yes	90-160	4.5%
Li-Manganese	Yes	150	~4.5%

delivery, a weakness with most primary batteries.

Alkaline	No	85–190	0.17%
Lithium Primary	No	150–330	1%

Depending on the load of your electronic device and how long it needs to run you may want to specifically choose whether you want a primary or rechargeable battery. The higher the Wh/Kg the longer your battery is likely to last depending on the current. Most torches are a low draw device and if it's in a BOB you won't need to recharge it before reaching your destination within 3 days if you choose a primary battery. You aren't likely to have a solar panel in your BOB anyway, they should be in an INCH bag.

Charge Cycles

A charge cycle is the process of charging a rechargeable battery and discharging it as required into a load. The term is typically used to specify a battery's expected life, as the number of charge cycles affects life more than the mere passage of time. Discharging the battery fully before recharging may be called "deep discharge"; partially discharging then recharging may be called "shallow discharge". In general, number of cycles for a rechargeable battery indicates how many times it can undergo the process of complete charging and discharging until failure or it starting to lose capacity.

Apple Inc. clarifies that a charge cycle means using all the battery's capacity, but not necessarily by discharging it from 100% to 0%: "You complete one charge cycle when you've used (discharged) an amount that equals 100% of your battery's capacity — but not necessarily all from one charge. For instance, you might use 75% of your battery's capacity one day, then recharge it fully overnight. If you use 25% the next day, you will have discharged a total of 100%, and the two days will add up to one charge cycle."

Different types and makes of batteries have different levels of charge cycles based on what they're made for. For example an Eneloop Pro is designed for high-drain devices such as camera flashes and would be inefficient if used in a clock, it also has much fewer charge cycles than other Eneloop lines. An Eneloop Lite battery is optimised for light use and would optimally be used in a clock or radio as you will be able to recharge it many more times even though the mAh is significantly less than the Eneloop Pro batteries.

Battery Type	Bty Colour	AAA Cycles	AAA mAh	AA Cycles	AA mAh	C Cycles	C mAh	D Cycles	D mAh
Eneloop Lite (2nd Gen)	Light Blue	3,000 min	550	3,000 min	950	N/A	N/A	N/A	N/A
Eneloop White (4th Gen)	White	2,100 min	750	2,100 min	1,900	1,000 min	3,000	1,000 min	5,700
Eneloop Pro (5th Gen)	Black	500 min	930	500 min	2,500	N/A	N/A	N/A	N/A

As per the table above I recommend choosing the Eneloop White batteries in your INCH bag for a good average between milliamp-hours and charge cycles, but only if you plan on recharging them. For a BOB I recommend **not** choosing rechargeable batteries as 'primary' batteries can hold a much higher charge and you'll only really be needing them for 3 days until you reach your bug out location - bring 'primary' spares just in case it takes longer than you thought to reach your destination.

Secondary Battery Comparison

This table compares the characteristics of the four commonly used rechargeable battery systems, showing average performance ratings at time of publication. Li-ion is divided into different types, named by their active materials, which are cobalt, manganese, phosphate and titanate.

Characteristic	Lead Acid	NiCd	NiMH	Li-ion Cobalt	Li-ion Manganese	Li-ion Phosphate
Specific Energy	30-50	45-80	60-120	150-250	100-150	90-120
Internal Resistance	Very Low	Very Low	Low	Moderate	Low	Very Low
Cycle Life (80% DoD)	200-300	1,000	300-500	500-1,000	500-1,000	1,000-2,000
Overcharge Tolerance	High	Moderate	Low	Low	Low	Low
Self-Discharge / Month (Room Temp)	5%	20%	30%	<5%	<5%	<5%
Cell Voltage	2V	1.2V	1.2V	3.6V	3.7V	3.2-3.3V
Charge Voltage Cut-off	2.4	Full Charge Detection		4.2	4.2	3.6
Discharge Cut-off Voltage	1.75V	1.00V	1.00V	2.5-3V	2.5-3V	2.5V
Peak Load Current - Best Result	5C 0.2	20C 1C	5C 0.5C	2C <1C	>30C <10C	>30C <10C
Charge Temperature	-20 to 50°C -4 to 122°F	0 to 45°C 32 to 113°F	0 to 45°C 32 to 113°F	0 to 45°C 32 to 113°F	0 to 45°C 32 to 113°F	0 to 45°C 32 to 113°F

Dangers

Lead	Lead is a toxic metal that can enter the body by inhalation of lead dust or ingestion when touching the mouth with lead-contaminated hands. If leaked onto the ground, acid and lead particles contaminate the soil and become airborne when dry. Children and fetuses of pregnant women are most vulnerable to lead exposure because their bodies are developing. Excessive levels of lead can affect a child's growth, cause brain damage, harm kidneys, impair hearing and induce behavioural problems. In adults, lead can cause memory loss and lower the ability to concentrate, as well as harm the reproductive system. Lead is also known to cause high blood pressure, nerve disorders, and muscle and joint pain. Researchers speculate that Ludwig van Beethoven became ill and died because of lead poisoning. Lead occurs naturally in soil at 15–40mg/kg level. This level can increase multi-fold near lead battery manufacturing and recycling plants. Soil levels in developing countries, including on the continent of Africa, recorded lead contamination levels of 40–140,000mg/kg.
Sulfuric Acid	The sulphuric acid in a lead acid battery is highly corrosive and is more harmful than acids used in most other battery systems. Contact with eye can cause permanent blindness; swallowing damages internal organs that can lead to death. First aid treatment calls for flushing the skin for 10–15 minutes with large amounts of water to cool the affected tissue and to prevent secondary damage. Immediately remove contaminated clothing and thoroughly wash the underlying skin. Always wear protective equipment when handling sulphuric acid.

Cadmium	Cadmium used in nickel-cadmium batteries is considered more harmful than lead if ingested. Workers at NiCd manufacturing plants in Japan have been experiencing health problems from prolonged exposure to the metal, and governments have banned disposal of nickel-cadmium batteries in landfills. The soft, whitish metal that occurs naturally in the soil can damage kidneys. Cadmium can be absorbed through the skin by touching a spilled battery. Since most NiCd batteries are sealed, there are no health risks in handling intact cells; caution is required when working with an open battery. Nickel-metal-hydride is considered non-toxic and the only concern is the electrolyte. Although toxic to plants, nickel is not harmful to humans. Lithium-ion is also benign — the battery contains little toxic material. Nevertheless, caution is required when working with a damaged battery. When handling a spilled battery, do not touch your mouth, nose or eyes. Wash your hands thoroughly.
Ventilation	Charging batteries in living quarters should be safe, and this also applies to lead acid. Ventilate the area regularly as you would a kitchen when cooking. Lead acid produces some hydrogen gas but the amount is minimal when charged correctly. Hydrogen gas becomes explosive at a concentration of 4 percent. This would only be achieved if large lead acid batteries were charged in a sealed room. Over-charging a lead acid battery can produce hydrogen sulphide. The gas is colourless, very poisonous, flammable and has the odour of rotten eggs. Hydrogen sulphide also occurs naturally during the breakdown of organic matter in swamps and sewers; it is present in volcanic gases, natural gas and some well waters. Being heavier than air, the gas accumulates at the bottom of poorly ventilated spaces. Although noticeable at first, the sense of smell deadens the sensation with time and potential victims may be unaware of its presence. As a simple guideline, hydrogen sulphide becomes harmful to human life if the odour is noticeable. Turn off the charger, vent the facility and stay outside until the odour disappears. Other gases that can develop during charging and the operations of lead acid batteries are arsine (arsenic hydride, AsH_3) and (antimony hydride, SbH_3). Although the levels of these metal hydrides stay well below the occupational exposure limits, they are a reminder to provide adequate ventilation.
Protection Circuits	Batteries can release high energies and the safety requirements for nickel- and lithium-based batteries and cells for portable applications are harmonized under IEC 62133. The standard came into effect in 2012 to reduce the global risk in transporting, storing and operating batteries. The most basic safety device in a battery is a fuse that opens on high current. Some fuses open permanently and render the battery useless; others are more forgiving and reset. The resistance of the positive thermal coefficient (PTC) (blue) is low during normal operation and increases when the temperature rises above a critical level to reduce current flow. The PTC is reversible and returns to high conductivity when the temperature normalizes. The current interrupt device (CID) is a fuse-type device that cuts off the electrical circuit permanently when triggered by excessive cell pressure, high temperature, or high voltage, depending on design. The last safety device is the vent that releases gas during an anomaly and can be resealed. However, the pressure of a disintegrating cell can be so large that the gases are unable to escape in an orderly way and venting with flame occurs. In some cases the top of the cell escapes like a bullet from a shotgun. Similar to a nuclear meltdown that cannot be stopped once in progress; a Li-ion battery once in disintegration should be allowed to burn out in a safe place with ventilation.
Children	Keep small batteries out of children's reach. Children younger than four are the most likely to swallow batteries, and the most common types that are ingested are button cells. Each year in the United States alone, more than 2,800 children are treated in emergency rooms for swallowing button batteries. According to a 2015 report, serious injuries and deaths from swallowing batteries have increased nine-fold in the last decade. The battery often gets stuck in the oesophagus (the tube that passes food). Water or saliva creates an electrical current that can trigger a chemical reaction producing hydroxide, a caustic ion that causes serious burns to the surrounding tissue. Doctors often misdiagnose the symptoms, which can reveal themselves as fever, vomiting, poor appetite and weariness. Batteries that make it through the oesophagus often move through the digestive tract with little or no lasting damage. The advice to a parent is to choose safe toys and to keep small batteries away from young children.
Recycling	Spent batteries should be removed from the household. Old primary cells are known to leak and cause damage to the surrounding area. Do not store old lead acid batteries where children play. Simply touching the lead poles can be harmful. Each battery chemistry has its own recycling procedure and the process begins by sorting the batteries into the correct categories. When NiCd batteries are disposed of carelessly, the metallic cell cylinder eventually corrode in the landfill. Cadmium dissolves and seeps into the water supply. Once contamination begins, authorities are helpless to stop the carnage. Nickel and the electrolyte in NiMH are semi-toxic. If no disposal service is available in an area, individual NiMH batteries can be discarded with other household waste in small quantities; however, with 10 or more batteries, the user should consider disposal them in a secure waste landfill. These batteries contain metallic lithium that reacts violently when in contact with moisture and must be disposed of appropriately. If thrown in a landfill in a charged state, heavy equipment operating on top could crush the cases and the exposed lithium could ignite a fire. Landfill fires are difficult to extinguish and can burn for years underground. Before recycling, apply a full discharge to consume the lithium content. Li-ion is reasonably harmless but spent packs should be disposed of properly. Li-ion contains harmful elements that are at the toxicity level of electronic devices.

Battery Voltage Chart

This is a battery voltage chart I created to determine how full a battery is based on its voltage. It also contains many other useful fields discussed above. Table by Fluidic Ice.

Battery Voltage to Percentage 2024-10-03

Small Batteries (<=12v)

Small batteries are those such as AAA, AA, C, D, 9v. Keep the battery at a cool temperature and out of direct sunlight. Check them occasionally if they are still charged before you require them in emergencies.

Battery Sizes

Type	Capacity	Size	Weight	Use
AAA	Alkaline: 1,200 mAh	D: 10.5mmØ L: 44.5mm	Alkaline: 11.5g (0.41 oz) Lithium: 7.6 g (0.27 oz)	
AA	Alkaline: 2,700 mAh Zinc-Carbon: 400-900 mAh	D: 14.5mmØ L: 50.5mm	Alkaline: 23g (0.81 oz) Lithium: 15 g (0.53 oz) NiMH: 31 g (1.1 oz)	
C	Alkaline: 8,000 mAh NiMH: 6,000 mAh Zinc-Carbon: 3,800 mAh	D: 26.2mmØ L: 50mm	Alkaline: 65g NiCad: 72g NiMH: 80g	
D	Alkaline: 12,000 mAh	D: 34.2mmØ L: 61.5mm	Alkaline: 135g NiCad: 105-145 NiMH: 105-160g	
9v	Alkaline: 565 mAh	L: 26.5mm W:17.5mm H: 48.5mm	Alkaline: 45g	
6v Lantern (Rectangular)	Alkaline: 26,000 mAh Carbon-Zinc: 10,500 mAh	W: 68.2mm L: 68.2mm H: 115mm		
18650	2,600-3,600 mAh	D: 18mmØ L: 68mm Protected L: 65mm Unprotected		
12 Sealed Solar	Varies	Varies	0.31kg/Ah Average	Lead Acid for radio and solar setups.
12 Sealed Car	Varies	Varies	0.31kg/Ah Average	High Instant-Discharge for 30s to start engine.

Small Battery Information
- Do not store batteries in the freezer, it does not extend the life but instead diminishes it.
- It's recommended to have D Cell Alkaline batteries for torches as they have 4x the life of AA's.
- If stored at room temperature 22°C (72°F) the battery will have 82-84% of original energy at the date.
- For greater life for consumer electronics use x D cells in series and connect to the appliance via wires.

Power Banks

Power banks can be highly useful items in a SHTF scenario due to their portability and rechargeability. Their best feature is the ability to be charged from solar panels during the day so you can use its power at night. Power banks most commonly contain the 18650 batteries and a small protection circuit against overloads. They typically have a minimum power draw of about 50mA otherwise they will sense that they aren't being used and turn off. This can be a problem when directly powering radios and LEDs.

Recharge Capacity	**Recharge Formula** (Bank Capacity x 3.7 / Output Voltage) x 0.85 / Device Capacity = Recharges	**Example (iPhone 8)** Bank Capacity - 16,000 Output Volts - 5v iPhone8 Bty - 1,821mAh (16,000 x 3.7 / 5) x 0.85 / 1821 = 5.5 Charges	**Example (Samsung S8)** Bank Capacity - 16,000 Output Volts - 5v SamsungS8 Bty - 3,000mAh (16,000 x 3.7 / 5) x 0.85 / 3000 = 3.3 Charges

Size / Storage

Educated guesses on how long each sized power bank will power a mobile for, without being recharged.

5,000mAh	A fairly small power bank. This size should be fine for charging during the day and charging at night.
10,000mAh	An average sized power bank which would provide enough power to charge mobiles multiples times over a few days.
15,000mAh	A high amount of power which should last almost a week of charges for a mobile phone.
25,000mAh	A very large power bank which will keep most mobiles constantly charged for over a week. Anything larger encroaches on the 'Power Station' terrain.

Amperage Output

5v @ 1A = 5 Watts	Will charge a device slowly
5v @ 2.4A = 12 Watts	Will charge a device faster
9-12v @ 2.4A = 21.6-28.8 Watts	A modern 'fast charger' where the voltage can vary between 9v and 12v.

LED Charge Lights

A lot of power banks come with the same type of charge indicator lights which are explained below.

Battery Level	4 LEDs	Red/Green LED
Dead	No Lights	No Lights
~0% Battery	No Lights	Solid Red LED
0-25% Battery	First light is flashing	Flashing Red LED
25-50% Battery	Second light is flashing	Flashing Red LED
50-75% Battery	Third light is flashing	Flashing Red LED
75-100% Battery	Fourth light is flashing	Flashing Red LED
100% Battery	All four lights are solid	Solid Green LED

Protection

Over Current Protection	OCP prevents too much power going into the battery pack and the power going out to the connected equipment, protecting the delicate circuitry of both devices.
Over Voltage Protection	Like OCP, OVP protects both the battery pack and the connected device by keeping the voltage within recommended safety parameters to avoid damage.
Over Discharge/Charge Protection	High-performing batteries should not be overcharged or fully discharged to prolong their life expectancy. Some battery packs consistently monitor charge states to prevent this from happening.
Extreme Temperatures	While using batteries in extreme temperatures isn't advised anywhere, it can be a good indicator of weaknesses in design and construction. Batteries which pass such stringent testing will be more durable and offer improved assurances of overall safety and performance.

Large Batteries (12v+)

Large batteries are those which generally have capacities over 1Ah and power larger electronics such as cars or golf buggies. They are also used for off-grid home power sources which generally consist of an array of batteries connected in series and parallel.

Tables and important information relevant to 12v batteries.	**12v Charge Voltage** 100%: 12.7v 80%: 12.4v 60%: 12.2v 40%: 11.9v 20%: 11.5v 0%: 10.5v	**Battery Weight (0.31kg/Ah Average)** 20Ah: ~6.2kg 50Ah: ~16kg 100Ah: ~31kg 150Ah: ~42kg 200Ah: ~62kg 250Ah: ~72kg	**Depth of Discharge** 100% DOD: 250 Discharges 50% DOD: 625 Discharges 30% DOD: 1600 Discharges This shows the number of discharges before the battery dies - based on how deeply the battery is discharged.

Large Battery Storage
Deep cycle batteries can tolerate deep discharges and car batteries are supposed to be constantly topped up. Batteries will always eventually fail in SHTF, it just may take some time. The Nickel Iron/Edison Battery lasts the longest.

Connections

Series Connection	Connecting the opposite polarities together increases the voltage but not the capacity.
Parallel Connection	Connecting the same polarities together increases the capacity but not the voltage.
Series/Parallel Connection	Connect first the series and then parallel batteries to increase both capacities.

Tips

- Keep the battery at a cool temperature and out of direct sunlight.
- 1 Ah = 1 amp per hour at the designated voltage.
- Choose a deep cycle battery for camping as they won't leak, have thick walls and can be greatly discharged without much capability loss.
- Don't discharge more then 50-70% as they will last longer and provide backup power in case it can't be charged. Ideal = 30% used.
- Discharging below 20% will have a devastating effect on the battery.
- Wire in parallel by connecting same polarities together = 12v, Doubles the duration
- Wire in series by connecting the opposite polarities together = 24v, Halves the duration.
- Car batteries give large current for a short time. Deep cycle batteries give a steady current for a long time.

Integrated Batteries

Integrated batteries are any batteries that are used in a modern device that are rarely replaced. Below is a list of common mobile phones and the size of the batteries so you can calculate the number of recharges from power banks. Some phone batteries such as in the Galaxy S5 can be swapped out easily but are still considered integrated as they generally aren't.

Phones

Apple

Power Stations

Power stations are essentially heavy duty power banks, often having large batteries that can can power 240/120v devices. The advantages over generators is that they are silent and can be recharged by solar power. The disadvantages include having to wait for them to recharge unlike simply refilling the fuel tank. Their ideal use is for taking on camping trips and campervans to power fridges, coffee makers and to recharge your mobile devices.

They generally have at least one AC wall-plug, a 12v DC Car Port, a few USB ports, a digital display and an input port for charging it via solar and/or AC. These kinds of power banks are often very heavy ranging from 3kg up to 20kg due to the battery they contain.

Below is an estimated guide to appliance run-time. X's indicate that this size power station can't run this appliance due to not meeting the minimum energy draw.

Appliance Running Time Guide (in hours)

Appliance	200W Station	300W Station	500W Station	1000W Station	1500W Station
Laptop	3.5	5.4	10.75	21.5	29.7
Tablet	35.6	54	107.5	215	297
Fridge (Medium)	1.7	2.7	5.4	10.8	14.9
Freezer	5.9	9	17.9	35.8	49.5
Washing Machine (1200W Min)	X	X	X	2.2	3
Vacuum Cleaner	X	X	1.2	2.4	3.3
Water Filter and Cooler	2.5	3.9	7.7	15.4	21.2
Radio	35.6	54	107.5	215	297
Home Phone	59.4	90	179	358	495
Electric Kettle	X	X	X	X	1.2
LED Light Bulb	25.4	38.6	76.8	153.6	212.1
Phone Charger	17.8	27	53.75	107.5	148.5
65" LED TV	1.5	2.3	4.5	9	12.4

Battery Arrays

Battery arrays are a set of non-portable batteries used for powering caravans or homesteads. They generally consist of deep cycle marine batteries in a series of 2-48 batteries, however they can be in any configuration you wish.

8 Componentry

An electronic component is any basic discrete device or physical entity in an electronic system used to affect electrons or their associated fields. Electronic components have a number of electrical terminals or leads. These leads connect to create an electronic circuit with a particular function (for example an amplifier, radio receiver, or oscillator). This sections aims to give you the ability to recognise components and repair essential electronics if they break down during a disaster or even create your own using the schematics below.

These are the different classifications of components in electronics.

Wire	The basic source of electrical transmission, wires come in a huge range of types, sizes and styles.
Active Components	Rely on a source of energy (usually from the DC circuit) and usually can inject power into a circuit, though this is not part of the definition.
Passive Components	Can't introduce net energy into the circuit or rely on a source of power, except for what is available from the (AC) circuit they are connected to. As a consequence they can't amplify (increase the power of a signal), although they may increase a voltage or current (such as is done by a transformer or resonant circuit). Passive components include two-terminal components such as resistors, capacitors, inductors, and transformers.
Electromechanical Components	Carries out electrical operations by using moving parts or by using electrical connections

Wire

Everything wire related is in this section.

Wiring Selector Chart

This is a chart I created to determine what type of cable is needed for an electrical project.

Electrical Cable Specifications & Conversions

Active Components

Semiconductors

Diode	A diode is a two-terminal electronic component that conducts current primarily in one direction (asymmetric conductance); it has low (ideally zero) resistance in one direction, and high (ideally infinite) resistance in the other. A diode vacuum tube or thermionic diode is a vacuum tube with two electrodes, a heated cathode and a plate, in which electrons can flow in only one direction, from cathode to plate. A semiconductor diode, the most common type today, is a crystalline piece of semiconductor material with a p–n junction connected to two electrical terminals.
Rectifier	A rectifier is an electrical device that converts alternating current (AC), which periodically reverses direction, to direct current (DC), which flows in only one direction. The process is known as rectification, since it "straightens" the direction of current. Physically, rectifiers take a number of forms, including vacuum tube diodes, mercury-arc valves, stacks of copper and selenium oxide plates, semiconductor diodes, silicon-controlled rectifiers and other silicon-based semiconductor switches.
Bridge Rectifier	A diode bridge is an arrangement of four (or more) diodes in a bridge circuit configuration that provides the same polarity of output for either polarity of input. When used in its most common application, for conversion of an alternating-current (AC) input into a direct-current (DC) output, it is known as a bridge rectifier. A bridge rectifier provides full-wave rectification from a two-wire AC input, resulting in lower cost and weight as compared to a rectifier with a 3-wire input from a transformer with a centre-tapped secondary winding.
Light-Emitting Diode	A light-emitting diode (LED) is a two-lead semiconductor light source. It is a p–n junction diode that emits light when activated. When a suitable current is applied to the leads, electrons are able to recombine with electron holes within the device, releasing energy in the form of photons. This effect is called electroluminescence, and the colour of the light (corresponding to the energy of the photon) is determined by the energy band gap of the semiconductor. LEDs are typically small (less than 1 mm2) and integrated optical components may be used to shape the radiation pattern. Appearing as practical electronic components in 1962, the earliest LEDs emitted low-intensity infrared light. Infrared LEDs are still frequently used as transmitting elements in remote-control circuits, such as those in remote controls for a wide variety of consumer electronics. The first visible-light LEDs were of low intensity and limited to red. Modern LEDs are available across the visible, ultraviolet, and infrared wavelengths, with very high brightness.

Photodiode

A photodiode is a semiconductor device that converts light into an electrical current. The current is generated when photons are absorbed in the photodiode. Photodiodes may contain optical filters, built-in lenses, and may have large or small surface areas. Photodiodes usually have a slower response time as their surface area increases. The common, traditional solar cell used to generate electric solar power is a large area photodiode. Photodiodes are similar to regular semiconductor diodes except that they may be either exposed (to detect vacuum UV or X-rays) or packaged with a window or optical fibre connection to allow light to reach the sensitive part of the device. Many diodes designed for use specifically as a photodiode use a PIN junction rather than a p–n junction, to increase the speed of response. A photodiode is designed to operate in reverse bias.

Avalanche Photodiode	An avalanche photodiode (APD) is a highly sensitive semiconductor electronic device that exploits the photoelectric effect to convert light to electricity. APDs can be thought of as photodetectors that provide a built-in first stage of gain through avalanche multiplication. From a functional standpoint, they can be regarded as the semiconductor analog photomultipliers. By applying a high reverse bias voltage (typically 100–200 V in silicon), APDs show an internal current gain effect (around 100) due to impact ionization (avalanche effect). However, some silicon APDs employ alternative doping and beveling techniques compared to traditional APDs that allow greater voltage to be applied (> 1500 V) before breakdown is reached and hence a greater operating gain (> 1000). In general, the higher the reverse voltage, the higher the gain. Among the various expressions for the APD multiplication factor (M), an instructive expression is given by the formula.

Solar Cell, Photovoltaic Cell, PV array	A solar cell, or photovoltaic cell, is an electrical device that converts the energy of light directly into electricity by the photovoltaic effect, which is a physical and chemical phenomenon. It is a form of photoelectric cell, defined as a device whose electrical characteristics, such as current, voltage, or resistance, vary when exposed to light. Individual solar cell devices can be combined to form modules, otherwise known as solar panels. In basic terms a single junction silicon solar cell can produce a maximum open-circuit voltage of approximately 0.5 to 0.6 volts. Solar cells are described as being photovoltaic, irrespective of whether the source is sunlight or an artificial light. They are used as a photodetector (for example infrared detectors), detecting light or other electromagnetic radiation near the visible range, or measuring light intensity. In contrast, a solar thermal collector supplies heat by absorbing sunlight, for the purpose of either direct heating or indirect electrical power generation from heat. A "photoelectrolytic cell" (photoelectrochemical cell), on the other hand, refers either to a type of photovoltaic cell, or to a device that splits water directly into hydrogen and oxygen using only solar illumination.
Constant-Current Diode	Constant-current diode is an electronic device that limits current to a maximal specified value for the device. It is known as current-limiting diode (CLD), current-regulating diode (CRD). These diodes consist of an n-channel JFET with the gate shorted to the source, which functions like a two-terminal current limiter or current source (analogous to a voltage-limiting Zener diode). They allow a current through them to rise to a certain value, and then level off at a specific value. Unlike Zener diodes, these diodes keep the current constant instead of the voltage constant. These devices keep the current flowing through them unchanged when the voltage changes.
Peltier Cooler	Thermoelectric cooling uses the Peltier effect to create a heat flux between the junction of two different types of materials. A Peltier cooler, heater, or thermoelectric heat pump is a solid-state active heat pump which transfers heat from one side of the device to the other, with consumption of electrical energy, depending on the direction of the current. Such an instrument is also called a Peltier device, Peltier heat pump, solid state refrigerator, or thermoelectric cooler (TEC). It can be used either for heating or for cooling, although in practice the main application is cooling. It can also be used as a temperature controller that either heats or cools. This technology is far less commonly applied to refrigeration than vapour-compression refrigeration is. The primary advantages of a Peltier cooler compared to a vapour-compression refrigerator are its lack of moving parts or circulating liquid, very long life, invulnerability to leaks, small size, and flexible shape. Its main disadvantages are high cost and poor power efficiency. Many researchers and companies are trying to develop Peltier coolers that are cheap and efficient. A Peltier cooler can also be used as a thermoelectric generator. When operated as a cooler, a voltage is applied across the device, and as a result, a difference in temperature will build up between the two sides. When operated as a generator, one side of the device is heated to a temperature greater than the other side, and as a result, a difference in voltage will build up between the two sides (the Seebeck effect).

Transistors

A transistor is a semiconductor device used to amplify or switch electronic signals and electrical power. It is composed of semiconductor material usually with at least three terminals for connection to an external circuit. A voltage or current applied to one pair of the transistor's terminals controls the current through another pair of terminals. Because the controlled (output) power can be higher than the controlling (input) power, a transistor can amplify a signal.

Bipolar Junction Transistor	A bipolar junction transistor (bipolar transistor or BJT) is a type of transistor that uses both electron and hole charge carriers. In contrast, unipolar transistors, such as field-effect transistors, only use one kind of charge carrier. The basic function of a BJT is to amplify current. This allows BJTs to be used as amplifiers or switches, giving them wide applicability in electronic equipment, including computers, televisions, mobile phones, audio amplifiers, industrial control, and radio transmitters.
Photo Transistor	A photodiode is a semiconductor device that converts light into an electrical current. The current is generated when photons are absorbed in the photodiode. Photodiodes may contain optical filters, built-in lenses, and may have large or small surface areas. Photodiodes usually have a slower response time as their surface area increases. The common, traditional solar cell used to generate electric solar power is a large area photodiode. Photodiodes are similar to regular semiconductor diodes except that they may be either exposed (to detect vacuum UV or X-rays) or packaged with a window or optical fibre connection to allow light to reach the sensitive part of the device. Many diodes designed for use specifically as a photodiode use a PIN junction rather than a p–n junction, to increase the speed of response. A photodiode is designed to operate in reverse bias.

Field-Effect Transistor

The field-effect transistor (FET) is a transistor that uses an electric field to control the electrical behaviour of the device. FETs are also known as unipolar transistors since they involve single-carrier-type operation. Many different implementations of field effect transistors exist. Field effect transistors generally display very high input impedance at low frequencies. The conductivity between the drain and source terminals is controlled by an electric field in the device, which is generated by the voltage difference between the source and the gate of the device.

JFET	The junction gate field-effect transistor (JFET or JUGFET) is one of the simple type of field-effect transistor. JFETs are three-terminal semiconductor devices that can be used as electronically-controlled switches, amplifiers, or voltage-controlled resistors. A JFET is usually ON when there is no potential difference between its gate and source terminals.
MOSFET	The metal-oxide-semiconductor field-effect transistor (MOSFET, MOS-FET, or MOS FET) is a type of field-effect transistor (FET), most commonly fabricated by the controlled oxidation of silicon. It has an insulated gate, whose voltage determines the conductivity of the device. This ability to change conductivity with the amount of applied voltage can be used for amplifying or switching electronic signals. The MOSFET is by far the most common transistor in digital circuits, as billions may be included in a memory chip or microprocessor.

Thyristors

A thyristor is a solid-state semiconductor device with four layers of alternating P- and N-type materials. It acts exclusively as a bistable switch, conducting when the gate receives a current trigger, and continuing to conduct until the voltage across the device is reversed biased, or until the voltage is removed (by some other means). A three-lead thyristor is designed to control the larger current of the Anode to Cathode path by controlling that current with the smaller current of its other lead, known as its Gate. In contrast, a two-lead thyristor is designed to switch on if the potential difference between its leads is sufficiently large (breakdown voltage). Thyristors may be used in power-switching circuits, relay-replacement circuits, inverter circuits, oscillator circuits, level-detector circuits, chopper circuits, light-dimming circuits, low-cost timer circuits, logic circuits, speed-control circuits, phase-control circuits, etc.

Integrated Circuits

Digital Electronics	Digital electronics or digital (electronic) circuits are electronics that operate on digital signals. In contrast, analog circuits manipulate analog signals whose performance is more subject to manufacturing tolerance, signal attenuation and noise. Digital techniques are helpful because it is a lot easier to get an electronic device to switch into one of a number of known states than to accurately reproduce a continuous range of values. Digital electronic circuits are usually made from large assemblies of logic gates (often printed on integrated circuits), simple electronic representations of Boolean logic functions.

Analog	Analogue electronics (American English: analog electronics) are electronic systems with a continuously variable signal, in contrast to digital electronics where signals usually take only two levels. The term "analogue" describes the proportional relationship between a signal and a voltage or current that represents the signal. The word analogue is derived from the Greek word ανάλογος (analogous) meaning "proportional". An analogue signal uses some attribute of the medium to convey the signal's information. For example, an aneroid barometer uses the angular position of a needle as the signal to convey the information of changes in atmospheric pressure. Electrical signals may represent information by changing their voltage, current, frequency, or total charge. Information is converted from some other physical form (such as sound, light, temperature, pressure, position) to an electrical signal by a transducer which converts one type of energy into another (e.g. a microphone).

Current Sensor	A current sensor is a device that detects electric current in a wire, and generates a signal proportional to that current. The generated signal could be analog voltage or current or even a digital output. The generated signal can be then used to display the measured current in an ammeter, or can be stored for further analysis in a data acquisition system, or can be used for the purpose of control. The sensed current and the output signal can be:	**Alternating Current Input** • Analog output, which duplicates the wave shape of the sensed current. • Bipolar output, which duplicates the wave shape of the sensed current. • Unipolar output, which is proportional to the average or RMS value of the sensed current.	**Direct Current Input** • Unipolar, with a unipolar output, which duplicates the wave shape of the sensed current • Digital output, which switches when the sensed current exceeds a certain threshold

Optoelectronic Devices

Optoelectronics is the study and application of electronic devices and systems that source, detect and control light, usually considered a sub-field of photonics. In this context, light often includes invisible forms of radiation such as gamma rays, X-rays, ultraviolet and infrared, in addition to visible light. Optoelectronic devices are electrical-to-optical or optical-to-electrical transducers, or instruments that use such devices in their operation. Electro-optics is often erroneously used as a synonym, but is a wider branch of physics that concerns all interactions between light and electric fields, whether or not they form part of an electronic device. Optoelectronics is based on the quantum mechanical effects of light on electronic materials, especially semiconductors, sometimes in the presence of electric fields.	**Photoelectric or Photovoltaic Effect Uses** • Photodiodes (including solar cells) • Phototransistors • photomultipliers • Optoisolators • Integrated optical circuit (IOC) elements	**Photoconductivity Uses** • Photoresistors • Photoconductive camera tubes • Charge-coupled imaging devices

LED Display	An LED display is a flat panel display, which uses an array of light-emitting diodes as pixels for a video display. Their brightness allows them to be used outdoors where they are visible in the sun for store signs and billboards, and in recent years they have also become commonly used in destination signs on public transport vehicles, as well as variable-message signs on highways. LED displays are capable of providing general illumination in addition to visual display, as when used for stage lighting or other decorative (as opposed to informational) purposes.

Display Technologies

Filament Lamp	An incandescent light bulb, incandescent lamp or incandescent light globe is an electric light with a wire filament heated to such a high temperature that it glows with visible light (incandescence). The filament is protected from oxidation with a glass or fused quartz bulb that is filled with inert gas or a vacuum. In a halogen lamp, filament evaporation is slowed by a chemical process that redeposits metal vapour onto the filament, thereby extending its life. The light bulb is supplied with electric current by feed-through terminals or wires embedded in the glass. Most bulbs are used in a socket which provides mechanical support and electrical connections. They require no external regulating equipment, have low manufacturing costs, and work equally well on either alternating current or direct current. As a result, the incandescent bulb is widely used in household and commercial lighting, for portable lighting such as table lamps, car headlamps, and flashlights, and for decorative and advertising lighting. Incandescent bulbs are much less efficient than other types of electric lighting; incandescent bulbs convert less than 5% of the energy they use into visible light, with standard light bulbs averaging about 2.2%. The remaining energy is converted into heat. Incandescent bulbs typically have short lifetimes compared with other types of lighting; around 1,000 hours for home light bulbs versus typically 10,000 hours for compact fluorescents and 30,000 hours for lighting LEDs.
Vacuum Fluorescent Display	A vacuum fluorescent display (VFD) is a display device used commonly on consumer electronics equipment such as video cassette recorders, car radios, and microwave ovens. A VFD operates on the principle of cathodoluminescence, roughly similar to a cathode ray tube, but operating at much lower voltages. Each tube in a VFD has a phosphor coated anode that is bombarded by electrons emitted from the cathode filament. Standard illumination figures for VFDs are around 640 cd/m2 with high-brightness VFDs operating at 4,000 cd/m2, and experimental units as high as 35,000 cd/m2 depending on the drive voltage and its timing. The choice of colour (which determines the nature of the phosphor) and display brightness significantly affect the lifetime of the tubes, which can range from as low as 1,500 hours for a vivid red VFD to 30,000 hours for the more common green ones. VFDs can display seven-segment numerals, multi-segment alpha-numeric characters or can be made in a dot-matrix to display different alphanumeric characters and symbols.
Cathode Ray Tube	The cathode ray tube (CRT) is a vacuum tube that contains one or more electron guns and a phosphorescent screen, and is used to display images. It modulates, accelerates, and deflects electron beam(s) onto the screen to create the images. The images may represent electrical waveforms (oscilloscope), pictures (television, computer monitor), radar targets, or other phenomena. CRTs have also been used as memory devices, in which case the visible light emitted from the fluorescent material (if any) is not intended to have significant meaning to a visual observer (though the visible pattern on the tube face may cryptically represent the stored data). In television sets and computer monitors, the entire front area of the tube is scanned repetitively and systematically in a fixed pattern called a raster. An image is produced by controlling the intensity of each of the three electron beams, one for each additive primary colour (red, green, and blue) with a video signal as a reference. In all modern CRT monitors and televisions, the beams are bent by magnetic deflection, a varying magnetic field generated by coils and driven by electronic circuits around the neck of the tube.
LCD	A liquid-crystal display (LCD) is a flat-panel display or other electronically modulated optical device that uses the light-modulating properties of liquid crystals. Liquid crystals do not emit light directly, instead using a backlight or reflector to produce images in colour or monochrome. LCDs are available to display arbitrary images or fixed images with low information content, which can be displayed or hidden, such as preset words, digits, and seven-segment displays, as in a digital clock. They use the same basic technology, except that arbitrary images are made up of a large number of small pixels, while other displays have larger elements. LCDs are used in a wide range of applications including LCD televisions, computer monitors, instrument panels, aircraft cockpit displays, and indoor and outdoor signage. Small LCD screens are common in portable consumer devices such as digital cameras, watches, calculators, and mobile telephones, including smartphones. Since LCD screens do not use phosphors, they rarely suffer image burn-in when a static image is displayed on a screen for a long time, e.g., the table frame for an airline flight schedule on an indoor sign. LCDs are, however, susceptible to image persistence. The LCD screen is more energy-efficient and can be disposed of more safely than a CRT can. Its low electrical power consumption enables it to be used in battery-powered electronic equipment more efficiently than CRTs can be.

Neon	Neon lighting consists of brightly glowing, electrified glass tubes or bulbs that contain rarefied neon or other gases. Neon lights are a type of cold cathode gas-discharge light. A neon tube is a sealed glass tube with a metal electrode at each end, filled with one of a number of gases at low pressure. A high potential of several thousand volts applied to the electrodes ionizes the gas in the tube, causing it to emit colored light. The color of the light depends on the gas in the tube. Neon lights were named for neon, a noble gas which gives off a popular orange light, but other gases and chemicals are used to produce other colors, such as hydrogen (red), helium (yellow), carbon dioxide (white), and mercury (blue). Neon tubes can be fabricated in curving artistic shapes, to form letters or pictures. They are mainly used to make dramatic, multicolored glowing signage for advertising, called neon signs, which were popular from the 1920s to the 1950s.
LED	A light-emitting diode (LED) is a two-lead semiconductor light source. It is a p–n junction diode that emits light when activated. When a suitable current is applied to the leads, electrons are able to recombine with electron holes within the device, releasing energy in the form of photons. This effect is called electroluminescence, and the colour of the light (corresponding to the energy of the photon) is determined by the energy band gap of the semiconductor. LEDs are typically small (less than 1 mm2) and integrated optical components may be used to shape the radiation pattern. Appearing as practical electronic components in 1962, the earliest LEDs emitted low-intensity infrared light. Infrared LEDs are still frequently used as transmitting elements in remote-control circuits, such as those in remote controls for a wide variety of consumer electronics. The first visible-light LEDs were of low intensity and limited to red. Modern LEDs are available across the visible, ultraviolet, and infrared wavelengths, with very high brightness.
Plasma Display	A plasma display panel (PDP) is a type of flat panel display common to large TV displays 30 inches (76 cm) or larger. They are called "plasma" displays because they use small cells containing electrically charged ionized gases, which are plasmas. Plasma displays have lost nearly all market share, mostly due to competition from low-cost LCD and more expensive but high-contrast OLED flat-panel displays. Plasma displays are bright (1,000 lux or higher for the module), have a wide colour gamut, and can be produced in fairly large sizes—up to 3.8 metres (150 in) diagonally. They had a very low-luminance "dark-room" black level compared with the lighter grey of the unilluminated parts of an LCD screen (as plasma panels are locally lit and do not require a backlight, blacks are blacker on plasmas and greyer on LCDs).

Optical Detectors & Emitters

Photodetectors, also called photosensors, are sensors of light or other electromagnetic radiation. A photo detector has a p–n junction that converts light photons into current. The absorbed photons make electron–hole pairs in the depletion region. Photodiodes and photo transistors are a few examples of photo detectors. Solar cells convert some of the light energy absorbed into electrical energy.

Phototube or Photodiode	A phototube or photoelectric cell is a type of gas-filled or vacuum tube that is sensitive to light. Such a tube is more correctly called a 'photoemissive cell' to distinguish it from photovoltaic or photoconductive cells. Phototubes were previously more widely used but are now replaced in many applications by solid state photodetectors. The photomultiplier tube is one of the most sensitive light detectors, and is still widely used in physics research. Phototubes operate according to the photoelectric effect: Incoming photons strike a photocathode, knocking electrons out of its surface, which are attracted to an anode. Thus current is dependent on the frequency and intensity of incoming photons. Unlike photomultiplier tubes, no amplification takes place, so the current through the device is typically of the order of a few microamperes. The light wavelength range over which the device is sensitive depends on the material used for the photoemissive cathode. A caesium-antimony cathode gives a device that is very sensitive in the violet to ultra-violet region with sensitivity falling off to blindness to red light. Caesium on oxidised silver gives a cathode that is most sensitive to infra-red to red light, falling off towards blue, where the sensitivity is low but not zero.

Power Sources

Battery	An electric battery is a device consisting of one or more electrochemical cells with external connections provided to power electrical devices such as flashlights, smartphones, and electric cars. When a battery is supplying electric power, its positive terminal is the cathode and its negative terminal is the anode. The terminal marked negative is the source of electrons that when connected to an external circuit will flow and deliver energy to an external device. When a battery is connected to an external circuit, electrolytes are able to move as ions within, allowing the chemical reactions to be completed at the separate terminals and so deliver energy to the external circuit. It is the movement of those ions within the battery which allows current to flow out of the battery to perform work. Historically the term "battery" specifically referred to a device composed of multiple cells, however the usage has evolved additionally to include devices composed of a single cell. Primary (single-use or "disposable") batteries are used once and discarded; the electrode materials are irreversibly changed during discharge. Common examples are the alkaline battery used for flashlights and a multitude of portable electronic devices. Secondary (rechargeable) batteries can be discharged and recharged multiple times using an applied electric current; the original composition of the electrodes can be restored by reverse current.
Fuel Cell	A fuel cell is an electrochemical cell that converts the chemical energy from a fuel into electricity through an electrochemical reaction of hydrogen fuel with oxygen or another oxidizing agent. Fuel cells are different from batteries in requiring a continuous source of fuel and oxygen (usually from air) to sustain the chemical reaction, whereas in a battery the chemical energy comes from chemicals already present in the battery. Fuel cells can produce electricity continuously for as long as fuel and oxygen are supplied. The first fuel cells were invented in 1838. The first commercial use of fuel cells came more than a century later in NASA space programs to generate power for satellites and space capsules. Since then, fuel cells have been used in many other applications. Fuel cells are used for primary and backup power for commercial, industrial and residential buildings and in remote or inaccessible areas. They are also used to power fuel cell vehicles, including forklifts, automobiles, buses, boats, motorcycles and submarines. In addition to electricity, fuel cells produce water, heat and, depending on the fuel source, very small amounts of nitrogen dioxide and other emissions. The energy efficiency of a fuel cell is generally between 40–60%; however, if waste heat is captured in a cogeneration scheme, efficiencies up to 85% can be obtained.
Power Supply	A power supply is an electrical device that supplies electric power to an electrical load. The primary function of a power supply is to convert electric current from a source to the correct voltage, current, and frequency to power the load. As a result, power supplies are sometimes referred to as electric power converters. Some power supplies are separate standalone pieces of equipment, while others are built into the load appliances that they power. Examples of the latter include power supplies found in desktop computers and consumer electronics devices. Other functions that power supplies may perform include limiting the current drawn by the load to safe levels, shutting off the current in the event of an electrical fault, power conditioning to prevent electronic noise or voltage surges on the input from reaching the load, power-factor correction, and storing energy so it can continue to power the load in the event of a temporary interruption in the source power.

All power supplies have a power input connection, which receives energy in the form of electric current from a source, and one or more power output connections that deliver current to the load. The source power may come from the electric power grid, such as an electrical outlet, energy storage devices such as batteries or fuel cells, generators or alternators, solar power converters, or another power supply.

The input and output are usually hardwired circuit connections, though some power supplies employ wireless energy transfer to power their loads without wired connections. Some power supplies have other types of inputs and outputs as well, for functions such as external monitoring and control.

Photo Voltaic Device (Solar)	A solar cell, or photovoltaic cell, is an electrical device that converts the energy of light directly into electricity by the photovoltaic effect, which is a physical and chemical phenomenon. It is a form of photoelectric cell, defined as a device whose electrical characteristics, such as current, voltage, or resistance, vary when exposed to light. Individual solar cell devices can be combined to form modules, otherwise known as solar panels. In basic terms a single junction silicon solar cell can produce a maximum open-circuit voltage of approximately 0.5 to 0.6 volts. Solar cells are described as being photovoltaic, irrespective of whether the source is sunlight or an artificial light.	**The operation of a photovoltaic (PV) cell requires three basic attributes:** • The absorption of light, generating either electron-hole pairs or excitons. • The separation of charge carriers of opposite types. • The separate extraction of those carriers to an external circuit.

They are used as a photodetector (for example infrared detectors), detecting light or other electromagnetic radiation near the visible range, or measuring light intensity. In contrast, a solar thermal collector supplies heat by absorbing sunlight, for the purpose of either direct heating or indirect electrical power generation from heat.

A "photoelectrolytic cell" (photoelectrochemical cell), on the other hand, refers either to a type of photovoltaic cell (like that developed by Edmond Becquerel and modern dye-sensitized solar cells), or to a device that splits water directly into hydrogen and oxygen using only solar illumination.

Thermo Electric Generator	A thermoelectric generator (TEG), also called a Seebeck generator, is a solid state device that converts heat flux (temperature differences) directly into electrical energy through a phenomenon called the Seebeck effect (a form of thermoelectric effect). Thermoelectric generators function like heat engines, but are less bulky and have no moving parts. However, TEGs are typically more expensive and less efficient. Thermoelectric generators could be used in power plants in order to convert waste heat into additional electrical power and in automobiles as automotive thermoelectric generators (ATGs) to increase fuel efficiency. Another application is radioisotope thermoelectric generators which are used in space probes, which has the same mechanism but use radioisotopes to generate the required heat difference.
Electrical Generator	In electricity generation, a generator is a device that converts motive power (mechanical energy) into electrical power for use in an external circuit. Sources of mechanical energy include steam turbines, gas turbines, water turbines, internal combustion engines and even hand cranks. Generators provide nearly all of the power for electric power grids. The reverse conversion of electrical energy into mechanical energy is done by an electric motor, and motors and generators have many similarities. Many motors can be mechanically driven to generate electricity and frequently make acceptable manual generators.
Piezoelectric Generator	Direct piezoelectricity of some substances, like quartz, can generate potential differences of thousands of volts. The best-known application is the electric cigarette lighter: pressing the button causes a spring-loaded hammer to hit a piezoelectric crystal, producing a sufficiently high-voltage electric current that flows across a small spark gap, thus heating and igniting the gas. The portable sparkers used to ignite gas stoves work the same way, and many types of gas burners now have built-in piezo-based ignition systems. A similar idea is being researched by DARPA in the United States in a project called Energy Harvesting, which includes an attempt to power battlefield equipment by piezoelectric generators embedded in soldiers' boots. However, these energy harvesting sources by association affect the body. DARPA's effort to harness 1–2 watts from continuous shoe impact while walking were abandoned due to the impracticality and the discomfort from the additional energy expended by a person wearing the shoes. Other energy harvesting ideas include harvesting the energy from human movements in train stations or other public places and converting a dance floor to generate electricity. Vibrations from industrial machinery can also be harvested by piezoelectric materials to charge batteries for backup supplies or to power low-power microprocessors and wireless radios.

Passive Components

Resistors

Power Resistor	Power resistors are designed to withstand and dissipate large amounts of power. In general they have a power rating of at least 5 Watt. They are made from materials with a high thermal conductivity, allowing efficient cooling. They are often designed to be coupled with heat sinks to be able to dissipate the high amount of power. Some might even need forced air or liquid cooling while under maximum load. Some are wire wound, some are made from wire grids for ease of cooling, but the common thing for all power resistors is that they are built to dissipate the most power while keeping their size as small as possible. An example use for power resistors are load banks used to dissipate power generated during engine braking in vehicles using electrical motors, such as locomotives or trams.
Wirewound Resistors	Wire wound resistors are made by winding a metal wire around a solid form, often made of ceramic, fibreglass or plastic. Metal caps are attached to the end of the winding and metallic leads are attached to the ends. The end product is often coated with a non-conductive paint or enamel to offer some protection from the environment. Wire wound resistors can be built to withstand high temperatures, sometimes up to 450 °C. These resistors are often built to tight tolerances thanks to the material used, an alloy of nickel and chrome called Nichrome. The body of the device is then coated with a non-conductive paint, enamel or plastic.
Chip/SMD Resistors	Chip resistors are resistors which look like integrated circuit chips. Surface mount power resistors are made from many different materials, such as pressed carbon, ceramics and metal (cermet resistors) or metal foil. Wire wound chip resistors are also available. SMD resistors are actually smaller form, surface mounted chip resistors. The resistor itself consists of a metal oxide film deposited onto a ceramic substrate. The thickness and length of film determines the resistance. They have power dissipation ratings much lower than those of grid resistors or water resistors and can usually dissipate no more than a few watts, provided they have appropriate cooling.

Variable Resistors

Potentiometer	A potentiometer is a three-terminal resistor with a sliding or rotating contact that forms an adjustable voltage divider. If only two terminals are used, one end and the wiper, it acts as a variable resistor or rheostat. The measuring instrument called a potentiometer is essentially a voltage divider used for measuring electric potential (voltage); the component is an implementation of the same principle, hence its name. Potentiometers are commonly used to control electrical devices such as volume controls on audio equipment. Potentiometers operated by a mechanism can be used as position transducers, for example, in a joystick. Potentiometers are rarely used to directly control significant power (more than a watt), since the power dissipated in the potentiometer would be comparable to the power in the controlled load.
Thermistor	A thermistor is a type of resistor whose resistance is dependent on temperature, more so than in standard resistors. The word is a portmanteau of thermal and resistor. Thermistors are widely used as inrush current limiters, temperature sensors (negative temperature coefficient or NTC type typically), self-resetting overcurrent protectors, and self-regulating heating elements (positive temperature coefficient or PTC type typically). Thermistors are of two opposite fundamental types: With NTC thermistors, resistance decreases as temperature rises. An NTC is commonly used as a temperature sensor, or in series with a circuit as an inrush current limiter. With PTC thermistors, resistance increases as temperature rises. PTC thermistors are commonly installed in series with a circuit, and used to protect against overcurrent conditions, as resettable fuses. Thermistors differ from resistance temperature detectors (RTDs) in that the material used in a thermistor is generally a ceramic or polymer, while RTDs use pure metals. The thermistors are in the form of beads, rods and discs but RTDs are in different shapes and sizes. The temperature response is also different; RTDs are useful over larger temperature ranges, while thermistors typically achieve a greater precision within a limited temperature range, typically −90 °C to 130 °C.

Humistor	A humistor is a type of variable resistor whose resistance varies based on humidity. A capacitive humidity sensor detects humidity based on a change of capacitance between two detection electrodes provided on a semiconductor substrate. The capacitance type humidity sensor detects humidity by measuring the change in the electrostatic capacity of an element corresponding to the ambient humidity. A resistive humidity sensor detects relative humidity by measuring the change in the resistance of an element corresponding to the ambient humidity. Most of the resistance type humidity sensors include an electrolytic, polymeric, or metallic oxide sensor element. An impedance humidity sensor changes its electrical impedance as the humidity of the surrounding environment changes, and the measured impedance is converted into humidity readings.
Photoresistor	A photoresistor (or light-dependent resistor, LDR, or photo-conductive cell) is a light-controlled variable resistor. The resistance of a photoresistor decreases with increasing incident light intensity; in other words, it exhibits photoconductivity. A photoresistor can be applied in light-sensitive detector circuits, and light-activated and dark-activated switching circuits. A photoresistor is made of a high resistance semiconductor. In the dark, a photoresistor can have a resistance as high as several megohms (MΩ), while in the light, a photoresistor can have a resistance as low as a few hundred ohms. If incident light on a photoresistor exceeds a certain frequency, photons absorbed by the semiconductor give bound electrons enough energy to jump into the conduction band. The resulting free electrons (and their hole partners) conduct electricity, thereby lowering resistance. The resistance range and sensitivity of a photoresistor can substantially differ among dissimilar devices.

Moreover, unique photoresistors may react substantially differently to photons within certain wavelength bands. A photoelectric device can be either intrinsic or extrinsic. An intrinsic semiconductor has its own charge carriers and is not an efficient semiconductor, for example, silicon. In intrinsic devices the only available electrons are in the valence band, and hence the photon must have enough energy to excite the electron across the entire bandgap.

Extrinsic devices have impurities, also called dopants, added whose ground state energy is closer to the conduction band; since the electrons do not have as far to jump, lower energy photons (that is, longer wavelengths and lower frequencies) are sufficient to trigger the device. If a sample of silicon has some of its atoms replaced by phosphorus atoms (impurities), there will be extra electrons available for conduction. This is an example of an extrinsic semiconductor.

Memristor	A memristor is a hypothetical non-linear passive two-terminal electrical component relating electric charge and magnetic flux linkage. According to the characterizing mathematical relations, the memristor would hypothetically operate in the following way: the memristor's electrical resistance is not constant but depends on the history of current that had previously flowed through the device, i.e., its present resistance depends on how much electric charge has flowed in what direction through it in the past; the device remembers its history — the so-called non-volatility property. When the electric power supply is turned off, the memristor remembers its most recent resistance until it is turned on again. In 2008, a team at HP Labs claimed to have found Chua's missing memristor based on an analysis of a thin film of titanium dioxide thus connecting the operation of ReRAM devices to the memristor concept. There are, however, some serious doubts as to whether a genuine memristor can actually exist in physical reality. Additionally, some experimental evidence contradicts Chua's generalization since a non-passive nanobattery effect is observable in resistance switching memory. A simple test has been proposed by Pershin and Di Ventra to analyse whether such an ideal or generic memristor does actually exist or is a purely mathematical concept. Up to now, there seems to be no experimental resistance switching device (ReRAM) which can pass the test.
Heater	Heaters are appliances whose purpose is to generate heat (i.e. warmth) for the building. This can be done via central heating. Such a system contains a boiler, furnace, or heat pump to heat water, steam, or air in a central location such as a furnace room in a home, or a mechanical room in a large building. The heat can be transferred by convection, conduction, or radiation. Heaters exist for various types of fuel, including solid fuels, liquids, and gases. Another type of heat source is electricity, normally heating ribbons composed of high resistance wire (see Nichrome). This principle is also used for baseboard heaters and portable heaters. Electrical heaters are often used as backup or supplemental heat for heat pump systems.

Capacitors

Fixed Capacitors

Ceramic Capacitor	A ceramic capacitor is a fixed-value capacitor in which ceramic material acts as the dielectric. It is constructed of two or more alternating layers of ceramic and a metal layer acting as the electrodes. The composition of the ceramic material defines the electrical behaviour and therefore applications. Ceramic capacitors are divided into two application classes: ● Class 1 ceramic capacitors offer high stability and low losses for resonant circuit applications. ● Class 2 ceramic capacitors offer high volumetric efficiency for buffer, by-pass, and coupling applications. Ceramic capacitors, especially multilayer ceramic capacitors (MLCCs), are the most produced and used capacitors in electronic equipment that incorporate approximately one trillion (1012) pieces per year. Ceramic capacitors of special shapes and styles are used as capacitors for RFI/EMI suppression, as feed-through capacitors and in larger dimensions as power capacitors for transmitters.
Electrolytic Capacitor	An electrolytic capacitor (e-cap) is a polarized capacitor whose anode or positive plate is made of a metal that forms an insulating oxide layer through anodization. This oxide layer acts as the dielectric of the capacitor. A solid, liquid, or gel electrolyte covers the surface of this oxide layer, serving as the (cathode) or negative plate of the capacitor. Due to their very thin dielectric oxide layer and enlarged anode surface, electrolytic capacitors have a much higher capacitance-voltage (CV) product per unit volume compared to ceramic capacitors or film capacitors, and so can have large capacitance values. There are three families of electrolytic capacitor: aluminium electrolytic capacitors, tantalum electrolytic capacitors, and niobium electrolytic capacitors. The large capacitance of electrolytic capacitors makes them particularly suitable for passing or bypassing low-frequency signals, and for storing large amounts of energy.

They are widely used for decoupling or noise filtering in power supplies and DC link circuits for variable-frequency drives, for coupling signals between amplifier stages, and storing energy as in a flashlamp. Electrolytic capacitors are polarized components due to their asymmetrical construction, and must be operated with a higher voltage (ie, more positive) on the anode than on the cathode at all times. For this reason the anode terminal is marked with a plus sign and the cathode with a minus sign.

Applying a reverse polarity voltage, or a voltage exceeding the maximum rated working voltage of as little as 1 or 1.5 volts, can destroy the dielectric and thus the capacitor. The failure of electrolytic capacitors can be hazardous, resulting in an explosion or fire. Bipolar electrolytic capacitors which may be operated with either polarity are also made, using special constructions with two anodes connected in series.

Aluminium Electrolytic Capacitor	Aluminium electrolytic capacitors are polarized electrolytic capacitors whose anode electrode (+) is made of a pure aluminium foil with an etched surface. The aluminium forms a very thin insulating layer of aluminium oxide by anodization that acts as the dielectric of the capacitor. A non-solid electrolyte covers the rough surface of the oxide layer, serving in principle as the second electrode (cathode) (-) of the capacitor. A second aluminium foil called "cathode foil" contacts the electrolyte and serves as the electrical connection to the negative terminal of the capacitor. Aluminium electrolytic capacitors are divided into three subfamilies by the type of electrolyte: ● Non-solid (liquid, wet) aluminium electrolytic capacitors, ● Solid manganese dioxide aluminium electrolytic capacitors, and ● Solid polymer aluminium electrolytic capacitors.

Aluminium electrolytic capacitors with non-solid electrolyte are the most inexpensive type and also those with widest range of sizes, capacitance and voltage values. They are made with capacitance values from 0.1 µF up to 2,700,000 µF (2.7 F), and rated voltages values from 4 V up to 630 V. The liquid electrolyte provides oxygen for re-forming or self-healing of the dielectric oxide layer.

However, it can evaporate through a temperature-dependent drying-out process, which causes electrical parameters to drift, limiting the service life time of the capacitors. Due to their relatively high capacitance values aluminium electrolytic capacitors have low impedance values even at lower frequencies like mains frequency.

They are typically used in power supplies, switched-mode power supplies and DC-DC converters for smoothing and buffering rectified DC voltages in many electronic devices as well as in industrial power supplies and frequency converters as DC link capacitors for drives, inverters for photovoltaic, and converters in wind power plants. Special types are used for energy storage, for example in photoflash or strobe applications or for frequency coupling in audio applications. Aluminium electrolytic capacitors are polarized capacitors because of their anodization principle. They can only be operated with DC voltage applied with the correct polarity. Operating the capacitor with wrong polarity or with AC voltage leads to a short circuit and can destroy the component.

Lithium-Ion Capacitor	A lithium-ion capacitor (LIC) is a hybrid type of capacitor classified as a type of supercapacitor. Activated carbon is typically used as the cathode. The anode of the LIC consists of carbon material which is pre-doped with lithium ions. This pre-doping process lowers the potential of the anode and allows a relatively high output voltage compared with other supercapacitors.	**Typical Properties** ● High capacitance compared to a capacitor, because of the large anode, though low capacity compared to a Li-ion cell ● High energy density compared to a capacitor(14 Wh/kg reported), though low energy density compared to a Li-ion cell ● High power density ● High reliability ● Operating temperatures ranging from −20 °C to 70 °C ● Low self-discharge (<5% voltage drop at 25 °C over three months)

Variable Capacitor

Tuning Capacitor	A tuning capacitor is a variable capacitor used in an electronic circuit of a radio. It usually connects in parallel to a loop antenna. There are many uses and applications for a variable capacitor; the most typical use is in an AM Radio Circuit. If you were building a crystal radio, then you will most definitely need this component. A typical capacitor will look like this. It will often have six pins at the back, and sometimes an additional pin at the front-side, which connects to the shaft. It is normally used in a radio capable of receiving AM and FM bands. They typically consist of four individually ganged variable capacitors inside. There are two gangs of equal capacitance for the AM side, and two gangs of equal capacitance for the FM side. The first priority is to figure which is the top side and the lower side. There is normally some writing at the back to provide a clue to the orientation of the component. The three pins on the lower side are for the FM Radio. If you are building an AM Crystal Radio, then you ignore those pins. The three pins on the top side are for the AM radio. For a crystal radio, you need to connect the centre pin to the earthy side of your coil, and only one of the side pins to the antenna side of your coil.
Trimmer Capacitor	The Trimmer capacitor is the parts that its capacitance can be changed freely. The Trimmer capacitor is used in some applications that generally have no need to adjust again after the initial adjustment. The trimmer capacitor has an adjustable structure adding to general ceramic capacitor to adjust capacitance. There are basically three different principles shown in below that can be adjust capacitance. Generally most of the commercial products are using the first principle. ● Principle 1: change the overlap electrode area between parallel facing electrodes. ● Principle 2: change the distance between parallel facing electrodes. ● Principle 3: change the dieelectric constant of ceramics. The actual trimmer capacitor product has a dielectric ceramic between two parallel facing electrodes. One side of electrode is movable (can be rotated) so that a capacitance can be changed by adjusting the overlap electrode area between the movable and the fixed electrode. According to this process, a capacitance value can be changed linearly depending on the rotation angle of a movable electrode. Murata trimmer capacitor is also using above the Principle 1 and has more than 50% market share in the world.

Capacitors for Special Applications

Power Capacitor	Power capacitors are passive electronic components that provide a static source of reactive power in electrical distribution systems. They consist of two conducting plates separated by an insulating material called the dielectric. Multilayer dielectrics provide excellent temperature stability and frequency characteristics. Single layer dielectrics are also available. Capacitance, a measure of energy storage ability, is typically expressed as C = K A/D, where A is the area of the electrodes, D is their separation, and K is a function of the dielectric between the electrodes. Power capacitors are used in: ● The aerospace and automotive industries ● Power factor correction and lighting circuits ● Power supplies ● Motor starters. Some devices can handle one-phase voltages while others are designed for three-phase voltages.
Light-Emitting Capacitor	Light emitting capacitor (LEC) is an electroluminescent device in which the active layer is an electroluminescent polymer - a polymer which emits photons when an electrical current is passed through it. The polymers used are conjugated polymers, meaning the chemical and electronic structure of the material allow it to act as an ionic conductor, giving it the electronic and optical properties of a semiconductors. LECs provide multiple advantages - they are compatible with inexpensive manufacturing processes, eliminate the need for a transparent anode, and are independent of the difference in the work function of the electrodes. This article will elaborate on the working, construction and applications of LECs. The active polymer layer consists of electronic and ionic conductors. This layer is in between the two electrodes. When an electric charge is applied on the electrodes, electrons and holes are released and they accumulate around the polymer layer. The recombination of the electron hole pairs causes the polymer layer to emit light.

Motor Capacitor	A motor capacitor, such as a start capacitor or run capacitor (including a dual run capacitor) is an electrical capacitor that alters the current to one or more windings of a single phase AC induction motor to create a rotating magnetic field. There are two common types of motor capacitors, run capacitors and start capacitors. The units of capacitance are labelled in microfarads (μF). Older capacitors may be labelled with the obsolete terms "mfd" or "MFD" which can be ambiguous but are, especially in this context, used for microfarad as well (a millifarad is 1000 microfarad and not usually seen on motors). Motor capacitors are used with air conditioners, hot tub/Jacuzzi spa pumps, powered gates, large fans or forced-air heat furnaces for example. A "dual run capacitor" is used in some air conditioner compressor units, to boost both the fan and compressor motors. Start capacitors briefly increase motor starting torque and allow a motor to be cycled on and off rapidly. A start capacitor stays in the circuit long enough to rapidly bring the motor up to a predetermined speed, which is usually about 75% of the full speed, and is then taken out of the circuit, often by a centrifugal switch that releases at that speed. Afterward the motor works more efficiently with a run capacitor. Start capacitors have ratings above 70 μF, with four major voltage classifications: 125 V, 165 V, 250 V, and 330 V.
	Examples of motor capacitors are: a 35 μF, at 370 V, run capacitor, or an 88–108 μF at 250 V start capacitor. Start capacitors above 20 μF are always non-polarized aluminium electrolytic capacitors with non solid electrolyte and therefore they are only applicable for the short motor starting time. The motor will not work properly if the centrifugal switch is broken. If the switch is always "open", the start capacitor is not part of the circuit thus preventing startup of the motor. If the switch is always "closed", the start capacitor is always enabled, thus likely destroying the capacitor. If a motor does not start, the capacitor is far more likely the problem than the switch. Some single-phase AC electric motors require a "run capacitor" to energize the second-phase winding (auxiliary coil) to create a rotating magnetic field while the motor is running. Run capacitors are designed for continuous duty while the motor is powered, which is why electrolytic capacitors are avoided, and low-loss polymer capacitors are used. Run capacitors are mostly polypropylene film capacitors (historically: metallised paper capacitors) and are energized the entire time the motor is running. Run capacitors are rated in a range of 1.5 to 100 μF, with voltage classifications of 370 V or 440 V. If a wrong capacitance value is installed, it will cause an uneven magnetic field around the rotor. This causes the rotor to hesitate at the uneven spots, resulting in irregular rotation, especially under load. This hesitation can cause the motor to become noisy, increase energy consumption, cause performance to drop and the motor to overheat.
Photoflash Capacitor	A photoflash capacitor is an electrolytic capacitor used in flash cameras, professional flashes, and also in solid-state laser power supplies. Their usual purpose is to briefly power a high-voltage flash tube, used to illuminate a photographic subject or optically pump a laser rod. As flash tubes require very high current for a very short time to operate, photoflash capacitors are designed to supply high discharge current pulses without excessive internal heating. The light energy emitted by a flash is supplied by the capacitor, and is proportional to the product of the capacitance and the voltage squared; photoflash capacitors have capacitance in the range 80-160 microfarads (μF) and voltages from 180–330 volts for flash units built into small disposable and compact cameras, increasing for units delivering higher light energy. A typical manufacturer's range includes capacitors operating at 330–380V, with capacitance from 80 to 1,500 μF.

Magnetic (Inductive) Devices

Inductor, Coil, Choke, Variable Inductor	An inductor, also called a coil, choke, or reactor, is a passive two-terminal electrical component that stores energy in a magnetic field when electric current flows through it. An inductor typically consists of an insulated wire wound into a coil around a core. When the current flowing through an inductor changes, the time-varying magnetic field induces an electromotive force (e.m.f.) (voltage) in the conductor, described by Faraday's law of induction. According to Lenz's law, the induced voltage has a polarity (direction) which opposes the change in current that created it. As a result, inductors oppose any changes in current through them. An inductor is characterized by its inductance, which is the ratio of the voltage to the rate of change of current. Inductors have values that typically range from 1 μH (10−6 H) to 20 H. Many inductors have a magnetic core made of iron or ferrite inside the coil, which serves to increase the magnetic field and thus the inductance. Along with capacitors and resistors, inductors are one of the three passive linear circuit elements that make up electronic circuits. Inductors are widely used in alternating current (AC) electronic equipment, particularly in radio equipment. They are used to block AC while allowing DC to pass; inductors designed for this purpose are called chokes. They are also used in electronic filters to separate signals of different frequencies, and in combination with capacitors to make tuned circuits, used to tune radio and TV receivers.
Transformer	A transformer is a static electrical device that transfers electrical energy between two or more circuits. A varying current in one coil of the transformer produces a varying magnetic field, which in turn induces a varying electromotive force (emf) or "voltage" across a second coil. Electric power can be transferred between the two coils, without a metallic connection between the two circuits. Faraday's law of induction discovered in 1831 described the effect of induced voltage across the secondary coil. Transformers are used to increase or decrease the alternating voltages in electric power applications. Since the invention of the first constant-potential transformer in 1885, transformers have become essential for the transmission, distribution, and utilization of alternating current electrical energy. A wide range of transformer designs is encountered in electronic and electric power applications. Transformers range in size from RF transformers less than a cubic centimetre in volume to units interconnecting the power grid weighing hundreds of tons.
Magnetic Amplifier (Toroid)	The magnetic amplifier (colloquially known as a "mag amp") is an electromagnetic device for amplifying electrical signals. The magnetic amplifier was invented early in the 20th century, and was used as an alternative to vacuum tube amplifiers where robustness and high current capacity were required. The magnetic amplifier has now been largely superseded by the transistor-based amplifier, except in a few safety critical, high-reliability or extremely demanding applications.
Ferrite Impedances, Beads	A ferrite bead or ferrite choke is a passive electric component that suppresses high frequency noise in electronic circuits. It is a specific type of electronic choke. Ferrite beads employ high frequency current dissipation in a ferrite ceramic to build high frequency noise suppression devices. Ferrite beads may also be called blocks, cores, rings, EMI filters, or chokes. Ferrite beads prevent electromagnetic interference(EMI) in two directions: from a device or to a device. A conductive cable acts as an antenna – if the device produces radio frequency energy, this can be transmitted through the cable, which acts as an unintentional radiator. In this case the bead is required for regulatory compliance, to reduce EMI. Conversely, if there are other sources of EMI, such as household appliances, the bead prevents the cable from acting as an antenna and receiving interference from these other devices. This is particularly common on data cables and on medical equipment. Large ferrite beads are commonly seen on external cabling. Various smaller ferrite beads are used internally in circuits—on conductors or around the pins of small circuit-board components, such as transistors, connectors and integrated circuits. Ferrite beads are used as a passive low-pass filter, by converting RF energy to heat, by design. The energy is either reflected back up the cable, or dissipated as low level heat. Only in extreme cases is the heat noticeable.
Motor	An electric motor is an electrical machine that converts electrical energy into mechanical energy. Most electric motors operate through the interaction between the motor's magnetic field and winding currents to generate force in the form of rotation. Electric motors can be powered by direct current (DC) sources, such as from batteries, motor vehicles or rectifiers, or by alternating current (AC) sources, such as a power grid, inverters or electrical generators. An electric generator is mechanically identical to an electric motor, but operates in the reverse direction, accepting mechanical energy (such as from flowing water) and converting this mechanical energy into electrical energy. Electric motors may be classified by considerations such as power source type, internal construction, application and type of motion output. In addition to AC versus DC types, motors may be brushed or brushless, may be of various phase (see single-phase, two-phase, or three-phase), and may be either air-cooled or liquid-cooled.

General-purpose motors with standard dimensions and characteristics provide convenient mechanical power for industrial use. The largest electric motors are used for ship propulsion, pipeline compression and pumped-storage applications with ratings reaching 100 megawatts. Electric motors are found in industrial fans, blowers and pumps, machine tools, household appliances, power tools and disk drives.

Small motors may be found in electric watches. In certain applications, such as in regenerative braking with traction motors, electric motors can be used in reverse as generators to recover energy that might otherwise be lost as heat and friction. Electric motors produce linear or rotary force (torque) and can be distinguished from devices such as magnetic solenoids and loudspeakers that convert electricity into motion but do not generate usable mechanical force, which are respectively referred to as actuators and transducers.

Generator	In electricity generation, a generator is a device that converts motive power (mechanical energy) into electrical power for use in an external circuit. Sources of mechanical energy include steam turbines, gas turbines, water turbines, internal combustion engines and even hand cranks. The first electromagnetic generator, the Faraday disk, was invented in 1831 by British scientist Michael Faraday. Generators provide nearly all of the power for electric power grids. The reverse conversion of electrical energy into mechanical energy is done by an electric motor, and motors and generators have many similarities. Many motors can be mechanically driven to generate electricity and frequently make acceptable manual generators.
Solenoid	A solenoid and eidos is a coil wound into a tightly packed helix. The term was invented by French physicist André-Marie Ampère to designate a helical coil. In physics, the term refers to a coil whose length is substantially greater than its diameter, often wrapped around a metallic core, which produces a uniform magnetic field in a volume of space (where some experiment might be carried out) when an electric current is passed through it. A solenoid is a type of electromagnet whose purpose is to generate a controlled magnetic field. If the purpose of the solenoid is instead to impede changes in the electric current, a solenoid can be more specifically classified as an inductor rather than an electromagnet. Not all electromagnets and inductors are solenoids; for example, the first electromagnet, invented in 1824, had a horseshoe rather than a cylindrical solenoid shape. In engineering, the term may also refer to a variety of transducer devices that convert energy into linear motion. The term is also often used to refer to a solenoid valve, which is an integrated device containing an electromechanical solenoid which actuates either a pneumatic or hydraulic valve, or a solenoid switch, which is a specific type of relay that internally uses an electromechanical solenoid to operate an electrical switch; for example, an automobile starter solenoid, or a linear solenoid, which is an electromechanical solenoid. Solenoid bolts, a type of electronic-mechanical locking mechanism, also exist.
Loudspeaker (Speaker)	A loudspeaker is an electroacoustic transducer; which converts an electrical audio signal into a corresponding sound. The most widely used type of speaker in the 2010s is the dynamic speaker. The dynamic speaker operates on the same basic principle as a dynamic microphone, but in reverse, to produce sound from an electrical signal. When an alternating current electrical audio signal is applied to its voice coil, a coil of wire suspended in a circular gap between the poles of a permanent magnet, the coil is forced to move rapidly back and forth due to Faraday's law of induction, which causes a diaphragm (usually conically shaped) attached to the coil to move back and forth, pushing on the air to create sound waves. Besides this most common method, there are several alternative technologies that can be used to convert an electrical signal into sound.

The sound source must be amplified or strengthened with an audio power amplifier before the signal is sent to the speaker. Speakers are typically housed in a speaker enclosure or speaker cabinet which is often a rectangular or square box made of wood or sometimes plastic. The enclosure's materials and design play an important role in the quality of the sound.

Where high fidelity reproduction of sound is required, multiple loudspeaker transducers are often mounted in the same enclosure, each reproducing a part of the audible frequency range. In this case the individual speakers are referred to as "drivers" and the entire unit is called a loudspeaker. Drivers made for reproducing high audio frequencies are called tweeters, those for middle frequencies are called mid-range drivers, and those for low frequencies are called woofers.

Microphone	A microphone, colloquially nicknamed mic or mike is a transducer that converts sound into an electrical signal. Microphones are used in many applications such as telephones, hearing aids, public address systems for concert halls, motion picture production, sound recording, two-way radios, megaphones, radio broadcasting, and in computers for recording voice and for non-acoustic purposes such as ultrasonic sensors or knock sensors. Several different types of microphone are in use, which employ different methods to convert the air pressure variations of a sound wave to an electrical signal. The most common are the dynamic microphone, which uses a coil of wire suspended in a magnetic field; the condenser microphone, which uses the vibrating diaphragm as a capacitor plate, and the piezoelectric microphone, which uses a crystal of piezoelectric material. Microphones typically need to be connected to a preamplifier before the signal can be recorded or reproduced.

Transducers, Sensors, Detectors

Buzzer	A buzzer or beeper is an audio signalling device, which may be mechanical, electromechanical, or piezoelectric (piezo for short). Typical uses of buzzers and beepers include alarm devices, timers, and confirmation of user input such as a mouse click or keystroke. The electric buzzer was invented in 1831 by Joseph Henry. They were mainly used in early doorbells until they were phased out in the early 1930s in favour of musical chimes, which had a softer tone. Piezoelectric buzzers, or piezo buzzers, as they are sometimes called, were invented by Japanese manufacturers and fitted into a wide array of products during the 1970s to 1980s. This advancement mainly came about because of cooperative efforts by Japanese manufacturing companies. In 1951, they established the Barium Titanate Application Research Committee, which allowed the companies to be "competitively cooperative" and bring about several piezoelectric innovations and inventions.	**Types** ● Electromechanical ● Mechanical ● Piezoelectric
Inclinometer	An inclinometer or clinometer is an instrument used for measuring angles of slope (or tilt), elevation, or depression of an object with respect to gravity's direction. It is also known as a tilt indicator, tilt sensor, tilt meter, slope alert, slope gauge, gradient meter, gradiometer, level gauge, level meter, declinometer, and pitch & roll indicator. Clinometers measure both inclines (positive slopes, as seen by an observer looking upwards) and declines (negative slopes, as seen by an observer looking downward) using three different units of measure: degrees, percent, and topo. A tilt sensor can measure the tilting in often two axes of a reference plane in two axes. In contrast, a full motion would use at least three axes and often additional sensors. One way to measure tilt angle with reference to the earth's ground plane, is to use an accelerometer.	
Motion Sensor	A motion detector is a device that detects moving objects, particularly people. Such a device is often integrated as a component of a system that automatically performs a task or alerts a user of motion in an area. They form a vital component of security, automated lighting control, home control, energy efficiency and other useful systems. An electronic motion detector contains an optical, microwave, or acoustic sensor, and in many cases a transmitter for illumination. However, a passive sensor senses a signature only from the moving object via emission or reflection, i.e., it can be emitted by the object, or by some ambient emitter such as the sun or a radio station of sufficient strength. Changes in the optical, microwave, or acoustic field in the device's proximity are interpreted by the electronics based on one of the technologies listed below. Most low-cost motion detectors can detect up to distances of at least 15 feet (4.6 m).	

Tomographic motion detection systems can cover much larger areas because the radio waves are at frequencies which penetrate most walls and obstructions, and are detected in multiple locations, not only at the location of the transmitter. Motion detectors have found wide use in domestic and commercial applications. One common application is activating automatic door openers in businesses and public buildings. Motion sensors are also widely used in lieu of a true occupancy sensor in activating street lights or indoor lights in walkways, such as lobbies and staircases.

In such smart lighting systems, energy is conserved by only powering the lights for the duration of a timer, after which the person has presumably left the area. A motion detector may be among the sensors of a burglar alarm that is used to alert the home owner or security service when it detects the motion of a possible intruder. Such a detector may also trigger a security camera to record the possible intrusion.

Sensor Technology Passive Infrared (PIR)	Passive infrared (PIR) sensors are sensitive to a person's skin temperature through emitted black body radiation at mid-infrared wavelengths, in contrast to background objects at room temperature. No energy is emitted from the sensor, thus the name passive infrared.
Sensor Technology Microwave	These detect motion through the principle of Doppler radar, and are similar to a radar speed gun. A continuous wave of microwave radiation is emitted, and phase shifts in the reflected microwaves due to motion of an object toward (or away from) the receiver result in a heterodyne signal at a low audio frequency.
Sensor Technology Ultrasonic	An ultrasonic transducer emits an ultrasonic wave (sound at a frequency higher than a human ear can hear) and receivers reflections from nearby objects. Exactly as in Doppler radar, heterodyne detection of the received field indicates motion. The detected doppler shift is also at low audio frequencies (for walking speeds) since the ultrasonic wavelength of around a centimetre is similar to the wavelengths used in microwave motion detectors.
Sensor Technology Tomographic Motion Detector	These systems sense disturbances to radio waves as they pass from node to node of a mesh network. They have the ability to detect over large areas completely because they can sense through walls and other obstructions.
Flow Meter	Flow measurement is the quantification of bulk fluid movement. Flow can be measured in a variety of ways. Positive-displacement flow meters accumulate a fixed volume of fluid and then count the number of times the volume is filled to measure flow. Other flow measurement methods rely on forces produced by the flowing stream as it overcomes a known constriction, to indirectly calculate flow. Flow may be measured by measuring the velocity of fluid over a known area. For very large flows, tracer methods may be used to deduce the flow rate from the change in concentration of a dye or radioisotope.
Accelerometer	An accelerometer is a device that measures proper acceleration. Proper acceleration, being the acceleration (or rate of change of velocity) of a body in its own instantaneous rest frame, is not the same as coordinate acceleration, being the acceleration in a fixed coordinate system. For example, an accelerometer at rest on the surface of the Earth will measure an acceleration due to Earth's gravity, straight upwards (by definition) of g ≈ 9.81 m/s2. By contrast, accelerometers in free fall (falling toward the centre of the Earth at a rate of about 9.81 m/s2) will measure zero. Accelerometers have multiple applications in industry and science. Highly sensitive accelerometers are components of inertial navigation systems for aircraft and missiles. Accelerometers are used to detect and monitor vibration in rotating machinery. Accelerometers are used in tablet computers and digital cameras so that images on screens are always displayed upright.

Accelerometers are used in drones for flight stabilisation. Coordinated accelerometers can be used to measure differences in proper acceleration, particularly gravity, over their separation in space; i.e., gradient of the gravitational field. This gravity gradiometry is useful because absolute gravity is a weak effect and depends on local density of the Earth which is quite variable.

Single- and multi-axis models of accelerometer are available to detect magnitude and direction of the proper acceleration, as a vector quantity, and can be used to sense orientation (because direction of weight changes), coordinate acceleration, vibration, shock, and falling in a resistive medium (a case where the proper acceleration changes, since it starts at zero, then increases). Micromachined microelectromechanical systems (MEMS) accelerometers are increasingly present in portable electronic devices and video game controllers, to detect the position of the device or provide for game input.

Thermistor	A thermistor is a type of resistor whose resistance is dependent on temperature, more so than in standard resistors. The word is a portmanteau of thermal and resistor. Thermistors are widely used as inrush current limiters, temperature sensors (negative temperature coefficient or NTC type typically), self-resetting overcurrent protectors, and self-regulating heating elements (positive temperature coefficient or PTC type typically). Thermistors are of two opposite fundamental types: With NTC thermistors, resistance decreases as temperature rises. An NTC is commonly used as a temperature sensor, or in series with a circuit as an inrush current limiter. With PTC thermistors, resistance increases as temperature rises. PTC thermistors are commonly installed in series with a circuit, and used to protect against overcurrent conditions, as resettable fuses. Thermistors differ from resistance temperature detectors (RTDs) in that the material used in a thermistor is generally a ceramic or polymer, while RTDs use pure metals. The thermistors are in the form of beads, rods and discs but RTDs are in different shapes and sizes. The temperature response is also different; RTDs are useful over larger temperature ranges, while thermistors typically achieve a greater precision within a limited temperature range, typically −90 °C to 130 °C.
Resistance Temperature Detector (RTD)	Resistance thermometers, also called resistance temperature detectors (RTDs), are sensors used to measure temperature. Many RTD elements consist of a length of fine wire wrapped around a ceramic or glass core but other constructions are also used. The RTD wire is a pure material, typically platinum, nickel, or copper. The material has an accurate resistance/temperature relationship which is used to provide an indication of temperature. As RTD elements are fragile, they are often housed in protective probes. RTDs, which have higher accuracy and repeatability, are slowly replacing thermocouples in industrial applications below 600 °C.
Magnetometer	A magnetometer or magnetic sensor is an instrument that measures magnetism—either the magnetization of a magnetic material like a ferromagnet, or the direction, strength, or relative change of a magnetic field at a particular location. A compass is a simple type of magnetometer, one that measures the direction of an ambient magnetic field. The first magnetometer capable of measuring the absolute magnetic intensity was invented by Carl Friedrich Gauss in 1833 and notable developments in the 19th century included the Hall effect, which is still widely used. Magnetometers are widely used for measuring the Earth's magnetic field and in geophysical surveys to detect magnetic anomalies of various types. They are also used in the military to detect submarines. Consequently, some countries, such as the United States, Canada and Australia, classify the more sensitive magnetometers as military technology, and control their distribution. Magnetometers can be used as metal detectors: they can detect only magnetic (ferrous) metals, but can detect such metals at a much larger depth than conventional metal detectors; they are capable of detecting large objects, such as cars, at tens of metres, while a metal detector's range is rarely more than 2 metres. In recent years, magnetometers have been miniaturized to the extent that they can be incorporated in integrated circuits at very low cost and are finding increasing use as miniaturized compasses (MEMS magnetic field sensor).

Hygrometer	A hygrometer is an instrument used for measuring the amount of humidity and water vapour in the atmosphere, in soil, or in confined spaces. Humidity measurement instruments usually rely on measurements of some other quantity such as temperature, pressure, mass or a mechanical or electrical change in a substance as moisture is absorbed. By calibration and calculation, these measured quantities can lead to a measurement of humidity. Modern electronic devices use temperature of condensation (the dew point), or changes in electrical capacitance or resistance to measure humidity differences. The first crude hygrometer was invented by the Italian Renaissance polymath Leonardo da Vinci in 1480 and a more modern version was created by Swiss polymath Johann Heinrich Lambert in 1755. The maximum amount of water vapour that can be held in a given volume of air (saturation) varies greatly by temperature; cold air can hold less mass of water per unit volume than hot air. Most instruments respond to (or are calibrated to read) relative humidity (RH), which is the amount of water relative to the maximum at a particular temperature expressed as per cent.
Photo Resistor	A photoresistor (or light-dependent resistor, LDR, or photo-conductive cell) is a light-controlled variable resistor. The resistance of a photoresistor decreases with increasing incident light intensity; in other words, it exhibits photoconductivity. A photoresistor can be applied in light-sensitive detector circuits, and light-activated and dark-activated switching circuits. A photoresistor is made of a high resistance semiconductor. In the dark, a photoresistor can have a resistance as high as several megohms (MΩ), while in the light, a photoresistor can have a resistance as low as a few hundred ohms. If incident light on a photoresistor exceeds a certain frequency, photons absorbed by the semiconductor give bound electrons enough energy to jump into the conduction band. The resulting free electrons (and their hole partners) conduct electricity, thereby lowering resistance. The resistance range and sensitivity of a photoresistor can substantially differ among dissimilar devices. Moreover, unique photoresistors may react substantially differently to photons within certain wavelength bands.

A photoelectric device can be either intrinsic or extrinsic. An intrinsic semiconductor has its own charge carriers and is not an efficient semiconductor, for example, silicon. In intrinsic devices the only available electrons are in the valence band, and hence the photon must have enough energy to excite the electron across the entire bandgap. Extrinsic devices have impurities, also called dopants, added whose ground state energy is closer to the conduction band; since the electrons do not have as far to jump, lower energy photons (that is, longer wavelengths and lower frequencies) are sufficient to trigger the device. If a sample of silicon has some of its atoms replaced by phosphorus atoms (impurities), there will be extra electrons available for conduction. This is an example of an extrinsic semiconductor.

Antennas

Elemental Dipole	In radio and telecommunications a dipole antenna or doublet is the simplest and most widely used class of antenna. The dipole is any one of a class of antennas producing a radiation pattern approximating that of an elementary electric dipole with a radiating structure supporting a line current so energized that the current has only one node at each end. A dipole antenna commonly consists of two identical conductive elements such as metal wires or rods. The driving current from the transmitter is applied, or for receiving antennas the output signal to the receiver is taken, between the two halves of the antenna. A common example of a dipole is the "rabbit ears" television antenna found on broadcast television sets. The dipole is the simplest type of antenna from a theoretical point of view. Most commonly it consists of two conductors of equal length oriented end-to-end with the feedline connected between them.
Yagi	A Yagi–Uda antenna, commonly known as a Yagi antenna, is a directional antenna consisting of multiple parallel elements in a line, usually half-wave dipoles made of metal rods. Yagi–Uda antennas consist of a single driven element connected to the transmitter or receiver with a transmission line, and additional "parasitic elements" which are not connected to the transmitter or receiver: a so-called reflector and one or more directors. The reflector element is slightly longer than the driven dipole, whereas the directors are a little shorter. The parasitic elements absorb and reradiate the radio waves from the driven element with a different phase, modifying the dipole's radiation pattern. The waves from the multiple elements superpose and interfere to enhance radiation in a single direction, achieving a very substantial increase in the antenna's gain compared to a simple dipole.

Also called a "beam antenna", or "parasitic array", the Yagi is very widely used as a high-gain antenna on the HF, VHF and UHF bands. It has moderate to high gain which depends on the number of elements used, typically limited to about 20 dBi, linear polarization, unidirectional (end-fire) beam pattern with high front-to-back ratio of up to 20 db. and is lightweight, inexpensive and simple to construct.

The bandwidth of a Yagi antenna, the frequency range over which it has high gain, is narrow, a few percent of the centre frequency, and decreases with increasing gain, so it is often used in fixed-frequency applications. The largest and best-known use is as rooftop terrestrial television antennas, but it is also used for point-to-point fixed communication links, in radar antennas, and for long distance shortwave communication by shortwave broadcasting stations and radio amateurs.

Phased Array	In antenna theory, a phased array usually means an electronically scanned array, a computer-controlled array of antennas which creates a beam of radio waves that can be electronically steered to point in different directions without moving the antennas. In an array antenna, the radio frequency current from the transmitter is fed to the individual antennas with the correct phase relationship so that the radio waves from the separate antennas add together to increase the radiation in a desired direction, while cancelling to suppress radiation in undesired directions. In a phased array, the power from the transmitter is fed to the antennas through devices called phase shifters, controlled by a computer system, which can alter the phase electronically, thus steering the beam of radio waves to a different direction.

Since the array must consist of many small antennas (sometimes thousands) to achieve high gain, phased arrays are mainly practical at the high frequency end of the radio spectrum, in the UHF and microwave bands, in which the antenna elements are conveniently small. Phased arrays were invented for use in military radar systems, to scan the radar beam quickly across the sky to detect planes and missiles. These phased array radar systems are now widely used, and phased arrays are spreading to civilian applications.

The phased array principle is also used in acoustics, and phased arrays of acoustic transducers are used in medical ultrasound imaging scanners (phased array ultrasonics), oil and gas prospecting (reflection seismology), and military sonar systems. The term is also used to a lesser extent for unsteered array antennas in which the phase of the feed power and thus the radiation pattern of the antenna is fixed. For example, AM broadcast radio antennas consisting of multiple mast radiators fed so as to create a specific radiation pattern are also called "phased arrays".

Loop Antenna	A loop antenna is a radio antenna consisting of a loop or coil of wire, tubing, or other electrical conductor usually fed by a balanced source or feeding a balanced load. Within this physical description there are two distinct antenna types. The large self-resonant loop antenna has a circumference close to one wavelength of the operating frequency and so is resonant at that frequency. This category also includes smaller loops 5% to 30% of a wavelength in circumference, which use a capacitor to make them resonant. These antennas are used for both transmission and reception. In contrast, small loop antennas less than 1% of a wavelength in size are very inefficient radiators, and so are only used for reception. An example is the ferrite (loopstick) antenna used in most AM broadcast radios. Loop antennas have a dipole radiation pattern; they are most sensitive to radio waves in two broad lobes in opposite directions, 180° apart. Due to this directional pattern they are used for radio direction finding (RDF), to locate the position of a transmitter.

Parabolic Dish	A parabolic (or paraboloid or paraboloidal) reflector (or dish or mirror) is a reflective surface used to collect or project energy such as light, sound, or radio waves. Its shape is part of a circular paraboloid, that is, the surface generated by a parabola revolving around its axis. The parabolic reflector transforms an incoming plane wave travelling along the axis into a spherical wave converging toward the focus. Conversely, a spherical wave generated by a point source placed in the focus is reflected into a plane wave propagating as a collimated beam along the axis. Parabolic reflectors are used to collect energy from a distant source (for example sound waves or incoming star light). Since the principles of reflection are reversible, parabolic reflectors can also be used to focus radiation from an isotropic source into a narrow beam. In optics, parabolic mirrors are used to gather light in reflecting telescopes and solar furnaces, and project a beam of light in flashlights, searchlights, stage spotlights, and car headlights. In radio parabolic antennas are used to radiate a narrow beam of radio waves for point-to-point communications in satellite dishes and microwave relay stations, and to locate aircraft, ships, and vehicles in radar sets. In acoustics, parabolic microphones are used to record faraway sounds such as bird calls, in sports reporting, and to eavesdrop on private conversations in espionage and law enforcement.
Log-Periodic Dipole Array	A log-periodic antenna (LP), also known as a log-periodic array or log-periodic aerial, is a multi-element, directional antenna designed to operate over a wide band of frequencies. The most common form of log-periodic antenna is the log-periodic dipole array or LPDA, The LPDA consists of a number of half-wave dipole driven elements of gradually increasing length, each consisting of a pair of metal rods. The dipoles are mounted close together in a line, connected in parallel to the feedline with alternating phase. Electrically, it simulates a series of two or three-element Yagi antennas connected together, each set tuned to a different frequency. LPDA antennas look somewhat similar to Yagi antennas, in that they both consist of dipole rod elements mounted in a line along a support boom, but they work in very different ways. Adding elements to a Yagi increases its directionality, or gain, while adding elements to a LPDA increases its frequency response, or bandwidth. One large application for LPDAs is in rooftop terrestrial television antennas, since they must have large bandwidth to cover the wide television bands of roughly 54–88 and 174–216 MHz in the VHF and 470–890 MHz in the UHF while also having high gain for adequate fringe reception. One widely used design for television reception combined a Yagi for UHF reception in front of a larger LPDA for VHF.
Biconical	In radio systems, a biconical antenna is a broad-bandwidth antenna made of two roughly conical conductive objects, nearly touching at their points. Biconical antennas are broadband dipole antennas, typically exhibiting a bandwidth of three octaves or more. A common subtype is the bowtie antenna, essentially a two-dimensional version of the biconial design which is often used for short-range UHF television reception. These are also sometimes referred to as butterfly antennas. The biconical antenna has a broad bandwidth because it is an example of a travelling wave structure; the analysis for a theoretical infinite antenna resembles that of a transmission line. For an infinite antenna, the characteristic impedance at the point of connection is a function of the cone angle only and is independent of the frequency. Practical antennas have finite length and a definite resonant frequency. A simple conical monopole antenna is a wire approximation of the solid biconical antenna and has increased bandwidth (over a simple monopole). Biconical (or "bicon") antennas are often used in electromagnetic interference (EMI) testing either for immunity testing, or emissions testing.
Feedhorn	In parabolic antennas such as satellite dishes, a feed horn (or feedhorn) is a small horn antenna used to convey radio waves between the transmitter and/or receiver and the parabolic reflector. In transmitting antennas, it is connected to the transmitter and converts the radio frequency alternating current from the transmitter to radio waves and feeds them to the rest of the antenna, which focuses them into a beam. In receiving antennas, incoming radio waves are gathered and focused by the antenna's reflector on the feed horn, which converts them to a tiny radio frequency voltage which is amplified by the receiver. Feed horns are used mainly at microwave (SHF) and higher frequencies. The feedhorn also selects the polarization of the waves to be received, which helps to attenuate unwanted signals from adjacent channels and transponders, and from other communications satellites at nearby orbital positions.

This can be either horizontal or vertical if the polarization is linear, or clockwise or counter clockwise (also called left- and right-handed) if it is circular. Certain devices can also allow a feedhorn to accept both linear and circular, though these cause a slight insertion loss to all incoming signals. When used with a parabolic reflector or lens antenna, the phase centre of the horn is usually placed at the focal point of the reflector, with the 3 dB points of the horn's radiation pattern set to be at the edge of the reflector.

On a satellite dish, the feedhorn is what is mounted at the end of a mast from the centre of the dish, or on tripod legs mounted to the edge of the dish. In satellite dishes, part of the receiver electronics, the RF front end, is usually mounted in a box just behind the feed horn. This converts the high satellite microwave downlink frequencies to a lower frequency so it can be more easily sent through the coaxial cable feedline to the receiver inside the building.

Assemblies, Modules

Oscillator	An electronic oscillator is an electronic circuit that produces a periodic, oscillating electronic signal, often a sine wave or a square wave. Oscillators convert direct current (DC) from a power supply to an alternating current (AC) signal. They are widely used in many electronic devices. Common examples of signals generated by oscillators include signals broadcast by radio and television transmitters, clock signals that regulate computers and quartz clocks, and the sounds produced by electronic beepers and video games. Oscillators are often characterized by the frequency of their output signal. A low-frequency oscillator (LFO) is an electronic oscillator that generates a frequency below approximately 20 Hz. An audio oscillator produces frequencies in the audio range, about 16 Hz to 20 kHz. An RF oscillator produces signals in the radio frequency (RF) range of about 100 kHz to 100 GHz. Oscillators designed to produce a high-power AC output from a DC supply are usually called inverters.	
Digital Voltmeters	A digital voltmeter (DVM) measures an unknown input voltage by converting the voltage to a digital value and then displays the voltage in numeric form. DVMs are usually designed around a special type of analog-to-digital converter called an integrating converter. DVM measurement accuracy is affected by many factors, including temperature, input impedance, and DVM power supply voltage variations. Less expensive DVMs often have input resistance on the order of 10 MΩ. Precision DVMs can have input resistances of 1 GΩ or higher for the lower voltage ranges (e.g. less than 20 V). To ensure that a DVM's accuracy is within the manufacturer's specified tolerances, it must be periodically calibrated against a voltage standard such as the Weston cell.	
Filter	Electronic filters are circuits which perform signal processing functions, specifically to remove unwanted frequency components from the signal, to enhance wanted ones, or both. The most common types of electronic filters are linear filters, regardless of other aspects of their design. See the article on linear filters for details on their design and analysis.	**Filters Can Be** ● Passive or Active ● Analog or Digital ● High-pass, low-pass, band-pass, band-stop (band-rejection; notch), or all-pass. ● Discrete-time (sampled) or continuous-time ● Linear or non-linear ● Infinite impulse response (IIR type) or finite impulse response (FIR type)

Prototyping Aids

Wire-Wrap	Wire wrap was invented to wire telephone crossbar switches, and later adapted to construct electronic circuit boards. Electronic components mounted on an insulating board are interconnected by lengths of insulated wire run between their terminals, with the connections made by wrapping several turns of uninsulated sections of the wire around a component lead or a socket pin. Wires can be wrapped by hand or by machine, and can be hand-modified afterwards. Wire wrap construction can produce assemblies which are more reliable than printed circuits: connections are less prone to fail due to vibration or physical stresses on the base board, and the lack of solder precludes soldering faults such as corrosion, cold joints and dry joints.
Breadboard	A breadboard is a construction base for prototyping of electronics. Originally it was literally a bread board, a polished piece of wood used for slicing bread. In the 1970s the solderless breadboard (a.k.a. plugboard, a terminal array board) became available and nowadays the term "breadboard" is commonly used to refer to these. Because the solderless breadboard does not require soldering, it is reusable. This makes it easy to use for creating temporary prototypes and experimenting with circuit design. For this reason, solderless breadboards are also popular with students and in technological education. Older breadboard types did not have this property. A stripboard (Veroboard) and similar prototyping printed circuit boards, which are used to build semi-permanent soldered prototypes or one-offs, cannot easily be reused. A variety of electronic systems may be prototyped by using breadboards, from small analog and digital circuits to complete central processing units (CPUs).

Electromechanical

Piezoelectric Devices, Crystals, Resonators

Crystal	A crystal oscillator is an electronic oscillator circuit that uses the mechanical resonance of a vibrating crystal of piezoelectric material to create an electrical signal with a precise frequency. This frequency is often used to keep track of time, as in quartz wristwatches, to provide a stable clock signal for digital integrated circuits, and to stabilize frequencies for radio transmitters and receivers. The most common type of piezoelectric resonator used is the quartz crystal, so oscillator circuits incorporating them became known as crystal oscillators, but other piezoelectric materials including polycrystalline ceramics are used in similar circuits.	
Ceramic Resonator	A ceramic resonator is an electronic component consisting of a piece of a piezoelectric ceramic material with two or more metal electrodes attached. When connected in an electronic oscillator circuit, resonant mechanical vibrations in the device generate an oscillating signal of a specific frequency. Like the similar quartz crystal, they are used in oscillators for purposes such as generating the clock signal used to control timing in computers and other digital logic devices. The thickness of the ceramic substrate determines the resonant frequency of the device. A typical ceramic resonator package has either two or three connections. They come in both surface-mount and through-hole varieties with a number of different footprints. The oscillation takes place across two of the pins (connections). The third pin (if present; typically the centre pin) is connected to ground. Ceramic resonators can be used as the source of the clock signal for digital circuits such as microprocessors where the frequency accuracy is not critical. Quartz has a 0.001% frequency tolerance, while PZT has a 0.5% tolerance. They are used in timing circuitry for a wide array of applications such as TVs, VCRs, automotive electronic devices, telephones, cameras, communication equipment, remote controls and toys. A ceramic resonator is often used in place of quartz crystals as a reference clock or signal generator in electronic circuitry due to its low cost and smaller size.	
Surface Acoustic Qave (SAW) Filters	Electronic filters are circuits which perform signal processing functions, specifically to remove unwanted frequency components from the signal, to enhance wanted ones, or both. The most common types of electronic filters are linear filters, regardless of other aspects of their design. See the article on linear filters for details on their design and analysis.	**Electronic Filters** ● Passive or Active ● Analog or Digital ● High-pass, low-pass, band-pass, band-stop (band-rejection; notch), or all-pass. discrete-time (sampled) or continuous-time ● Linear or Non-Linear
Ultrasonic Motor	An ultrasonic motor is a type of electric motor powered by the ultrasonic vibration of a component, the stator, placed against another component, the rotor or slider depending on the scheme of operation (rotation or linear translation). Ultrasonic motors differ from piezoelectric actuators in several ways, though both typically use some form of piezoelectric material, most often lead zirconate titanate and occasionally lithium niobate or other single-crystal materials.	

Terminals / Connectors

Terminal	A terminal is the point at which a conductor from an electrical component, device or network comes to an end and provides a point of connection to external circuits. A terminal may simply be the end of a wire or it may be fitted with a connector or fastener. In network analysis, terminal means a point at which connections can be made to a network in theory and does not necessarily refer to any real physical object. In this context, especially in older documents, it is sometimes called a pole. The connection may be temporary, as seen in portable equipment, may require a tool for assembly and removal, or may be a permanent electrical joint between two wires or devices. All electric cells have two terminals. The first is the positive terminal and the second is the negative terminal. The positive terminal looks like a metal cap and the negative terminal looks like a metal disc. The current flows from the positive terminal, and out through the negative terminal, replicative of current flow (positive (+) to negative (-) flow).	**Terminal Types** ● Splices ● Cups ● Hooks ● Solder Lugs ● Tongue Crimp terminals (ring terminals) ● Turrets ● Test probes (pogo terminals) ● Clips ● Screw terminals
Connector	An electrical connector, is an electro-mechanical device used to join electrical terminations and create an electrical circuit. Electrical connectors consist of plugs (male-ended) and jacks (female-ended). The connection may be temporary, as for portable equipment, require a tool for assembly and removal, or serve as a permanent electrical joint between two wires or devices. An adapter can be used to effectively bring together dissimilar connectors. Hundreds of types of electrical connectors are manufactured for power, signal and control applications. Connectors may join two lengths of flexible copper wire or cable, or connect a wire or cable to an electrical terminal. In computing, an electrical connector can also be known as a physical interface (compare physical layer in OSI model of networking). Cable glands, known as cable connectors in the US, connect wires to devices mechanically rather than electrically and are distinct from quick-disconnects performing the latter.	
Socket	Plug and socket connectors are usually made up of a male plug (typically pin contacts) and a female receptacle (typically socket contacts) Jack commonly refers to a connector often with the female electrical contact or socket, and is the "more fixed" connector of a connector pair. Plug commonly refers to a movable connector, often (but not always) with the male electrical contact or pin, and is the movable (less fixed) connector of a connector pair. Some connector styles may contain both pin and socket connection types. Plugs generally have one or more pins or prongs that are inserted into openings in the mating socket. The connection between the mating metal parts must be sufficiently tight to make a good electrical connection and complete the circuit. When working with multi-pin connectors, it is helpful to have a pinout diagram to identify the wire or circuit node connected to each pin.	

ELECTRICITY	Componentry	Electromechanical Components	Terminals / Connectors	**Screw Terminal, Terminal Blocks**	A screw terminal is a type of electrical connector where a wire is held by the tightening of a screw. The wire may be wrapped directly under the head of a screw, may be held by a metal plate forced against the wire by a screw, or may be held by what is, in effect, a set screw in the side of a metal tube. The wire may be directly stripped of insulation and inserted under the head of a screw or into the terminal. Otherwise, it may be either inserted first into a ferrule, which is then inserted into the terminal, or else attached to a connecting lug. which is then fixed under the screw head. Screw terminals are used extensively in building wiring for the distribution of electricity - connecting electrical outlets, luminaires and switches to the mains, and for directly connecting major appliances such as clothes dryers and ovens drawing in excess of 15 amperes.
				Pin Header	A pin header (often abbreviated as PH, or simply header) is a form of electrical connector. It consists of one or more rows of male pins typically spaced 2.54 millimetres (0.1 in) apart. The distance between pins is commonly referred as pitch in the electronic community. Pin headers are often associated with ribbon cable connectors, pin headers often also function as recipients for jumpers. The most common jumper spacing is 2.54 millimetres (0.1 in), though 2.0 millimetres (0.079 in) is sometimes used in smaller products.
ELECTRICITY	Componentry		Cable	**Cable Assemblies**	
ELECTRICITY	Componentry	Electromechanical Components	Cable Assemblies	**Power Cord**	A power cord, line cord, or mains cable is an electrical cable that temporarily connects an appliance to the mains electricity supply via a wall socket or extension cord. The terms are generally used for cables using a power plug to connect to a single-phase alternating current power source at the local line voltage—(generally 100 to 240 volts, depending on the location). The terms power cable, mains lead, flex or kettle lead are also used.
				Patch Cord	A patch cable, patch cord or patch lead is an electrical or optical cable used to connect ("patch in") one electronic or optical device to another for signal routing. Devices of different types (e.g., a switch connected to a computer, or a switch to a router) are connected with patch cords. Patch cords are usually produced in many different colours so as to be easily distinguishable, and are relatively short, perhaps no longer than two metres. Types of patch cords include microphone cables, headphone extension cables, XLR connector, Tiny Telephone (TT) connector, RCA connector and ¼" TRS phone connector cables (as well as modular Ethernet cables), and thicker, hose-like cords (snake cable) used to carry video or amplified signals. A patch cord cable differs from a standard structured cabling in that a patch cable is stranded for flexibility, whereas a standard cable is solid copper. As length increases, the cables are usually thicker and/or made with more shielding, to prevent signal loss (attenuation) and the introduction of unwanted radio frequencies and hum (electromagnetic interference). Patch cords are often made of coaxial cables, with the signal carried through a shielded core, and the electrical ground or earthed return connection carried through a wire mesh surrounding the core. Each end of the cable is attached to a connector so that the cord may be plugged in.
				Test Lead	A test probe is a physical device used to connect electronic test equipment to a device under test (DUT). Test probes range from very simple, robust devices to complex probes that are sophisticated, expensive, and fragile. Specific types include test prods, oscilloscope probes and current probes. A test probe is often supplied as a test lead, which includes the probe, cable and terminating connector.
				Switches	
ELECTRICITY	Componentry	Electromechanical Components	Switches	**Switch**	In electrical engineering, a switch is an electrical component that can "make" or "break" an electrical circuit, interrupting the current or diverting it from one conductor to another. The mechanism of a switch removes or restores the conducting path in a circuit when it is operated. It may be operated manually, for example, a light switch or a keyboard button, may be operated by a moving object such as a door, or may be operated by some sensing element for pressure, temperature or flow. A switch will have one or more sets of contacts, which may operate simultaneously, sequentially, or alternately. Switches in high-powered circuits must operate rapidly to prevent destructive arcing, and may include special features to assist in rapidly interrupting a heavy current. Multiple forms of actuators are used for operation by hand or to sense position, level, temperature or flow. Special types are used, for example, for control of machinery, to reverse electric motors, or to sense liquid level. Many specialized forms exist. A common use is control of lighting, where multiple switches may be wired into one circuit to allow convenient control of light fixtures.
			Switches	**Keypad**	A keypad is a set of buttons arranged in a block or "pad" which bear digits, symbols or alphabetical letters. Pads mostly containing numbers are called a numeric keypad. Numeric keypads are found on alphanumeric keyboards and on other devices which require mainly numeric input such as calculators, push-button telephones, vending machines, ATMs, Point of Sale devices, combination locks, and digital door locks. Many devices follow the E.161 standard for their arrangement.
ELECTRICITY	Componentry	Electromechanical Components	Switches	**DIP Switch**	A DIP switch is a manual electric switch that is packaged with others in a group in a standard dual in-line package (DIP). The term may refer to each individual switch, or to the unit as a whole. This type of switch is designed to be used on a printed circuit board along with other electronic components and is commonly used to customize the behaviour of an electronic device for specific situations. DIP switches are an alternative to jumper blocks. Their main advantages are that they are quicker to change and there are no parts to lose. There are many different kinds of DIP switches. Some of the most common are the slide, rocker, piano (side), and rotary types. Rotary DIP switches contain multiple electrical contacts, one of which is selected by rotating the switch to align it with a number printed on the package. These may be large like thumbwheels, or so small that a screwdriver must be used to change them (although there are also small potentiometers of this type). The slide and rocker types, which are very common, are arrays of simple single pole, single throw (SPST) contacts, which can be either on or off.
ELECTRICITY	Componentry	Electromechanical Components	Switches	**Relay**	A relay is an electrically operated switch. Many relays use an electromagnet to mechanically operate a switch, but other operating principles are also used, such as solid-state relays. Relays are used where it is necessary to control a circuit by a separate low-power signal, or where several circuits must be controlled by one signal. The first relays were used in long distance telegraph circuits as amplifiers: they repeated the signal coming in from one circuit and re-transmitted it on another circuit. Relays were used extensively in telephone exchanges and early computers to perform logical operations. A type of relay that can handle the high power required to directly control an electric motor or other loads is called a contactor. Solid-state relays control power circuits with no moving parts, instead using a semiconductor device to perform switching. Relays with calibrated operating characteristics and sometimes multiple operating coils are used to protect electrical circuits from overload or faults; in modern electric power systems these functions are performed by digital instruments still called "protective relays". Magnetic latching relays require one pulse of coil power to move their contacts in one direction, and another, redirected pulse to move them back. Repeated pulses from the same input have no effect. Magnetic latching relays are useful in applications where interrupted power should not be able to transition the contacts.

Thermostat	A thermostat is a component which senses the temperature of a physical system and performs actions so that the system's temperature is maintained near a desired setpoint. Thermostats are used in any device or system that heats or cools to a setpoint temperature, examples include building heating, central heating, air conditioners, HVAC systems, water heaters, as well as kitchen equipment including ovens and refrigerators and medical and scientific incubators. In scientific literature, these devices are often broadly classified as thermostatically controlled loads (TCLs). Thermostatically controlled loads comprise roughly 50% of the overall electricity demand in the United States. A thermostat operates as a "closed loop" control device, as it seeks to reduce the error between the desired and measured temperatures. Sometimes a thermostat combines both the sensing and control action elements of a controlled system, such as in an automotive thermostat.
Humidistat	A humidistat is an electronic device analogous to a thermostat but which responds to relative humidity, not temperature. Humidistats are used in a number of devices including dehumidifiers, humidifiers, and microwave ovens. In humidifiers and dehumidifiers the humidistat is used where constant relative humidity conditions need to be maintained such as a refrigerator, greenhouse, or climate-controlled warehouse. When adjusting the controls in these applications the humidistat would be what is being set. In microwaves they are used in conjunction with "smart cooking" one-button features such as those for microwave popcorn. Humidistats employ hygrometers but are not the same. A humidistat has the functionality of a switch and is not just a measuring instrument like a hygrometer is. For heating, ventilation, and air conditioning (HVAC) of buildings, humidistats or humidity sensors are used to sense the air relative humidity in the controlled space and turn on and off the HVAC equipment.

Protection Devices

Fuse	In electronics and electrical engineering, a fuse is an electrical safety device that operates to provide overcurrent protection of an electrical circuit. Its essential component is a metal wire or strip that melts when too much current flows through it, thereby interrupting the current. It is a sacrificial device; once a fuse has operated it is an open circuit, and it must be replaced or rewired, depending on type. Fuses have been used as essential safety devices from the early days of electrical engineering. Today there are thousands of different fuse designs which have specific current and voltage ratings, breaking capacity and response times, depending on the application. The time and current operating characteristics of fuses are chosen to provide adequate protection without needless interruption. Wiring regulations usually define a maximum fuse current rating for particular circuits. Short circuits, overloading, mismatched loads, or device failure are the prime reasons for fuse operation. A fuse is an automatic means of removing power from a faulty system; often abbreviated to ADS (Automatic Disconnection of Supply). Circuit breakers can be used as an alternative to fuses, but have significantly different characteristics.
Circuit Breaker	A circuit breaker is an automatically operated electrical switch designed to protect an electrical circuit from damage caused by excess current from an overload or short circuit. Its basic function is to interrupt current flow after a fault is detected. Unlike a fuse, which operates once and then must be replaced, a circuit breaker can be reset (either manually or automatically) to resume normal operation. Circuit breakers are made in varying sizes, from small devices that protect low-current circuits or individual household appliance, up to large switchgear designed to protect high voltage circuits feeding an entire city. The generic function of a circuit breaker, RCD or a fuse, as an automatic means of removing power from a faulty system is often abbreviated as OCPD (Over Current Protection Device).
Resettable Fuse	A resettable fuse is a polymeric positive temperature coefficient (PPTC) device that is a passive electronic component used to protect against overcurrent faults in electronic circuits. The device is also known as a multifuse or polyfuse or polyswitch. They are similar in function to PTC thermistors in certain situations but operate on mechanical changes instead of charge carrier effects in semiconductors.
Ground-Fault Protection / Residual-Current Device	A residual-current device (RCD), or residual-current circuit breaker (RCCB), is a device that instantly breaks an electric circuit to prevent serious harm from an ongoing electric shock. Injury may still occur in some cases, for example if a human falls after receiving a shock. These electrical wiring devices are designed to quickly and automatically disconnect a circuit when it detects that the electric current is not balanced between the supply and return conductors of a circuit. Any difference between the currents in these conductors indicates leakage current, which presents a shock hazard. Current of around 30 mA (0.030 amperes) through the human body is potentially sufficient to cause cardiac arrest or serious harm if it persists for more than a small fraction of a second. RCDs are designed to disconnect the conducting wires ("trip") quickly enough to prevent serious injury. An RCD does not provide protection against overcurrent (overload) or short circuit in the circuit, and so cannot replace a fuse. RCDs are often integrated with some kind of circuit breaker, such as a fuse or miniature circuit breaker (MCB), which protects against excess current in the circuit. RCDs also cannot detect a human accidentally touching both conductors at the same time. RCDs are testable and resettable devices.
Inrush Current Limiter	An inrush current limiter is a component used to limit inrush current to avoid gradual damage to components and avoid blowing fuses or tripping circuit breakers. Negative temperature coefficient (NTC) thermistors and fixed resistors are often used to limit inrush current. NTC thermistors can be used as inrush-current limiting devices in power supply circuits when added in series with the circuit being protected. They present a higher resistance initially, which prevents large currents from flowing at turn-on. As current continues to flow, NTC thermistors heat up, allowing higher current flow during normal operation. NTC thermistors are usually much larger than measurement type thermistors, and are purposely designed for power applications.
Lightning Arrester	A lightning arrester (alternative spelling lightning arrestor) (also called lightning diverter) is a device used on electric power systems and telecommunication systems to protect the insulation and conductors of the system from the damaging effects of lightning. The typical lightning arrester has a high-voltage terminal and a ground terminal. When a lightning surge (or switching surge, which is very similar) travels along the power line to the arrester, the current from the surge is diverted through the arrester, in most cases to earth. In telegraphy and telephony, a lightning arrester is placed where wires enter a structure, preventing damage to electronic instruments within and ensuring the safety of individuals near them. Smaller versions of lightning arresters, also called surge protectors, are devices that are connected between each electrical conductor in power and communications systems and the Earth.

These prevent the flow of the normal power or signal currents to ground, but provide a path over which high-voltage lightning current flows, bypassing the connected equipment. Their purpose is to limit the rise in voltage when a communications or power line is struck by lightning or is near to a lightning strike. If protection fails or is absent, lightning that strikes the electrical system introduces thousands of kilovolts that may damage the transmission lines, and can also cause severe damage to transformers and other electrical or electronic devices.

Lightning-produced extreme voltage spikes in incoming power lines can damage electrical home appliances. Lightning arresters are used to protect electric fences. They consist of a spark gap and sometimes a series inductor. Lightning arresters can form part of large electrical transformers and can fragment during transformer ruptures.

Other

Printed Circuit Boards	A printed circuit board (PCB) mechanically supports and electrically connects electronic components or electrical components using conductive tracks, pads and other features etched from one or more sheet layers of copper laminated onto and/or between sheet layers of a non-conductive substrate. Components are generally soldered onto the PCB to both electrically connect and mechanically fasten them to it. Printed circuit boards are used in all but the simplest electronic products. PCBs require additional design effort to lay out the circuit, but manufacturing and assembly can be automated. Mass-producing circuits with PCBs is cheaper and faster than with other wiring methods, as components are mounted and wired in one operation. Large numbers of PCBs can be fabricated at the same time, and the layout only has to be done once.

PCBs can also be made manually in small quantities, with reduced benefits. PCBs can be single-sided (one copper layer), double-sided (two copper layers on both sides of one substrate layer), or multi-layer (outer and inner layers of copper, alternating with layers of substrate). Multi-layer PCBs allow for much higher component density, because circuit traces on the inner layers would otherwise take up surface space between components.

The rise in popularity of multilayer PCBs with more than two, and especially with more than four, copper planes was concurrent with the adoption of surface mount technology. However, multilayer PCBs make repair, analysis, and field modification of circuits much more difficult and usually impractical.

Lamp	An electric light is a device that produces visible light from electric current. It is the most common form of artificial lighting and is essential to modern society, providing interior lighting for buildings and exterior light for evening and night time activities. In technical usage, a replaceable component that produces light from electricity is called a lamp. Lamps are commonly called light bulbs; for example, the incandescent light bulb. Lamps usually have a base made of ceramic, metal, glass or plastic, which secures the lamp in the socket of a light fixture. The electrical connection to the socket may be made with a screw-thread base, two metal pins, two metal caps or a bayonet cap. The three main categories of electric lights are incandescent lamps, which produce light by a filament heated white-hot by electric current, gas-discharge lamps, which produce light by means of an electric arc through a gas, and LED lamps, which produce light by a flow of electrons across a band gap in a semiconductor.

Component Symbols

Traces	IEC-Style Trace Junction	Trace Crossing								
Circuit Return	IEC-Style Ground (GND) Symbol	Signal/Low Noise Ground (GND) Symbol	IEC-Style Chassis-Ground Symbol							
Sources	Single Cell, Multi-Cell Battery	Battery, Multi-Cell	Voltage Source	Controlled Voltage Source	Current Source	Controlled Current Source	AC Voltage Source

9 Repairs

These are the most common problems with electronic devices and ways you can fix them. Devices are sorted alphabetically.

Air Conditioner Repairs

Failed Capacitor

Problem Motors not running or compressor fails to start.	**Symptoms** Air con labours to start the compressor or tries but can't start it. The longer it takes to start up the more degraded the capacitor is.	**Cause** Most common cause of failure is the fan or compressor capacitor.	**Solution** Replacement capacitors may be difficult to salvage in SHTF due to needing to replace with an exact or very similar capacitor. Salvaging a similar one off another broken air conditioner should suffice. The failed air conditioner capacitor can either be a start motor or running motor one. Instead of replacing a start capacitor you can give the fan a push and see if it takes off.

Low Gas Levels

Problem There isn't enough gas in the system to cool the air.	**Symptoms** Air isn't very cold or there's no temperature change.	**Cause** The gas levels may drop over time and require re-gassing at this point.	**Solution** o

Inverter

Problem o	**Symptoms** o	**Cause** o	**Solution** o

Radio

How to fix bad reception or static from a radio.

Repositioning	The antenna may be in the wrong spot to receive a strong signal. Try moving it around or head to the top of a hill.
Longer Antenna	Lengthen the antenna by attaching another antenna or soldering a long wire to it.
Interference	Interference can be caused by anything with an electrical or magnetic current. Changing weather patterns can also cause problems with radio reception.
Distance	You may be too far from the transmitter and so the signal will be weak.

10 Schematics

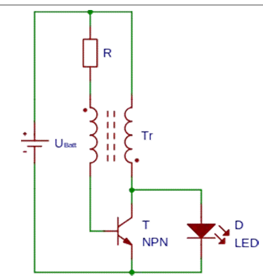
These are schematics which can be built to assist in your survival. Each schematic serves a different purpose and require varying degrees of components to build, some which may be difficult to find.

Joule Thief

Used for creating electricity from 'apparently dead' batteries by flashing the LED multiple times every second. This uses up any residual power which higher draw electronics are unable to use.

Materials
- LED
- 2N440 Transistor
- 1K Ohm Resistor (500-2Kohm)
- Insulated Wiring
- Dead Battery
- Toroidal Inductor

Method
1. Strip Toroidal Core of wires.
2. Pass both wires through the core with a little space leaving 3cm wire each end. Leave 1cm of core unwired.
3. Solder two strands from opposite sides together.
4. Solder the middle lead of the transistor to the resistor.
5. Solder the other resistor end to a wire from the core.
6. Separate transistor legs and solder LED to one leg.
7. Connect remaining core wire to positive LED leg.
8. Connect negative LED leg to battery.
9. Connect core wire to positive battery side.



If you don't know what a toroidal inductor is, it's those circular rings with wire wrapped around them multiple times which are commonly found on modern electronics.

Chlorine Producing Unit

Purifies water by generating chlorine using salt and electrolysis.

Materials
- 12v Battery
- Titanium Mesh Cathode
- Iridium/Ruthenium Metal Anode

Method
o

Using the Device
1. Mix salt & water solution (approx. ¼ cup salt to 16 oz water)
2. Connect wires to 12 volt source
3. Pour the saltwater solution through the CPU into another bottle (observe the bubbling process)
4. Carefully repeat the pour-through process 5 times. This is different from a chlorate cell as that the water free flows through the unit which does not allow chlorates or perchlorates to form. This process operates at a different voltage and a much lower temperature.
5. Unhook the battery wires.
6. Rinse the CPU by pouring clean water through it.
7. Add 10 drops of the solution for each gallon of drinking water.
8. Wait one hour before drinking.

One of the major obstacles has been finding appropriate electrodes to do the splitting, particularly the anode. Efficient electrodes exist, but they involve oxides of platinum group metals such as iridium or ruthenium to act as catalysts. Iridium costs more than half as much as gold, and even ruthenium is far too expensive for large-scale use. The anodes and cathodes can often be found in pool purification and chlorine systems as metal plates through which the water passes.

Colloidal Silver Generator

Generates a silver colloid (silver suspended in a liquid) from a piece of pure silver.

EMP Generator

EMP Generator (By Christopher Voute)
In this series, I'll be exploring electromagnetic weapons, how to build them, their function and application to the future, and the amazing possibilities electromagnetism has to offer. First, the electromagnetic pulse generator, or EMP. You've probably heard of these before, and their devastating effects on electronics. A simple EMP consists of a capacitor, transformer, trigger, and coil of copper wire. This, when triggered, would produce an intense magnetic field for a brief period, similar to a coil gun (see this article for more info). On a small scale, this would be enough to reset a calculator or electronic clock, but not enough to be of any use. However, it is quite easy to make a more effective one (at close range), with a few more components, and time. I'll be going over capacitors and transformers in this article, and discussing which are most applicable to an EMP.

Capacitors
There are many kinds of capacitors, but I'll categorize them in "electrolyte" and "non-electrolyte". In a way, capacitors are quite similar to batteries. They both store electrical energy; however, there is a major difference. That is, capacitors only STORE electrons, never produce them. In a battery, a chemical reaction between two terminals and an acidic solution PRODUCES electrons. Inside the capacitor, the terminals connect to two metal plates separated by a non-conducting substance, or dielectric. Its quite easy to make a capacitor from two pieces of aluminium foil and a piece of paper or plastic, like a leyden jar. Depending on the voltage rating and capacitance rating, capacitors can be a small as a grain of rice, or as large as a garbage can and bigger. For a practical DIY EMP, a simple 5000uf 400V capacitor (or capacitor bank) would be legitimate. There are two ways to create a capacitor bank; series or parallel. This article explains the differences in series and parallel quite well. A capacitor bank for an EMP should have capacitors linked together in parallel. This increases the capacitance and reduces electrolyte damage. For example, if you had six capacitors at 650uf 400V each in parallel, your final capacitance and voltage would be 3900uf 400V. The voltage does not change, but the capacitance increases. The image below is a circuit diagram representation of capacitors in parallel. Your capacitor bank should be similar (if not exact) in design. Also, keep in mind electrolyte capacitors have a positive and a negative (polarity). The white line on an electrolyte capacitor represents negative, ensure your capacitor bank has an orderly, constant polarity.

Transformers
Now you have the storage availability, what about filling it? For that, you'll need a transformer. A transformer takes electricity and basically shifts around the voltage: current ratio. In a transformer, there is generally a primary winding/coil, and a secondary winding/coil. They rarely are made up of exact gauge/number of windings, and usually contain a core made out of ferrite or metal. A transformer turns electricity into a magnetic field with a coil of copper, then back into electricity again using another coil. You'll need a fairly powerful high voltage transformer to fill your capacitor bank quickly, a MOT (microwave transformer) or ZVS flyback transformer would work nicely, if properly used (these are VERY DANGEROUS and can KILL YOU INSTANTLY). Of course, you'll need a DC voltage source to charge your capacitor bank, so ensure you have a diode (or similar rectification device). The two outside "humps" or coils represent inductors, and the centre portion represents a core. Most (all) flyback transformers have a ferrite core, and most MOTs have a steel or similar metal core. In this article, I'll be covering Triggers and Coils, part two of the series (see part one here). Generally, a simple EMP generator consists of four components; a capacitor, a transformer, a trigger and a coil of copper wire. The transformer component can be varied, but the coil is very important, and must be precisely tuned.

Triggers
Simply said, a trigger is basically a way of closing the circuit and allowing the energy stored in the capacitor(s) to flow through the coil and create the magnetic field. However, the trigger (or switch) must be capable of handling large loads of current. For example, imagine trying to cross a river by bridging it with a thin, weak stick vs a large tree. The bridge represents the switch, and you the load (current). Pretty simple, eh? Just bridging a circuit gap. In an EMP generator, the size and operation of the switch is proportional to the amount of current (basically how big your capacitor bank is) you are switching. If you followed my earlier article on capacitors and transformers, then your looking at a fairly big switch. Depending on the dimensions of your finished product (whether its a "gun shape" or simply a bench top experiment), you'll either want to use a relay and trigger switch, or just a relay. The relay should consist of a solenoid and two thick metal contacts that, when triggered, are "smashed" together by the solenoid, completing the circuit. As seen above, there are two very large conductive terminals encased in an acrylic case (spark/molten metal shield). When triggered, the linear actuator (most likely a solenoid) will smash these terminals together very quickly, completing the circuit and triggering the EMP generator.

Coils
Now here's the difficult part, the coil. Depending on your voltage, current, and size of your EMP generator, the coil could either be very big and effective, or very small and ineffective unless used at close range to target. A typical EMP generator doesn't require hundreds of windings, quite the opposite. Thick copper tubing works very effectively. In this case, a capacitor bank at 400v 4000uf would need a coil of medium sized copper tubing and probably 8 to 12 turns (or windings). I've experimented with different coil formations, and the "inclined plain wrapped helically around an axis" works best, in other words, the picture above. However, feel free to experiment with different coil formations and an (old) calculator. Set a constant (distance from calculator) and voltage, then change the coil layout until the calculator stops working.

Warnings
- The electricity discussed in this article is more than enough to literally fry you to a crisp. Be extremely careful! I cannot stress this enough.
- When testing an EMP generator, be sure to keep all valuable electronics away! It could potentially (more than likely) destroy them.
- I am not responsible for any damage you cause!
- DO NOT use this as a weapon and/or to destroy electronics you do not own!

11 Generators

Petrol Generator

Small and very quiet generator, easily portable. Can usually power up to 550W of equipment. Can last up to 1000 hours if well maintained.

Diesel Generator

Diesel Generator 6-15kVA
Perfect if you make your own Biodiesel at home and require power. Standard generator for when mains isn't accessible or reliable. Requires minor maintenance with air filters, fuel filters and oil filters.

Noise reduction highly recommended.
Industrial: 78db @ 7m
Residential L1: 63db @ 7m
Residential L2: 58db @ 7m

Diesel Generator 20-300kVA
For use at 150m ASL and 30°C (86°F) ambient.

Gas Generator

Current Modification

Any way that an electrical current can be modified and therefore change its uses.

DC > AC (Inverter)	Inverter, Lets you power 240v equipment from 12v source. Not recommended to have 240v appliances off-grid as they will sap energy. Use the inverter occasionally when needed for high-power devices for short periods. Connected leads between the battery and inverter should be as short as possible to minimise loss and voltage reduction. Inverter efficiency should be > 90%.
AC > DC (Rectifier)	Rectifier, Lets you power 12v equipment from a 240v source.
Voltage Stabiliser	Placed in front of a UPS to stabilise fluctuating AC current for sensitive equipment.
UPS	Uninterrupted Power Supply, To back up the power supply of 240v equipment with an independent power source.

12 Power Transmission

Transmission lines carry electric energy from one point to another in an electric power system. They can carry alternating current or direct current or a system can be a combination of both. Also, electric current can be carried by either overhead or underground lines. The main characteristics that distinguish transmission lines from distribution lines are that they are operated at relatively high voltages, they transmit large quantities of power and they transmit the power over large distances.

Overhead Power Lines

Low Voltage (LV) Distribution Lines	Less than 1,000 volts, used for connection between a residential or small commercial customer and the utility.
Medium Voltage (MV) Subtransmission / Distribution Lines	Between 1,000 volts (1 kV) and 69 kV, used for distribution in urban and rural areas.
High Voltage (HV) Subtransmission Lines	Subtransmission or transmission at voltages such as 115 kV and 138 kV), used for sub-transmission and transmission of bulk quantities of electric power and connection to very large consumers.
Extra High Voltage (EHV)	From 345 kV, up to about 800 kV, used for long distance, very high power transmission.
Ultra High Voltage (UHV)	800 kV+.

Line Conductors

Power Line Materials
- Copper
- Aluminium
- Steel

Solid Conductor	A single conductor of solid circular section
Stranded Conductor	A group of wires made into a single conductor

Other Lines

Overhead AC Lines	These share one characteristic; they carry 3-phase current. The voltages vary according to the particular grid system they belong to. Transmission voltages vary from 69 Tv up to 765 Tv. The following are examples of different overhead transmission line structures in use today. The DC voltage transmission tower has lines in pairs rather than in threes (for 3-phase current) as in AC voltage lines. One line is the positive current line and the other is the negative current line.
Subtransmission Lines (Distribution Lines)	Carry voltages reduced from the major transmission line system. Typically, 34.5 Tv to 69 Tv, this power is sent to regional distribution substations. Sometimes the subtransmission voltage is tapped along the way for use in industrial or large commercial operations. Some utilities categorize these as transmission lines.
Underground Transmission Lines	Are more common in populated areas. They may be buried with no protection, or placed in conduit, trenches, or tunnels.

Line Components

Towers	Towers for support of the lines are made of wood either grown or laminated, steel or aluminum (either lattice structures or tubular poles), concrete, and occasionally reinforced plastics. The bare wire conductors on the line are generally made of aluminum (either plain or reinforced with steel or composite materials such as carbon and glass fiber), though some copper wires are used in medium-voltage distribution and low-voltage connections to customer premises. A major goal of overhead power line design is to maintain adequate clearance between energized conductors and the ground so as to prevent dangerous contact with the line, and to provide reliable support for the conductors, resilience to storms, ice loads, earthquakes and other potential damage causes. Today overhead lines are routinely operated at voltages exceeding 765,000 volts between conductors.
Structures	
Pole in Ground	Often has cross-arm beams to support conductors. Found in suburbs.

Lattice Structure	Large structures used for high voltage transmission over longer distances.
Circuits	
Single Line	A single-circuit transmission line carries conductors for only one circuit. For a three-phase system, this implies that each tower supports three conductors.
Double Line	A double-circuit transmission line has two circuits. For three-phase systems, each tower supports and insulates six conductors. Single phase AC-power lines as used for traction current have four conductors for two circuits. Usually both circuits operate at the same voltage.
Insulators	Insulators must support the conductors and withstand both the normal operating voltage and surges due to switching and lightning. Insulators are broadly classified as either pin-type, which support the conductor above the structure, or suspension type, where the conductor hangs below the structure.
Conductors	The most common conductor in use for transmission today is aluminium conductor steel reinforced (ACSR). Also seeing much use is all-aluminium-alloy conductor (AAAC). Aluminium is used because it has about half the weight of a comparable resistance copper cable (though larger diameter due to lower specific conductivity), as well as being cheaper. Typical 4cm wide ASCR conductors have 6 layers of 4mm circular wires with slight air gaps between the circles. Modern carbon core conductors eliminate the space between layers by using trapezoidal shape strands.
Bundle Conductors	For transmission of power across long distances, high voltage transmission is employed. Transmission higher than 132 kV poses the problem of corona discharge, which causes significant power loss and interference with communication circuits. To reduce this corona effect, it is preferable to use more than one conductor per phase, or bundled conductors. Bundle conductors consist of several parallel cables connected at intervals by spacers, often in a cylindrical configuration. The optimum number of conductors depends on the current rating, but typically higher-voltage lines also have higher current.
Ground Wires	Overhead power lines are often equipped with a ground conductor (shield wire, static wire, or overhead earth wire). The ground conductor is usually grounded (earthed) at the top of the supporting structure, to minimize the likelihood of direct lightning strikes to the phase conductors. In circuits with earthed neutral, it also serves as a parallel path with the earth for fault currents. Very high-voltage transmission lines may have two ground conductors. These are either at the outermost ends of the highest cross beam, at two V-shaped mast points, or at a separate cross arm. Older lines may use surge arresters every few spans in place of a shield wire; this configuration is typically found in the more rural areas of the United States. By protecting the line from lightning, the design of apparatus in substations is simplified due to lower stress on insulation.
Insulated Conductors	Overhead insulated cables are rarely used, usually for short distances (less than a kilometre). Insulated cables can be directly fastened to structures without insulating supports. An overhead line with bare conductors insulated by air is typically less costly than a cable with insulated conductors. A more common approach is "covered" line wire. It is treated as bare cable, but often is safer for wildlife, as the insulation on the cables increases the likelihood of a large-wing-span raptor to survive a brush with the lines, and reduces the overall danger of the lines slightly. These types of lines are often seen in the eastern United States and in heavily wooded areas, where tree-line contact is likely. The only pitfall is cost, as insulated wire is often costlier than its bare counterpart. Many utility companies implement covered line wire as jumper material where the wires are often closer to each other on the pole, such as an underground riser/pothead, and on reclosers, cutouts and the like.
Train Power	Overhead lines or overhead wires are used to transmit electrical energy to trams, trolleybuses or trains. Overhead line is designed on the principle of one or more overhead wires situated over rail tracks. Feeder stations at regular intervals along the overhead line supply power from the high-voltage grid. For some cases low-frequency AC is used, and distributed by a special traction current network.

Electricity Distribution

A text flowchart of the process and modifications to electricity during distribution.

Generating Station	Generates power via any number of means at about 13,000 volts.
Transmission Substation (Step Up)	Increases the voltage to 345,000 volts for efficient long distance delivery.
Transmission	Multiple high power transmission lines. Industrial customer with unique electrical requirements may have a private substation and lines going to the factory.
Transmission Substation (Step Down)	Drops the voltage down to around 69,000 volts.
Subtransmission Substation	Transmits 69,000 volts over a distance.
Distribution Substation (Step Down)	A second voltage reduction drops the voltage down to around 13,800 volts.
Commercial Customer	Customers with high power requirements use this higher voltage.
Distribution Transformer	Lowers the voltage to 120/240 volts for household use.
Residential Customer	Home power use.

Power Line Safety

13 Modern Electronics

Modern electronics which can be of benefit in a SHTF scenario and require little maintenance and knowledge.

World Possible Store **(Rachel Corrections 3.0)** **(Rachel-Plus 3.0)** **(Rachel-Pi)**	A portable wifi router which hosts web pages found on the internal SD card which have been previously downloaded. Just power up the server and users can easily connect over wifi or Ethernet to access an enormous collection of top quality materials including Wikipedia, Khan Academy (KA Lite), and much more. The latest version of the RACHEL-Pi comes complete and ready-to-use for serving RACHEL content for approximately 10 computers or tablets simultaneously, depending on usage. Requires wall socket power but they can be run from power banks or batteries if adapted.	**Included Content** ● KA Lite Essentials ● Wikipedia for Schools ● Interactive World Map ● GCF LearnFree.org ● Wikivoyage ● Wiktionary ● CK-12 Textbooks	**Included Content** ● Great Books of the World ● African Storybook Proj. ● Infonet-Biovision ● Practical Action ● MedlinePlus Medical ● Hesperian Health ● Music Theory

Computers

Any form of modern computers and anything related to them.

Hardware Repairs

Hardware Repairs	This is a list of pc components and connections between them which could be causing errors.	**Pc Hardware (Essential)** ● Case ● Motherboard (MB) ● PSU (Power Supply) ● CPU (Processor) ● CPU Fan / Heatsink ● RAM / Memory ● Hard Drive / SSD ● GPU (Graphics) ● Monitor ● Keyboard ● Mouse	**Pc Hardware (Extras)** ● Keyboard ● Mouse ● Router
Cabling	A list of all the essential cables in a computer and where they should be plugged into. It is often good to unplug them and replug them to fix connection issues.	**Power Pc Cables** ● Wall > PSU ● Wall > Monitor ● PSU > MB (24 Pin) ● PSU > MB (4 Pin) ● PSU > HDD ● PSU > GPU ● GPU or MB > Monitor	**Motherboard Pc Cables** ● MB > HDD / SSD ● MB > Case Buttons ● MB > USB Header ● MB > 3 Pin Fans ● Mouse > MB ● Keyboard > MB
Common Solutions	**Dusting:** Dust is a computers enemy so ensure it is kept dust free and clean it out from time to time. Ensure the heat sinks, fans and air filters are cleaned when they become dusty. **RAM Reseating:** RAM is a common cause of problems so take it out and reseat it or take one out and see if the remaining one works or not. **Replug Cables:** Sometimes the cables are the cause of the problems so unplug them and replug them in again.		

Internet Repairs

You may have an internet connection nearby which isn't working, but don't have the internet to troublesheet the problem, that's where this section comes in handy.

Type of Problem	**Narrow Down:** Try to narrow down the problem to either hardware or software. Then try to eliminate working hardware devices down to one.
Hardware Checks	**Check Cables:** Check and re-plug all the cables between the router, switch, wall and pc. **Wireless to Wired:** If you are using the wireless and the device has an ethernet port, try plugging in a cable and seeing if it works. **Restart Devices:** Restart all the devices that the signal travels through.
Software Checks	**Connectivity:** Check that the router has internet connectivity and you have entered the passwords correctly.

Fuel

All types of fuels from solid to liquid to gas and its effectiveness

"You are a wicked motorcar, and I shall not give you any more petrol until you go."
Bertrand Russell

Introduction

Information on all types of fuel from butane, hexamine, and petrol to wood.

Purpose	The aim of FUEL is provide a detailed description of the common types of fuels, whether that's solid fuel, liquid fuel or gas fuels. It also goes into how you can create your own fuels at home.
Lost?	● For a list of the stoves and equipment that can be used with these fuels, see the GEAR section. ● For a list of the different types of woods and their recommended uses, see the MATERIALS section. ● To learn more about the fire burning the fuel, see the FIRE section. ● For information on cooking on stoves, see the COOKING section.

Contents

1 Solid Fuels

Solid fuel refers to various forms of solid material that can be burnt to release energy, providing heat and light through the process of combustion. Solid fuels can be contrasted with liquid fuels and gaseous fuels. Common examples of solid fuels include wood, charcoal, peat, coal, Hexamine fuel tablets, wood pellets, corn, wheat, rye, and other grains. Solid fuels are extensively used in rocketry as solid propellants. Solid fuels have been used throughout human history to create fire and solid fuel is still in widespread use throughout the world in the present day.

Wood

Wood is a cheap and abundant fuel source which is readily available in most countries around the world.

Wood Power

These are all the different ways wood can be used as energy.

Direct Combustion (Heat Energy)

This is the most straightforward method, where the heat from burning wood is used directly or to create steam.

Fireplaces and Wood Stoves	The most common domestic application, providing warmth and a cozy ambiance.
Cookstoves/Rocket Stoves	Efficient designs for cooking food, especially in off-grid or developing regions.
Outdoor Ovens/BBQs	Wood-fired pizza ovens, smokers, and traditional barbecues.

Water Heaters	Boilers that heat water for domestic use.
Industrial Kilns & Furnaces	Historically used for firing pottery, bricks, glass, and for smelting in early metallurgy.
Bread Ovens	Traditional bakeries often use wood-fired ovens.
Steam Locomotives (Trains)	Many early, and some historical, steam trains were entirely wood-fired, particularly in regions with abundant timber.
Traction Engines	Large, self-propelled steam engines used for agricultural work (ploughing, threshing) and hauling heavy loads. They were common in the late 19th and early 20th centuries and were often wood-fired.
Steamships and Steamboats	Early steam-powered vessels used wood to fire their boilers.
Sawmills	Steam engines powered by wood (often sawdust and waste wood from the mill itself) were common in sawmills for cutting timber.
Factories and Mills	The steam engine, a cornerstone of the Industrial Revolution, was frequently powered by wood (and later coal) to drive machinery via belts and shafts (e.g., textile mills, mining operations, general manufacturing).
Stationary Steam Engines	Used to power pumps, generators, and other industrial equipment.
Steam Rollers	Used for road construction.
Steam Turbines	Modern biomass power plants burn wood (chips, pellets, waste wood) to heat water, produce high-pressure steam, which then drives a turbine connected to a generator to produce electricity. This is a significant source of renewable energy today.
Combined Heat and Power (CHP) Systems	These systems generate both electricity and useful heat from wood combustion, improving overall efficiency.

Gasification (Producing Wood Gas)

This process involves heating wood in a low-oxygen environment to produce "wood gas" (also known as producer gas or syngas), which is a combustible mixture primarily of carbon monoxide, hydrogen, and methane. This gas can then be used to power internal combustion engines.

Vehicles (during fuel shortages)	Famously used during World War II and other periods of petroleum scarcity, cars, trucks, buses, tractors, and even some military vehicles were converted to run on wood gas generators mounted to them or on trailers. This technology is still used in some remote or developing regions today.
Internal Combustion Engines	Any engine designed to run on gasoline or natural gas can potentially be modified to run on wood gas, though with lower power output and requiring extensive gas cleaning. This includes: ● Generators: To produce electricity in off-grid or emergency situations. ● Pumps: For irrigation or water supply. ● Small Industrial Equipment: Where an engine is needed to drive machinery.
Heating Systems	Wood gas can be burned directly in boilers or furnaces for space heating or water heating.

Pyrolysis (Producing Bio-Oil or Biochar)

Heating wood in the complete absence of oxygen produces bio-oil (a liquid fuel) and biochar (a charcoal-like solid).

Engines/Turbines (with bio-oil)	Bio-oil can be used as a substitute for fuel oil or diesel in some engines or turbines, though often requiring significant processing.
Cooking and Heating (with biochar/charcoal)	Biochar, or charcoal, is a much cleaner-burning solid fuel than raw wood, producing less smoke and burning hotter. It's used in grills, traditional stoves, and can even be powdered for fuel briquettes.

Wood Stoves

Homemade wood stoves can be as simple as setting up a windscreen and burning the wood inside it (pot set on stakes or rocks). More complex versions are elevated off the ground to protect your fire and ground, incorporate integrated pot stands and sometimes even have electric fans.

Advantages
● Don't have to carry fuel
● Able to melt enormous amounts of snow without carrying huge amounts of fuel
● Cheap to make, free fuel
● Potential for unlimited hot water and even water purification
● Smoke may decrease the amount of bugs in your campsite
● Use as a heater to warm you up
● Produces less overall pollution than other fuels (no drilling, refining, transporting, etc)
● Renewable energy source

Disadvantages
● Weight, bulk
● Blackening of pots and everything your pot and stove touches
● Everything you hike with will smell like smoke
● Need to hunt for fuel at the end of the day or during your trek
● Dependence on availability of dry burnable wood
● Slow cook time
● Need to fiddle with the fire
● Knowledge of fire building required
● Potential to start forest fire in dry windy areas
● May be banned in your hike area

Toxic Solid Fuels

These are woods and other things you should avoid burning.

"Poisonous" Plants

These are at the top of the list for good reason. They contain irritating oils (like urushiol in poison ivy) that become airborne in smoke and can cause severe reactions.
● Poison Ivy
● Poison Oak
● Poison Sumac
● Brazilian Peppertree (also known as Mexican Pepper)
● Poisonwood

Highly Toxic Trees/Shrubs

These plants contain various toxic compounds that can be released when burned, affecting respiratory systems, skin, or causing systemic poisoning.
● Oleander: Every part of this plant is highly toxic. Burning it can release dangerous fumes. Never use its branches for roasting food.
● Yew (Taxus baccata and Japanese Yew): All parts of the tree (except the fleshy red aril of the berry) contain highly toxic alkaloids called taxines.
● Manchineel Tree: Found in tropical regions, this is considered one of the most dangerous trees in the world. Its sap causes extreme blistering, and even standing near its smoke can cause severe respiratory issues and temporary blindness.
● Laburnum: Poisonous wood.

Treated or Manufactured Wood Products

These are perhaps the most dangerous to burn due to the chemicals they contain.
● Pressure-Treated Wood: Often green or greenish, this wood is treated with chemicals like copper, chromium, and arsenic (CCA, common before the early 2000s) to prevent rot and insects. Burning it releases highly toxic fumes, including arsenic compounds, which are extremely dangerous and carcinogenic.
● Painted, Stained, Varnished, or Sealed Wood: The finishes contain various chemicals, pigments, and heavy metals (like lead in old paint) that release toxic fumes when burned.
● Plywood, Particle Board, MDF (Medium-Density Fiberboard), Chipboard: These are made with glues, resins, and formaldehyde, which release toxic fumes when burned.
● Laminated Flooring/Wood: Contains adhesives and plastics that are toxic when burned.
● Wood Pallets (unless certified as heat-treated - HT): Many pallets are chemically treated (e.g., with methyl bromide, indicated by "MB") to prevent pest infestations. Only burn pallets marked "HT" (Heat Treated) and ensure they are clean and free of spills or contaminants.

Driftwood

While it might seem appealing, driftwood soaked in saltwater can release chlorine and other metal salts when burned, leading to the formation of dioxins. Dioxins are highly toxic and carcinogenic.

Green or Wet Wood

While not "toxic" in the same way as treated wood, burning green (freshly cut) or wet wood is extremely inefficient and harmful:
● Excessive Smoke: High moisture content creates a lot of smoke, which is irritating to the eyes and lungs.
● Creosote Buildup: The incomplete combustion of wet wood leads to a significant buildup of creosote in your chimney or flue. Creosote is highly flammable and is a leading cause of chimney fires.
● Low Heat Output: Much of the energy goes into boiling off the water rather than producing heat, making it inefficient.

Moldy or Rotten Wood

Burning moldy wood can release mold spores and toxins into the air, which can be particularly problematic for individuals with allergies, asthma, or compromised immune systems. Rotten wood also burns poorly and produces more smoke.

Some Softwoods

While not strictly toxic like the above, some softwoods like pine, spruce, and fir contain high levels of sap and resin. When burned, these resins can contribute significantly to creosote buildup in chimneys, increasing the risk of chimney fires. If you must burn them, ensure they are extremely well-seasoned and that your chimney is regularly cleaned.

Contaminated Wood

Any wood that has been in contact with chemicals, oil, grease, or other hazardous substances (e.g., old railway sleepers, some construction site offcuts) should not be burned.

Seasoning

Seasoning wood for a fireplace is crucial for efficient, clean, and safe burning. "Green" or unseasoned wood contains a high moisture content, making it difficult to light, producing excessive smoke, and leading to dangerous creosote buildup in your chimney. Seasoned wood, on the other hand, has had most of its moisture evaporated, resulting in a hotter, cleaner burn.

Timing is Key (Plan Ahead!):

When to Cut/Buy: The best time to cut or buy green wood for seasoning is in late winter or early spring (around February-April in the Northern Hemisphere, or August-October in the Southern Hemisphere like Queensland). This allows the wood to dry throughout the hottest and driest months.
Seasoning Duration:
● Softwoods (pine, spruce, fir): Typically need at least 6 months to a year.
● Hardwoods (oak, maple, ironbark, redgum, spotted gum - common in Australia): Can take 1 to 2 years, sometimes even longer for very dense wood.
Aim for Moisture Content: Properly seasoned wood should have a moisture content of below 20%, ideally closer to 10-15%. You can test this with a moisture meter (available at hardware stores).

Preparation (Cut and Split):

Cut to Size: Cut logs into manageable lengths that fit your fireplace or wood heater (typically around 35-40 cm or 14-16 inches).
Split the Wood: This is one of the most critical steps!
● Why split? Splitting exposes more surface area to the air and sun, significantly speeding up the drying process. Unsplt rounds will take much, much longer to dry and are prone to rot.
● Size: Aim for pieces that are 10-15 cm (4-6 inches) in diameter. Smaller pieces dry faster.
● Bark: While not essential to remove, some people split barkless or peel bark where possible, as bark can trap moisture.

Storage Location (The "Holy Trinity" of Air, Sun, and Protection):

Outdoors is Best: Wood seasons most effectively outdoors where it's exposed to wind and sun. Avoid storing large quantities indoors due to fire risk and potential pest issues.
Sunny Spot: Choose a location that receives as much direct sunlight as possible.
Good Airflow: This is paramount. The wind helps to wick moisture away.
- Avoid Stacking Against Walls: Leave space (at least a few inches) between the wood stack and any walls to allow air circulation on all sides.
- Don't Stack Too Tightly: Leave small gaps between individual logs within the stack.

Off the Ground: Elevate your stack to prevent moisture absorption from the ground and deter pests. Use pallets, concrete blocks, old tires, or dedicated firewood racks. Aim for at least 15 cm (6 inches) off the ground.

Protected from Rain: While sunlight and wind are good, rain is the enemy.
- Cover the Top Only: Use a waterproof cover (tarp, sheet of corrugated iron, custom firewood cover) over the top of the stack.
- Allow Ends to Be Open: Crucially, do not cover the sides or ends of the stack down to the ground. This traps moisture and inhibits airflow, leading to mold and slow drying. The ends of the logs are where most of the moisture escapes.
- Open-Sided Shed/Woodshed: An ideal solution is a dedicated woodshed or structure with a roof but open sides, providing excellent protection from rain while allowing maximum airflow.

Stacking Techniques

Single Rows: Stacking wood in single rows (or no more than two rows deep) maximizes exposure to wind and sun for each piece.
Criss-Cross or "Log Cabin" Style: This method (stacking alternate layers perpendicularly) creates excellent airflow pockets within the stack. While it takes up more space, it significantly speeds up drying.
Bark Up: When stacking, try to place logs with the bark side facing upwards. This helps shed rainwater away from the wood.
Orientation: If possible, orient your stacks perpendicular to the prevailing wind direction to maximize airflow through the pile.

Monitoring and Maintenance

Moisture Meter: Invest in an inexpensive moisture meter. This is the most reliable way to know when your wood is truly seasoned. Insert the probes into a freshly split face of a log for an accurate reading.
Visual/Auditory Cues (Less Precise but Helpful):
- Color: Seasoned wood will fade in color and look duller or grayer.
- Weight: It will feel significantly lighter than green wood.
- Sound: When you hit two seasoned pieces together, they'll make a hollow, ringing sound, as opposed to a dull thud from wet wood.
- End Cracks: Seasoned wood will often have visible cracks (checking) at the ends of the logs.
- Bark: Bark may be loose or peeling on seasoned wood.

Rotate (FIFO): If you have multiple stacks, use a "First In, First Out" system to ensure you're always burning the driest, oldest wood.
Keep it Clean: Remove any debris, leaves, or growth around your wood stacks that could impede airflow or harbor pests.

Hardwood Properties

	Heat	Weight (Pound/Cord - Seasoned)	Splitting Ease	Starting Ease	Coal Qualities	Sparks	Fragrance

Wood Gas

TODO: Wood gasifier.

Wood Storage

For storage of wood see the HOMESTEADING section.

Hexamine

Hexamine (also known as hexamethylenetetramine or methenamine) is a heterocyclic organic compound with the chemical formula $(CH_2)_6N_4$. It's formed by the reaction of formaldehyde and ammonia.

The tablets burn smokelessly, have a high energy density, do not liquefy while burning and leave no ashes. They burn for 5-7 minutes and can boil about 240ml of water. Fire starter tablets aren't as hot as hexamine and produce a black soot on pans. Can boil about 240ml with a tablet. Probably the third best choice for stealth cooking behind alcohol and gas cooking. Esbit tablets are about 14g and the 45x45mm tablets are 26g.

Hexamine tablets often come with a sheet metal stove to burn them on. The stove folds up to contain the tablets and unfolds to burn them. Hexamine can emit a variety of harmful gases, including formaldehyde, hydrogen cyanide, ammonia and oxides of nitrogen on combustion, and repeated or prolonged contact can cause skin sensitization. Half a hexamine tablet can boil about two cups of water.

Form: It's a white, crystalline solid, typically compressed into small, lightweight tablets.
Combustion: Hexamine tablets burn with a smokeless flame and produce a high energy density. They are known for being easy to ignite with a match or lighter.
Residue: A notable characteristic is that they do not liquify while burning and leave very little ash (though they can leave a sticky, dark residue on the bottom of pots).
Shelf Life: Hexamine has an almost unlimited shelf life if stored properly in a sealed, dry container.

Common Applications
● Camping and Backpacking: Extremely popular for lightweight cooking and heating in outdoor settings, often used with small, foldable stoves.
● Military Field Rations: Historically and currently used by various militaries for heating combat rations.
● Emergency Kits: Due to its stability and ease of use, it's a common component in emergency preparedness kits.
● Model Engines: Used to power small steam engines in models.
● Fire Starters: Can be used to help ignite larger fires.

Safety Considerations of Hexamine

● Combustion Byproducts: While smokeless, hexamine combustion can produce noxious fumes, including formaldehyde, ammonia, carbon oxides, nitrogen oxides, and potentially hydrogen cyanide (HCN), especially in poorly ventilated areas. This is why it's critical to use it outdoors or in very well-ventilated spaces.
● Respiratory Irritation: Inhaling these fumes can cause respiratory irritation.
● Ingestion: Harmful if ingested, potentially causing nausea, vomiting, gastrointestinal disturbances, and kidney damage.
● Precursor for Explosives: It's important to note that hexamine is a precursor chemical for the synthesis of certain high explosives, such as RDX. For this reason, its possession and sale can be regulated in some regions (e.g., the UK).
● Sticky Residue: Can leave a difficult-to-clean residue on cookware.
Sensitivity to Wind/Dampness: While effective, its efficiency can be reduced by strong wind or damp conditions, requiring wind shelters or additional tablets.

Hexamine vs Trioxane
● For maximum heat output and long burn time per gram, Hexamine (Esbit) is often cited as having a slightly higher energy output.
● For stealth (low luminosity flame), Trioxane has an advantage, which is why it's favoured by some military forces.
● For general safety, particularly regarding accidental ingestion by children/pets, Trioxane is generally considered less acutely dangerous than the neurotoxin metaldehyde, and arguably slightly safer in that specific regard than hexamine (though both are still very toxic if ingested).
● For general outdoor use, both require excellent ventilation due to the harmful byproducts (formaldehyde, CO, etc.).

Trioxane

AKA - triox, GI fuel tabs, metaformaldehyde, trioxane,1,3,5-trioxacyclohexane, 1,3,5-trioxane, aldeform, formagene. The US military uses trioxane fuel bars which are cheap (you can buy cases of 750 from many surplus dealers) and are said to have "an almost infinite shelf life." Because of this, they are great for survivalists who want to store large amounts of supplies that are easily procurable and economical (GI surplus is a also a plus with many of these folks). Trioxane has about half the potential heat value per ounce than hexamine but burns a light blue which is more tactically sound than the bright yellow of hexamine.

Warning
These fuel tabs contain metaformaldehyde which is toxic and releases formaldehyde gas (also toxic) when it decomposes. This fuel is toxic despite the many websites that claim theirs are "nontoxic".

Note
The Trioxane used in antimalarial agents is 1,2,4-Trioxane and is structurally different than Trioxane Fuel tabs.

Form: Like metaldehyde, trioxane is typically a white, crystalline solid at room temperature and is compacted into tablets or pellets for use as a fuel.
Flame Characteristics: It burns with a smokeless, low-luminosity flame. This low luminosity is particularly advantageous for military applications where maintaining a low visual signature is important, such as heating field rations without revealing a position at night.
Ease of Ignition: Trioxane is known for its easy ignition.

Applications
● Military Field Rations: Widely used by armed forces (e.g., US military) for heating MREs (Meals, Ready-to-Eat) and other field cooking needs.
● Camping and Outdoor Cooking: Its compact size and ease of use make it suitable for lightweight backpacking and emergency kits.
● Fire Starting: Can be used as a fire starter to ignite larger fuels.

Safety Considerations
While often presented as a safer alternative to some other solid fuels, trioxane still has safety considerations that are important to understand:

Flammable Solid: It is classified as a flammable solid and requires careful handling and storage away from heat, sparks, and open flames.
Decomposition to Formaldehyde: When heated, trioxane can decompose and release formaldehyde vapor. Formaldehyde is a known irritant to the respiratory system, eyes, and skin. Prolonged or high-level exposure can be harmful and it is classified as a human carcinogen. Therefore, it's crucial to use trioxane in well-ventilated areas.

May Cause Respiratory Irritation: Inhalation of the fumes, particularly if ventilation is poor, can cause respiratory irritation.
Suspected of Damaging Fertility or Unborn Child: Some safety data sheets (SDS) indicate it is suspected of having reproductive toxicity.
Toxicity (if ingested): While generally considered less acutely toxic than metaldehyde, it is still not for ingestion and can cause harm if swallowed.
No Obvious Odor: Unlike some fuels, its burning may not produce a strong warning odor, which can be a concern if used in poorly ventilated areas.

Comparison with Metaldehyde

The key difference and reason for trioxane's more widespread use as a field fuel compared to metaldehyde is its lower acute toxicity when ingested. While neither should ever be eaten, metaldehyde is an extremely potent neurotoxin with a high risk of fatality even in small amounts, making it a serious hazard, especially around children and pets. Trioxane's primary concern revolves around the release of formaldehyde during combustion and its flammability, rather than acute systemic poisoning from accidental ingestion in the same way as metaldehyde.

Metaldehyde

Metaldehyde (met-AL-duh-hyde) is a chemical compound with the formula $(C_2H_4O)_x$, where 'x' represents a variable number, typically a tetramer (meaning four acetaldehyde units). It's primarily known as a molluscicide, used in slug and snail baits. However, it was originally developed and is still used as a solid fuel.

Key Characteristics and Uses

Form: It's typically sold in tablet form for use as a solid fuel. These tablets are often white, crystalline, and can have a mild, menthol-like odor.
Flammability: Metaldehyde is highly flammable and burns with a relatively smokeless flame. This makes it appealing for portable heating and cooking applications where smoke might be undesirable.
Applications:

- Camping Fuel: A common use is in small, portable camping stoves for heating water or cooking light meals.
- Military Purposes: Due to its solid form and efficiency, it has been used in military field rations for heating.
- Preheating Stoves: It can be used for preheating certain types of liquid-fuel stoves (like Primus stoves).
- Lamps: Sometimes used as a solid fuel in small lamps.
- Novelty Products: In some cases, it's used in products designed to produce colored flames.

Despite its utility as a fuel, metaldehyde has significant drawbacks due to its toxicity.

- Poisonous if Ingested: This is the most critical hazard. Metaldehyde is a potent neurotoxin. Ingesting even small amounts can cause severe poisoning in humans and animals, leading to symptoms like muscle tremors, seizures, hyperthermia (high body temperature), respiratory failure, and can be fatal. This is why it's so effective as a snail bait, but also why it poses a major risk to pets and young children who might mistake the pellets or tablets for food.
- Irritant: It can be irritating to the skin and eyes.

Fumes: While it burns smokelessly, it can release irritating and/or toxic gases, including oxides of carbon, if combustion is incomplete or in confined spaces. Inhalation of these fumes can cause central nervous system depression, dizziness, nausea, and even coma, especially in poorly ventilated areas.

- Decomposition: Upon heating (above 80°C), metaldehyde can depolymerize back into acetaldehyde, which is also a toxic chemical.

Contrast with other fuels

Unlike alcohol-based gels or gas canisters, metaldehyde provides a solid, compact fuel source. However, its significant toxicity means it must be handled with extreme care and stored well away from anything that could be accidentally ingested. Its widespread use as a molluscicide also adds to the risk, as people might not realize that the "snail bait" and the "camping fuel" can be the same dangerous substance.

Wax

	Advantages	Disadvantages
Wax has a great deal of heat potential per ounce but can be difficult to harness enough to make it worthwhile as much of the heat is used to heat up and melt the wax and some of the fuel will go unburnt and blacken your pot. Stoves fuelled by paraffin wax (not to be confused with kerosene - often referred to as paraffin) generally incorporate a wick and are basically wide candles with enough wick(s) to cook. These stoves have their own advantages and drawbacks compared to other stove types.	• Light Source • Heat Source • Can Waterproof Matches	• Lots of Soot • Easily Blown Out • Only Warms Food • Can't Boil Water

Wax Gasifier Stove	The G-Micro PSL wax gasifying stove will melt, gasify and burn solid wax and is purpose made for solo and duo outdoors use. It will also burn alcohol and a few other liquid fuels which makes it a truly multi-fuel stove. This makes for a very useful travel stove which runs on economical, waterproof fuel (wax) which will never spill in your pack. The G-Micro PSL with wax fuel can even be checked at an international airport which can make adventure travelling that much less complicated since you don't need to spend time looking for fuel at your destination as it's already packed. If you run out of fuel, you can use alcohol or wax from cut up candles, which are generally available world wide. It will also burn kerosene in a pinch, but will leave your pot quite sooty. There are certainly downsides to using this and other wax powered stoves, but there are certain applications where this one will shine.
Paraffin Candle Stoves	Nuwick paraffin candle stoves strive to be so environmentally friendly that they use soy wax in their stoves. You might be able to bring water to a boil with these and they work best indoors and protected from drafts. The LIFE LITE line is one of the few commercial beeswax survival candle options on the market. Beeswax is a renewable fuel and is thought to burn cleaner and longer than paraffin.
Tealight Candles	Tealights are widely used to cook with and to heat up tea and other items.
Candle Lanterns	Candle Lanterns are built with a transparent windscreen/chimney so that you can use the candle as a light without it blowing out. Some are even built with a stove top to allow you to melt, warm and/or boil. These tend to be made with glass and are on the heavy side. Smaller commercial tea candle lanterns may be lighter than their pound-plus brothers but are still on the hefty side for an ultralight hiker. A lightweight homemade lantern can be as simple as using a cut down plastic bottle for a wind screen or a bit fancier and constructed to be mobile, hangable and/or useable as a stove. The one above is lightweight and functions as both a candle lantern and as a stove. This sootless system works great for slowly heating up and keeping tea hot or for melting snow while providing a nice night light. If you want to use an aluminium can as a teapot, you might want to make your lantern out of a Guinness beer can which will support just about any size can (including a 24oz Heineken can). Note - various sized lantern chimney/globes can be purchased or made in stainless mesh or glass for those wanting something more heat resistant than a PET plastic. A plastic chimney will work if you are careful loading lit candles into your lantern and don't build them too narrow or tall for your flame. The Chinese have been making lanterns made from paper and bamboo since 250 BC. Paper lanterns don't seem weather resistant or durable enough for most hikers' use.

Buddy Burners	Homemade candle stoves have also been around for centuries. It doesn't take much imagination to envision one of Merlin's alchemists in a darkened room boiling up a small tonic with the heat from a smoky tallow candle. Commonly referred to as Tuna Can Stoves or Buddy Burners, a simple and more modern candle stove can be easily made by pouring melted wax in a metal can (tuna or 7oz cat food is fine) filled with rolled up corrugated cardboard (centre wick is optional). If you over fill the wax so that it covers your wick, use a knife to scrape it off before trying to light it. These candle stoves have several good qualities. They are completely waterproof, don't spill when stored, are easy and economical to make, are not an explosion hazard, don't decompose like other solid fuels, don't require any environmental constraints for storage and are ready to use as is without any special stove or equipment. Their indefinite storage life and easy of construction/use makes them ideal for stockpiling for an emergency. This makes them also popular with survivalists and the Zombie Apocalypse crowd. People who use this type of stove to cook report that using a cardboard to section off the wax as shown above allows for better air flow to the gasified wax. This allows more efficient burning of wax with less waste.
Liquid Candles	Liquid candles are just like solid candles in that they require a wick to vaporize fuel for burning but also need some sort of holder. Ready made liquid candles can be purchased in either refillable or disposable plastic containers such as the one above (also available in tealight 1oz size), all of which can be refilled (use a needle and syringe for or squeeze fill the non-refillable types) with various flammable fuels and oils. Vegetable oils, candle fuel, lamp fuel and other liquid oils can be burned with a wick but can be quite sooty, depending on your lamp, wick (type and length) and fuel. Remember that some oils will solidify or gel at low temperatures encountered on winter treks.
Plant/Vegetable Oil Stoves (Pflanzenölkocher)	A simple, yet adequate, stove can be made from an aluminium can, aluminium foil and tissue paper. Fuel such as plant or vegetable oil will allow you to cook with this stove system. Soy bean oil is classed as a drying oil and will leave a residue on metal parts and wick and should not be used, Corn oil leaves a crusty residue on wicks and should not be used. But blends of various oils including these are possible, and can be explored. There is a good amount of effort going into creating better vegetable oil burning stoves. Vegetable oil is readily available globally and is very renewable. These stove also offer many in the developing world a cook system with reduced emissions compared to biomass and kerosene fuelled stoves.
Oil Lamps	These can be a simple film canister or aluminium can with a tissue wick or as ornate as the carved wood version shown above. Ideally you will either want a good resealable lamp/stove so that you don't end up with leaks in your pack, or to carefully add just enough fuel (with syringe, straw or very careful pouring) to your lamp/stove as you would with a simple alcohol stove. If you plan to use plastic containers for lamps, you may need to distance the flame from your plastic parts to prevent melting. You can use a glass tube (wick holder), metal cylinder, or rolled up aluminium to distance the flame. If you want to use a resealable plastic bottle (e.g. pill bottle) with a narrow opening, you may need to build it so that the wick holder can be pulled up high enough to prevent damage to the container while being able to be pushed back in for storage. Gaskets can be made from bicycle inner tubes or do it yourself gasket sheets found at auto parts stores. Another option for a narrow topped bottle lamp is modifying the lid so that the wick holder and wick will fit within the top itself. This can be done by drilling a hole in the original lid and epoxying on a second lid (show above). If you would like to get fancy with a beverage can lamp, you can use a Monster Energy Drink can with a resealable lid to make a lamp/stove you can seal when you are done. You can also use a plastic or glass bottle/jar to make a resealable lamp with a built in globe to protect the flame from wind.
Qulliq (Blubber Lamp)	Stone qulliqs (blubber lamps, aka Kudlik) have been used for centuries in Alaska and Siberia. If you are in an area where seal blubber is the only fuel available, a stove can be made from a carved out stone or a an empty tin can. Take a handful of seal fat and mash it down with a kautaq (caribou antler hammer) inside a kaugarvik (stone bowl) and put it in your qulliq. Then set several wicks made with arctic cotton (kanugujak) or moss around one side of the stove and light.

Wax Types

Paraffin Wax	The most common and cheapest wax used in candles today. It is made from petroleum waste and produces smoke and soot. There is big talk these days about cancer caused by inhalation of paraffin candle smoke. Candles made form this wax are ideal for those who shop at the dollar store (or pound store) and don't worry themselves about cancer reports.
Beeswax	Made by bees, this is considered by many to be the cleanest burning wax around. This may stem from times of old when beeswax was reserved for the church as it is long burning, clean, flagrantly and didn't not stain the precious walls and windows of the church like tallow candles. It also burns much longer and produces more heat per gram than paraffin wax. And because of the lack of smoke and soot, these waxes are considered safe by many. This fuel is also more expensive than paraffin per gram but their longer burn times may offset the price difference. Some hunters use honey burners or beeswax candles to attract hungry bears, which could be a plus if you are hunting but not such a desirable feature after a long day of hiking. This is probably the best choice of wax for hikers unless the chance of attracting bears and other critters is undesirable.
Stearin	Stearin candles are made up of stearic acid that is often mixed with palmaitic acid. This wax is produced by the saponification (mixing with a strong alkali) of vegetable and/or animal fats. Stearic acid is also used to add firmness to paraffin wax and increases candle burn time.
Gel Wax	This wax is made of white mineral oil, gelliants, and butylated hydroxy toluene. Because of their softness, these waxes must be used in containers with ridged wicks. Ideal for those who like colours, smells and don't have allergies.
Soywax (Vegetable Wax)	Soywax is made from hydrogenated soybean oil. Not the best candle material around as it may only melt the core of the candle and can be brittle. It does burn cleaner than paraffin (but produces more soot than beeswax), is considered safe to use and doesn't shrink when it cools.
Carnuba Wax (Vegetable Wax)	A wax exuded by the leaves of the Brazilian Carnauba Palm nuts.
Ceresine (Vegetable Wax)	This is made from palm oil and coconut wastes modified with other vegetable waxes. It is a higher quality wax than paraffin.
Bayberry (Vegetable Wax)	Made from bayberries. A sweet-smelling wax that burns clean.
Tallow	Tallow is made from suet. Very smoky, sooty and produces an acrid odour when burned. Some of these candles can be made to be edible.
Stearic Acid	This is produced by the saponification (mixing with a strong alkali) of vegetable or animal fats (also found in chocolate) and is used to add firmness to paraffin wax and increases their burn time.
Spermacetiti	Made form the crystallizing oil found in the heads of sperm whales. A one pound candle made form this wax is the standard source of light for one "candle power." Spermaceti wax doesn't produce an acrid odour when burned, is harder than tallow or beeswax, doesn't soften or bend in the summer heat, and produces a pure bright light.
Seal Oil	Oil from blubber can be used with a wick and has been used for centuries in Alaska and Siberia.
Lamp and Candle Fuel	Many brands are straight kerosene, while others are refined into heavier and cleaner hydrocarbons in liquid form (at room temperature).

Vegetable Oils	Oils such as olive oil can be used for lamps, but tend to burn very sooty.

Wicks

A wick can really change and even improve the functionality of an alcohol stove.

1. Wicks fuel into a flame - important for ignitions of certain fuel depending on temperature.
2. Soaks up liquid fuel like a sponge to reduce spill hazard.
3. Works as a platform for fuel, such as when used as a priming bracelet around a stove.
4. Mobilizes fuel from one area to another.
5. Heat resistant structure for supporting pot, stove parts or as a protective handle for either.
6. Heat resistant insulation.

Wick Types

Flame Wick	For Candles and low volatility fuels, such as lamp fuel and various oils, the wick mobilizes fuel into a flame. This increases the surface area with oxygen and more importantly exposes the fuel to the hot part of a flame. After ignition, the wick continues to mobilize liquid fuel into the flame. This can be a simple and small as a candle wick in a tealight or as large as a "mop head" wick for a large kerosene heater.
Spill Protection Wick	Many stovers use wicks to hold fuel in their stoves. This makes it less likely that fuel will spill and spread flames everywhere if the stove is bumped or even knocked over. This can make a stove much safer to operate. In some cases, it even makes the stove easier to fill.
Wick Fuel Mobilizer	Wick have been used in conjunction with and without tubes to move liquid fuel from one area into another. Examples include wicking fuel from a fuel tank into tubes for the stove jet or even onto anther wick.
Wick Support	Wick material can be used to support a pot over a stove or hold stove parts together. Wicking fabric can be epoxied to surfaces, sewn together with heat resistant thread or even tied together to itself or other items. You can wrap a wick around your pot, and use this ridge to support your pot on a tight windscreen or potstand.
Wick Insulation	Since many wick materials used by stovers are also heat resistant, they can make excellent flame-proof/resistant insulation. You can use this to cover pots to create grab areas, make pot cozies, make stove sleeves to insulate stoves from the cold and many other high heat uses.
Non-Cored Wicks	
Cored Wicks	Usually cotton braided around a zinc, tin, lead, cotton or paper core. The core adds rigidity to the wick which is needed for candles that easily melt. In 1974 the US National Candle Association agreed to discontinue using lead-cored wicks and in 2003, the US Consumer Product Safety Commission banned lead-cored wicks because of health concern. But even with these bans in place, you can still find lead in candle wicks in the US and in other countries. There are also new concerns about the burning of zinc. If you are concerned about lead in your wick, you can rub a white piece of paper over an un-burnt wick and look for a lead streak. If it has a lead streak, look for a different candle or wick.

Wick Materials

Material	Melting Point °C	Melting Point °F	Notes
Graphite Felt	2000°C	4500°F	
Zoltek Pyron	1371°C	2500°F	Flame Protector
Silica Seals	1260°C	2300°F	Seals for ovens
Carbon Felt	1200°C	2192°F	
Asbestos	1200+°C	2192+°F	Cancer
Fibreglass	1200°C	2192°F	Softens and degrades
Wool	600°C	1112°F	Ignition temp
Kevlar	500°C	932°F	Doesn't melt - Degrades
Technora	500°C	932°F	Fancy Kevlar/Tech Cord
Vectran	330°C	626°F	
Baking Silicone Mat	316°C	600°F	
JB Weld Epoxy	316°C	600°F	10 minute exposure limits
Polyester	250-300°C	480-580°F	
Nylon	190-350°C	374-663°F	
Cotton	150°C	300°F	Decomposes; Easily burns at 255˚C
Sisal	150°C	300°F	
Manila	150°C	300°F	
Spectra	147°C	297°F	
Super Glue	82°C	180°F	Slightly better for Hi temp super glue

Makeshift Wicks

Fibreglass Insulation	Sections can be scavenged from the walls or attics of your house or from scraps at a construction site. A more user friendly size comes in 1/2 inch thick pipe insulation and can be trimmed and stacked or rolled up. Note: When burned, fibreglass produces a good deal of polycyclic aromatic hydrocarbon and Volatile organic compound (VOC i.e. benzene, toluene, ethyl benzene and styrene). Fibreglass can also cause local irritation and an inhalational hazard.
Fibreglass Wicks	Made for lanterns or for fire shows (often Kevlar blend), these can be wrapped around stoves as an alternative to using a primer pan. fibreglass comes in cord (with various weaves) and tape of all sizes.
Fibreglass Stove Gasket	You can find various braided wicks sold as stove gaskets. These can be rather large. You may have these at your local hardware centre or local stove shop.
Fibreglass Exhaust Wrap	Looks great when you first wrap it around your exhaust. It wears poorly on an off-road vehicle and leave dust on trailer queens. You should be able to find this in the better autoparts shops.
Fibreglass Medical Gauze	This has resin built in and begins to harden as soon as the package is opened. Water allows you to mould it and speed up setting. It's used to make casts and splints at the doctor's office. This material may be better suited as a structural part than a wick.

Fibreglass Cloth	Fibreglass cloth comes in various configurations for use as auto body and marine body repair. You should be able to find this in most autopart and marine shops.
Fibreglass Drywall Tape	Self-adhesive fibreglass gauze. It's like using duct tape, but you will need too technique in rolling your edges, else you'll have fuzzy edges.
Kevlar Cord/Rope	Used by fire jugglers and for other high temp applications which need a durable cord. Kevlar also comes in various sized tape, cloth and webbing for high strength, high temperature applications.
Kevlar Speargun Line	Kevlar cord is also used for spear guns.
Kevlar Thread	Kevlar thread has good thermal stability and retains a high percentage of room temperature properties even up to 300°C after one to two hours exposure in air. It does not melt, or support combustion, but will oxidize at 400-430°C. However, at temperatures as low as 196°C Kevlar shows no loss of strength. This makes it ideal for high temperature applications. It is good for up to 320°F continuous.
Alumina Thread	This is the highest temperature rated thread available. It's good for up to 2200°F continuous.
Carbon Felt	An asbestos replacement. Used for very high temp applications, such as for insulation or back drop for soldering/welding. Carbon felt will begin to slowly oxidize at approximately 300°F and can ignite in air above these temperatures. Carbon felt is heat resistant to 1200°C+.
Graphite Carbon Felt	Even a higher temperature rating than carbon felt. Graphite felt will begin to slowly oxidize above 500 degrees F and can ignite in air above these temperatures. Graphite carbon felt is heat resistant to 2000°C+.
Zoltek Pyron Fibre Sheet	This oxidized PAN fibre felt is found in the soldering and welding department of hardware stores. Good up to 2500°F.
Perlite	This is found in the gardening section of hardware stores and is made up of tiny volcanic rocks. This option can be very messy when used and requires metal mesh or something else to hold it in place. It may be best to use the larger pieces depending on your application and throw out the dust and small pieces. Expect to get a little (or a lot) of dust spillage. Expanded perlite has been used at service temperatures as high as 2,000°F (1,100°C) and is used in high temperature applications in the steel and foundry industries.
Cotton Wicks	This is popular for candle, lantern and stove use. Cotton begins to decompose at a relatively low temperature compared to other options, but will work fine for certain applications. You should be able to find these in most candle shops and many hobby shops or bigger stores with a crafts section. And just about anything cotton can be turned into a wick.
Natural Fibres	Anything from dried moss to twisted up wood fibres can be used as a wick. This will allow you to burn just about any flammable liquid or wax you can find in the woods.
Steel Wool	Many stovers have used steel wool in various ways as a "wick". The results are mixed as the mass and presence of the steel can alter the performance of your stove, sometime increasing your own performance goals due to thermal feedback or slowing warm up - depending on how you use it. I don't see it working as a "wick" in the sense that it moves fuel into it, but maybe I've missed something interesting here. If so, please let me know. Steel wool will also readily rust once it becomes wet, unless you are using stainless steel.

Wax Hazards

When solid, wax is pretty inert. It doesn't react with water or air, and can even be chewed and swallowed in most cases without much ill consequence, except for the potential of blocking up your intestines. But like with kerosene stoves, there are many who are concerned about exposure to the hydrocarbon by-products of burning candles. Many feel that synthetic paraffin creates more soot and cancer causing by-products when burned compared to beeswax or soy wax. It appears that Philip Fine (1999) found that beeswax does produce a different emissions signature than paraffin wax when burned. Beeswax did produce less sooting but had higher emission rates per mass of wax burned than the paraffin candle due to lower burn rates and longer smouldering times. Emissions from this smouldering would be limited by cutting off the tip of the wick, which avoids the creation of an ember at the end of the wick.

Some studies suggest that paraffin waxes are as safe as other waxes used to make candles. However their reports lack consideration of key hazards found in burning fumes which may make paraffin as well as other waxes potentially hazardous. It is also equally important to note that a good amount of the claims that beeswax is safer than paraffin waxes likewise comes from those selling beeswax. Soy wax claims are similar.

Soot

The thermal structure of combustion is quire complex for waxes. As it burns, it can produce various flame colours. The blue colour is due to chemiluminescence, while the visible yellow colour is due to radiative emission from hot soot particles. The soot is formed through a series of complex chemical reactions, leading from the fuel molecule through molecular growth, until multi-carbon ring compounds are formed. The majority of emissions include organic compounds such as alkanes, alkenes, alkanoic acids, wax esters, cyclohexylalkanes, and alkanals. Soot inhalation has known health hazards. Proper wick trimming and configuration will substantially reduce soot emissions from most candles but will not eliminate them. The amount of particulate matter found from burning incense and candles is thought to increases your risk of cancer more than burning tobacco.

Hot Wax

Wax gets really hot and because of the large size of its molecules, it stores a good deal of energy. So when hot liquid wax hits your skin, it sticks and keeps burning. Once burned, you are more likely to drop or throw your candle and ignite items nearby.

Fires

Fires started by candles are far more common than it should be worldwide. People aren't so concerned about leaving a burning candle in a room or tent unattended.

Lead

Lead core wicks were common prior to the 1970's where lead was used to stiffen wicks to hold them erect. The US candle manufacturing industry voluntarily agreed to cease production of lead-containing candles in 1974. In the developed world, metals other than lead are favoured in wicks, yet wicks in the developed world still can contain large amounts of lead in them. In less regulated parts of the world, you can expect lead to be more common in candles. Lead is a known health and developmental hazard and is still the dominating hazard from burning candles. Burning of lead core wick has be shown to produce hazardous levels of lead in the air.

Trace Metals

Metals such including Cd, Cr, Co, Mn, Ni, and Zn are found in addition to lead in candle smoke. These metals cause everything from minor irritation to chronic lung disease to cancer.

Carbon Monoxide

This is the odourless part of the smoke and fumes emitted by any wax powered stove or lantern. If you see a yellow flame, you can expect a fair amount of carbon monoxide. If you see a flame, you can expect some amount of carbon monoxide. See the Carbon Monoxide page for more information on this hazard.

Aroma Additives

These are all really bad for you. Avoid any waxes with scent additives - even if they claim to ward off mosquitoes or wolves.

Incense

There area several studies that show exposure to incense smoke is related to many illnesses, including cancer, leukaemia in children, childhood brain tumours, asthma, and contact dermatitis.

Bears

One common way hunters attract bears is by heating up honey or burning beeswax candles. Bears love honey and if you are in bear country, bears will take notice when you fire up a beeswax candle or stove. They may even be interested in your solid beeswax candle you have packed away in your pack.

Solid Alcohol

AKA - Dry Spirit, Waxed Solid Fuel, Pastilles Carburant Solide, Flaming Solid Alcohol, stearyl alcohol, octadecanol. Solid alcohol fuel is generally considered safer to use than liquid alcohol as it has much less of a spill hazard potential. These fuels range from pure solid alcohol to solid compounds to waxy semisolid forms to gel structures. And depending on makeup, they may be free standing, wrapped in shrink wrap with or without foil, sealed in thin plastic containers or stored in metal tins.

American Gelled Alcohol	Gelled alcohol is the most commonly used form of "solid alcohol." It generally an alcohol of blend of alcohols trapped in a chemical matrix - forming a gel. It must be stored in an airtight container (generally metal). More information on this may be found on the Gelled Alcohol Stoves page.
Chinese Solid Alcohol	"Flaming" solid alcohol is a solid alcohol made from carbinol, ethanol and "condensate." It is widely used in Asia as a safe alternative to liquid alcohol fuel (which causes a high number of burns each year). Since it is more of a solid than gelled alcohol and sublimes rather than melts, it does not require a metal container to contain it.
Japanese Waxed Methanol	Another popular cooking fuel in Asia is shrink-wrapped solid alcohol with foil wrapped around the bottom. The plastic not only protects the fuel for drying up, but is also flammable to help the fuel ignite. These are packed 10 per airtight bag. These are very common to see these in use in restaurants and hotels in Japan. For our Japanese speakers, here is a copy of the paper that came with the package. Although this fuel works rather nicely and is easy to find in Japan, it tends to dry out rather rapidly over time and is not a good choice if you don't plan on using it within a month time.
Stearyl Alcohol	Stearyl Alcohol and other large chained alcohols are often solid at room temperature and is quite flammable. META by LONZA Ltd had an alcohol fuel in a tube made from ethylene added to alcohol which had a calorific value of about 6,000kcal/kg.
Dry Spirit	One fuel includes waxed solid fuel tablets or "Dry Spirit." These are often used by miniature steam engines and are more common in Europe and Asia than in the USA. It can be difficult to determine what a fuel is made of as the term "Dry Spirit" is often used to describe hexamine fuels such as Esbit. It is not clear if the above fuel is a solid alcohol or hexamine. Another method of solidifying alcohol involves mixing it with stearin and sodium hydroxide. This has been used in the days of old in Europe and can be made at home pretty easily if you don't mind working with sodium hydroxide (lye) in your kitchen.

Homemade Solid Alcohol

Caution
The following recipes involve use of sodium hydroxide, which is a very caustic material and is very dangerous to work with. Please read up on this chemical prior to conducting any experiments and take precautions to protect exposed skin and eyes. This recipe is rather dangerous and can cause an explosion - showering the cook with very dangerous chemicals. Do so at your own risk.

Precautions
- Read up on soap and candle making prior to working with lye.
- Always wear gloves and goggles when working with lye
- Never pour water into lye (Caustic Soda).
- If you use water with lye - Never use warm or hot water with lye. Ideally use 50% ice with water.
- Never use tin, zinc or aluminium with lye.
- Have vinegar available to douse skin if lye comes in contact with it.
- Prevent overheating of fuels - as this can cause a fire and/or explosion.

Homemade Solid Alcohol Method 1	US Patent 4436525 describes a solid alcohol fuel that leaves only 6% residue.	**Ingredients (all ingredients are anhydrous)** • 67.7 parts Methanol • 26 parts Isopropanol • 5.5 parts Stearic Acid • 0.8 parts Sodium Hydroxide (aka - NaOH, lye or caustic soda)	**Directions** • Make a 10% NaOH/methanol solution - 10 gms of NaOH are dissolved in 90 gms of methanol • Warm solution to 100°F	**Directions** • Stearic acid is added to isopropanol and remaining methanol and heated to 140°F (stearic acid should melt) • Add NaOH/methanol mixture to stearic acid/alcohol mixture and mix • Pour in moulds

Homemade Solid Alcohol Method 2	**Ingredients** • 100 units of alcohol • 10 units of stearin (glyceryl ester of stearic acid) powder or finely chopped flakes (sold as candle/soap making material or can be made from edible 100% stearin candles) • 3 units of Sodium Hydroxide. Lye may also be homemade with certain wood ashes and distilled water.	**Directions** • Create a water bath to heat your ingredients without overheating them (which could cause an unexpected fire or explosion). This is done by placing a smaller pot (should not be aluminium) within a larger pan or pot filled with water. The larger pan/pot is heated which in turn heats the smaller pot floating in the heated water. • Add your sodium hydroxide and stir. • Add your alcohol to the smaller pot and slowly add stearin to allow it to melt. • Pour your solution into a non aluminium container and allow it to cool down and harden.
Fuel Paste	AKA - Fire Paste, Fire Starting Ribbon, etc. Often used for starting fires or preheating liquid stoves. These pastes can and have been made from many different ingredients.	

FUEL
Liquid Fuel

Liquid fuels are combustible or energy-generating molecules that can be harnessed to create mechanical energy, usually producing kinetic energy; they also must take the shape of their container. It is the fumes of liquid fuels that are flammable instead of the fluid. Most liquid fuels in widespread use are derived from fossil fuels; however, there are several types, such as hydrogen fuel (for automotive uses), ethanol, and biodiesel, which are also categorized as a liquid fuel. Many liquid fuels play a primary role in transportation and the economy.

Examples	**Alcohol** ● Denatured ● Grain ● Methyl ● Isopropyl ● Gelled ● Diethylene	**Petroleum's** ● Petrol ● Diesel ● Kerosene	**Kerosene** Can be used for lamps, wick burners, pressure burners and anti-freeze.	

Alcohol

Various types of alcohol fuels that are used by the camping & backpacking community.

Denatured Alcohol

Uses ● Alcohol Stoves ● Window Cleaning ● Removal of Ink Stains ● Paint Removal	(ethanol with methanol (added as a denaturing agent), methyl ethyl ketone, acetone, water, and possibly other chemicals - aka methylated spirits, metho, shellac thinner, marine stove fuel, liquid fondue fuel, chafing dish fuel)

Methylated spirits isn't light, control over the stove is poor by modern standards, it takes twice as long to boil some water and it uses twice the weight of fuel to do so. The efficiency of metho as a fuel is very poor. Fuel availability in some countries is also poor. Found in marine shops and in the paint department of most hardware stores. Many brands of this solvent are specifically marketed for use as marine stove fuel and/or chafing fuel. This form of fuel has anywhere from 1% to 80% methanol and other poisonous chemicals in it. Because of the great variability of contents in denatured alcohol, some brands burn better than others. One trick to test the suitability of a particular brand of denatured is to burn a small amount in a dish and reject it if there is any residue left after it has burned. Lab grade ethanol may have benzene or other chemicals mixed in with it.

Grain Alcohol

Uses ● Alcohol Stoves ● Fire Starters ● Disinfectant ● Cleaner	(aka pure ethanol, pure grain alcohol, PGA, grain neutral spirits, GNS, rectified spirit, rectified alcohol, medical grade ethanol, ethyl anhydrous, moonshine)

Everclear Grain Alcohol and Golden Grain alcohol from the David Sherman Corporation come in 95% (190 proof) bottles. This fuel works well but is an expensive option and may be illegal or difficult to purchase in many places. It is also non-toxic and can double for medicinal uses. Grain alcohol can also be made at home in large quantities, though perhaps not legally in your area without special permits or permission. Pure ethanol (aka absolute alcohol or dehydrated alcohol) can also be purchased from chemical supply distributors and as medical grade ethyl alcohol for a very high price. Since production of alcohol greater than 95.4% requires a special dehydration process that includes benzene or glycerine, these fuels can be very toxic.

Methyl Alcohol

Uses ● Alcohol Stoves ● Antifreeze ● Producing Biodiesel ● Denaturant Additive	(aka methanol, wood alcohol, methyl hydrate, liquid fondue fuel, camp stove fuel, gas line antifreeze)

Found in some hardware store paint departments as paint thinner or at gas stations and general stores as gas-line antifreeze such as HEET brand (Yellow is Methanol, Red is Isopropyl). Hikers can stock up on HEET at Wal-Mart at the end of winter when surplus antifreeze goes on sale. You may also be able to purchase this for around US$3 per gallon at race shops that sell it as race fuel. The vaporization pressures of methanol are much higher than ethanol throughout the applicable temperature ranges and the jets in your stove might light up faster when using this fuel. This is also a very poisonous fuel and you should consider the health concerns of this fuel if you decide to use it long term (thru-hikers beware and others may want to avoid storing contaminated stoves in their cook pots or bowls). Air Brake Antifreeze is also mainly methanol with other additives. It can be purchased by the gallon, half gallon and quart at big truck parts shops.

Isopropyl Alcohol

Uses ● Alcohol Stoves ● Cleaning ● Disinfectant ● Removing Ink and Marker Stains	(Isopropanol, 2-Propanol, rubbing alcohol) Not recommended

Found in drug, food and general stores (HEET in red container). Rubbing alcohol is generally only 70% alcohol and won't work in many stoves. Alcohol with 91% or greater alcohol content will work, but will leave a sooty residue on your pot and brown water in your stove. The heat potential for this fuel is high, but it doesn't generally burn completely (yellow flame and unburned soot) and is generally mixed with water that isn't burned and hinders fuel efficiency. If you want to use rubbing alcohol (cheapest easily available fuel on this list) for fuel, you may want to use an open flame stove instead of a jetted stove. If you decided to use a jetted stove, you may need to use larger jets in your stove (#57 drill, pushpin size, ~1.4mm or larger) and try to empty as much left over liquid from your stove as you can after each use (as this will further hinder future fire ups) for it to operate.

Gelled Alcohol

Uses ● Alcohol Stoves ● Buffet Heating ● Heat Source	(Sterno, Canned Heat, jelled alcohol)

This is either methanol or ethanol trapped in a network of solid calcium acetate forming a gel. This gel is a little safer to use than liquid alcohol since there is less of a spill hazard. Unfortunately, most gelled alcohol stoves have small top openings and often don't get food hot enough to cook or bring water to a boil. This fuel usually comes in a resealable can and may be the best choice for young and clumsy campers, since kicking it over is less likely to cause a significant fire hazard as would other liquid and gas stoves. Due to costs and limitations, it is not highly recommended for most long distance backpackers.

Diethylene Glycol

Uses ● Alcohol Stoves ● Solvent for Resins, Dyes and Oils ● A component in brake fluid, lubricants, artificial fog and more	(DEG, 3-oxa-1,5-pentanediol, diglycol, ethylene diglycol, or dihydroxy diethyl ether) Not recommended

Diethylene glycol is used in many brands of chafing fuels and must use a wick to burn. It is considered non-flammable by the US Department of Transportation, can be air transported and is therefore much more economical to transport and store. These transportation and storage classifications make it ideal for the retail market and it's safe to assume that any chafing fuel can with a wick uses diethylene glycol until proven otherwise. This fuel is difficult to light and is extremely poisonous. It is in fact the deadly chemical implicated in the 1937 Elixir Sulfanilamide Incident that killed 107 and was the main motivation for hastening of the enactment of the 1938 Federal Food, Drug, and Cosmetic Act. This fuel can be used but is not recommended for backpacking stove use due to its toxicity and non-flammable nature.

Petroleums

Petrol

Petrol can keep six months at 20°C (68°F) or three months at 30°C (86°F). Fuel stabilizer can preserve fuel for up to a year. Should be protected from the sun, well ventilated and free of flammable materials. Keep a fire extinguisher and sand on hand. Never use genuine petrol in a stove. The refinery adds a number of quite nasty things to it to make cars run better which aren't good for your health such as lead (brain damage), benzene (serious carcinogen) and other more esoteric things.

Petrol Stove Lighting
In general you do not need to prime a petrol stove. There are enough volatiles in petrol that it should light quite easily under most conditions. However, in the snow you may need to help it a long a bit as the 'volatiles' may no longer be evaporating. In warm weather most jets will spray the fuel out in a manner fit for a flame-thrower. In fact, the greatest hazard is fumbling the action of lighting the stove, such that liquid petrol spills everywhere. This is extremely dangerous: do it well outside your tent. If cooking in a hut, consider lighting the stove outside, or at least in the stone fireplace.

Petrol Hazards
'Whoomp' is all very well, but sometimes petrol goes slightly more than whoomp. The following is true by the way: the information was obtained directly from the people concerned. A canoe party was travelling in outback Canada and they were cooking a meal for the whole party over two petrol stoves of a very well-known brand. Unfortunately, either through too much familiarity with the stoves, or perhaps not quite enough knowledge of the hazards, they made several mistakes.

- They put the two stoves very close together.
- They were using very large diameter cooking pots which nearly overhung the petrol tanks.
- They did not have someone sitting there looking after the stoves all the time.

The result was that radiation, and possibly hot exhaust air too, from under the pots hit the tanks and heated them up. One tank in particular got far too hot. Yes, they did notice that the stoves were sounding rather noisy after a while, but did not realise the hazard until too late. Then as a member of the party went to check the stoves, the over-heated petrol tank exploded. Yes, one of those pumped aluminium fuel tanks we all know so well: it split opened up. Instant petrol vapour fireball. The adjacent tent flashed of course, but you can always buy another tent. Far worse was the damage done to a couple in the party who were near the stoves. The man had his face burnt a bit and one hand severely damaged. His wife got fuel up one arm and lost the skin there. The pictures show the damage, I believe some time later, after extensive treatment.

Kerosene

This is really just a less volatile part of the refinery output, and kero stoves are very similar to petrol ones. The fuel is not souped up with extra additives like with petrol, which is optimised for a car engine. In fact, kero is at least partly designed for lighting and for stoves. Anyhow, kero is not as volatile as Shellite, and it does not go whoomp if you throw a lighted match onto a pool of it. You have to heat it up to get it to vaporise before you can get a flame. Technically, it has larger or longer molecules than petrol, going up to very roughly around C14. That is, petrol consists largely of hydrocarbons with small numbers of carbon atoms per molecule, while the hydrocarbon molecules in kero are bigger.

There is no real concrete borderline. The vaporising of the fuel is done by running the liquid kero through a preheat or generator tube which goes over the top of the burner, through the flame. Many petrol stoves have one of these as well to make them work well in cold conditions. Brands of stoves are generally the same as for petrol. Some can burn both petrol and kero, although you're meant to change both the generator tube and the jet when swapping fuels.

Several manufacturers recommend doing this changeover. The larger kero molecules require more heating to vaporise them and a smaller jet. Anyhow, kero has several definite advantages over 'petrol': it does not go whoomp and it does not have all sorts of toxic nasties in it. As a result it is a preferred choice for many people in the mountains. Also it is readily available everywhere around the world, including places like Nepal, where kero stoves and kero lamps are the order of the day. If you are going to use kero there are few other tricks of the trade to watch. Sure, it isn't as volatile as 'petrol', but you still have to seal the container tightly. Kero can creep out of bottles under strange circumstances, and can contaminate anything surrounding it (especially food). The red nylon ""Nalgene"" fuel bottles sold in bushwalking shops can hold kero, but the caps will not seal well in practice.

Kero is not a lubricant, and the surface of the nylon seems to go ""rough"" and the cap will not do up properly. Putting a fat neoprene O-ring into the sealing groove will solve this if you can find suitable O-rings. (Try the yellow pages: O-rings are readily available.) Luminium bottles (Sigg, Laken) can also be used provided you make sure the O-ring seal is in good condition. But make sure you know which bottles contain fuel and which contain water! For that matter, the author has successfully cached kero in the Australian Alps for some time in sheltered spots in 1.25L soft drink PET bottles. They have a fair seal under the cap too.

Failure to seal a kero container can have worse consequences than a bad taste in your food. There are a couple of stories about Antarctic explorers having trouble with unsealed kero containers. One was leaving kero in cans in his caches on the outward trip, but found on the return trip that the kero had crept out of the cans despite the lids being ""tight"". The lack of fuel had unfortunate results for the party.

Another party with this problem was Treseder and Jarvis in October 1999, who had to abort a trip after losing seven litres of fuel and the food which absorbed it. Keep your kero (and petrol) separate from your food! For historical interest, the first 'wickless kerosene pressure stoves' were made by Primus. It was believed for a while that a Swede by the name of F.W. Lindqvist was responsible for this invention, but it now seems that the real inventor was a Dane - Frederik Ferdinand Tretow-Loof. Or so an article on the Classic Camp Stove web site says. Just thought you might be interested.

Lighting Kerosene

Lighting a kero stove takes more skill than lighting a petrol stove, but it isn't that difficult if you know how. There usually is a bit of a kerosene smell when starting, which can pong out a tent or hut. Prime the stove and preheat the generator tube. You can do this with kero, but that is unreliable and smoky, and good at blocking the jet too. A little metho works very well and is much cleaner. A good way of handling this is with a small dropper bottle: you can get some suitable Nalgene ones in good bushwalking shops, or you may find some miniature shampoo bottles in hotels. A quite small squish of metho is usually enough, although using too little can make it difficult to repeat the exercise without cooling the stove down first.

Now for the magic (and essential) bit: before you light the metho make sure the generator tube is full of kero! Otherwise, when you open the valve the cold kero coming in will chill the generator tube back down so the kero doesn't vaporise and the stove won't light. Just as the metho flame runs out, gently open the kero valve and the stove should spring into life. Once you have done this a few times (practice at home!) it gets to be fairly easy. A side benefit of having the generator tube quite full before you start is that some kero leaks out when it gets warm, adding a little extra burn time to the priming process.

Shellite	It is a volatile mix of hydrocarbons from the petroleum refineries.
Coleman Fuel	
White Gas	
Diesel	
Vodka	These fuels have very long carbon-chain molecules and generate a fair bit of tar in the generator tube and block the jets.
Straight Vegetable Oil	

3 Gas Fuel

Gas fuel refers to any type of fuel that is in a gaseous state under normal conditions. These fuels are typically composed of hydrocarbons like methane or propane, but can also include hydrogen or carbon monoxide, or mixtures thereof. They are highly efficient energy sources that can be readily transported and distributed through pipelines or in pressurized containers, making them versatile for applications ranging from heating and cooking to power generation and vehicle propulsion.

Gas Types
- Butane
- Propane
- Isobutane
- LPG
- Biogas
- Natural Gas (NG)

Gas Uses
- Stoves (Cooking)
- Lanterns (Light)
- Heaters (Heat)
- Torch (Welding)
- Sterilizing (Medical)
- Attacking (Defence)

Butane Gas

Butane is a flammable hydrocarbon gas with the chemical formula C_4H_{10}. It is a member of the alkane family, characterized by its single carbon-carbon bonds. This gas exists in two isomeric forms, n-butane and isobutane, which share the same chemical formula but have slightly different arrangements of their atoms, leading to subtle variations in their physical properties, such as boiling point.

Under normal room temperature and pressure, butane is a gas, but it can be readily liquefied under moderate pressure or by cooling it slightly. This property is fundamental to its widespread use, as it allows for efficient storage and transport in cylinders. The boiling point of butane is around -0.5°C to 1°C, a crucial detail because its performance as a fuel is significantly impacted by ambient temperature. If the temperature drops below this range, the liquid butane within a container may not vaporize effectively, leading to poor or no operation of appliances.

Butane Gas Stove Use
Keep the notch on butane bottle upright when in use or it will shoot liquid into the stove and flare up and could possibly explode.

In its pure state, butane is colorless and odorless. For safety, a strong-smelling chemical, typically a mercaptan, is intentionally added to commercial butane products. This additive provides the distinctive "rotten egg" smell that allows for easy detection of leaks, which is vital given butane's high flammability. Butane vapor is also heavier than air, meaning that in the event of a leak, it will sink and accumulate in low-lying areas. This characteristic presents a significant fire and explosion risk if an ignition source is present in such an accumulated gas pocket.

Butane's versatility and high energy content make it suitable for numerous applications. It is a primary component of Liquefied Petroleum Gas (LPG). However, smaller, disposable gas canisters for camping stoves often contain pure butane or a butane/propane mix. Butane is also the fuel used in many cigarette lighters and is employed as a propellant in various aerosol products, such as deodorants and hairsprays. Furthermore, forms of butane, particularly isobutane (R600a), are utilized as environmentally friendlier refrigerants in modern cooling systems. In the petrochemical industry, butane serves as a chemical feedstock for producing other valuable compounds.

Given its flammable nature, safety is paramount when handling butane. It must be used in well-ventilated areas to prevent the accumulation of gas and to ensure adequate oxygen. Direct contact with liquid butane can cause severe cold burns or frostbite due to its rapid vaporization. Tragically, butane is also a substance sometimes abused through inhalation, which carries severe health risks, including fatal cardiac arrhythmias.

Propane Gas

Propane is a hydrocarbon and an alkane with the chemical formula C_3H_8. It is a three-carbon chain molecule, entirely composed of carbon and hydrogen atoms linked by single bonds. At standard room temperature and pressure, propane exists as a gas, but it is easily liquefied under relatively low pressure or by cooling, a characteristic that makes it highly efficient for storage and transport in cylinders.

The boiling point of propane is notably low, approximately -42°C. This low boiling point is a significant advantage as it allows propane to readily vaporize and turn back into a gas even in very cold ambient temperatures. This property makes it a reliable fuel source for outdoor storage and use in a wide range of climates.

In its natural state, pure propane is colorless and odorless. For safety purposes, a pungent odorant, typically ethyl mercaptan, is always added to commercial propane. This additive provides the distinctive "rotten egg" smell, enabling prompt detection of leaks, which is crucial due to propane's high flammability. Propane vapor is heavier than air, meaning that if a leak occurs, the gas will sink and accumulate in low-lying areas such as basements, pits, or depressions. Such accumulations pose a severe fire and explosion hazard if an ignition source is present.

The versatility and high energy content of propane lead to its widespread use across numerous applications. It is a major component of Liquefied Petroleum Gas (LPG) and is commonly used for residential heating, water heating, and cooking, both indoors and for outdoor activities like grilling. Propane also serves as a fuel for various industrial processes, agricultural equipment, and is used to power some vehicles, referred to as autogas. Furthermore, it acts as a propellant in certain aerosol products and finds use as a refrigerant in some systems.

Despite its utility, strict safety precautions are essential when handling propane. Its extreme flammability means that any leak in an enclosed space, without proper ventilation, can lead to a dangerous fire or explosion. Due to its nature as a heavier-than-air gas, areas where it is stored or used must be well-ventilated to prevent hazardous accumulations. In high concentrations, propane can also act as an asphyxiant by displacing oxygen in the air. Direct skin contact with liquid propane can cause severe cold burns or frostbite.

Isobutane Gas

Isobutane, also known as 2-methylpropane, is a hydrocarbon that shares the same chemical formula as n-butane (C_4H_{10}), making it an isomer of butane. While they have the same number and type of atoms, their molecular structures are different: n-butane has a straight chain of four carbon atoms, whereas isobutane has a branched structure with a central carbon atom bonded to three other carbon atoms (a methyl group attached to propane).

This difference in structure gives isobutane distinct physical properties compared to n-butane. Notably, isobutane has a lower boiling point of approximately -11.7°C (10.9°F), which is significantly lower than n-butane's boiling point of around -0.5°C. This characteristic makes isobutane more suitable for use in colder conditions, as it will vaporize more readily at lower temperatures, leading to better stove performance.

Like n-butane, isobutane is a colorless, highly flammable gas at room temperature and pressure. It is typically shipped as a liquefied gas under pressure. While naturally odorless, an odorant is added to commercial isobutane for safety, allowing leaks to be detected. Its vapors are heavier than air and will accumulate in low-lying areas if there is a leak, posing a fire and explosion hazard.

Common uses for isobutane include:

- Refrigerant: Isobutane (often designated as R600a) is widely used as an environmentally friendly refrigerant in household refrigerators, freezers, and air conditioning systems, as it has a very low global warming potential and no ozone depletion potential.
- Fuel: It is frequently blended with propane and n-butane in camping gas canisters, particularly in "four-season" or "winter blend" mixes, to improve performance in colder weather due to its lower boiling point.
- Aerosol Propellant: It serves as a propellant in various aerosol products, including cosmetics and spray paints.
- Chemical Feedstock: Isobutane is an important precursor molecule in the petrochemical industry, used in processes like alkylation to produce high-octane gasoline components and other chemicals.

Safety considerations for isobutane are similar to those for other highly flammable liquefied petroleum gases. It is extremely flammable, and any leak, especially in an enclosed or poorly ventilated space, can lead to a fire or explosion. Inhalation of high concentrations can act as an asphyxiant by displacing oxygen, and direct contact with liquid isobutane can cause severe cold burns or frostbite.

LPG Gas

LPG, or Liquefied Petroleum Gas, is a highly versatile and flammable fuel composed primarily of a mixture of hydrocarbon gases, specifically propane and butane. It is derived from the processing of natural gas and the refining of crude oil. What makes LPG so useful is its ability to be easily liquefied under relatively low pressure. This transformation from a gas to a liquid significantly reduces its volume, allowing large quantities to be stored and transported efficiently in cylinders or tanks. When the pressure is released, such as by opening a valve on a gas bottle, the liquid rapidly converts back into a usable gas.

The specific composition of LPG can vary, with the proportion of propane to butane being influenced by factors like climate and intended use. Propane has a very low boiling point (around -42°C), meaning it vaporizes readily even in very cold conditions. This characteristic makes propane-heavy LPG blends ideal for outdoor storage and use in colder climates.

Butane, on the other hand, has a higher boiling point (around -0.5°C) and performs less effectively in freezing temperatures, making it more suited for warmer environments or specific indoor applications. Regardless of the blend, a strong-smelling odorant is always added to LPG, as it is naturally odorless, providing a crucial safety feature for detecting leaks.

LPG is utilized in a vast array of applications globally. In residential settings, it powers cooktops, ovens, water heaters, and heating systems, especially in areas without access to natural gas pipelines. Its portability makes it an indispensable fuel for outdoor cooking with barbecues and for heating in caravans, RVs, and boats. Beyond domestic use, LPG is a significant fuel for commercial kitchens, industrial processes, agriculture, and as a motor fuel (autogas) for vehicles. Its clean-burning properties, high energy density, and ease of transport contribute to its widespread adoption as an efficient and convenient energy source.

Odorant: A strong-smelling chemical like ethyl mercaptan (ethanethiol) is always added to LPG. In its pure form, LPG is odorless, so the odorant provides the distinctive "rotten egg" smell that allows people to detect leaks for safety reasons.

Biogas

Biogas is a renewable energy source produced from the breakdown of organic matter in the absence of oxygen, a process known as anaerobic digestion. This natural biological process is carried out by microorganisms, primarily bacteria, that feed on and decompose various types of organic waste materials. These feedstocks can include animal manure, food scraps, agricultural residues (like crop waste), municipal solid waste, and sewage sludge. The controlled environment for this decomposition is typically a sealed container called an anaerobic digester or biodigester.

The gas produced from this digestion process is a mixture, primarily consisting of methane (CH_4), which is the combustible component, and carbon dioxide (CO_2). Methane typically makes up 50-75% of biogas, while carbon dioxide accounts for 25-50%. Biogas can also contain trace amounts of other gases such as hydrogen sulfide (H_2S), nitrogen (N_2), hydrogen (H_2), and water vapor. The exact composition varies depending on the type of organic waste used as feedstock and the operating conditions of the digester.

Biogas is a valuable energy source with a range of applications. It can be burned directly for heating and cooking, which is common in rural areas or developing countries. It can also be used to generate electricity and heat in combined heat and power (CHP) plants. Furthermore, if biogas is cleaned and purified to remove carbon dioxide, hydrogen sulfide, and other impurities, it becomes what is known as biomethane (or renewable natural gas, RNG). Biomethane is essentially pure methane and is chemically identical to fossil natural gas, meaning it can be injected into existing natural gas pipelines or used as a vehicle fuel. This makes biogas a key component in sustainable waste management and the transition to a low-carbon energy economy, as it captures methane that would otherwise be released into the atmosphere from decomposing organic waste, a potent greenhouse gas.

Natural Gas

Natural gas, as a gas fuel, is a naturally occurring fossil fuel primarily composed of methane (CH_4). While methane constitutes the bulk of natural gas, typically ranging from 70% to over 90%, it often includes smaller amounts of other light hydrocarbons like ethane, propane, and butane, as well as non-combustible gases such as nitrogen and carbon dioxide, and sometimes impurities like hydrogen sulfide.

A key characteristic of natural gas is that it is lighter than air. This means that in the event of a leak, it tends to rise and disperse into the atmosphere, which can be a safety advantage compared to heavier-than-air gases like propane or butane that can accumulate in low-lying areas. In its pure form, natural gas is odorless, colorless, and tasteless. For safety reasons, a strong-smelling odorant, such as mercaptan, is deliberately added to give it a distinctive "rotten egg" smell, allowing leaks to be readily detected by humans.

Natural gas is a highly valued fuel due to its clean-burning properties, producing fewer greenhouse gas emissions and air pollutants compared to other fossil fuels like coal or oil when combusted. It is delivered to consumers directly through extensive underground pipeline networks, providing a continuous and on-demand supply. This makes it an incredibly convenient and often cost-effective energy source for a wide range of applications globally, including electricity generation in power plants, heating homes and water, cooking, and various industrial processes. It can also be converted into liquefied natural gas (LNG) for transport over long distances by ship.

Gas Canister Tips

Canister Circumferences
- Butane 220g: 6.7cm
- Jetboil 100g: 8.75cm
- Jetboil 230g: 10.66cm
- Jetboil 450g: 10.66cm

Canister Durations
- Butane 220g: Boils ~15L
- Jetboil 100g: Boils ~10L
- Jetboil 230g: Boils ~23L
- Jetboil 450g: Boils ~45L

Canister Weights Full
- Butane 220g Full: 322g
- Isobutane 100g Full: 200g
- Isobutane 230g Full: 380g
- Isobutane 450g Full: 670g

Gas Canisters will pop their convex base out when about to explode. Don't use Propane gas on a Butane stove. You can pre-heat gas canisters with a candle if it's very cold and the gas won't work.

Boiling Points:
- Butane: -0.4°C (31.2°F)
- Isobutane: -11.75°C (10.8°F)
- Propane: -42°C (-43.6°F)

Canister Weights Empty
- Butane 220g Empty: 102g
- Isobutane 100g Empty: 94g
- Isobutane 230g Empty: 126g
- Isobutane 450g Empty: 195g

Canister Prices (2018[n])
($ per 100g)
- Butane 220g: $1.25 ($0.56)
- Jetboil 100g: $12.00 ($12)
- Jetboil 230g: $8 ($3.47)
- Jetboil 450g: $12 ($2.66)

Refilling Gas Canisters

Refilling gas canisters is the transfer of some or all the gas from one canister to another less-full one. Refilling gas canisters can lower the cost, fill only what you will use for a trip to reduce weight and topping off cans.

Warning
- Only refill each canister between 12-15 times. If the threads look old, toss the canister.
- Never fill backpacking canisters with 100% propane, it may not have the strength.
- Only refill each canister between 12-15 times. If the threads look old, toss the canister.
- Never fill backpacking canisters with 100% propane, the canister may not have the strength.

Weigh the canisters when they are full and empty so you know the weight of the liquid inside and how full it is. Weigh the refiller component and write it down. Mark the canisters' full and empty weights and how many times it's been refilled.

Dangers
- Overfilling
- Gas Leaks
- Damage to Threads
- Too Much Pressure
- Water in threads
- Overheating

Adapter Weights
G-Works R1 - 36g?
G-Works Plus - ?
Butane Adapter - ?

Setup
Place the donor canister into a pot of warm water keeping the threads dry. Prepare an ice bath for the receiving canister, also keeping the threads dry.

Connecting Canisters
Dry the donating canister. Make sure the latch is closed. Hook up the receiving canister then the donor canister to the adapter then open the latch. Every few minutes check the weight of the receiving canister and re-warm the top canister until the receiving canister is full. If using butane, there is a vapour feed tube in the canister in an L bend pointing down toward the notch. For maximum transfer tilt the canister with the notch pointing down. Transfers are very slow and could take a couple of hours. The receiving canister may need to be chilled and the donating canister warmed. Can hear a bubbling in the donating canister if it's transferring and you press your ear up to it. Refill canisters outside as vapours can escape and explode if lighting sources are nearby. No two canisters have the same strength, propane has more pressure then butane.

4 Creating Fuel

This section explains how to create different types of fuel for yourself.

Wood Gasifier

A wood gasifier is a device that converts solid biomass, typically wood or other carbon-containing materials like charcoal or agricultural waste, into a combustible gas known as wood gas (also called producer gas or syngas). This process is called gasification, and it's fundamentally different from simple burning or combustion.

Instead of burning the wood completely with ample oxygen, a gasifier operates in an oxygen-limited environment and at high temperatures. Within the gasifier, the wood undergoes several stages:

Drying	Any moisture in the wood is evaporated.
Pyrolysis (Devolatilization)	As the wood heats up without much oxygen, it decomposes, releasing volatile gases (which include methane, hydrogen, carbon monoxide, and also tars and other complex organic compounds) and leaving behind a solid residue called char (or charcoal).
Combustion/Oxidation	A small, controlled amount of oxygen (usually air) is introduced, causing some of the char and volatile gases to partially burn. This partial combustion generates the high temperatures needed to drive the subsequent reactions.
Reduction	The hot gases produced (like carbon dioxide and water vapor) then pass through a bed of incandescent char. Here, they react with the hot carbon in a reduction process, converting them into more desirable combustible gases like carbon monoxide (CO) and hydrogen (H_2). This is where the majority of the usable "wood gas" is formed.

The resulting wood gas is a mixture primarily of carbon monoxide, hydrogen, and some methane, along with non-combustible gases like nitrogen (from the air introduced) and carbon dioxide, and potentially impurities like tar and particulates (soot). This raw wood gas needs to be cooled and filtered to remove tars and particulates, especially if it's going to be used in an internal combustion engine, as these contaminants can cause significant damage.

Once cleaned, the wood gas can be used as a versatile fuel. Historically, wood gasifiers were notably used during fuel shortages, such as World War II, to power vehicles like cars, trucks, and buses. Today, they are still used, particularly in rural or off-grid areas, to generate electricity using internal combustion engines, provide heat, or even for direct cooking and heating applications. Wood gasification is considered a renewable energy technology because it utilizes biomass, which can be regrown, and it offers a cleaner burning alternative to direct wood combustion.

Building a Wood Gasifier

Building a wood gasifier is a complex project that requires significant technical understanding, metalworking skills, and a strong commitment to safety. It is absolutely not a beginner's project and should only be undertaken by individuals with experience in welding, fabrication, and a solid grasp of thermodynamics and gas chemistry. Improperly built or operated gasifiers can be extremely dangerous, posing risks of explosions, carbon monoxide poisoning, and serious burns.

Since it's impractical to include a complete set of instructions with pictures on this document, I have given an outline as to to how to proceed if you want to build one. I recommend purchasing my 'Prep Drive' if you want a collection of information such as this all on a USB drive.

Phase 1: Design and Planning

1. Research Thoroughly:
This is paramount. Do not proceed without deeply understanding the principles of gasification, different gasifier designs (e.g., downdraft, updraft, stratified), and the specific implications of each. Look for established plans (like the FEMA gasifier plans from WWII or modern open-source designs) and adapt them only with caution and understanding.

2. Determine Your Needs:
Fuel Type: While "wood" gasifier, the specific type and size of wood fuel (chips, chunks, pellets) will influence design.
Output (Gas Quality/Quantity): What do you want to power? A small engine for a generator? A cookstove? This dictates the size and complexity of the gasifier and the necessary gas cleaning.
Materials: Identify available materials. Steel drums, propane tanks (empty and properly purged!), exhaust pipes, and various fittings are common. Never use galvanized steel for hot components, as welding it produces toxic fumes.

3. Component Sizing: The size of key components like the fire tube (reactor/reduction zone) and nozzles is critical and depends on the desired engine horsepower or heat output. Consult established charts and formulas for this.

4. Safety First: Integrate safety features into your design from the outset. This includes robust construction, pressure relief mechanisms, flashback arrestors, and well-designed seals. Plan for proper ventilation during operation.

5. Tools & Skills Assessment: Be honest about your capabilities. You will likely need:
- Welder (arc, MIG, or TIG) and welding safety gear.
- Angle grinder, drill press, cutting tools.
- Metal fabrication experience.
- Understanding of airtight sealing.

Phase 2: Gathering Materials and Fabrication

1. Main Body/Reactor:
Outer Shell: Often constructed from large steel drums (e.g., 200-liter oil drums) or repurposed propane tanks (expertly emptied and purged first!). This forms the outer casing and often part of the gas collection chamber.
Inner Reactor/Fire Tube: A smaller diameter steel pipe or drum is used for the core reaction zone. This needs to be very robust and heat-resistant.

2. Fuel Hopper:
This sits above the reactor and feeds fuel into it. It needs to be airtight to prevent air ingress.
Often a larger steel drum or cone-shaped section.

3. Grate System:
A robust, heat-resistant grate (e.g., made from thick steel plate, rebar, or cast iron) is needed at the bottom of the reaction zone to support the fuel bed and allow ash and char to fall through. Many designs incorporate a "shaker grate" mechanism to clear ash and maintain gas flow.

4. Air Inlets (Nozzles/Tuyeres):
Pipes or tubes that introduce a controlled amount of air into the combustion/oxidation zone. Their size, number, and placement are critical for efficient gasification and tar cracking. They are often made of durable materials like stainless steel.

5. Ash Clean-out:
An airtight access port at the bottom of the gasifier to remove accumulated ash and char. This typically involves a removable plate with a gasket and bolts.

6. Gas Outlet:
A pipe that draws the raw wood gas out of the gasifier. This should be positioned to collect the gas efficiently.

Phase 3: Gas Cleaning System

This is often as complex as the gasifier itself and critical for reliable operation and engine longevity.

1. Cyclone Filter: The first stage, using centrifugal force to remove larger particulate matter (soot, char dust) from the hot gas.
2. Condenser/Cooler: A heat exchanger that cools the gas, causing water vapor and heavier tars to condense out. This can be a tube-in-shell design or simply long runs of pipe.
3. Media Filter (Dry Filter): A secondary filter using materials like wood chips, sawdust, steel wool, or even specialized filter media to trap smaller particulates and remaining tar aerosols. This needs to be easily cleanable or replaceable.
4. Fine Filter (Optional but Recommended): For very sensitive engines, a final, even finer filter might be used.

Phase 4: Ancillary Components and Controls

1. Draft System
- Vacuum Source: For downdraft gasifiers, a vacuum source (e.g., a fan, a dedicated blower, or the engine's manifold vacuum once running) is needed to pull air through the gasifier and draw out the gas.
- Flare Stack: A simple pipe where the raw gas can be ignited and burned off initially to confirm gas quality before feeding it to an engine.

2. Ignition Port: An access point to ignite the wood fuel inside the gasifier.

3. Instrumentation:
- Temperature gauges in various zones.
- Pressure gauges (manometers) to monitor pressure drop across the system and filters.
- Carbon monoxide detectors (absolutely essential for safety).

4. Seals and Gaskets: All connections, access ports, and joints must be absolutely airtight to prevent air leaks into the gasifier (which can lead to uncontrolled combustion or explosions) and gas leaks out (posing CO poisoning risks). High-temperature gaskets and sealants are required.

Phase 5: Testing and Operation

1. Leak Testing: Before any fuel is introduced, thoroughly leak-test the entire system.
2. Initial Startup: This is a delicate process involving careful ignition and managing air supply to establish the correct reaction zone.
3. Gas Quality Testing: Observe the flare flame (should be clear and blue, not smoky or yellow) to assess gas quality.
4. Engine Integration: If powering an engine, careful tuning and carburetor adjustments will be required to run on wood gas, which has a lower energy density than gasoline or natural gas.
5. Ongoing Maintenance: Regular cleaning of ash, char, and especially the gas cleaning system is vital.

Phase 6: Improvements

Once you have a working gasifier you are likely to have picked up some tips that you could have done better next time. You may even come up with some better ideas on how to redesign the components for better efficiency. As with all things, safety first.

Biodiesel

Biodiesel is made from vegetable and animal oils and fats or triglycerides. It can't be made from engine oil. Triglycerides consist of three long-chain fatty acid molecules joined by a glycerine molecule. Lye acts as a catalyst breaking off the glycerine molecule and combining each of the three fatty acids chains with a molecule of methanol creating mono-alkyl esters. The glycerine sinks to the bottom and is removed. The process is called transesterification. It can be used straight in any diesel tank without modifications.

Processor Materials
- 3L HDPE Container with 2 lids
- Electric Hotplate w/Temp
- Pasta Cooker/Square
- Colander
- Electric Drill
- Stirrer
- 2 x 1/2L PET Bottles
- Thermometer
- 1/2L 50% Translucent HDPE Container with screw on cap and spare cap
- Scrap 3cm angle iron for drill stand.

Chemicals Required
- Alcohol - Either Methanol or Ethanol (Harder with Ethanol but it's also renewable)
- 1L Vegetable Oil
200ml Methanol 99%+
- Lye Catalyst - 97%+ 3.5g of Sodium Hydroxide or Potassium Hydroxide (99% - 4.9g, 92% - 5.3g, 90% - 5.5g, 85% - 5.8g)
- Mini-Processor and Attachments (Left)
- Scales accurate to 0.01g
- Measuring Beakers for meth and oil
- Duct Tape
- Thermometer

Finding Methanol
Methanol can be called methyl alcohol, wood alcohol, wood naphtha, wood spirits, methyl hydrate, carbinol, colonial spirits, columbian spirits, Manhattan spirits, methylol, methyl hydroxide, hydroxymethane, monohydroxymethane, pyroxylic spirit or MeOH. The methanol must be 99%+ pure. Also used as a paint solvent.

Finding Lye/ Caustic Soda
Can be potassium hydroxide (KOH) or sodium hydroxide (caustic soda, NaOH) Lye is hygroscopic - they rapidly absorb moisture from the atmosphere which makes them less effective. Keep containers sealed and airtight.

NaOH is cheaper but KOH is a better catalyst. The process is the same for both but KOH requires 1.4025x more and comes in various qualities. NaOH is a drain cleaner and found in hardware stores.

Dangers
Lye is extremely caustic, keep it off your skin and out of your eyes and don't breathe in the fumes and keep the process away from food. Lye reacts with aluminium, tin and zinc. Use HDPE (High-Density Polyethylene), glass, enamel or stainless steel containers for methoxide.

Best Oil
Beginners should use new, unused oil.

Use: Rapeseed oil, canola oil, corn oil, soy oil and sunflower oil.
Avoid: Peanut oil, palm oil, coconut oil, tallow, lard and olive oil.

Procedure Overview
1. Pre-heat the oil to 55°C (131°F) and pour into blender.
2. Pour in the methoxide from the HDPE container and secure lid tightly.
3. Mix for 20-30 minutes or longer on a low speed.
4. Pour it into the 2L PET bottle for settling and screw the lid on tightly, let air in if it contracts.
5. Let it settle for 12-24+ hours. The darker glycerine will collect at the bottom with the biodiesel above.
6. Separate the biodiesel from the glycerine and store in a PET bottle being careful not to mix any glycerine in.
7. Use the wash-test and the methanol test to check the quality of the biodiesel.
8. If the biodiesel passed the tests, wash the rest of it.

Procedure

This is the procedure on creating biodiesel.

1	**Building the Mini-Processor** Create a drill stand above the 3L container's lid so it can attach and keep churning the oil handsfree. The stirrer is a length of 6mm steel rod with a churning end which fits through the lid of the 3L container. Add a lid strengthening piece of wood/metal to the lid with a 6mm hole in it to keep the drill bit straight and lubricate it. The container should be mostly airtight and a close a fit as possible. Secure with epoxy.
2	**Warming Up** Heat up the oil in a saucepan and pour it into the mini-processor. Slide the stirrer inside and put the lid on firmly. Fill the other 1/2L bottles with water at or above the processing temperature. Put the Processor in the colander and wedge in position with a PET bottle on either side. Add hot water to the cooker just below the level of the oil or before it floats. Adjust the heat to the processing temperature then turn off the heat. Attach the drill to the stand, tighten and start stirring.
3	**Methoxide Bottle** Using the transparent bottle drill two holes in the lid and fit two short sections of plastic or 4mm copper piping, fix on both sides with strong epoxy. To one on the inside fix a length of rigid 6mm plastic tubing that almost touches the bottom. To the other on the outside add a length of flexible 6mm tubing. Fit a third section of copper piping to the small lid of the processor.

4	**Creating Methoxide** Measure 200ml methanol into 1/2L container via the funnel quickly as it absorbs water in the air. Add Lye to the container via the second funnel and replace the bung and screw on tightly. Swirl the container around to mix them together for a minute over a period of time the lye will dissolve forming sodium methoxide/potassium methoxide which will also heat up. When the mixture is clear with no undissolved particles it's ready.
5	**Methoxide Mixing** Add methoxide by removing the lid and bung from the bottle of pre-mixed (cool) methoxide and screw on the transfer lid tightly. Fit the other end of flexible tubing to the inlet pipe of the processor. Carefully lift the methoxide bottle above the processor and turn it upside-down. Air goes into the open pipe through the processor lid into the oil to be mixed. When empty righten the bottle and put it down beside the processor. Any stray methanol fumes that don't condense inside the processor vent into the methoxide bottle and condense there.
6	**Mixing and Draining** Mix the compound with the drill? monitoring the temperature, heating when necessary which should only be twice an hour at room temp. When the process is complete disconnect the drill, remove the container and stand on it's side to settle with the small lid down to drain it later. Once settled loosen the small lid and let the orange glycerine liquid drain out.
7	**Wash-Test** Put 150ml of settled unwashed biodiesel in a 1/2L glass jar or PET bottle. Add 150ml (room temp) water, screw the lid on tight and shake it violently for 10s and let it settle. The biodiesel should separate from the water in half an hour or less with amber biodiesel on the top and milky water below with nothing more then a paper thin line between them. Go to the washing stage. If it looks like mayonnaise or won't separate or separates slowly with a thick white dividing line in the middle, the process needs improving.
8	**Methanol Test** Take 25ml biodiesel and dissolve it in 225ml methanol in a measuring glass. The biodiesel should be fully soluble in it forming a clear bright phase. If not there is pollution in the biodiesel. Each ml of undissolved material corresponds to 4% by volume and it shows the reaction is not complete. The biodiesel will dissolve readily while the oils and fats won't, remaining on the bottom. To fix, alter the processing method and mixing time and check chemical quantities.
9	**Test Tips** It may take several attempts to pass the tests based on different blenders and processors. Ensure the chemicals are the correct measurements and top quality. **Wash Failure:** Either there's too much catalyst which made excess soap. Or there's an incomplete reaction with poor conversion that has left fuel contaminants that also act as emulsifiers. Emulsifiers are used to make stable mixtures of oil and water.
10	**Washing** If the biodiesel passed the tests, wash the rest of it by using 2 2L PET bottles in succession with 1/2L tap water added for each of the 3-4 washes required. Pierce a small 2mm hole in the bottom corner of each of the two bottles and cover the hole securely with duct tape. Pour the biodiesel into one of the wash bottles. Add the 1/2L of fresh water.
11	**Stir-Washing** Using a paint stirrer and a variable drill, mix until the liquids appear homogenous. Settle 3h+ then drain off the water from the bottom of the bottle by removing the duct tape from the hole and block it when it reaches biodiesel. Transfer the biodiesel to the second wash bottle, add fresh water and wash again. Clean the first bottle and replace the duct tape and repeat until finished.
12	**Drying** When it's clear/translucent it's dry and ready to use. It might clear quickly or it might take a few days. To speed it up - gently heat it to 48°C (118.4°F) and allow to cool. This evaporates the remaining water, so let it ventilate.

Alcohol Distillation

Zeolite 3A for getting alcohol above 95% so it can be mixed with Gasoline. It is reusable.	**Materials** ● Bucket ● Fermentation Lock ● Pure Raw Sugar ● 16L Water ● Yeast	**Materials** ● Distiller ● Electric Timer ● Hygrometer ● 3A Zeolite Beads ● Large Steel Mixing Pot ● Thermometer

Method - Fermentation
Pour 4.5kg's (9.9 lbs) sugar into 19L (5 gal) bucket. Add 16L (4.2 gal) water. Mix. Add Yeast and mix. Seal the lid on. Add fermentation lock, take the cover off and add water. Let it sit in a warm place 27-30°C (80.6-86°F) for 7-10 days.

Method
Distill #1: Solution should look thicker and white. Fill the distiller with the wash. Add the lid and plug into the wall with a timer inline set for 2h 25m which results in about 50% alc. Alc level slowly drops over distilling time. Stop process when it's about 50%. Wait 30m until distiller cools before removing lid.
Distill #2: Distil the 50% solution which will then go above 80% alc. Stop when it reaches about 80%. Pour any left over alc after distilling back into the bucket.
Distill #3: Start third distillation of the 80% alc which should return 89-90% alc at about 1.9L.
Distill #4: = 93%+ alc.

Covert 93.5% to 95% Alc **Method 1** 1.9L 90% Ethanol 1.9L E85 3.8L Gasoline **Method 2** 3 Angstrom Molecular Sieve for water Adsorption. Pour both into a pot and stir, heat will be released and leave 95%-99.8% Alc.	**Mixing Alc + Gas** Car should be newer then 1982. Mix 50% Gasoline with 50% Alcohol. Must be 95% or higher Alc or it won't all mix together.	

Purity of Alcohol (Ethanol) Per Distillation Cycle

FUEL | Creating Fuel | Alcohol Distillation | Purity of Alcohol (Ethanol) Per Distillation Cycle

When making alcohol (specifically ethanol) through distillation, achieving high purity is a stepwise process. The fundamental principle is that ethanol has a lower boiling point (78.4°C) than water (100°C), so it vaporizes more readily. However, a significant limitation arises due to the formation of an azeotrope with water.

An azeotrope is a mixture of two or more liquids that boils at a constant temperature and has the same composition in the vapor phase as in the liquid phase. For ethanol and water, this occurs at approximately 95.6% ethanol by weight (or ~96% by volume). Once this concentration is reached, further simple distillation will not increase the purity, as the vapor produced will have the same 95.6% ethanol / 4.4% water ratio as the liquid.

When making alcohol (specifically ethanol) through distillation, achieving high purity is a stepwise process. The fundamental principle is that ethanol has a lower boiling point (78.4°C) than water (100°C), so it vaporizes more readily. However, a significant limitation arises due to the formation of an azeotrope with water.

An azeotrope is a mixture of two or more liquids that boils at a constant temperature and has the same composition in the vapor phase as in the liquid phase. For ethanol and water, this occurs at approximately 95.6% ethanol by weight (or ~96% by volume). Once this concentration is reached, further simple distillation will not increase the purity, as the vapor produced will have the same 95.6% ethanol / 4.4% water ratio as the liquid.

To achieve purities above this azeotropic point (i.e., "absolute" or "anhydrous" alcohol, approaching 100%), more advanced and specialized techniques are required. These methods typically involve breaking the azeotrope. Common industrial methods include:

- Azeotropic Distillation: Adding a third component (an "entrainer" like benzene, cyclohexane, or toluene) that forms a new, lower-boiling azeotrope with the water, effectively removing the water. This method often leaves trace impurities of the entrainer, making the alcohol unsuitable for consumption.
- Molecular Sieves: Using a desiccant material (like synthetic zeolites) that selectively absorbs water molecules from the 95.6% ethanol.
- Pressure Swing Distillation: Distilling at different pressures to shift the azeotropic point.
- Extractive Distillation: Adding a solvent to alter the relative volatilities of ethanol and water.

Given these limitations, here is a generalized table showing how alcohol purity might increase with successive distillation cycles using standard fractional distillation, and then acknowledging the methods required to go beyond the azeotrope:

This table assumes an initial fermented wash of 10-15% alcohol, and efficient fractional distillation setups. Actual results can vary based on still design (pot still vs. reflux still, number of theoretical plates), operating conditions, and starting concentration.

Distillation Cycle	Ethanol Purity	Notes
Initial Wash	5% - 20%	This is the starting fermented liquid (e.g., beer, wine, sugar wash). Purity is limited by yeast tolerance to alcohol.
Distillation #1	40% - 80%	A single pass in a pot still or initial run in a reflux still. Often referred to as "stripping run" or "low wines." Significant increase in alcohol concentration.
Distillation #2	80% - 92%	Re-distilling the product from the first cycle. Purity increases further, and heads (volatile impurities like acetone, methanol) and tails (fusel oils, higher alcohols) are typically separated in this stage for quality.
Distillation #3	92% - 95%	Continued fractional distillation. Gains in purity become smaller with each subsequent run as you approach the azeotrope.
Distillation #4	~95.6% (Azeotrope)	This is the practical maximum purity achievable through conventional fractional distillation of an ethanol-water mixture. At this point, the vapor and liquid compositions are the same, preventing further separation by distillation alone. This is often called "rectified spirit."
Beyond Azeotrope (Requires Specialized Methods)		
Azeotropic Distillation / Molecular Sieves / etc.	96% - 99.5%	To break the azeotrope, techniques like adding an entrainer (e.g., benzene, cyclohexane) or using molecular sieves are employed. This process removes the remaining water. The resulting alcohol is often referred to as "absolute" or "anhydrous" ethanol.
Further Purification (Advanced Labs/Industrial)	99.5% - 99.999%	Achieving extremely high purities (e.g., for analytical grade or specific industrial applications) requires further rigorous drying methods, specialized chromatography, or very precise vacuum distillation techniques in highly controlled laboratory or industrial settings, often with continuous monitoring and strict contamination control.

Light

Generating light and understanding lighting

"It is during our darkest moments that we must focus to see the light."
Aristotle

Introduction

This section will cover all types of lights, lighting and benefits of different lights. Lighting can be a valuable asset as much as a detriment to your vision in a night scenario. It's important to get your choice of lighting right for the type of expedition you're going on. The speed of light in vacuum, commonly denoted c, is a universal physical constant important in many areas of physics. Its exact value is 299,792,458 metres per second (approximately 300,000 km/s (186,000 mi/s)).

Purpose	The aim of LIGHT is to inform you about the different types and uses of lights and to demonstrate the effects of lighting with respect to the colour, the range and the different power levels. It also includes how to ignite and use the various forms of light you may encounter, such as butane lanterns and kerosene lanterns. The category concludes with information on using light as a becon to signal to others, and information on darkness and light concealment if you wish to remain hidden from sight.
Lost?	• If you're looking for light based equipment, see the GEAR section. • For more information on the power sources of light, see the ELECTRICITY section. • If you're looking for information on power-outages, see the MAN-MADE DISASTERS section. • For using fire as light, see the FIRE section. • If you're looking for the light-weight definition of light, see the GEAR > Backpacks section. • For light-based deterrence mechanisms, see the DEFENCE section. • For offensive light-based weapons such as lasers, see the OFFENCE section. • For information on lightning, see the METEOROLOGY section.

Contents

1 Light

Without light and the ability to see, it becomes much more difficult and slower to accomplish even simple tasks. You will almost always need a couple of light sources in a SHTF situation. A couple of ways it can be used follows in the next cell.

Light Uses
• Reading Maps
• Lighting Paths
• Signalling

Advantages	● Eliminates Darkness ● Bright lights lets you see more detail ● Expels fear when you can see ● Can be used as a form of communication.
Disadvantages	● Light can give away your position ● Lights generally take batteries or a decaying source of power to run ● Lights can get very hot when running ● Some lights are single use only ● Light can make it hard to sleep
Speed	The speed of light in vacuum, commonly denoted c, is a universal physical constant important in many areas of physics. Its exact value is 299,792,458 metres per second (approximately 300,000 km/s (186,000 mi/s)). It is exact because by international agreement a metre is defined to be the length of the path travelled by light in vacuum during a time interval of 1/299792458 second.

Wavelengths

Name	Wavelength	Frequency (Hz)	Photon energy (eV)		
Gamma ray	less than 0.01 nm	more than 30 EHz	more than 124 keV		
X-ray	0.01 nm – 10 nm	30 EHz – 30 PHz	124 keV – 124 eV		
Ultraviolet	10 nm – 400 nm	30 PHz – 790 THz	124 eV – 3.3 eV		
Visible	400 nm–700 nm	790 THz – 430 THz	3.3 eV – 1.7 eV		
Infrared	700 nm – 1 mm	430 THz – 300 GHz	1.7 eV – 1.24 meV		
Microwave	1 mm – 1 meter	300 GHz – 300 MHz	1.24 meV – 1.24 µeV		
Radio	1 meter – 100,000 km	300 MHz –3 Hz	1.24 µeV – 12.4 feV		

Measurement

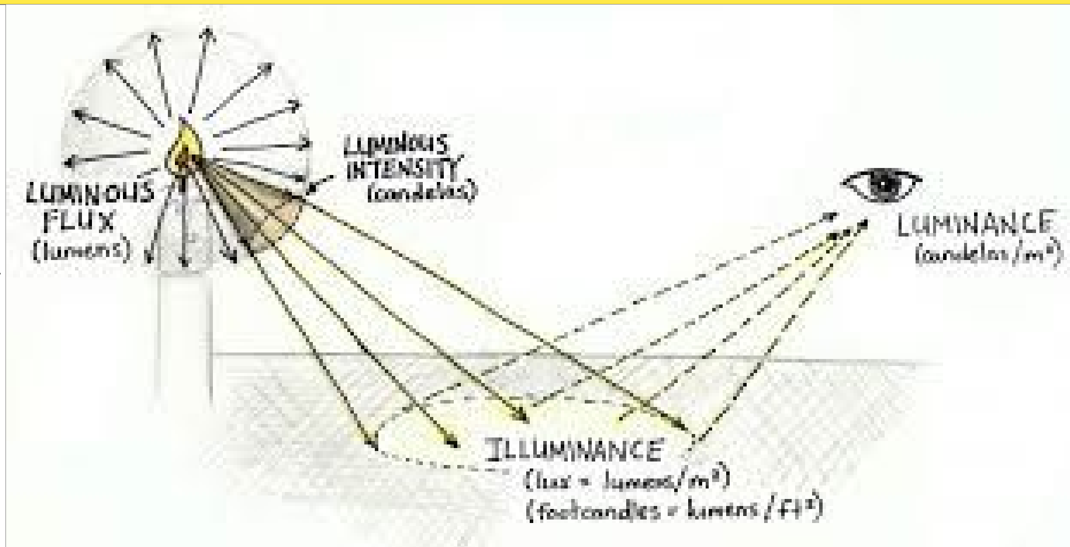
Lumen (lm)
Unit of light flow or luminous flux measuring the total perceived power of light.

Candela (cd)
Unit of luminous intensity, measuring the amount of light travelling in a certain direction from the source.

Luminance
The amount of light reaching your eye.

Illumination (Lux)
Full Daylight - 10,752
Overcast Day - 1,075
Room Lighting - 500
Twilight - 10.8
Full Moon - 0.108
Starlight - 0.0011

Foot-candle (fc/ftc/ftcd)
British standard of Illuminance (Lux). Measured in lumens/ft².



Lux (lx)
Illuminance, The amount of light falling on a surface. Measured in lumens/m².
1 lux = 1 lumen/m².

2 Colour

Coloured light can assist you in various circumstances depending on the colour of the light. The section below will discuss the different colours of lights you can use and the benefits and drawbacks of each.

Light Type
The type of light can vastly affect the colour of the light, particularly between LED and incandescent bulbs. Most lights colour can't be changed once it's made, however some lights chance colour over their life due to ageing. RGB LED's colour can be changed only because they contain multiple diodes to create each visible colour. Incandescent bulbs with coloured filters and even white LED's with filters aren't as effective as an LED made to output a single colour.

Colour Rendering Index

A colour rendering index (CRI) is a quantitative measure of the ability of a light source to reveal the colours of various objects faithfully in comparison with an ideal or natural light source. Light sources with a high CRI are desirable in colour-critical applications such as neonatal care and art restoration. It is defined by the International Commission on Illumination (CIE) as follows: Colour rendering: Effect of an illuminate on the colour appearance of objects by conscious or subconscious comparison with their colour appearance under a reference illuminate. The CRI of a light source does not indicate the apparent colour of the light source; that information is given by the correlated colour temperature (CCT). The CRI is determined by the light source's spectrum. An incandescent lamp has a continuous spectrum, a fluorescent lamp has a discrete line spectrum; the incandescent lamp has the higher CRI. Numerically, the highest possible CIE Ra value is 100 and would only be given to a source identical to standardized daylight or a black body (incandescent lamps are effectively black bodies), dropping to negative values for some light sources. Low-pressure sodium lighting has negative CRI; fluorescent lights range from about 50 for the basic types, up to about 98 for the best multi-phosphor type. Typical LEDs have about 80+ CRI, while some manufacturers claim that their LEDs have achieved up to 98 CRI.

Light Colours

There are various effects light colour can have on the situation which are mentioned in the following cells.

Blue Light	● Third brightest light ● Resembles moon colour ● Best for avoiding detection ● Ruins night-vision ● May miss rivers or lakes on maps ● May prevent seeing veins
Green Light	● Second brightest light ● Second best for avoiding detection, especially in forests ● May not see forests or fields on a map
Red Light	● Fourth Brightest Light ● Easy to detect ● Retains night vision ● May not see highways on a map
Amber Light	● Attracts Fewer Bugs
Neutral White (5,500K)	● Brightest Light ● Easy to detect ● No negatives viewing maps
Cool White	● Brightest Light ● Easy to detect ● No negatives viewing maps
Warm White	● Brightest Light ● Easy to detect ● No negatives viewing maps
Infrared	● Invisible
Ultraviolet (UV-A) (Blacklight)	● Invisible ● Causes fluorescent colours to glow ● UV-B light can kill bacteria ● Lights up scorpions

Colour & Heat Retention

The colour of an object can dramatically affect how hot it gets in direct sunlight. Most of us know that white reflects the most light while black absorbs the more light, but what about all the colours between? This can be used to help choose your gear colour based on requirements, such as choosing a darker coloured bottle which will be used to boil water. The following table shows the temperature of different coloured plastic squares which have been exposed to the same amount of sunlight for the same amount of time.

Colour	°C	°F	Description
White	36.7	98.06	Use white if you want to keep items cool.
Grass	41.3	106.34	Used as a 'control' item to see the temperature difference verses grass.
Pink	44.8	112.64	
Yellow	51.5	124.7	
Red	55.7	132.26	
Green	57.7	135.86	
Brown	60.8	141.44	
Blue	61.3	142.34	
	71.5	160.7	Choose black if you want items to be warmer than usual.

As you can see, black retains almost twice the amount of heat as white.

Gear Colours

These are examples of different colours you can buy gear in and their features.

White	Reflects sunlight and keeps the item cooler than if it was another colour. Use it to prevent items in the sun getting as hot. Light colours don't attract mosquitoes as much.
Black	Black absorbs light and heat more than any other colour. Useful to keep things hot.
Transparent	Allows light through the material and provides disinfection if placed in the sun.
Camo	The best colour scheme to conceal items in the environment.
Bright Colours	Bright Lime, Orange, Red, Blue etc, attract the eye, especially if in the wild. It also attracts various types of bugs over duller colours.

Kelvin Colours

These are the different colours of the Kelvin scale with an example of that coloured light.

1,000 Kelvin	
2,000 Kelvin	**Match Flame** - 1,700-1,800K **Candle** - 1,850-1,930K **Sunrise** - 2,000-3,000K **Street Lights** - 2,200K
3,000 Kelvin	**Warm White Halogen Lamp** - 2,700-3,000K **Tungsten Lamp** - 3,000K
4,000 Kelvin	**Natural White Metal Halide** - 4,000-4,500K **Fluorescent** - 2,700-6,500K **White LED** - 3,000-5,600K
5,000 Kelvin	**Direct Sunlight** - 4,800K **Daylight** - 5,000-6,000K
5,500 Kelvin	**Pure White**
6,000 Kelvin	**Hydrargyrum Medium-Arc Iodine (HDI)** - 5,600K **Sunlight and Sky** - 6,500K
7,000 Kelvin	**Cool White** - 7,000-7,500K
8,000 Kelvin	**Summer Shade** - 8,000K
9,000 Kelvin	
10,000 Kelvin	**Blue Sky** - 10,000K

Colour Wavelengths

This shows the colour wavelengths of the various colours of light.

Colour Wavelength Frequency	**Far Ultraviolet**	**Near Ultraviolet**	**Violet**	**Blue**	**Cyan**	**Green**	**Yellow**	**Orange**	**Red**	**Infrared**
Wavelength	<200–250	250–380 nm	380–450 nm	450–485 nm	485–500 nm	500–565 nm	565–590 nm	590–625 nm	625–740 nm	740–1000+
Frequency	>1500 THz	1000 THz	680–790 THz	620–680 THz	600–620 THz	530–600 THz	510–530 THz	480–510 THz	405–480 THz	<300 THz

3 Light Sources

These are the different sources of light which you can utilize.

Natural

The Sun **Lux:** 10,752 **Duration:** 12h/day **Source:** Sun **Notes:** Sunlight hours may differ based on region **Warning:** Never look directly at the sun	**LED Torch** **Lumens:** 1-10,000 **Duration:** 10h **Source:** Electricity **Notes:** None **Warning:** None	**Butane Lantern** **Lumens:** 500 **Duration:** 10h **Source:** Butane Gas **Notes:** None **Warning:** Replaces Oxygen with Carbon Monoxide - Use in open spaces	**Kerosene Lantern** **Lumens:** 37 **Duration:** 10h **Source:** Kerosene **Notes:** Kerosene lasts about 75h per 1L **Warning:** Consumes oxygen, so ensure ventilation	**Candle** **Lumens:** 15 **Duration:** 10h **Source:** Wick **Notes:** None **Warning:** Consumes oxygen, so ensure ventilation

4 Natural Light

Natural light is any source of light which comes from external sources not made by man.

Natural Sources (Space)
- Sun
- Moon
- Stars
- Airglow
- Meteor

Natural Sources (Land)
- Fire
- Lightning
- Aurora
- Lava
- Earthquake

Subheadings

1. Sun	2. Moon	3. Stars	4. Airglow
5. Meteor	6. Fire	7. Lightning	8. Aurora
9. Lava	10. Earthquake		

1 Sun

Sunlight is a portion of the electromagnetic radiation given off by the Sun, in particular infrared, visible, and ultraviolet light. On Earth, sunlight is filtered through Earth's atmosphere, and is obvious as daylight when the Sun is above the horizon. When the direct solar radiation is not blocked by clouds, it is experienced as sunshine, a combination of bright light and radiant heat. When it is blocked by clouds or reflects off other objects, it is experienced as diffused light.

The World Meteorological Organization uses the term "sunshine duration" to mean the cumulative time during which an area receives direct irradiance from the Sun of at least 120 watts per square meter. Other sources indicate an "Average over the entire earth" of "164 Watts per square meter over a 24 hour day". The ultraviolet radiation in sunlight has both positive and negative health effects, as it is both a requisite for vitamin D3 synthesis and a mutagen. Sunlight takes about 8.3 minutes to reach Earth from the surface of the Sun.

A photon starting at the centre of the Sun and changing direction every time it encounters a charged particle would take between 10,000 and 170,000 years to get to the surface. Sunlight is a key factor in photosynthesis, the process used by plants and other autotrophic organisms to convert light energy, normally from the Sun, into chemical energy that can be used to synthesize carbohydrates and to fuel the organisms' activities.

Sunlight at the top of Earth's atmosphere is composed (by total energy) of about 50% infrared light, 40% visible light, and 10% ultraviolet light. The atmosphere in particular filters out over 70% of solar ultraviolet, especially at the shorter wavelengths. Solar ultraviolet radiation ionizes Earth's dayside upper atmosphere, creating the electrically conducting ionosphere.

Measurement
Researchers can measure the intensity of sunlight using a sunshine recorder, pyranometer, or pyrheliometer. To calculate the amount of sunlight reaching the ground, both the eccentricity of Earth's elliptic orbit and the attenuation by Earth's atmosphere have to be taken into account. The total amount of energy received at ground level from the Sun at the zenith depends on the distance to the Sun and thus on the time of year. It is about 3.3% higher than average in January and 3.3% lower in July.

If the extra-terrestrial solar radiation is 1367 watts per square meter (the value when the Earth–Sun distance is 1 astronomical unit), then the direct sunlight at Earth's surface when the Sun is at the zenith is about 1050 W/m2, but the total amount (direct and indirect from the atmosphere) hitting the ground is around 1120 W/m2. In terms of energy, sunlight at Earth's surface is around 52 to 55 percent infrared (above 700 nm), 42 to 43 percent visible (400 to 700 nm), and 3 to 5 percent ultraviolet (below 400 nm).
At the top of the atmosphere, sunlight is about 30% more intense, having about 8% ultraviolet (UV), with most of the extra UV consisting of biologically damaging short-wave ultraviolet. Direct sunlight has a luminous efficacy of about 93 lumens per watt of radiant flux. This is higher than the efficacy (of source) of most artificial lighting (including fluorescent), which means using sunlight for illumination heats up a room less than using most forms of artificial lighting. Multiplying the figure of 1050 watts per square metre by 93 lumens per watt indicates that bright sunlight provides an illuminance of approximately 98 000 lux (lumens per square meter) on a perpendicular surface at sea level.

The illumination of a horizontal surface will be considerably less than this if the Sun is not very high in the sky. Averaged over a day, the highest amount of sunlight on a horizontal surface occurs in January at the South Pole. Dividing the irradiance of 1050 W/m2 by the size of the sun's disk in steradians gives an average radiance of 15.4 MW per square metre per steradian.

Composition

The spectrum of the Sun's solar radiation is close to that of a black body with a temperature of about 5,800 K. The Sun emits EM radiation across most of the electromagnetic spectrum. Although the Sun produces gamma rays as a result of the nuclear-fusion process, internal absorption and thermalization convert these super-high-energy photons to lower-energy photons before they reach the Sun's surface and are emitted out into space. As a result, the Sun does not emit gamma rays from this process, but it does emit gamma rays from solar flares. The Sun also emits X-rays, ultraviolet, visible light, infrared, and even radio waves; the only direct signature of the nuclear process is the emission of neutrinos. Although the solar corona is a source of extreme ultraviolet and X-ray radiation, these rays make up only a very small amount of the power output of the Sun (see spectrum at right). The spectrum of nearly all solar electromagnetic radiation striking the Earth's atmosphere spans a range of 100 nm to about 1 mm (1,000,000 nm). This band of significant radiation power can be divided into five regions in increasing order of wavelengths:

Ultraviolet C (UVC)	Which spans a range of 100 to 280 nm. The term ultraviolet refers to the fact that the radiation is at higher frequency than violet light. Due to absorption by the atmosphere very little reaches Earth's surface. This spectrum of radiation has germicidal properties, as used in germicidal lamps.
Ultraviolet B (UVB)	Spans 280 to 315 nm. It is also greatly absorbed by the Earth's atmosphere, and along with UVC causes the photochemical reaction leading to the production of the ozone layer. It directly damages DNA and causes sunburn, but is also required for vitamin D synthesis in the skin and fur of mammals.
Ultraviolet A (UVA)	Spans 315 to 400 nm. This band is used in cosmetic artificial sun tanning (tanning booths and tanning beds). However, UVA is now known to cause significant damage to DNA via indirect routes (formation of free radicals and reactive oxygen species), and can cause cancer.
Visible Range	Light spans 380 to 780 nm. As the name suggests, this range is visible to the naked eye. It is also the strongest output range of the Sun's total irradiance spectrum.
Infrared Range	Spans 700 nm to 1,000,000 nm (1 mm). It comprises an important part of the electromagnetic radiation that reaches Earth. Scientists divide the infrared range into three types on the basis of wavelength: ● Infrared-A: 700 nm to 1,400 nm ● Infrared-B: 1,400 nm to 3,000 nm ● Infrared-C: 3,000 nm to 1 mm.

Brightness

The perceived brightness varies based on the time of day. The following shows the average levels of brightness during a day.	12am-6am 0 Lux	6am-7am 30>45 Lux	7-9am 45>60 Lux	9-11am 60>95 Lux	11-1pm 95>100>95 Lux	1-3pm 95>60 Lux	3-5pm 60>45 Lux	5-6pm 45>30 Lux	6-12am 0 Lux

Sun Power

Brightest Sunlight 120,000 lux	**Bright Sunlight** 111,000 lux	**Global Solar Sunlight** 109,870 lux	**Shade Illuminated by Clear Blue Sky** 20,000 lux	**Overcast Day** 1,000 - 2,000 lux	
Thickest Clouds <200 lux	**Sunrise/set Ambience** 400 lux	**Fully Overcast Sunrise/set** 40 lux	**Thickest Clouds Sunrise/set** <1 lux		

Twilight

Twilight on Earth is the illumination of the lower atmosphere when the Sun itself is not directly visible because it is below the horizon. Twilight is produced by sunlight scattering in the upper atmosphere, illuminating the lower atmosphere so that Earth's surface is neither completely lit nor completely dark. The word twilight is also used to denote the periods of time when this illumination occurs. The farther the Sun is below the horizon, the dimmer the twilight (other things such as atmospheric conditions being equal). When the Sun reaches 18° below the horizon, the twilight's brightness is nearly zero, and evening twilight becomes night-time. When the Sun again reaches 18° below the horizon, night-time becomes morning twilight.

Owing to its distinctive quality, primarily the absence of shadows and the appearance of objects silhouetted against the lit sky, twilight has long been popular with photographers, who sometimes refer to it as "sweet light", and painters, who often refer to it as the blue hour, after the French expression l'heure bleue. Twilight should not be confused with auroras, which can have a similar appearance in the night sky at high latitudes. By analogy with evening twilight, the word twilight is also sometimes used metaphorically, to imply that something is losing strength and approaching its end.

Three subcategories of twilight are established and widely accepted: civil twilight (brightest), nautical twilight, and astronomical twilight (darkest).	**Civil Twilight** The typical colour of the sky when civil twilight is occurring. Occurs between 0°-6°. The sun takes 24 minutes to move 6°.	**Nautical Twilight** The typical colour of the sky when nautical twilight is occurring. Occurs between 6°-12°. The sun takes 24 minutes to move 6°.	**Astronomical Twilight** The typical colour of the sky when astronomical twilight is occurring. Occurs between 12°-18°. The sun takes 24 minutes to move 6°.

Civil Twilight

Morning civil twilight begins when the geometric centre of the sun is 6° below the horizon and ends at sunrise. Evening civil twilight begins at sunset and ends when the geometric centre of the sun reaches 6° below the horizon. In the United States' military, the initialisms BMCT (begin morning civil twilight, i.e. civil dawn) and EECT (end evening civil twilight, i.e. civil dusk) are used to refer to the start of morning civil twilight and the end of evening civil twilight, respectively. Civil dawn is preceded by morning nautical twilight and civil dusk is followed by evening nautical twilight. Under clear weather conditions, civil twilight approximates the limit at which solar illumination suffices for the human eye to clearly distinguish terrestrial objects. Enough illumination renders artificial sources unnecessary for most outdoor activities. At civil dawn and at civil dusk sunlight clearly defines the horizon while the brightest stars and planets can appear.

As observed from the Earth, sky-gazers know Venus, the brightest planet, as the "morning star" or "evening star" because they can see it during civil twilight. Lawmakers have enshrined the concept of civil twilight. Such statutes typically use a fixed period after sunset or before sunrise (most commonly 20–30 minutes), rather than how many degrees the sun is below the horizon. Examples include the following periods: when drivers of automobiles must turn on their headlights (called lighting-up time in the UK); when hunting is restricted; when the crime of burglary is to be treated as night-time burglary, which carries stiffer penalties in some jurisdictions. The period may affect when extra equipments, such as anti-collision lights, are required for aircraft to operate. In the US, civil twilight for aviation is defined in Part 1.1 of the Federal Aviation Regulations (FARs) as the time listed in the American Air Almanac.

Nautical Twilight

Morning nautical twilight begins (nautical dawn) when the geometric centre of the sun is 12° below the horizon in the morning and ends when the geometric centre of the sun is 6° below the horizon in the morning. Evening nautical twilight begins when the geometric centre of the sun is 6° below the horizon in the evening and ends (nautical dusk) when the geometric centre of the sun is 12° below the horizon in the evening. Nautical dawn is the moment when the geometric centre of the Sun is 12° below the horizon in the morning. It is preceded by morning astronomical twilight and followed by morning nautical twilight. Nautical dusk is the moment when the geometric centre of the Sun is 12° below the horizon in the evening. It marks the beginning of evening astronomical twilight and the end of evening nautical twilight. Before nautical dawn and after nautical dusk, sailors cannot navigate via the horizon at sea as they cannot clearly see the horizon.

At nautical dawn and nautical dusk, the human eye finds it difficult, if not impossible, to discern traces of illumination near the sunset or sunrise point of the horizon ("first light" after nautical dawn but before civil dawn and "nightfall" after civil dusk but before nautical dusk). Under good atmospheric conditions with the absence of other illumination, during nautical twilight, the human eye may distinguish general outlines of ground objects but cannot participate in detailed outdoor operations. Nautical twilight has military considerations as well. The initialisms BMNT (begin morning nautical twilight, i.e. nautical dawn) and EENT (end evening nautical twilight, i.e. nautical dusk) are used and considered when planning military operations. A military unit may treat BMNT and EENT with heightened security, e.g. by "standing to", in which everyone assumes a defensive position. This is partially due to tactics dating back to the French and Indian War, when combatants on both sides would launch attacks at nautical dawn or dusk.

Astronomical Twilight

Astronomical dawn is the moment when the geometric centre of the Sun is 18° below the horizon in the morning. Astronomical dusk is the moment when the geometric centre of the Sun is 18 degrees below the horizon in the evening. After astronomical dusk and before astronomical dawn, the sky is not illuminated by the sun. Morning astronomical twilight begins (astronomical dawn) when the geometric centre of the sun is 18° below the horizon in the morning and ends when the geometric centre of the sun is 12° below the horizon in the morning. Evening astronomical twilight begins when the geometric centre of the sun is 12° below the horizon in the evening and ends (astronomical dusk) when the geometric centre of the sun is 18° below the horizon in the evening. In some places (away from urban light pollution, moonlight, auroras, and other sources of light), where the sky is dark enough for nearly all astronomical observations, astronomers can easily make observations of point sources such as stars both during and after astronomical twilight in the evening and both before and during astronomical twilight in the morning.

However, some critical observations, such as of faint diffuse items such as nebulae and galaxies, may require observation beyond the limit of astronomical twilight. Theoretically, the faintest stars detectable by the naked eye (those of approximately the sixth magnitude) will become visible in the evening at astronomical dusk, and become invisible at astronomical dawn. However, in other places, especially those with skyglow, astronomical twilight may be almost indistinguishable from night. In the evening, even when astronomical twilight has yet to end and in the morning when astronomical twilight has already begun, most casual observers would consider the entire sky fully dark. Because of light pollution, observers in some localities, generally in large cities, may never have the opportunity to view even fourth-magnitude stars, irrespective of the presence of any twilight at all, and to experience truly dark skies.

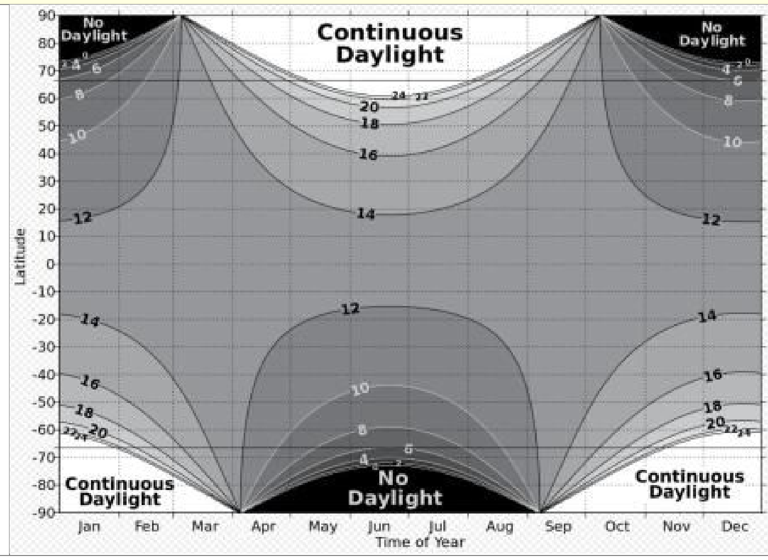
Observers within 48.5 degrees of the Equator can view twilight twice each day on every date of the year between astronomical dawn, nautical dawn, or civil dawn, and sunrise as well as between sunset and civil dusk, nautical dusk, or astronomical dusk. This also occurs for most observers at higher latitudes on many dates throughout the year, except those around the summer solstice. However, at latitudes closer than 9 degrees to either Pole, the Sun cannot rise above the horizon nor sink more than 18 degrees below it on the same day on any date, this example of twilight cannot occur because the angular difference between solar noon and solar midnight elevates less than 18 degrees. At latitudes greater than about 48.5 degrees North or South, on dates near the summer solstice, twilight can last from sunset to sunrise, since the Sun does not go more than 18 degrees below the horizon, so complete darkness does not occur even at solar midnight. These latitudes include many densely populated regions of the Earth, including the entire United Kingdom and other countries in northern Europe.

In Arctic and Antarctic latitudes in wintertime, the polar night only rarely produces complete darkness for 24 hours each day. This can occur only at locations within 5.5 degrees of latitude of the Pole, and there only on dates close to the winter solstice. At all other latitudes and dates, the polar night includes a daily period of twilight, when the Sun is not far below the horizon. Around winter solstice, when the solar declination changes slowly, complete darkness lasts several weeks at the Pole itself, e.g., from May 11 to July 31 at Amundsen–Scott South Pole Station. North Pole has the experience of this from November 12 to January 30. At latitudes within 9 degrees of either Pole, as the sun's angular elevation difference is less than 18 degrees, twilight can last for the entire 24 hours. This occurs for one day at latitudes near 9 degrees from the Pole and extends up to several weeks the further towards the Pole one goes. The only permanent settlement to experience this condition is Alert, Nunavut, Canada, where it occurs for a week in late February, and again in late October.

Duration

The number of daylight hours depends on the latitude and time of year. Each pole has continuous daylight near its summer solstice. The apparent travel of the sun occurs at the rate of 15° per hour (360° per day), but sunrise and sunset happen typically at oblique angles to the horizon and the actual duration of any twilight period will be a function of that angle, being longer for more oblique angles. This angle of the sun's motion with respect to the horizon changes with latitude as well as the time of year (affecting the angle of the Earth's axis with respect to the sun).

At Greenwich, England (51.5°N), the duration of civil twilight will vary from 33 minutes to 48 minutes, depending on the time of year. At the equator, conditions can go from day to night in as little as 20–25 minutes. This is true because at low latitudes the sun's apparent movement is perpendicular to the observer's horizon. But at the poles, civil twilight can be as long as 2–3 weeks. In the Arctic and Antarctic regions, twilight (if there is any) can last for several hours. There is no astronomical twilight at the poles near the winter solstice (for about 74 days at the North Pole and about 80 days at the South Pole).



As one gets closer to the Arctic and Antarctic circles, the sun's disk moves toward the observer's horizon at a lower angle. The observer's earthly location will pass through the various twilight zones less directly, taking more time. Within the polar circles, twenty-four-hour daylight is encountered in summer, and in regions very close to the poles, twilight can last for weeks on the winter side of the equinoxes. Outside the polar circles, where the angular distance from the polar circle is less than the angle which defines twilight (see above), twilight can continue through local midnight near the summer solstice. The precise position of the polar circles, and the regions where twilight can continue through local midnight, varies slightly from year to year with Earth's axial tilt. The lowest latitudes at which the various twilights can continue through local midnight are approximately 60.561° (60°33′43″) for civil twilight, 54.561° (54°33′43″) for nautical twilight and 48.561° (48°33′43″) for astronomical twilight.

These are the largest cities of their respective countries where the various twilights can continue through local solar midnight:	**Civil twilight from sunset to sunrise:** Tampere, Umeå, Trondheim, Tórshavn, Reykjavík, Nuuk, Whitehorse, Anchorage, Fairbanks, Ålesund, Nome, and Baltasound.	**Nautical twilight from civil dusk to civil dawn:** Moscow, Vitebsk, Vilnius, Riga, Tallinn, Wejherowo, Flensburg, Helsinki, Stockholm, Copenhagen, Oslo, Newcastle upon Tyne, Glasgow, Belfast, Letterkenny, Petropavl, Grande Prairie, Juneau, Ushuaia, and Puerto Williams.	**Astronomical twilight from nautical dusk to nautical dawn:** Hulun Buir, Erdenet, Astana, Samara, Kiev, Minsk, Warsaw, Košice, Paris, Dublin, Zwettl, Prague, Stanley (Falkland Islands), Berlin, Luxembourg City, Brussels, Amsterdam, London, Cardiff, Calgary, Unalaska, Bellingham (largest in the continental USA), Rio Gallegos, and Punta Arenas.

Major cities that near astronomical twilight from nautical dusk to nautical dawn: Saguenay (48°25′0″N), Brest (48°23′26″N), Thunder Bay (48°22′56″N), Vienna (48°12′30″N), Bratislava (48°8′38″N), Munich (48°8′0″N)

Although Helsinki, Oslo, Stockholm, Tallinn, and Saint Petersburg also enter into nautical twilight after sunset, they do have noticeably lighter skies at night during the summer solstice than other locations mentioned in their category above, because they do not go far into nautical twilight. A white night is a night with only civil twilight which lasts from sunset to sunrise.

At the winter solstice within the polar circle, twilight can extend through solar noon at latitudes below 72.561° (72°33′43″) for civil twilight, 78.561° (78°33′43″) for nautical twilight, and 84.561° (84°33′43″) for astronomical twilight.

Twilight on Mars is longer than on Earth, lasting for up to two hours before sunrise or after sunset. Dust high in the atmosphere scatters light to the night side of the planet. Similar twilights are seen on Earth following major volcanic eruptions.

2 Moon

Moonlight consists of mostly sunlight (with little earthlight) reflected from the parts of the Moon's surface where the Sun's light strikes. The intensity of moonlight varies greatly depending on its phase, but even the full Moon typically provides only about 0.05–0.1 lux illumination. When the full Moon is at perigee and viewed around upper culmination from the tropics, the illuminance can reach up to 0.32 lux. From Earth, the apparent magnitude of the full Moon is only about 1⁄380,000 that of the Sun. The colour of moonlight, particularly around full Moon, appears bluish to the human eye compared to most artificial light sources due to the Purkinje effect. Moonlight is not actually tinted blue, and although moonlight is often referred to as "silvery", it has no inherent silvery quality. The Moon's albedo is 0.136, meaning only 13.6% of incident sunlight is reflected from the lunar surface. Moonlight generally hampers astronomical viewing, so astronomers usually avoid observing sessions around full Moon. It takes approximately 1.26 seconds for moonlight to reach Earth's surface.

Moon Power	**Moonlight Clear Night** <1 lux	**Full Moon Clear Night** 0.25 lux	**Quarter Moon Clear Night** 0.01 lux								

3 Stars

Starlight is the light emitted by stars. It typically refers to visible electromagnetic radiation from stars other than the Sun observable from Earth during the night time although a component of starlight is observable from the Earth during the daytime. Sunlight is the term used for the Sun's starlight observed during daytime. During night-time, albedo describes solar reflections from other Solar System objects including moonlight.

Starlight Power	Starlight, Moonless Night w/airglow	Starlight Moonless Night wo/airglow	Venus at Brightest	Starlight Overcast Moonless Night							
	0.002 lux	0.0002 lux	0.00014 lux	0.0001 lux							

4 Airglow

Airglow (also called nightglow) is a faint emission of light by a planetary atmosphere. In the case of Earth's atmosphere, this optical phenomenon causes the night sky to never be completely dark, even after the effects of starlight and diffused sunlight from the far side are removed. Airglow is caused by various processes in the upper atmosphere of Earth, such as the recombination of atoms which were photoionized by the Sun during the day, luminescence caused by cosmic rays striking the upper atmosphere, and chemiluminescence caused mainly by oxygen and nitrogen reacting with hydroxyl free radicals at heights of a few hundred kilometres. It is not noticeable during the daytime due to the glare and scattering of sunlight. Even at the best ground-based observatories, airglow limits the photosensitivity of optical telescopes. Partly for this reason, space telescopes like Hubble can observe much fainter objects than current ground-based telescopes at visible wavelengths. Airglow at night may be bright enough for a ground observer to notice and appears generally bluish.

Although airglow emission is fairly uniform across the atmosphere, it appears brightest at about 10° above the observer's horizon, since the lower one looks, the greater the depth of atmosphere one is looking through. Very low down, however, atmospheric extinction reduces the apparent brightness of the airglow. One airglow mechanism is when an atom of nitrogen combines with an atom of oxygen to form a molecule of nitric oxide (NO). In the process, a photon is emitted. This photon may have any of several different wavelengths characteristic of nitric oxide molecules. The free atoms are available for this process, because molecules of nitrogen (N2) and oxygen (O2) are dissociated by solar energy in the upper reaches of the atmosphere and may encounter each other to form NO. Other species that can create air glow in the atmosphere are hydroxyl (OH), atomic oxygen (O), sodium (Na), and lithium (Li). The sky brightness is typically measured in units of apparent magnitude per square arcsecond of sky.

5 Meteor

When a meteoroid, comet, or asteroid enters Earth's atmosphere at a speed typically in excess of 20 km/s (72,000 km/h; 45,000 mph), aerodynamic heating of that object produces a streak of light, both from the glowing object and the trail of glowing particles that it leaves in its wake. This phenomenon is called a meteor or "shooting star". A series of many meteors appearing seconds or minutes apart and appearing to originate from the same fixed point in the sky is called a meteor shower.

6 Fire

A flame is a mixture of reacting gases and solids emitting visible, infrared, and sometimes ultraviolet light, the frequency spectrum of which depends on the chemical composition of the burning material and intermediate reaction products. In many cases, such as the burning of organic matter, for example wood, or the incomplete combustion of gas, incandescent solid particles called soot produce the familiar red-orange glow of "fire". This light has a continuous spectrum. Complete combustion of gas has a dim blue colour due to the emission of single-wavelength radiation from various electron transitions in the excited molecules formed in the flame. Usually oxygen is involved, but hydrogen burning in chlorine also produces a flame, producing hydrogen chloride (HCl). Other possible combinations producing flames, amongst many, are fluorine and hydrogen, and hydrazine and nitrogen tetroxide. Hydrogen and hydrazine/UDMH flames are similarly pale blue, while burning boron and its compounds, evaluated in mid-20th century as a high energy fuel for jet and rocket engines, emits intense green flame, leading to its informal nickname of "Green Dragon".

The glow of a flame is complex. Black-body radiation is emitted from soot, gas, and fuel particles, though the soot particles are too small to behave like perfect blackbodies. There is also photon emission by de-excited atoms and molecules in the gases. Much of the radiation is emitted in the visible and infrared bands. The colour depends on temperature for the black-body radiation, and on chemical makeup for the emission spectra. The dominant colour in a flame changes with temperature. The photo of the forest fire in Canada is an excellent example of this variation. Near the ground, where most burning is occurring, the fire is white, the hottest colour possible for organic material in general, or yellow. Above the yellow region, the colour changes to orange, which is cooler, then red, which is cooler still. Above the red region, combustion no longer occurs, and the uncombusted carbon particles are visible as black smoke.

7 Lightning

The charged regions in the atmosphere temporarily equalize themselves through this discharge referred to as a flash. A lightning flash can also be a strike if it involves an object on the ground. Lightning creates light in the form of black body radiation from the very hot plasma created by the electron flow, and sound in the form of thunder. Lightning may be seen and not heard when it occurs at a distance too great for the sound to carry as far as the light from the strike or flash.

8 Aurora

An aurora sometimes referred to as polar lights, northern lights (aurora borealis) or southern lights (aurora australis), is a natural light display in the Earth's sky, predominantly seen in the high-latitude regions (around the Arctic and Antarctic). Auroras are produced when the magnetosphere is sufficiently disturbed by the solar wind that the trajectories of charged particles in both solar wind and magnetospheric plasma, mainly in the form of electrons and protons, precipitate them into the upper atmosphere (thermosphere/exosphere) due to Earth's magnetic field, where their energy is lost. The resulting ionization and excitation of atmospheric constituents emits light of varying colour and complexity. The form of the aurora, occurring within bands around both polar regions, is also dependent on the amount of acceleration imparted to the precipitating particles. Precipitating protons generally produce optical emissions as incident hydrogen atoms after gaining electrons from the atmosphere. Proton auroras are usually observed at lower latitudes. Most auroras occur in a band known as the "auroral zone", which is typically 3° to 6° wide in latitude and between 10° and 20° from the geomagnetic poles at all local times (or longitudes), most clearly seen at night against a dark sky.

A region that currently displays an aurora is called the "auroral oval", a band displaced towards the night side of the Earth. Early evidence for a geomagnetic connection comes from the statistics of auroral observations. In northern latitudes, the effect is known as the aurora borealis or the northern lights. The former term was coined by Galileo in 1619, from the Roman goddess of the dawn and the Greek name for the north wind. The southern counterpart, the aurora australis or the southern lights, has features almost identical to the aurora borealis and changes simultaneously with changes in the northern auroral zone. The Aurora Australis is visible from high southern latitudes in Antarctica, Chile, Argentina, New Zealand, and Australia. A geomagnetic storm causes the auroral ovals (north and south) to expand, and bring the aurora to lower latitudes. The instantaneous distribution of auroras ("auroral oval") is slightly different, being centred about 3–5° nightward of the magnetic pole, so that auroral arcs reach furthest toward the equator when the magnetic pole in question is in between the observer and the Sun. The aurora can be seen best at this time, which is called magnetic midnight. See METEOROLOGY for more information on auroras.

Colour

Red
At the highest altitudes, excited atomic oxygen emits at 630 nm (red); low concentration of atoms and lower sensitivity of eyes at this wavelength make this colour visible only under more intense solar activity. The low number of oxygen atoms and their gradually diminishing concentration is responsible for the faint appearance of the top parts of the "curtains". Scarlet, crimson, and carmine are the most often-seen hues of red for the auroras.

Green
At lower altitudes, the more frequent collisions suppress the 630-nm (red) mode: rather the 557.7 nm emission (green) dominates. Fairly high concentration of atomic oxygen and higher eye sensitivity in green make green auroras the most common. The excited molecular nitrogen (atomic nitrogen being rare due to high stability of the N2 molecule) plays a role here, as it can transfer energy by collision to an oxygen atom, which then radiates it away at the green wavelength. The rapid decrease of concentration of atomic oxygen below about 100 km is responsible for the abrupt-looking end of the lower edges of the curtains.

Blue
At yet lower altitudes, atomic oxygen is uncommon, and molecular nitrogen and ionized molecular nitrogen take over in producing visible light emission, radiating at a large number of wavelengths in both red and blue parts of the spectrum, with 428 nm (blue) being dominant. Blue and purple emissions, typically at the lower edges of the "curtains", show up at the highest levels of solar activity. The molecular nitrogen transitions are much faster than the atomic oxygen ones.

Ultraviolet
Ultraviolet radiation from auroras (within the optical window but not visible to virtually all humans) has been observed with the requisite equipment. Ultraviolet auroras have also been seen on Mars, Jupiter and Saturn.

Infrared
Infrared radiation, in wavelengths that are within the optical window, is also part of many auroras.

Yellow & Pink
A mix of red and green or blue. Other shades of red, as well as orange, may be seen on rare occasions; yellow-green is moderately common. As red, green, and blue are the primary colours of additive synthesis of colours, in theory, practically any colour might be possible, but the ones mentioned in this article comprise a virtually exhaustive list.

9 Lava

10 Earthquake

An earthquake light (EQL) is a luminous aerial phenomenon that reportedly appears in the sky at or near areas of tectonic stress, seismic activity, or volcanic eruptions. Sceptics point out that the phenomenon is poorly understood and many of the reported sightings can be accounted for by mundane explanations. One of the first records of earthquake lights is during 869 Sanriku earthquake, described as "strange lights in the sky" in Nihon Sandai Jitsuroku.

The lights are reported to appear while an earthquake is occurring, although there are reports of lights before or after earthquakes, such as reports concerning the 1975 Kalapana earthquake. They are reported to have shapes similar to those of the auroras, with a white to bluish hue, but occasionally they have been reported having a wider colour spectrum. The luminosity is reported to be visible for several seconds, but has also been reported to last for tens of minutes. Accounts of viewable distance from the epicentre varies: in the 1930 Idu earthquake, lights were reported up to 70 miles (110 km) from the epicentre.

Earthquake lights were reportedly spotted in Tianshui, Gansu, approximately 400 kilometres (250 mi) north-northeast of the 2008 Sichuan earthquake's epicentre. During the 2003 Colima earthquake in Mexico, colourful lights were seen in the skies for the duration of the earthquake. During the 2007 Peru earthquake lights were seen in the skies above the sea and filmed by many people. The phenomenon was also observed and caught on film during the 2009 L'Aquila and the 2010 Chile earthquakes.

Video footage has also recorded this happening during the 9 April 2011 eruption of Sakurajima Volcano, Japan. The phenomenon was also reported around the Amuri Earthquake in New Zealand, that occurred 1 September 1888. The lights were visible in the morning of 1 September in Reefton, and again on 8 September.

More recent appearances of the phenomenon, along with video footage of the incidents, happened in Sonoma County of California on August 24, 2014, and in Wellington New Zealand on November 14, 2016 where blue flashes like lightning were seen in the night sky, and recorded on several videos. In September 8, 2017, many people reported such sightings in Mexico City after a 8.2 magnitude earthquake with epicentre 460 miles (740 km) away, near Pijijiapan in the state of Chiapas. Appearances of the earthquake light seem to occur when the quakes have a high magnitude, generally 5 or higher on the Richter scale. There have also been incidents of yellow, ball-shaped lights appearing before earthquakes.

Earthquake lights may be classified into two different groups based on their time of appearance: (1) preseismic EQL, which generally occur a few seconds to up to a few weeks prior to an earthquake, and are generally observed closer to the epicentre and (2) coseismic EQL, which can occur either near the epicentre ("earthquake-induced stress"), or at significant distances away from the epicentre during the passage of the seismic wavetrain, in particular during the passage of S waves ("wave-induced stress"). EQL during the lower magnitude aftershock series seem to be rare.

5 Artificial Light

Operation

This sections details the types of common lights used in survival situations and how to operate them.

Fire

Fire has been the primal source of light for most of the history of the world.

Bonfire	
Signal Fire	

For more on fire, see the FIRE section.

Glowstick

A glow stick is a self-contained, short-term light-source. It consists of a translucent plastic tube containing isolated substances that, when combined, make light through chemiluminescence, so it does not require an external energy source. The light cannot be turned off and can only be used once. Glow sticks are often used for recreation, but may also be relied upon for light during military, police, fire, or EMS operations. They are also used by military and police to mark 'clear' areas. Glow sticks emit light when two chemicals are mixed. The reaction between the two chemicals is catalysed by a base, usually sodium salicylate. The sticks consist of a tiny, brittle container within a flexible outer container. Each container holds a different solution. When the outer container is flexed, the inner container breaks, allowing the solutions to combine, causing the necessary chemical reaction. After breaking, the tube is shaken to thoroughly mix the components. The glow stick contains two chemicals, a base catalyst, and a suitable dye (sensitizer, or fluorophor). This creates an exothermic reaction. The chemicals inside the plastic tube are a mixture of the dye, the base catalyst, and diphenyl oxalate. The chemical in the glass vial is hydrogen peroxide. By mixing the peroxide with the phenyl oxalate ester, a chemical reaction takes place, yielding two moles of phenol and one mole of peroxyacid ester (1,2-dioxetanedione). The peroxyacid decomposes spontaneously to carbon dioxide, releasing energy that excites the dye, which then relaxes by releasing a photon.

The wavelength of the photon—the colour of the emitted light—depends on the structure of the dye. The reaction releases energy mostly as light, with very little heat. By adjusting the concentrations of the two chemicals and the base, manufacturers can produce glow sticks that either glow brightly for a short amount of time or more dimly for an extended length of time. This also allows design of glow sticks that perform satisfactorily in hot or cold climates, by compensating for the temperature dependence of reaction. At maximum concentration (typically only found in laboratory settings), mixing the chemicals results in a furious reaction, producing large amounts of light for only a few seconds. The same effect can be achieved by adding copious amounts of sodium salicyate or other bases. Heating a glow stick also causes the reaction to proceed faster and the glow stick to glow more brightly for a brief period. Cooling a glow stick slows the reaction a small amount and causes it to last longer, but the light is dimmer. This can be demonstrated by refrigerating or freezing an active glow stick; when it warms up again, it will resume glowing. The dyes used in glow sticks usually exhibit fluorescence when exposed to ultraviolet radiation—even a spent glow stick may therefore shine under a black light.

Chemicals

Blue Light 9,10-Diphenylanthracene (DPA).	**Blue-Green Light** 1-chloro-9,10-diphenylanthracene (1-chloro(DPA)) and 2-chloro-9,10-diphenylanthracene (2-chloro(DPA)) emit blue-green light more efficiently than nonsubstituted DPA	**Green Light** 9,10-Bis(phenylethynyl)anthracene (BPEA) emits green light with maximum at 486 nm.	**Yellow-Green Light** 1-Chloro-9,10-bis(phenylethynyl)anthracene emits yellow-green light, used in 30-minute high-intensity Cyalume sticks.	**Green Light** 2-Chloro-9,10-bis(phenylethynyl)anthracene emits green light, used in 12-hour low-intensity Cyalume sticks.	**Yellow Light** 1,8-dichloro-9,10-bis(phenylethynyl)anthracene emits yellow light, used in Cyalume sticks.
Orange-Yellow Light Rubrene emits orange-yellow at 550 nm.	**Orange Light** 5,12-Bis(phenylethynyl)naphthacene emits orange light	**Orange Light** Violanthrone emits orange light at 630 nm.	**Infrared Light** 1-N,N-dibutylaminoanthracene emits infrared & 6-methylacridinium iodide emits infrared & 16,17-butyloxyviolanthrone.	**Infrared at 725nnm** 16,17-dihexyloxyviolanthrone.	**Deep Red Light** 2,4-di-tert-butylphenyl 1,4,5,8-tetracarboxynaphthalene diamide emits deep red light, together with DPA is used to produce white or hot-pink light, depending on their ratio.
Red Light N,N'-bis(2,5,-di-tert-butylphenyl)-3,4,9,10-perylenedicarboximide emits red.	**Red Light at 680nm** 16,17-(1,2-ethylenedioxy)violanthrone.				

Operation	**Step 1** Hold the glow stick with both hands and bend it until the glass vial breaks and you see some light.	**Turning Off** Glowsticks can't be turned off once activated so just hide it under something if you don't need the light.	You can speed up the mixing by breaking the vial in multiple places and then shaking the glow stick.	**Increase Brightness** Heating the glowstick will cause the reaction to progress faster thus producing more light in a shorter amount of time.	**Reduce Brightness** To dim the glowstick slow down the reaction by cooling or freezing the chemicals.

Beta Light

Tritium radioluminescence is the use of gaseous tritium, a radioactive isotope of hydrogen, to create visible light. Tritium emits electrons through beta decay and, when they interact with a phosphor material, light is emitted through the process of phosphorescence. The overall process of using a radioactive material to excite a phosphor and ultimately generate light is called radioluminescence.

As tritium illumination requires no electrical energy, it has found wide use in applications such as emergency exit signs, illumination of wristwatches, and portable yet very reliable sources of low intensity light which won't degrade human night vision. Gun sights for night use and small lights (which need to be more reliable than battery powered lights yet not interfere with night vision or be bright enough to easily give away one's location) used mostly by military personnel fall under the latter application.

Tritium lighting is made using glass tubes with a phosphor layer in them and tritium gas inside the tube. Such a tube is known as a "gaseous tritium light source" (GTLS), or beta light (since the tritium undergoes beta decay). The tritium in a gaseous tritium light source undergoes beta decay, releasing electrons that cause the phosphor layer to phosphoresce. During manufacture, a length of borosilicate glass tube that has had the inside surface coated with a phosphor-containing material is filled with radioactive tritium.

The tube is then sealed at the desired length using a carbon dioxide laser. Borosilicate is preferred for its strength and resistance to breakage. In the tube, the tritium gives off a steady stream of electrons due to beta decay. These particles excite the phosphor, causing it to emit a low, steady glow. Tritium is not the only material that can be used for self-powered lighting.

Promethium briefly replaced radium as a radiation source. Tritium is the only radiation source used in radioluminescent light sources today. Various preparations of the phosphor compound can be used to produce different colours of light. Some of the colours that have been manufactured in addition to the common phosphors are green, red, blue, yellow, purple, orange, and white. The GTLSs used in watches give off a small amount of light: not enough to be seen in daylight, but enough to be visible in the dark from a distance of several meters.

The average such GTLS has a useful life of 10–20 years. As the tritium component of the lighting is often more expensive than the rest of the watch itself, manufacturers try to use as little as possible. Being an unstable isotope with a half-life of 12.32 years, the rate of beta emissions decreases by half in that period. Additionally, phosphor degradation will cause the brightness of a tritium tube to drop by more than half in that period.

The more tritium that is initially placed in the tube, the brighter it is to begin with, and the longer its useful life. Tritium exit signs usually come in three brightness levels guaranteed for 10-, 15-, or 20-year useful life expectancies. The difference between the signs is how much tritium the manufacturer installs. The light produced by GTLSs varies in colour and size. Green is usually the brightest colour and white the least bright. Sizes range from tiny tubes small enough to fit on the hand of a watch to ones the size of a pencil. Large tubes (5mm diameter and up to 100mm long) are usually only found in green, and can surprisingly be not as bright as the standard 22.5mm x 3mm sized tritium; this smaller size is usually the brightest and is used mainly in keychains available commercially.

Operation	**Step 1** These lights are permanently activated from manufacture and have a glow life of about 10 years.	**Turning Off** Beta lights can't be turned off so just hide it under something if you don't need the light.	Beta lights give a fairly weak light, enough to read a few words at a time but best suited as a marker.		

LED Lights

Generally have a button to activate an deactivate the light, although modern torches have many settings. The settings on the light vary between devices but a few tips can be found in the "Modes" section below.

Operation	**Step 1** Press the On/Off switch until the torch activates.	**Turning Off** Press or hold the On/Off switch until the torch deactivates.	There may be other buttons or modes with additional features so see the user guide.		

Gas Lamp

Modern gas lamps can be purchased to fit onto canisters of gas to provide light. These gas lamps utilize propane, butane, LPG or a mixture of these fuels. Gas lamps are safer to use than kerosene or other petroleum based lamps due to being a gas already.

Operation	**Step 1** Ensure the lamp has a mantle attached or attach one if it doesn't.	**Step 2** Attach the lantern to the gas bottle ensuring it's on tight and upright.	**Step 3** Rotate the lever on the lamp until you hear a hissing sound of gas.	**Step 4** Ignite the gas using any open flame or piezo button. The mantle should slowly get brighter as it heats up.	**Turning Off** Rotate the lever in the opposite direction you turned it on until you can't turn it anymore and it stops emitting light.

Kerosene Lantern (Flat-Wick)

These lanterns have a wick dipped into kerosene which allows long burn times and light output similar to a candle. Flat-wick lamps have the lowest light output, centre-draft round-wick lamps have 3–4 times the output of flat-wick lamps, and pressurized lamps have higher output yet; the range is from 8 to 100 lumens. A kerosene lamp producing 37 lumens for 4 hours per day consumes about 3 litres of kerosene per month.

AKA
- Storm Lantern
- Paraffin Lamp

Requirements
- Lantern
- Kerosene
- Wicks
- Lighter / Matches

Output (12.57 Lumens = 1 CP)	Flat-Wick Width	0.95cm (3/8")	1.27cm (1/2")	1.58cm (5/8")	1.9cm (3/4")	2.2-2.5cm (7/8"–1")	3.81cm (1-1/2)"	2× 2.5cm (1") 2.69cm (1-1/16") 2.85cm (1-1/8")	2× 3.81cm (1-1/2")	3.17cm (1-1/4") Round "Dressel"	3.81cm (1-1/2") Round "Rayo"
	Candle Power	4 CP	7 CP	9 CP	10 CP	12 CP	20 CP	30 CP	50 CP	67 CP	80 CP
	Lumens	50 Lumen	88 Lumen	113 Lumen	125 Lumen	151 Lumen	251 Lumen	377 Lumen	628.5 Lumen	842 Lumen	1000 Lumen
	Watts	3.3w	5.9w	7.5w	8.3w	10.1w	16.7w	25w	42w	56w	66.6w

Operation	**Step 1** Fill the lantern with kerosene via the inlet.	**Step 2** Ensure the wick is long enough to touch the kerosene.	**Step 3** Light the wick.	**Step 4** Rotate the knob to adjust the wick height and thus the amount of light.	**Turning Off** o
Fuel	Flat-wick kerosene lamps should only be operated with kerosene or lamp oil, but alternative fuels can be used in an emergency. Such fuels may produce additional smoke and odour and may not be usable indoors. Tractor vaporizing oil is made from kerosene with some additive to make a motor fuel for tractors. No. 1 diesel fuel (also called winter diesel) is about the same as kerosene but with the additives to make it a motor fuel. Jet A jet-engine fuel is essentially kerosene with a few additives. RP-1 (Rocket Propellant-1) is a highly refined form of kerosene outwardly similar to jet fuel, used as rocket fuel.				

Kerosene Lantern (Pressure)

A kerosene lantern that converts kerosene to a gas via pressure and allows this gas to be lit thus lighting the mantle. These lanterns are very complicated to use and must be cleaned occasionally. They give off much more light than unpressurised lanterns due to the mantle. Flat-wick lamps have the lowest light output, centre-draft round-wick lamps have 3–4 times the output of flat-wick lamps, and pressurized lamps have higher output yet; the range is from 8 to 100 lumens. A kerosene lamp producing 37 lumens for 4 hours per day consumes about 3 litres of kerosene per month.

AKA
- Storm Lantern
- Paraffin Lamp
- Petromax
- Coleman Lamp

Requirements
- Lantern
- Kerosene
- Mantle
- Alcohol
- Lighter / Matches

Mantle Priming / Replacement If you have a new mantle on the lantern it needs to be primed prior to use.	**Step 1** Remove the old mantle if necessary by pulling it off or cutting the string.	**Step 2** Attach the mantle to the lantern, tying it off or removing the metal prongs depending on the type.	**Step 3** With a lighter or match burn the mantle until it's black. Once complete the mantle is very fragile.	

Operation
Step 1: Ensure the lantern is clean, there's no blockages, you have kerosene and alcohol and there's a mantle attached.
Step 2: Fill the lantern with kerosene via the inlet.
Step 3: Close the fuel valve.
Step 4: Add pressure to the tank by pumping the valve.
Step 5: If the lantern has a cleaning lever, make sure it's in the correct position. (Usually down)
Step 6: Take the top and glass off the lantern and fill the preheater cup with alcohol and light until it's almost all burnt off.
Step 7: Before the flames go out open the fuel valve slightly until the burning alcohol lights the mantle.
Step 8: Ensure the mantle is lit and the flames turn into light. The alcohol should burn itself out.

Turning Off
To stop the lantern turn the fuel valve in the opposite direction until you can't anymore and the light should soon go out.

Care Instructions
The mantle is extremely fragile and will break if it's bumped too much or touched by anything. If it breaks it generally needs replacing. If the glass becomes sooty rub it with a coarse cloth in water. Know how to take apart and clean the lantern, everything from the handle to the generator. If the lantern is subjected to bumps and shock, the mantle could tear. Always have a few backup just in case but in general mantles can last forever if taken care of. Mantles aren't fragile prior to being burnt so they can be placed or shoved into any pockets in your BOB.

If the lantern bursts into flames it could mean:
- The lantern wasn't primed
- There's incomplete conversion to a gas
- The pressure is too high
- The fuel valve is open too much

Fuel
Generic lamp oil is available clear or in a choice of several colours and in scented and unscented forms. Although more expensive, lamp oil is highly refined and burns more cleanly and with less odour than kerosene. "Lamp oil" must not be liquid paraffin. "Water-clear" K-1 kerosene is the next grade of preferred fuel for kerosene wick lamps. In some locations "red kerosene" is sold, which is dyed red and is slightly less expensive than K-1 kerosene, as no motor-fuel taxes are collected on it.

Red kerosene is not recommended because the dye will gradually clog the lantern wick, causing odour and reduced performance. Citronella-scented lamp oil containing lemongrass oil is sold for its insect repellent properties. Citronella fuels should only be used outdoors. Liquid paraffin-based "lamp oil" should only be used in round-wick lamps with a wick diameter of less than 5⁄8 inch (16 mm). Used in larger wicks, this fuel causes the wicks to clog.

Note: Contamination of lamp fuel with even a small amount of gasoline results in a lower flash point and higher vapour pressure for the fuel, with potentially dangerous consequences. Vapours from spilled fuel may ignite; vapour trapped above liquid fuel may lead to excess pressure and fires. Kerosene lamps are still extensively used in areas without electrical lighting; the cost and dangers of combustion lighting are a continuing concern in many countries.

Direction

The direction of light is important in understanding how it travels and how far it's visible for.

Angle

Lights can have various beam widths and angles each with unique properties.
0° Spread: A beam of light with no (or virtually no) spread such as a laser which travels extreme distances.
10° Spread: A very narrow light typically used for scouting very long distances.
30° Spread: A narrow beam for fair distances.
45° Spread: A spread that is good for mid-distance observing.
60° Spread: An average spread of light in torches to provide a nice amount of coverage.
90° Spread: Another common spread of light used for medium range.
120° Spread: The angle of typical SMD lights to light building interiors.
150° Spread: Very wide angled light which would be beneficial as a short throw torch.
180° Spread: This type of light (if it exists) would light up almost an entire side from the torch.
360° Spread: A light such as a glowstick which emits light in every direction.

Power

Lights have different levels of power, these different outputs are discussed here. Lumen levels between 0-10 can be seen as stealth levels, especially if you use your natural night vision to see as well. Lumen levels over 5,000 are optimal for strategic use such as signalling, blinding enemies and searching.

0-1 Lumens	Generally called "moonlight" mode which can give you enough light to see basic objects and find items in a backpack. It can include phosphorous charged lights and beta (tritium) lights.
1-5 Lumens	These light up the surrounds a bit more than the 1 lumen allowing easier detection of local objects.
5-10 Lumens	Lights that are usable for reading and close range tasks. String lights and Christmas lights are about 5 lumens.
10-25 Lumens	Covers the range of basic torches and mini torches. These can be used to light a room dimly and are the lowest recommended lumens for reading.
25-50 Lumens	Slightly brighter torches, these can be used to light a room fairly well.
50-100 Lumens	A torch which can light a room well where it's aimed. A good medium between light and power consumption.
100-500 Lumens	A well rounded lumen level for short distance night viewing.
500-1,000 Lumens	A common range for tactical lights while keeping them small which light up a small area very well. This is the minimum light level for intensive staring work.
1,000-5,000 Lumens	Powerful lights used for extensively lighting an area, these torches may get quite hot with heavy use.

5,000-10,000 Lumens	Very powerful lights used for extensively lighting an area, these torches may get very hot with use.
10,000+ Lumens	Ridiculously powerful lights which require lots of cooling. These are used by search parties and scouting locations. These torches are generally wide beamed due to the extreme amount of light.

Modes

Some lights come pre-programmed with different modes. This section will discuss the most common ones. The values for lumen outputs are subjective and based on the torch you have.

Moonlight Mode	**0.5 - 1 Lumens**	This mode is useful for finding items in your bag and for stealthy operations. This mode will have the longest battery life of all the modes and often lasts a few weeks.
Low	**5 - 50 Lumens**	A good level for general use such as cooking food.
Medium	**50 - 300 Lumens**	Better viewing distance for setting up tents and other activities that require looking for things around camp.
High	**300 - 1,000 Lumens**	A level which would be best used for hiking and observing the path ahead for trip hazards.
Ultra/Turbo Mode	**1,000 - 30,000+ Lumens**	This mode can't be used for long so it's use is limited to scouting a specific area or looking for the source of a sound. A mode which pushes the capability of the torch higher for a limited period of time. Generally with this mode the torch increases the lumen output for up to 2-5 minutes before swapping down a level to cool down. Torches often get very hot in this mode and the duration of the brightness is based on the battery percentage and the heat.
Strobe Mode	The strobe mode is a quick succession of flashes which easily draw the eye. It is best used if you are lost and are wanting the attention of someone else. Strobe mode can also be used defensively when shone in the eyes of an attacker. The bucha effect is an effect of bright strobing lights which disorients the subject. It has become quite popular with police as an aid in subduing belligerent suspects.	
SOS Mode	The SOS mode is a timed succession of flashes in the common international distress signal format. The SOS mode makes it easier to distinguish people with torches from people who need saving. See the COMMUNICATION section for more information on SOS.	**SOS** • • • — — — • • •

Common Lumens

Minimum Room Lumens	**Reading** - 98 **Closet** - 381 **Dressing** - 1,680	**Dining Table** - 315 **Kitchen Counters** - 360 **Range** - 450	**Sink** - 450 **Toilet** - 45 **Vanity** - 1,680	**Outdoor Entrance** - 996 **Paths** - 297 **Stairs/Hallway** - 1,200	**Adequate Room Lumens** **Kitchens:** 5,000-10,000 Lumens **Bathroom:** 4,000-8,000 Lumens **Bedrooms:** 2,000-4,000 Lumens **Living Rooms:** 1,500-3,000 **Dining Rooms:** 3,000-6,000 Lumens **Study:** 3,000-6,000 Lumens

6 Luminescence

Luminence is the emission of light by a substance that has not been heated, as in fluorescence and phosphorescence.

Luminence	Description	Example
Chemoluminescence	This process creates light through a chemical reaction.	• Glow Sticks
Crystalloluminescence	Light is made during crystallization and it is theorized that the light comes from small fractures in the crystal.	• Crushing Sugar or Salt
Electroluminescence	This occurs when an electromagnetic field is applied to solid or gaseous material. This excites the molecules and the substance glows. Requires AC current.	• Watch Backlight
Fluorescence	Fluorescent materials absorb light and then they glow for a certain time. A cheaper form of Phosphorescence and glows less.	• Glowing Stickers
Phosphorescence	Phosphorescent materials also glow in the dark; but, their glow lasts longer than fluorescence, making them good for glow in the dark applications.	• UvPaqlite • Watch Dials
Photoluminescence	This is a process where a substance absorbs photons and then re-emits them. The electromagnetic energy is absorbed at a certain wavelength and is emitted at a different wavelength which is most commonly longer.	
Radioluminescence	Light from this process is made from using radiation or high energy particles to bombard a substance. This is used in medical physics and radar screens.	• Beta-Light • Tritium Light
Sonoluminescence	This produces light from bubbles that are hitting one another when sound waves passed through the liquid. The sound waves cause bubbles which emit light when popped.	• Popping Bubbles by Sound
Thermoluminescence	Light comes from using heat to release of electrons that were trapped in a substance. This process is used in archaeological dating.	• Irradiated Crystals
Triboluminescence	In this process, the light coming from the substance is made by friction, like rubbing, crushing, or scratching. The friction pulls apart chemical bonds, thus causing electrical charges.	• Tearing Duct Tape

Fluorescence / Phosphorescence
Reusable, rechargeable glowing camp lights which can stay glowing for most of the night after exposure of a few minutes to strong light. Useful for saving battery power if you only need a small amount of light to read, or navigate by. Doesn't draw much attention to yourself during the night if you wish to stay concealed. Requires a strong light (1000+ Lumens) to charge it well for up to a minute which could give your position away unless covered. UvPaqlite is an example company which makes quality phosphorescence lights.

7 Types

Different types of lights.

Light Types

	Torch Handheld torch for illumination.	**Automatic Light** Turns on when power is cut.	**Solar Light** Turn on when it gets dark and recharges during the day.	**Flood Light** o	

Light Positioning

Positioning	**Hand** A light held in the hand.	**Head** A headlamp is a handsfree light.	**Gun** Lights are often mounted on guns to allow more control of the gun.	**Hanging** A light which hangs from another object.	

Interior

Lighting Types	**Ambient Lighting** Provides an even, overall light to a room. Also known as general lighting, it radiates a comfortable level of brightness without glare and allows you to see and walk about safely. In some spaces such as laundry rooms, the ambient lighting also serves as the primary source of task lighting. **Task Lighting** Helps you perform specific tasks, such as reading, grooming, preparing and cooking food and studying. It can be provided by recessed and track lighting, pendant lighting and under cabinet lighting, as well as by portable floor and desk lamps. **Accent Lighting** Used to create different focal points. As part of an interior design scheme, it is used to draw the eye to houseplants, paintings, sculptures and other prized possessions. It can also be used to highlight the texture of a brick or stone wall, window treatments or outdoor landscaping.

Lighting Fixtures	**Architectural Cove** Cove lighting is located in a ledge, shelf or recess high up on a wall, and the light is bounced toward the ceiling or upper wall.	**Architectural Soffit** Soffit lighting is located in a soffit or cornice near the ceiling, and the light radiates downward, washing the wall with light.	**Architectural Valance** Valance lighting is located in a wood, metal or glass valance (horizontal shield) mounted above a window or high on the wall, and the light bounces both upward and downward.	**Track** Mounted or suspended from the ceiling, track lighting consists of a linear housing containing several heads that can be positioned anywhere along a track; the direction of the heads is adjustable also. Track lighting is often used for task or accent lighting.	**Recessed** Installed above the ceiling, this type of lighting has an opening that is flush with the ceiling. A recessed light requires at least 6 inches of clearance above the ceiling, and insulation is essential to ensure that condensation does not drip into the fixture. Recessed lighting sends a relatively narrow band of light in one direction; it can be used to provide ambient, task or accent lighting.
Lighting Fixtures	**Under Cabinet** Mounted under kitchen cabinets, this type of lighting can be linear or a single puck-shaped fixture. Under cabinet lighting is extremely popular as task lighting in a kitchen.	**Pendants** Suspended from the ceiling, a pendant light directs its light down, typically over a table or kitchen island. A pendant can enhance the decorative style of a room. Pendants can provide ambient or task lighting.			

8 Beacon

You may use light as a beacon to be seen easier or to assist in being rescued. This section will go into detail in using light to be found in various ways.

Reflection	The reflection of light, particularly sunlight is the simplest way to get someone's attention without having to generate any light yourself. A small mirror with a hole in the middle can be effectively used to bounce light towards a potential rescuer. The light can grab attention from many kilometres away due to the flash that is observed.
Torch	Torches and other light sources can be effective at signalling for attention if done correctly. If you know where the potential rescuers are you can use reflective material to act as a cone around the lights emitter to focus it more precisely at the target. Movement and flashes also works well for attracting attention so move it as much as possible in their general direction. You can flash the torch in the SOS pattern to signal for help if there are people nearby who aren't rescuers to let them know you need assistance.

Laser	A laser is an effective signalling tool over long distances, particularly ones that have a strong visible beam. Starting at 50mw, a lasers beam can begin to be seen in the dark as a line. Although the colour of the laser greatly affects how much it can be seen. The further the lasers colour is from green the dimmer it is perceived to be, so for maximum impact you should use a 555nm laser.
Communication	A beacon of light directed at another individual can be used as a means of communication if both people know the light code. Morse code is one type of these codes which can be used to transmit a message to a distant party. See the COMMUNICATION section for more information.

9 Darkness

Darkness, the polar opposite of brightness, is understood as a lack of illumination or an absence of visible light. Human vision is unable to distinguish colour in conditions of either high brightness or high darkness. In conditions with insufficient light levels, colour perception ranges from achromatic to ultimately black. Darkness is generally synonymous with night which begins when the sun drops lower than 18° below the horizon. Before this point it is considered twilight and the sky isn't completely dark yet.

Advantages
- Greatly increased stealth
- Aids stealth and concealment
- Easier to sleep
- Enables astronomical observation
- Visibility of light sources
- Energy conservation
- Circadian rhythm regulation
- Deep space photography
- Sensory enhancement (other senses)
- Reduced human disturbance (for wildlife)
- Increased quietude
- Reduced insect attraction (to lights)

Disadvantages
- Increased accident risk
- Reduced visibility
- Only lit objects are visible
- Can't perform fine work
- Vulnerability
- Lower productivity
- Hindered emergency response
- Crime facilitation
- Reduced plant photosynthesis
- Compromised security (if no lighting)
- Impacts on mental alertness
- Limited outdoor activities
- Negative mood effects
- Increased/Fear Anxiety
- Becoming Lost
- Unseen Hazards
- Typically requires a light source
- Reduced perception of depth
- Challenges for vulnerable individuals
- Increased need for safety equipment
- Nightvision required for operations

Natural Nightvision

These are some tricks to improving your natural nightvision.

Wear Red-tinted Glasses	This is a common trick that aviators use when they don't have time to sit in perfect darkness and adjust before night flying. Wearing red-tinted glasses before you go out into low light will help train your eye to focus better. If you are looking at a map with a flashlight, cover the flashlight with a red glazed paper. The red light will make the map appear sharper. And if you're buying a new car, look for a dashboard with red illuminated buttons, rather than blue, green, or white.
Use Your Peripheral Vision	Your eyes have natural blind spots and navigating your way through an area in darkness can cause problems if you try to center your gaze. Try to focus your gaze on the side of any object you think is there, or just off-center of the direction you are going as you move forward through a dark area. This allows your peripheral vision to help detect movement and object shape much better than trying to look at something directly. Using your peripheral vision engages more rod cells, which are key in navigating your way through a dark area, identifying shapes, and detecting movement.
Utilise Your Rod Cells	Your rod cells take about 30 to 45 minutes to adapt to a change of light around you. Rod cells can only see black and white and have poor resolution but are very sensitive in night vision circumstances. Photopigments are chemicals contained in both rod and cone cells that are light-sensitive and convert what you see into a language that your brain can understand. Rhodopsin is a photopigment found in rod cells that is critical to night vision. Your ability to adapt to darkness depends on some things that may be out of your control, such as your age, previous eye injury or damage, and any existing eye conditions. In order to see in the darkness, you need to understand what it takes to improve your utilisation of the rod cells and manipulate your eyes to more quickly adapt to a sudden change in light. If you are trying to look at a dim light, don't look directly at it. By doing this, you are utilising your rod cells instead of your cone cells which would happen if you look directly at the dim light. This trick is often used by astronomers.
Avoid Looking at Light Sources	When you look directly at a light source, your pupils are forced to contract. This increases the amount of time it takes for your vision to acclimatize to the low light. If you can't avoid looking at a light source, cover or close one eye until it passes. Looking directly at light sources is a common concern while driving at night. If you are faced with oncoming high-beams, protecting one eye will prevent you from getting flash blindness in both eyes (like a deer in headlights). Another trick while driving at night is to take your eyes off the oncoming high beams and look at the white line on your side of the road to maintain a safe course.
Let your Eyes Adjust to the Dark Naturally	The best way to see in the dark is to let your eyes slowly acclimatize to low light. You can do this by sitting in darkness 20 to 30 minutes before going out into the night. Or you can wear a sleep mask or just cover your eyes. This simple trick helps your eyes easily adjust to the night. Special Forces use the technique of squeezing their eyes shut tightly for 10 seconds once they are in the dark.
Keep your Eyes Moving	Try not to stare at one object as it will cause your eyes to adapt to whatever light source that is available at the point of your focus. Dance your eyes around, scan the area, and you would be able to see better in dark. Keep blinking, too, to avoid your rods (cells in your eyes responsible for night vision) from desensitizing.

LIGHT Darkness Natural Nightvision

Consume More Vitamin A	One of the first signs of vitamin A deficiency is night blindness. In Ancient Egypt, it was discovered that night blindness could be cured by eating liver, which was later found to be a rich source of vitamin A. Low vitamin A levels can also cause the cornea to become very dry, leading to the clouding of the front of the eye, corneal ulcers and vision loss, as well as retina damage and problems with the conjunctiva. Carrots, broccoli, squash, cantaloupe, fish, liver, fortified cereals, dairy products, kale, blueberries, and apricots are all excellent sources of vitamin A. While increasing your consumption of foods that are rich in vitamin A may be helpful, research done in this area has revealed that, in the case of vitamin A, taking supplements provided higher levels than increasing the dietary sources. Plus, excessive consumption doesn't strengthen your eyes. Vitamin A supplements are available in oral doses, like tablets or capsules, and are marketed in either mcg strengths or units. The average recommended adult dose of vitamin A in mcgs is between 800 to 1000 mcg each day. In units, the dose range is between 2600 and 3300 units consumed daily. The protein rhodopsin found in the eye breaks down into retinal and opsin when exposed to light and reforms when back in the dark. A severe lack of vitamin A in the diet may result in night blindness, but extra vitamin A will not help one see better than normal.
Gently Massage Your Eyes	Just close your eyes tightly and apply slight pressure on both your eyes with your palms (use the fleshy part of your palm below your thumb) After about five or 10 seconds, instead of seeing black, your vision will turn white momentarily. When the white goes away and the black comes back, open your eyes, and your vision will be significantly better in the dark. While the above tricks can help improve night vision, they will work even better if you supplement your diet with vision-boosting nutrients.
Stop Smoking	There are studies that shown that smokers are 2 times more prone to night accidents than non-smokers. Nicotine and the hypoxic effect from carbon monoxide reduces your night vision. Just by avoiding both first and second hand smoking can help improve night vision.
Stay Well Hydrated	The surface of the eye is 98% water. Dry eyes will struggle to see at night and are linked to overall dehydration. Drinking plenty of water is essential to overall good health; however the direct link to fluid intake and improving vision is controversial. Some eye experts argue that certain circumstances that negatively impact your level of hydration cause a decrease in the quality of your vision and the overall health of your eyes. For example, being exposed to high temperatures, low humidity climates, or intense sunlight can cause the basal tear layer to dehydrate, resulting in a negative impact on your vision. Follow recommended dietary guidelines for water intake, aiming for about 64 ounces (1.9 liters) each day depending on your work situation and environmental factors, to maintain your eye health.

Bortle Scale

The Bortle scale is a nine-level numeric scale that measures the night sky's brightness of a particular location. NELM stands for Naked-Eye Limiting Magnitude. In astronomy, limiting magnitude is the faintest apparent magnitude of a celestial body that is detectable or detected by a given instrument. The limiting magnitude for naked eye visibility refers to the faintest stars that can be seen with the unaided eye near the zenith on clear moonless nights. The quantity is most often used as an overall indicator of sky brightness, in that light polluted and humid areas generally have brighter limiting magnitudes than remote desert or high altitude areas. The limiting magnitude will depend on the observer, and will increase with the eye's dark adaptation. On a relatively clear sky, the limiting visibility will be about 6th magnitude.

Bortle Class	Title	NELM	Description
Class 1	Excellent Dark-Sky Site	7.6–8.0	• The zodiacal light is visible and colourful • The gegenschein is visible • the zodiacal band is visible • Airglow is readily visible • The Scorpius and Sagittarius regions of the Milky Way cast obvious shadows • Many constellations, particularly fainter ones, are barely recognizable due to the large number of stars • Many Messier and globular clusters are naked-eye objects • M33 is a direct vision naked-eye object • limiting magnitude with 12.5 in (32 cm) reflector is 17.5 (with effort) • Venus and Jupiter affect dark adaptation
Class 2	Typical Truly Dark Site	7.1–7.5	• The zodiacal light is distinctly yellowish and bright enough to cast shadows at dusk and dawn • Airglow may be weakly visible near horizon • Clouds are only visible as dark holes against the sky • Surroundings are barely visible silhouetted against the sky • The summer Milky Way is highly structured • Many Messier objects and globular clusters are naked-eye objects • M33 is easily seen with naked eye • Limiting magnitude with 12.5" reflector is 16.5
Class 3	Rural Sky	6.6–7.0	• The zodiacal light is striking in spring and autumn, and colour is still visible • Some light pollution evident at the horizon • Clouds are illuminated near the horizon, dark overhead • Nearer surroundings are vaguely visible • The summer Milky Way still appears complex • M15, M4, M5, and M22 are naked-eye objects • M33 is easily visible with averted vision • Limiting magnitude with 12.5" reflector is 16
Class 4	Rural/Suburban Transition	6.1–6.5	• The zodiacal light is still visible, but does not extend halfway to the zenith at dusk or dawn • Light pollution domes visible in several directions • Clouds are illuminated in the directions of the light sources, dark overhead • Surroundings are clearly visible, even at a distance • The Milky Way well above the horizon is still impressive, but lacks detail • M33 is a difficult averted vision object, only visible when high in the sky • Limiting magnitude with 12.5" reflector is 15.5
Class 5	Suburban Sky	5.6–6.0	• Only hints of zodiacal light are seen on the best nights in autumn and spring • Light pollution is visible in most, if not all, directions • Clouds are noticeably brighter than the sky • The Milky Way is very weak or invisible near the horizon, and looks washed out overhead • When it is half moon (first/last quarter) in a dark location the sky appears like this, but with the difference that the sky appears dark blue • Limiting magnitude with 12.5" reflector is 15

Class 6	Bright Suburban Sky	5.1–5.5	● The zodiacal light is invisible ● Light pollution makes the sky within 35° of the horizon glow grayish white ● Clouds anywhere in the sky appear fairly bright ● Even high clouds (cirrus) appear brighter than the sky background ● Surroundings are easily visible ● The Milky Way is only visible near the zenith ● M33 is not visible, M31 is modestly apparent ● Limiting magnitude with 12.5" reflector is 14.5
Class 7	Suburban/Urban Transition	4.6–5.0	● Light pollution makes the entire sky light gray ● Strong light sources are evident in all directions ● Clouds are brightly lit ● The Milky Way is nearly or totally invisible ● M31 and M44 may be glimpsed, but with no detail ● Through a telescope, the brightest Messier objects are pale ghosts of their true selves ● When it is full moon in a dark location the sky appears like this, but with the difference that the sky appears blue ● Limiting magnitude with 12.5" reflector is 14
Class 8	City Sky	4.1–4.5	● The sky is light gray or orange – one can easily read ● Stars forming familiar constellation patterns may be weak or invisible ● M31 and M44 are barely glimpsed by an experienced observer on good nights ● Even with a telescope, only bright Messier objects can be detected ● Limiting magnitude with 12.5" reflector is 13
Class 9	Inner-City Sky	4	● The sky is brilliantly lit ● Many stars forming constellations are invisible and many fainter constellations are invisible ● Aside from the Pleiades, no Messier object is visible to the naked eye ● The only objects to observe are the Moon, the planets, and a few of the brightest star clusters

Concealment

In London during the blitz, the citizens had to block out all their windows to prevent light escaping so the Nazi bombers couldn't target them as accurately. In this day and age with GPS technology doing so would be useless, however there are many circumstances that you won't want to let light escape. This section contains ways you can reduce your light footprint and eliminate stray rays to prevent you being located as easily.

Reduce Use	Firstly you can reduce the use of light where possible, so try to complete activities in darkness if the situation allows. If light is required you could try to cut down the time spent with the light on and complete the task faster.
Reduce Lumens	Lowering the output of the light can greatly reduce the distance it's seen from. If you only require a small amount of light to only see where you're going you could make do with a 1 lumen light combined with your natural night vision, instead of a 180 lumen.
Light Colour	Changing the colour of the light based on the environment can reduce the visibility of the light. An example is using a green light in a forest instead of a white light. More about light colours and their purposes can be found the sections above.
Sealed Area	If none of the above options are viable for you and a bright light is required you should attempt to use it in a sealed room or other location. Rooms without windows or canvas swags are ideal for this purpose as they are much easier to seal up than a regular room. If light must be used you should always use it in the designated light room and ensure that the entry is sealed.
Blocking Out Windows	If bright light is required and you're indoors you can try to prevent its escape by sealing any cracks of crevices where it may leak. Keep in mind that light bounces quite a lot and can make its way out of even complex buildings with multiple turns. To block windows find a thick piece of light proof fabric or other dark material and cover the windows, using duct tape making sure to tape every crack. **Usable Materials** ● Curtains ● Blockout Material ● Garbage Bags ● Cardboard
Testing	Turn on the light and step outside, then wait for your natural night vision to work and look for any leaks and seal them while you're out there.

Health

How to keep fit, clean and healthy

"Exercise in the morning, before your brain figures out what you're doing."
Dr Josh Axe

Introduction

Nutrition is the science that interprets the nutrients and other substances in food in relation to maintenance, growth, reproduction, health and disease of an organism. It includes food intake, absorption, assimilation, biosynthesis, catabolism and excretion.

The diet of an organism is what it eats, which is largely determined by the availability and palatability of foods. For humans, a healthy diet includes preparation of food and storage methods that preserve nutrients from oxidation, heat or leaching, and that reduces risk of foodborne illnesses. The seven major classes of human nutrients are carbohydrates, fats, fiber, minerals, proteins, vitamins, and water. Nutrients can be grouped as either macronutrients or micronutrients (needed in small quantities).

In humans, an unhealthy diet can cause deficiency-related diseases such as blindness, anemia, scurvy, preterm birth, stillbirth and cretinism, or nutrient excess health-threatening conditions such as obesity and metabolic syndrome; and such common chronic systemic diseases as cardiovascular disease, diabetes, and osteoporosis. Undernutrition can lead to wasting in acute cases, and the stunting of marasmus in chronic cases of malnutrition.

Purpose	The aim of HEALTH is to provide you with a foundational knowledge for healthy eating, fitness and hygiene to help the human body function optimally.
Lost?	● For the illnesses that can occur from not eating right, see the ILLNESS section. ● For some healthy recipes, see the RECIPES section. ● For information on keeping your mind healthy, see the EMOTIONAL section. ● For growing your own nutritional food, see the GARDENING section. ● For self-defence related fitness activities, see the DEFENCE section. ● To make sure you can physically carry your BOB, see the GEAR > Backpacks section. ● For information on keeping your mind healthy, see the EMOTIONAL section. ● For outdoor activities to help keep you fit, see the ENTERTAINMENT section. ● For the terms and definitions of health and nutrition, see the ADDENDUM > Dictionary section.

Contents

1 Food Groups

These are the different food groups.

Grains	One quarter of your plate should be grains. Half of your grain servings should come from whole grains, meaning that the grain contains all three parts of the kernel – bran, germ and endosperm.	**Nutrition** Whole grains are a source of magnesium, B vitamins and fibre that work collectively to reduce the risk of heart disease and diabetes, while supporting a healthy metabolism.	**Food Types** • Wheat • Rice • Corn • Oats • Barley
Vegetables	Vegetables are loaded with good nutrition and are naturally low fat and cholesterol-free. The MyPlate guide recommends that one half of your plate contain vegetables, as well as fruit.	**Nutrition** Vegetables provide a variety of nutrients including potassium, fibre, folic acid, vitamin A and vitamin C. A diet rich in vegetables reduces the risk of many diseases, including heart disease, stroke, type-2 diabetes and certain types of cancer.	**Food Types** • Carrot • Potato • Broccoli • Tomato • Onion
Fruits	Fruits, as well as vegetables, are nutritional powerhouses that should make up one half of your plate at mealtime, in conjunction with vegetables. Fruits are good sources of potassium, vitamin C, folic acid and fibre.	**Nutrition** Fruits, like vegetables, contain antioxidants that protect cells against damaging free radicals. Many fruits are also naturally low in calories and can contribute to a healthy weight when eaten, instead of high-calorie foods.	**Food Types** • Apple • Banana • Orange • Grapes • Strawberry
Protein	One quarter of your plate should be protein foods, including meat, eggs, fish, shellfish, nuts and seeds. Protein supports muscles and is an important component of body tissues, blood and hormones.	**Nutrition** Fish and shellfish contain heart-healthy omega-3 fatty acids that help prevent heart disease.	**Food Types** • Chicken breast • Beef steak • Eggs • Lentils • Tofu
Dairy	Dairy foods have all the essential nutrients for bone health, including potassium, calcium and vitamin D. Research indicates that incorporating milk and milk products into the diet can help promote bone health and is associated with a lower risk of heart disease.	**Nutrition** The potassium in dairy products also helps reduce blood pressure.	**Food Types** • Milk • Cheese • Yogurt • Butter • Cream
Oils	Oils are often used in cooking and added to other foods in the form of salad dressings or sauces.	**Nutrition** Oils contribute essential fatty acids and the antioxidant vitamin E and are part of a healthful diet.	**Food Types** • Olive oil • Canola oil • Sunflower oil • Coconut oil

2 Nutrients

Human nutrition deals with the provision of essential nutrients in food that are necessary to support human life and health. Poor nutrition is a chronic problem often linked to poverty, food security or a poor understanding of nutrition and dietary practices. Malnutrition and its consequences are large contributors to deaths and disabilities worldwide.

Good nutrition is necessary for children to grow physically, and for normal human biological development. The human body contains chemical compounds such as water, carbohydrates, amino acids (found in proteins), fatty acids (found in lipids), and nucleic acids (DNA and RNA). These compounds are composed of elements such as carbon, hydrogen, oxygen, nitrogen, phosphorus.

Any study done to determine nutritional status must take into account the state of the body before and after experiments, as well as the chemical composition of the whole diet and of all the materials excreted and eliminated from the body (including urine and faeces). Comparing food to waste material can help determine the specific compounds and elements absorbed and metabolized by the body.

The effects of nutrients may only be discernible over an extended period of time, during which all food and waste must be analysed. The number of variables involved in such experiments is high, making nutritional studies time-consuming and expensive, which explains why the science of human nutrition is still slowly evolving.

These nutrient classes are categorized as either macronutrients or micronutrients (needed in small quantities). The macronutrients are carbohydrates, fats, fibre, proteins, and water. The micronutrients are minerals and vitamins. The macronutrients (excluding fibre and water) provide structural material (amino acids from which proteins are built, and lipids from which cell membranes and some signalling molecules are built), and energy. Some of the structural material can also be used to generate energy internally, and in either case it is measured in Joules or kilocalories (often called "Calories" and written with a capital 'C' to distinguish them from little 'c' calories). Carbohydrates and proteins provide 17 kJ approximately (4 kcal) of energy per gram, while fats provide 37 kJ (9 kcal) per gram, though the net energy from either depends on such factors as absorption and digestive effort, which vary substantially from instance to instance.

Nutrient Classes
- Carbohydrates
- Fats
- Fibre
- Minerals
- Proteins
- Vitamins
- Water

Subheadings

1. Carbohydrates	**2. Fat**	**3. Fibre**	**4. Protein**
5. Minerals	**6. Vitamins**	**7. Malnutrition**	**8. Eating Disorders**
9. Obesity	**10. Starvation**	**11. Nutrition Challenges**	**12. Food Insecurity**
13. Nutrition Policy	**14. Macronutrients**	**15. Micronutrients**	

1 Carbohydrates

Carbohydrates may be classified as monosaccharides, disaccharides or polysaccharides depending on the number of monomer (sugar) units they contain. They are a diverse group of substances, with a range of chemical, physical and physiological properties. They make up a large part of foods such as rice, noodles, bread, and other grain-based products, but they are not an essential nutrient, meaning a human does not need to eat carbohydrates.

The brain is the largest consumer of sugars in the human body, and uses particularly large amounts of glucose, accounting for 20% of total body glucose consumption. The brain uses mostly glucose for energy unless it is insufficient, in which case it switches to using fats. Monosaccharides contain one sugar unit, disaccharides two, and polysaccharides three or more. Monosaccharides include glucose, fructose and galactose.

HEALTH Nutrients Carbohydr

Disaccharides include sucrose, lactose, and maltose; purified sucrose, for instance, is used as table sugar. Polysaccharides, which include starch and glycogen, are often referred to as 'complex' carbohydrates because they are typically long multiple-branched chains of sugar units. Simple carbohydrates are absorbed quickly, and therefore raise blood-sugar levels more rapidly than other nutrients. However, the most important plant carbohydrate nutrient, starch, varies in its absorption.

Gelatinized starch (starch heated for a few minutes in the presence of water) is far more digestible than plain starch, and starch which has been divided into fine particles is also more absorbable during digestion. The increased effort and decreased availability reduces the available energy from starchy foods substantially and can be seen experimentally in rats and anecdotally in humans. Additionally, up to a third of dietary starch may be unavailable due to mechanical or chemical difficulty.

2 Fat

HEALTH Nutrients Fat

A molecule of dietary fat typically consists of several fatty acids (containing long chains of carbon and hydrogen atoms), bonded to a glycerol. They are typically found as triglycerides (three fatty acids attached to one glycerol backbone). Fats may be classified as saturated or unsaturated depending on the chemical structure of the fatty acids involved.

3 Fibre

HEALTH Nutrients Fibre

Dietary fibre is a carbohydrate, specifically a polysaccharide, which is incompletely absorbed in humans and in some animals. Like all carbohydrates, when it is metabolized, it can produce four Calories (kilocalories) of energy per gram, but in most circumstances, it accounts for less than that because of its limited absorption and digestibility. The two subcategories are insoluble and soluble fibre. Insoluble dietary fibre consists mainly of cellulose, a large carbohydrate polymer that is indigestible by humans, because humans do not have the required enzymes to break it down, and the human digestive system does not harbour enough of the types of microbes that can do so.

Soluble dietary fibre comprises a variety of oligosaccharides, waxes, esters, resistant starches, and other carbohydrates that dissolve or gelatinize in water. Many of these soluble fibres can be fermented or partially fermented by microbes in the human digestive system to produce short-chain fatty acids which are absorbed and therefore introduce some caloric content.

Whole grains, beans and other legumes, fruits (especially plums, prunes, and figs), and vegetables are good sources of dietary fibre. Fibre is important to digestive health and is thought to reduce the risk of colon cancer. For mechanical reasons, fibre can help in alleviating both constipation and diarrhoea.

Fibre provides bulk to the intestinal contents, and insoluble fibre especially stimulates peristalsis – the rhythmic muscular contractions of the intestines which move digesta along the digestive tract. Some soluble fibres produce a solution of high viscosity; this is essentially a gel, which slows the movement of food through the intestines. Additionally, fibre, perhaps especially that from whole grains, may help lessen insulin spikes and reduce the risk of type 2 diabetes.

4 Protein

HEALTH Nutrients Protein

Proteins are the basis of many animal body structures (e.g. muscles, skin, and hair) and form the enzymes which catalyse chemical reactions throughout the body. Each protein molecule is composed of amino acids which contain nitrogen and sometimes sulphur (these components are responsible for the distinctive smell of burning protein, such as the keratin in hair).

The body requires amino acids to produce new proteins (protein retention) and to replace damaged proteins (maintenance). Amino acids are soluble in the digestive juices within the small intestine, where they are absorbed into the blood. Once absorbed, they cannot be stored in the body, so they are either metabolized as required or excreted in the urine.

Proteins consist of amino acids in different proportions. The most important aspect and defining characteristic of protein from a nutritional standpoint is its amino acid composition. Amino acids which an animal cannot synthesize on its own from smaller molecules are deemed essential. The synthesis of some amino acids can be limited under special pathophysiological conditions, such as prematurity in the infant or individuals in severe catabolic distress, and those are called conditionally essential.

5 Minerals

HEALTH Nutrients Minerals

Dietary minerals are the chemical elements required by living organisms, other than the four elements carbon, hydrogen, nitrogen, and oxygen that are present in nearly all organic molecules. The term "mineral" is archaic, since the intent is to describe simply the less common elements in the diet. Some are heavier than the four just mentioned – including several metals, which often occur as ions in the body.

Some dietitians recommend that these be supplied from foods in which they occur naturally, or at least as complex compounds, or sometimes even from natural inorganic sources (such as calcium carbonate from ground oyster shells). Some are absorbed much more readily in the ionic forms found in such sources. On the other hand, minerals are often artificially added to the diet as supplements; the most well-known is likely iodine in iodized salt which prevents goiter.

6 Vitamins

HEALTH Nutrients Vitamins

As with the minerals discussed above, some vitamins are recognized as essential nutrients, necessary in the diet for good health. (Vitamin D is the exception: it can alternatively be synthesized in the skin, in the presence of UVB radiation). Certain vitamin-like compounds that are recommended in the diet, such as carnitine, are thought useful for survival and health, but these are not "essential" dietary nutrients because the human body has some capacity to produce them from other compounds.

Moreover, thousands of different phytochemicals have recently been discovered in food (particularly in fresh vegetables), which may have desirable properties including antioxidant activity; experimental demonstration has been suggestive but inconclusive.

Other essential nutrients not classed as vitamins include essential amino acids, essential fatty acids, and the minerals discussed in the preceding section. Vitamin deficiencies may result in disease conditions: goiter, scurvy, osteoporosis, impaired immune system, disorders of cell metabolism, certain forms of cancer, symptoms of premature aging, and poor psychological health (including eating disorders), among many others.

7 Malnutrition

HEALTH Nutrients Malnutrition

Malnutrition refers to insufficient, excessive, or imbalanced consumption of nutrients. In developed countries, the diseases of malnutrition are most often associated with nutritional imbalances or excessive consumption. Although there are more people in the world who are malnourished due to excessive consumption, according to the United Nations World Health Organization, the greatest challenge in developing nations today is not starvation, but insufficient nutrition – the lack of nutrients necessary for the growth and maintenance of vital functions. The causes of malnutrition are directly linked to inadequate macronutrient consumption and disease, and are indirectly linked to factors like "household food security, maternal and child care, health services, and the environment."

Illnesses

Nutrient	Deficiency	Excess
Food Energy	Lower Physical and Mental Abilities; Starvation, Marasmus	Obesity, Diabetes Mellitus, Cardiovascular Disease
Simple Carbohydrates	None	Diabetes Mellitus, Obesity
Complex Carbohydrates	None	Obesity
Saturated Fat	Low Sex Hormone Levels	Cardiovascular Disease
Trans Fat	None	Cardiovascular Disease
Unsaturated Fat	None	Obesity
Fat	During Development: Stunted Brain Development and Reduced Brain Weight; Neurodegenerative Diseases; Malabsorption of Fat-Soluble Vitamins, Rabbit Starvation (If protein intake is high),	Cardiovascular Disease
Omega-3 fats	Cardiovascular Disease	Bleeding, Haemorrhages
Omega-6 fats	None	Cardiovascular Disease, Cancer
Cholesterol	During Development: Deficiencies in Myelinization of the Brain; Demyelination of the Brain and Neurodegenerative Diseases (Multiple Sclerosis, Alzheimer)	Cardiovascular Disease
Protein	Kwashiorkor	
Sodium	Hyponatremia	Hypernatremia, Hypertension
Iron	Anaemia	Cirrhosis, Cardiovascular Disease
Iodine	Goiter, Hypothyroidism	Iodine Toxicity (Goiter, Hypothyroidism)
Vitamin A	Xerophthalmia and Night Blindness, Low Testosterone Levels	Hypervitaminosis A (Cirrhosis, Hair Loss)
Vitamin B1	Beriberi	
Vitamin B2	Cracking of skin and Corneal Unclearation	
Niacin	Pellagra	Dyspepsia, Cardiac Arrhythmias, Birth Defects
Vitamin B12	Pernicious Anaemia	
Vitamin C	Scurvy	Diarrhoea Causing Dehydration
Vitamin D	Rickets, Osteoporosis, Balance, Immune System, Inflammation	Hypervitaminosis D (Dehydration, Vomiting, Constipation)
Vitamin E	Nervous Disorders	Hypervitaminosis E (Anticoagulant: Excessive Bleeding)
Vitamin K	Haemorrhage	
Calcium	Osteoporosis, Tetany, Carpopedal Spasm, Laryngospasm, Cardiac Arrhythmias	Fatigue, Depression, Confusion, Anorexia, Nausea, Vomiting, Constipation, Pancreatitis, Increased Urination
Magnesium	Hypertension	Weakness, Nausea, Vomiting, Impaired Breathing, and Hypotension
Potassium	Hypokalemia, Cardiac Arrhythmias	Hyperkalemia, Palpitations
Nutrient	**Deficiency**	**Excess**

Disorders

Mental Agility
Research indicates that improving the awareness of nutritious meal choices and establishing long-term habits of healthy eating has a positive effect on a cognitive and spatial memory capacity, potentially increasing a student's potential to process and retain academic information. Some organisations have begun working with teachers, policymakers, and managed food service contractors to mandate improved nutritional content and increased nutritional resources in school cafeterias from primary to university level institutions. Health and nutrition have been proven to have close links with overall educational success.

Currently less than 10% of American college students report that they eat the recommended five servings of fruit and vegetables daily. Better nutrition has been shown to affect both cognitive and spatial memory performance; a study showed those with higher blood sugar levels performed better on certain memory tests. In another study, those who consumed yogurt performed better on thinking tasks when compared to those who consumed caffeine free diet soda or confections. Nutritional deficiencies have been shown to have a negative effect on learning behaviour in mice as far back as 1951. "Better learning performance is associated with diet induced effects on learning and memory ability".

Mental Disorders

Nutritional supplement treatment may be appropriate for major depression, bipolar disorder, schizophrenia, and obsessive compulsive disorder, the four most common mental disorders in developed countries. Lakhan and Vieira mentioned that the supplements possess amino acids that may change into neurotransmitters and improve mental disorders. Supplements that have been studied most for mood elevation and stabilization include eicosapentaenoic acid and docosahexaenoic acid (each of which are an omega-3 fatty acid contained in fish oil, but not in flaxseed oil), vitamin B12, folic acid, and inositol.

Cancer

Cancer has become common in developing countries. According to a study by the International Agency for Research on Cancer, "In the developing world, cancers of the liver, stomach and oesophagus were more common, often linked to consumption of carcinogenic preserved foods, such as smoked or salted food, and parasitic infections that attack organs." Lung cancer rates are rising rapidly in poorer nations because of increased use of tobacco. Developed countries "tended to have cancers linked to affluence or a 'Western lifestyle' – cancers of the colon, rectum, breast and prostate – that can be caused by obesity, lack of exercise, diet and age."

A comprehensive worldwide report, "Food, Nutrition, Physical Activity and the Prevention of Cancer: a Global Perspective", compiled by the World Cancer Research Fund and the American Institute for Cancer Research, states that there is a significant relation between lifestyle (including food consumption) and cancer prevention. The same report recommends eating mostly foods of plant origin and aiming to meet nutritional needs through diet alone, while limiting consumption of energy-dense foods, red meat, alcoholic drinks and salt and avoiding sugary drinks, processed meat and mouldy cereals (grains) or pulses (legumes). Protein consumption leads to an increase in IGF-1, which plays a role in cancer development.

Metabolic Syndrome and Obesity

Several lines of evidence indicate lifestyle-induced hyperinsulinemia and reduced insulin function (i.e. insulin resistance) as decisive factors in many disease states. For example, hyperinsulinemia and insulin resistance are strongly linked to chronic inflammation, which in turn is strongly linked to a variety of adverse developments such as arterial microinjuries and clot formation (i.e. heart disease) and exaggerated cell division (i.e. cancer). Hyperinsulinemia and insulin resistance (the so-called metabolic syndrome) are characterized by a combination of abdominal obesity, elevated blood sugar, elevated blood pressure, elevated blood triglycerides, and reduced HDL cholesterol.

Obesity can unfavourably alter hormonal and metabolic status via resistance to the hormone leptin, and a vicious cycle may occur in which insulin/leptin resistance and obesity aggravate one another. The vicious cycle is putatively fuelled by continuously high insulin/leptin stimulation and fat storage, as a result of high intake of strongly insulin/leptin stimulating foods and energy.

Both insulin and leptin normally function as satiety signals to the hypothalamus in the brain; however, insulin/leptin resistance may reduce this signal and therefore allow continued overfeeding despite large body fat stores. There is a debate about how and to what extent different dietary factors – such as intake of processed carbohydrates, total protein, fat, and carbohydrate intake, intake of saturated and trans fatty acids, and low intake of vitamins/minerals – contribute to the development of insulin and leptin resistance.

Evidence indicates that diets possibly protective against metabolic syndrome include low saturated and trans fat intake and foods rich in dietary fibre, such as high consumption of fruits and vegetables and moderate intake of low-fat dairy products.

8 Eating Disorders

An eating disorder is a mental disorder defined by abnormal eating habits that negatively affect a person's physical or mental health. They include binge eating disorder, where people eat a large amount in a short period of time; anorexia nervosa, where people eat very little and thus have a low body weight; bulimia nervosa, where people eat a lot and then try to rid themselves of the food; pica, where people eat non-food items; rumination disorder, where people regurgitate food; avoidant/restrictive food intake disorder, where people have a lack of interest in food; and a group of other specified feeding or eating disorders.

Anxiety disorders, depression, and substance abuse are common among people with eating disorders. These disorders do not include obesity. The causes of eating disorders are not clear. Both biological and environmental factors appear to play a role. Cultural idealization of thinness is believed to contribute. Eating disorders affect about 12 percent of dancers. Individuals who have experienced sexual abuse are also more likely to develop eating disorders. Some disorders such as pica and rumination disorder occur more often in people with intellectual disabilities.

Only one eating disorder can be diagnosed at a given time. Treatment can be effective for many eating disorders. Typically, this involves counselling, a proper diet, a normal amount of exercise, and the reduction of efforts to eliminate food. Hospitalization may be needed in more serious cases. Medications may be used to help with some of the associated symptoms. About 70% of people with anorexia and 50% of people with bulimia recover within five years. Recovery from binge eating disorder is less clear and estimated at 20% to 60%. Both anorexia and bulimia increase the risk of death. In the developed world, binge eating disorder affects about 1.6% of women and 0.8% of men in a given year.

Anorexia affects about 0.4% and bulimia affects about 1.3% of young women in a given year. Up to 4% of women have anorexia, 2% have bulimia, and 2% have binge eating disorder at some point in time. Anorexia and bulimia occur nearly ten times more often in females than males. Typically, they begin in late childhood or early adulthood. Rates of other eating disorders are not clear. Rates of eating disorders appear to be lower in less developed countries.

Classification

Bulimia nervosa is a disorder characterized by binge eating and purging, as well as excessive evaluation of one's self-worth in terms of body weight or shape. Purging can include self-induced vomiting, over-exercising, and the use of diuretics, enemas, and laxatives. Anorexia nervosa is characterized by extreme food restriction and excessive weight loss, accompanied by the fear of being fat.

The extreme weight loss often causes women and girls who have begun menstruating to stop having menstrual periods, a condition known as amenorrhea. Although amenorrhea was once a required criterion for the disorder, it is no longer required to meet criteria for anorexia nervosa due to its exclusive nature for sufferers who are male, post-menopause, or who do not menstruate for other reasons.

The DSM-5 specifies two subtypes of anorexia nervosa—the restricting type and the binge/purge type. Those who suffer from the restricting type of anorexia nervosa restrict food intake and do not engage in binge eating, whereas those suffering from the binge/purge type lose control over their eating at least occasionally and may compensate for these binge episodes.

The most notable difference between anorexia nervosa binge/purge type and bulimia nervosa is the body weight of the person. Those diagnosed with anorexia nervosa binge/purge type are underweight, while those with bulimia nervosa may have a body weight that falls within the range from normal to obese.

ICD and DSM

These eating disorders are specified as mental disorders in standard medical manuals, such as in the ICD-10, the DSM-5, or both.

- Bulimia nervosa (BN), characterized by recurrent binge eating followed by compensatory behaviours such as purging (self-induced vomiting, eating to the point of vomiting, excessive use of laxatives/diuretics, or excessive exercise). Fasting and over-exercising may also be used as a method of purging following a binge.

- Muscle dysmorphia is characterized by appearance preoccupation that one's own body is too small, too skinny, insufficiently muscular, or insufficiently lean. Muscle dysmorphia affects mostly males.

HEALTH Nutrients Eating Disorders ICD and DSM

- Binge Eating Disorder (BED), characterized by recurring binge eating at least once a week for over a period of 3 months while experiencing lack of control and guilt after overeating. The disorder can develop within individuals of a wide range of ages and socioeconomic classes.
- Other Specified Feeding or Eating Disorder (OSFED) is an eating or feeding disorder that does not meet full DSM-5 criteria for AN, BN, or BED. Examples of otherwise-specified eating disorders include individuals with atypical anorexia nervosa, who meet all criteria for AN except being underweight, despite substantial weight loss; atypical bulimia nervosa, who meet all criteria for BN except that bulimic behaviours are less frequent or have not been ongoing for long enough; purging disorder; and night eating syndrome.
- Anorexia nervosa (AN), characterized by lack of maintenance of a healthy body weight, an obsessive fear of gaining weight or refusal to do so, and an unrealistic perception, or non-recognition of the seriousness, of current low body weight. Anorexia can cause menstruation to stop, and often leads to bone loss, loss of skin integrity, etc. It greatly stresses the heart, increasing the risk of heart attacks and related heart problems. The risk of death is greatly increased in individuals with this disease. The most underlining factor researchers are starting to take notice of is that it may not just be a vanity, social, or media issue, but it could also be related to biological and or genetic components.

Other

- Compulsive overeating (COE), in which individuals habitually graze on large quantities of food rather than binging, as would be typical of binge eating disorder.
- Prader-Willi syndrome
- Diabulimia, characterized by the deliberate manipulation of insulin levels by diabetics in an effort to control their weight.
- Food maintenance, characterized by a set of aberrant eating behaviours of children in foster care.
- Orthorexia nervosa, a term used by Steven Bratman to characterize an obsession with a "pure" diet, in which people develop an obsession with avoiding unhealthy foods to the point where it interferes with a person's life.
- Avoidant/restrictive food intake disorder (ARFID), previously known as selective eating disorder is where the certain foods are limited based on appearance, smell, taste, texture, brand, presentation, or a past negative experience with the food.
- Drunkorexia, commonly characterized by purposely restricting food intake in order to reserve food calories for alcoholic calories, exercising excessively in order to burn calories from drinking, and over-drinking alcohol in order to purge previously consumed food.
- Pregorexia, characterized by extreme dieting and over-exercising in order to control pregnancy weight gain. Undernutrition during pregnancy is associated with low birth weight, coronary heart disease, type 2 diabetes, stroke, hypertension, cardiovascular disease risk, and depression.
- Gourmand syndrome, a rare condition occurring after damage to the frontal lobe, resulting in an obsessive focus on fine foods.

Signs and Symptoms

Symptoms and complications vary according to the nature and severity of the eating disorder:	• Acne • Constipation • Telogen Effluvium • Osteoporosis • Pellagra	• Xerosis • Diarrhoea • Cardiac Arrest • Electrolyte Imbalance • Scurvy	• Amenorrhoea • Water Retention and/or Edema • Hypokalemia • Hyponatremia • Kidney Failure	• Tooth Loss, Cavities • Lanugo • Death • Brain atrophy • Suicide

Some physical symptoms of eating disorders are weakness, fatigue, sensitivity to cold, reduced beard growth in men, reduction in waking erections, reduced libido, weight loss and failure of growth. Unexplained hoarseness may be a symptom of an underlying eating disorder, as the result of acid reflux, or entry of acidic gastric material into the laryngoesophageal tract. Patients who induce vomiting, such as those with anorexia nervosa, binge eating-purging type or those with purging-type bulimia nervosa are at risk for acid reflux.

Polycystic ovary syndrome (PCOS) is the most common endocrine disorder to affect women. Though often associated with obesity it can occur in normal weight individuals. PCOS has been associated with binge eating and bulimic behaviour. Other possible manifestations are dry lips, burning tongue, parotid gland swelling, and temporomandibular disorders.

Causes

The causes of eating disorders are not clear. Many people with eating disorders also have body dysmorphic disorder, altering the way a person sees themself. Studies have found that a high proportion of individuals diagnosed with body dysmorphic disorder also had some type of eating disorder, with 15% of individuals having either anorexia nervosa or bulimia nervosa.

This link between body dysmorphic disorder and anorexia stems from the fact that both BDD and anorexia nervosa are characterized by a preoccupation with physical appearance and a distortion of body image. There are also many other possibilities such as environmental, social and interpersonal issues that could promote and sustain these illnesses.

Also, the media are oftentimes blamed for the rise in the incidence of eating disorders due to the fact that media images of idealized slim physical shape of people such as models and celebrities motivate or even force people to attempt to achieve slimness themselves. The media are accused of distorting reality, in the sense that people portrayed in the media are either naturally thin and thus unrepresentative of normality or unnaturally thin by forcing their bodies to look like the ideal image by putting excessive pressure on themselves to look a certain way.

While past findings have described eating disorders as primarily psychological, environmental, and sociocultural, further studies have uncovered evidence that there is a genetic component.

Genetics

Numerous studies show a genetic predisposition toward eating disorders. Twin studies have found a slight instances of genetic variance when considering the different criterion of both anorexia nervosa and bulimia nervosa as endophenotypes contributing to the disorders as a whole. A genetic link has been found on chromosome 1 in multiple family members of an individual with anorexia nervosa.

An individual who is a first degree relative of someone who has had or currently has an eating disorder is seven to twelve times more likely to have an eating disorder themselves. Twin studies also show that at least a portion of the vulnerability to develop eating disorders can be inherited, and there is evidence to show that there is a genetic locus that shows susceptibility for developing anorexia nervosa.

About 50% of eating disorder cases are attributable to genetics. Other cases are due to external reasons or developmental problems. There are also other neurobiological factors at play tied to emotional reactivity and impulsivity that could lead to binging and purging behaviours. Epigenetics mechanisms are means by which environmental effects alter gene expression via methods such as DNA methylation; these are independent of and do not alter the underlying DNA sequence.

They are heritable, but also may occur throughout the lifespan, and are potentially reversible. Dysregulation of dopaminergic neurotransmission due to epigenetic mechanisms has been implicated in various eating disorders. Other candidate genes for epigenetic studies in eating disorders include leptin, pro-opiomelanocortin (POMC) and brain-derived neurotrophic factor (BDNF).

Psychological

Eating disorders are classified as Axis I disorders in the Diagnostic and Statistical Manual of Mental Health Disorders (DSM-IV) published by the American Psychiatric Association. There are various other psychological issues that may factor into eating disorders, some fulfil the criteria for a separate Axis I diagnosis or a personality disorder which is coded Axis II and thus are considered comorbid to the diagnosed eating disorder. Axis II disorders are subtyped into 3 "clusters": A, B and C.

The causality between personality disorders and eating disorders has yet to be fully established. Some people have a previous disorder which may increase their vulnerability to developing an eating disorder. Some develop them afterwards. The severity and type of eating disorder symptoms have been shown to affect comorbidity. The DSM-IV should not be used by laypersons to diagnose themselves even when used by professionals there has been considerable controversy over the diagnostic criteria used for various diagnoses, including eating disorders. There has been controversy over various editions of the DSM including the latest edition, DSM-V, due in May 2013.

Cognitive Attentional Bias Issues Attentional bias may have an effect on eating disorders. Many studies have been performed to test this theory.	**Comorbid Disorders** **Axis I** ● Depression ● Substance Abuse, Alcoholism ● Anxiety Disorders ● Obsessive Compulsive Disorder ● Attention-Deficit Hyperactivity Disorder	**Comorbid Disorders** **Axis II** ● Obsessive Compulsive Personality Disorder ● Borderline Personality Disorder ● Narcissistic Personality Disorder ● Histrionic Personality Disorder ● Avoidant Personality Disorder

Personality Traits

There are various childhood personality traits associated with the development of eating disorders. During adolescence these traits may become intensified due to a variety of physiological and cultural influences such as the hormonal changes associated with puberty, stress related to the approaching demands of maturity and socio-cultural influences and perceived expectations, especially in areas that concern body image.

Eating disorders have been associated with a fragile sense of self and with disordered mentalization. Many personality traits have a genetic component and are highly heritable.

Maladaptive levels of certain traits may be acquired as a result of anoxic or traumatic brain injury, neurodegenerative diseases such as Parkinson's disease, neurotoxicity such as lead exposure, bacterial infection such as Lyme disease or parasitic infection such as Toxoplasma gondii as well as hormonal influences.

While studies are still continuing via the use of various imaging techniques such as fMRI; these traits have been shown to originate in various regions of the brain such as the amygdala and the prefrontal cortex. Disorders in the prefrontal cortex and the executive functioning system have been shown to affect eating behaviour.

Celiac Disease

People with gastrointestinal disorders may be more risk of developing disordered eating practices than the general population, principally restrictive eating disturbances. An association of anorexia nervosa with celiac disease has been found. The role that gastrointestinal symptoms play in the development of eating disorders seems rather complex. Some authors report that unresolved symptoms prior to gastrointestinal disease diagnosis may create a food aversion in these persons, causing alterations to their eating patterns.

Other authors report that greater symptoms throughout their diagnosis led to greater risk. It has been documented that some people with celiac disease, irritable bowel syndrome or inflammatory bowel disease who are not conscious about the importance of strictly following their diet, choose to consume their trigger foods to promote weight loss.

On the other hand, individuals with good dietary management may develop anxiety, food aversion and eating disorders because of concerns around cross contamination of their foods. Some authors suggest that medical professionals should evaluate the presence of an unrecognized celiac disease in all people with eating disorder, especially if they present any gastrointestinal symptom (such as decreased appetite, abdominal pain, bloating, distension, vomiting, diarrhoea or constipation), weight loss, or growth failure; and also routinely ask celiac patients about weight or body shape concerns, dieting or vomiting for weight control, to evaluate the possible presence of eating disorders, specially in women.

Environmental Influences (Child Maltreatment)

Child abuse which encompasses physical, psychological and sexual abuse, as well as neglect has been shown to approximately triple the risk of an eating disorder. Sexual abuse appears to about double the risk of bulimia; however, the association is less clear for anorexia.

Environmental Influences (Social Isolation)

Social isolation has been shown to have a deleterious effect on an individual's physical and emotional well-being. Those that are socially isolated have a higher mortality rate in general as compared to individuals that have established social relationships. This effect on mortality is markedly increased in those with pre-existing medical or psychiatric conditions, and has been especially noted in cases of coronary heart disease.

"The magnitude of risk associated with social isolation is comparable with that of cigarette smoking and other major biomedical and psychosocial risk factors." Social isolation can be inherently stressful, depressing and anxiety-provoking.

In an attempt to ameliorate these distressful feelings an individual may engage in emotional eating in which food serves as a source of comfort. The loneliness of social isolation and the inherent stressors thus associated have been implicated as triggering factors in binge eating as well.

Waller, Kennerley and Ohanian (2007) argued that both bingeing–vomiting and restriction are emotion suppression strategies, but they are just utilized at different times. For example, restriction is used to pre-empt any emotion activation, while bingeing–vomiting is used after an emotion has been activated.

Environmental Influences (Parental Influence)

Parental influence has been shown to be an intrinsic component in the development of eating behaviours of children. This influence is manifested and shaped by a variety of diverse factors such as familial genetic predisposition, dietary choices as dictated by cultural or ethnic preferences, the parents' own body shape and eating patterns, the degree of involvement and expectations of their children's eating behaviour as well as the interpersonal relationship of parent and child.

This is in addition to the general psychosocial climate of the home and the presence or absence of a nurturing stable environment. It has been shown that maladaptive parental behaviour has an important role in the development of eating disorders. As to the more subtle aspects of parental influence, it has been shown that eating patterns are established in early childhood and that children should be allowed to decide when their appetite is satisfied as early as the age of two. A direct link has been shown between obesity and parental pressure to eat more. Coercive tactics in regard to diet have not been proven to be efficacious in controlling a child's eating behaviour.

Affection and attention have been shown to affect the degree of a child's finickiness and their acceptance of a more varied diet. Adams and Crane (1980), have shown that parents are influenced by stereotypes that influence their perception of their child's body. The conveyance of these negative stereotypes also affects the child's own body image and satisfaction. Hilde Bruch, a pioneer in the field of studying eating disorders, asserts that anorexia nervosa often occurs in girls who are high achievers, obedient, and always trying to please their parents.

Their parents have a tendency to be over-controlling and fail to encourage the expression of emotions, inhibiting daughters from accepting their own feelings and desires. Adolescent females in these overbearing families lack the ability to be independent from their families, yet realize the need to, often resulting in rebellion. Controlling their food intake may make them feel better, as it provides them with a sense of control.

Environmental Influences (Peer Pressure)

In various studies such as one conducted by The McKnight Investigators, peer pressure was shown to be a significant contributor to body image concerns and attitudes toward eating among subjects in their teens and early twenties. Eleanor Mackey and co-author, Annette M. La Greca of the University of Miami, studied 236 teen girls from public high schools in southeast Florida. "Teen girls' concerns about their own weight, about how they appear to others and their perceptions that their peers want them to be thin are significantly related to weight-control behaviour", says psychologist Eleanor Mackey of the Children's National Medical Centre in Washington and lead author of the study. "Those are really important."

According to one study, 40% of 9- and 10-year-old girls are already trying to lose weight. Such dieting is reported to be influenced by peer behaviour, with many of those individuals on a diet reporting that their friends also were dieting. The number of friends dieting and the number of friends who pressured them to diet also played a significant role in their own choices. Elite athletes have a significantly higher rate in eating disorders. Female athletes in sports such as gymnastics, ballet, diving, etc. are found to be at the highest risk among all athletes. Women are more likely than men to acquire an eating disorder between the ages of 13–30. 0–15% of those with bulimia and anorexia are men.

Environmental Influences (Cultural Pressure)

There is a cultural emphasis on thinness which is especially pervasive in western society. A child's perception of external pressure to achieve the ideal body that is represented by the media predicts the child's body image dissatisfaction, body dysmorphic disorder and an eating disorder. "The cultural pressure on men and women to be 'perfect' is an important predisposing factor for the development of eating disorders". Further, when women of all races base their evaluation of their self upon what is considered the culturally ideal body, the incidence of eating disorders increases.

Eating disorders are becoming more prevalent in non-Western countries where thinness is not seen as the ideal, showing that social and cultural pressures are not the only causes of eating disorders. For example, observations of anorexia in all of the non-Western regions of the world point to the disorder not being "culture-bound" as once thought. However, studies on rates of bulimia suggest that it might be culturally bound. In non-Western countries, bulimia is less prevalent than anorexia, but these non-Western countries where it is observed can be said to have probably or definitely been influenced or exposed to Western culture and ideology.
Socioeconomic status (SES) has been viewed as a risk factor for eating disorders, presuming that possessing more resources allows for an individual to actively choose to diet and reduce body weight. Some studies have also shown a relationship between increasing body dissatisfaction with increasing SES. However, once high socioeconomic status has been achieved, this relationship weakens and, in some cases, no longer exists. The media plays a major role in the way in which people view themselves.

Countless magazine ads and commercials depict thin celebrities like Lindsay Lohan, Nicole Richie, Victoria Beckham and Mary Kate Olsen, who appear to gain nothing but attention from their looks. Society has taught people that being accepted by others is necessary at all costs. Unfortunately this has led to the belief that in order to fit in one must look a certain way. Televised beauty competitions such as the Miss America Competition contribute to the idea of what it means to be beautiful because competitors are evaluated on the basis of their opinion.

Sports

In addition to socioeconomic status being considered a cultural risk factor so is the world of sports. Athletes and eating disorders tend to go hand in hand, especially the sports where weight is a competitive factor. Gymnastics, horse back riding, wrestling, body building, and dancing are just a few that fall into this category of weight dependent sports. Eating disorders among individuals that participate in competitive activities, especially women, often lead to having physical and biological changes related to their weight that often mimic prepubescent stages.

Oftentimes as women's bodies change they lose their competitive edge which leads them to taking extreme measures to maintain their younger body shape. Men often struggle with binge eating followed by excessive exercise while focusing on building muscle rather than losing fat, but this goal of gaining muscle is just as much an eating disorder as obsessing over thinness. The following statistics taken from Susan Nolen-Hoeksema's book, (ab)normal psychology, show the estimated percentage of athletes that struggle with eating disorders based on the category of sport.

- Aesthetic sports (dance, figure skating, gymnastics) – 35%
- Weight dependent sports (judo, wrestling) – 29%
- Endurance sports (cycling, swimming, running) – 20%
- Technical sports (golf, high jumping) – 14%
- Ball game sports (volleyball, soccer) – 12%

Although most of these athletes develop eating disorders to keep their competitive edge, others use exercise as a way to maintain their weight and figure. This is just as serious as regulating food intake for competition. Even though there is mixed evidence showing at what point athletes are challenged with eating disorders, studies show that regardless of competition level all athletes are at higher risk for developing eating disorders that non-athletes, especially those that participate in sports where thinness is a factor.

Media Exposure

While there are many influences to how an individual processes their body image, the media does play a major role. Along with the media, parental influence, peer influence, and self-efficacy beliefs also play a large role in an individual's view of themselves. The way the media presents images can have a lasting effect on an individual's perception of their body image. Eating disorders are a worldwide issue and while women are more likely to be affected by an eating disorder it still affects both genders (Schwitzer 2012). The media influences eating disorders whether shown in a positive or negative light, it then has a responsibility to use caution when promoting images that projects an ideal that many turn to eating disorders to attain.

To try to address unhealthy body image in the fashion world, in 2015, France passed a law requiring models to be declared healthy by a doctor to participate in fashion shows. It also requires re-touched images to be marked as such in magazines. There is a relationship between “thin ideal” social media content and body dissatisfaction and eating disorders among young adult women, especially in the Western hemisphere. New research points to an “internalization” of distorted images online, as well as negative comparisons among young adult women. Most studies have been based in the U.S, the U.K, and Australia, these are places where the thin ideal is strong among women, as well as the strive for the “perfect” body.

In addition to mere media exposure, there is an online "pro-eating disorder" community. Through personal blogs and Twitter, this community promotes eating disorders as a "lifestyle", and continuously posts pictures of emaciated bodies, and tips on how to stay thin. The hashtag "#proana" (pro-anorexia), is a product of this community, as well as images promoting weight loss, tagged with the term "thinspiration". According to social comparison theory, young women have a tendency to compare their appearance to others, which can result in a negative view of their own bodies and altering of eating behaviours, that in turn can develop disordered eating behaviours.

When body parts are isolated and displayed in the media as objects to be looked at, it is called objectification, and women are affected most by this phenomenon. Objectification increases self-objectification, where women judge their own body parts as a mean of praise and pleasure for others. There is a significant link between self-objectification, body dissatisfaction, and disordered eating, as the beauty ideal is altered through social media.

Mechanisms

- Biochemical: Eating behaviour is a complex process controlled by the neuroendocrine system, of which the Hypothalamus-pituitary-adrenal-axis (HPA axis) is a major component. Dysregulation of the HPA axis has been associated with eating disorders, such as irregularities in the manufacture, amount or transmission of certain neurotransmitters, hormones or neuropeptides and amino acids such as homocysteine, elevated levels of which are found in AN and BN as well as depression.

- Serotonin: a neurotransmitter involved in depression also has an inhibitory effect on eating behaviour.

- Norepinephrine is both a neurotransmitter and a hormone; abnormalities in either capacity may affect eating behaviour.

- Dopamine: which in addition to being a precursor of norepinephrine and epinephrine is also a neurotransmitter which regulates the rewarding property of food.

- Neuropeptide Y also known as NPY is a hormone that encourages eating and decreases metabolic rate. Blood levels of NPY are elevated in patients with anorexia nervosa, and studies have shown that injection of this hormone into the brain of rats with restricted food intake increases their time spent running on a wheel. Normally the hormone stimulates eating in healthy patients, but under conditions of starvation it increases their activity rate, probably to increase the chance of finding food. The increased levels of NPY in the blood of patients with eating disorders can in some ways explain the instances of extreme over-exercising found in most anorexia nervosa patients.

- Leptin and ghrelin: leptin is a hormone produced primarily by the fat cells in the body; it has an inhibitory effect on appetite by inducing a feeling of satiety. Ghrelin is an appetite inducing hormone produced in the stomach and the upper portion of the small intestine. Circulating levels of both hormones are an important factor in weight control. While often associated with obesity, both hormones and their respective effects have been implicated in the pathophysiology of anorexia nervosa and bulimia nervosa. Leptin can also be used to distinguish between constitutional thinness found in a healthy person with a low BMI and an individual with anorexia nervosa.

- Gut bacteria and immune system: studies have shown that a majority of patients with anorexia and bulimia nervosa have elevated levels of autoantibodies that affect hormones and neuropeptides that regulate appetite control and the stress response. There may be a direct correlation between autoantibody levels and associated psychological traits. Later study revealed that autoantibodies reactive with alpha-MSH are, in fact, generated against ClpB, a protein produced by certain gut bacteria e.g. Escherichia coli. ClpB protein was identified as a conformational antigen-mimetic of alpha-MSH. In patients with eating disorders plasma levels of anti-ClpB IgG and IgM correalated with patients' psychological traits.

- Infection: PANDAS, is an abbreviation for Paediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal Infections. Children with PANDAS "have obsessive-compulsive disorder (OCD) and/or tic disorders such as Tourette syndrome, and in whom symptoms worsen following infections such as "strep throat" and scarlet fever". (NIMH) There is a possibility that PANDAS may be a precipitating factor in the development of anorexia nervosa in some cases, (PANDAS AN).

- Lesions: studies have shown that lesions to the right frontal lobe or temporal lobe can cause the pathological symptoms of an eating disorder.

- Tumours: tumours in various regions of the brain have been implicated in the development of abnormal eating patterns.

- Brain Calcification: a study highlights a case in which prior calcification of the right thalumus may have contributed to development of anorexia nervosa.

- Somatosensory Homunculus: is the representation of the body located in the somatosensory cortex, first described by renowned neurosurgeon Wilder Penfield. The illustration was originally termed "Penfield's Homunculus", homunculus meaning little man. "In normal development this representation should adapt as the body goes through its pubertal growth spurt. However, in AN it is hypothesized that there is a lack of plasticity in this area, which may result in impairments of sensory processing and distortion of body image". (Bryan Lask, also proposed by VS Ramachandran)

- Obstetric complications: There have been studies done which show maternal smoking, obstetric and perinatal complications such as maternal anaemia, very pre-term birth (less than 32 weeks), being born small for gestational age, neonatal cardiac problems, preeclampsia, placental infarction and sustaining a cephalhematoma at birth increase the risk factor for developing either anorexia nervosa or bulimia nervosa.

- Symptom of Starvation: Evidence suggests that the symptoms of eating disorders are actually symptoms of the starvation itself, not of a mental disorder. In a study involving thirty-six healthy young men that were subjected to semi-starvation, the men soon began displaying symptoms commonly found in patients with eating disorders. In this study, the healthy men ate approximately half of what they had become accustomed to eating and soon began developing symptoms and thought patterns (preoccupation with food and eating, ritualistic eating, impaired cognitive ability, other physiological changes such as decreased body temperature) that are characteristic symptoms of anorexia nervosa...

The men used in the study also developed hoarding and obsessive collecting behaviours, even though they had no use for the items, which revealed a possible connection between eating disorders and obsessive compulsive disorder.

Diagnosis

The initial diagnosis should be made by a competent medical professional. "The medical history is the most powerful tool for diagnosing eating disorders"(American Family Physician). There are many medical disorders that mimic eating disorders and comorbid psychiatric disorders. All organic causes should be ruled out prior to a diagnosis of an eating disorder or any other psychiatric disorder. In the past 30 years eating disorders have become increasingly conspicuous and it is uncertain whether the changes in presentation reflect a true increase. Anorexia nervosa and bulimia nervosa are the most clearly defined subgroups of a wider range of eating disorders. Many patients present with subthreshold expressions of the two main diagnoses: others with different patterns and symptoms.

Psychological

After ruling out organic causes and the initial diagnosis of an eating disorder being made by a medical professional, a trained mental health professional aids in the assessment and treatment of the underlying psychological components of the eating disorder and any comorbid psychological conditions. The clinician conducts a clinical interview and may employ various psychometric tests. Some are general in nature while others were devised specifically for use in the assessment of eating disorders. Some of the general tests that may be used are the Hamilton Depression Rating Scale and the Beck Depression Inventory. Longitudinal research showed that there is an increase in chance that a young adult female would develop bulimia due to their current psychological pressure and as the person ages and matures, their emotional problems change or are resolved and then the symptoms decline.

Eating Disorder Specific Psychometric Tests
- Eating Attitudes Test
- Body Attitudes Test
- Eating Disorder Inventory
- SCOFF questionnaire
- Body Attitudes Questionnaire
- Eating Disorder Examination Interview

Differential Diagnoses

- Lyme disease which is known as the "great imitator", as it may present as a variety of psychiatric or neurological disorders including anorexia nervosa.

● Gastrointestinal diseases, such as celiac disease, Crohn's disease, peptic ulcer, eosinophilic esophagitis or non-celiac gluten sensitivity, among others. Celiac disease is also known as the "great imitator", because it may involve several organs and cause an extensive variety of non-gastrointestinal symptoms, such as psychiatric and neurological disorders, including anorexia nervosa.

● Addison's disease is a disorder of the adrenal cortex which results in decreased hormonal production. Addison's disease, even in subclinical form may mimic many of the symptoms of anorexia nervosa.

● Gastric adenocarcinoma is one of the most common forms of cancer in the world. Complications due to this condition have been misdiagnosed as an eating disorder.

● Hypothyroidism, hyperthyroidism, hypoparathyroidism and hyperparathyroidism may mimic some of the symptoms of, can occur concurrently with, be masked by or exacerbate an eating disorder.

● Toxoplasma seropositivity: even in the absence of symptomatic toxoplasmosis, toxoplasma gondii exposure has been linked to changes in human behaviour and psychiatric disorders including those comorbid with eating disorders such as depression. In reported case studies the response to antidepressant treatment improved only after adequate treatment for toxoplasma.

● Neurosyphilis: It is estimated that there may be up to one million cases of untreated syphilis in the US alone. "The disease can present with psychiatric symptoms alone, psychiatric symptoms that can mimic any other psychiatric illness". Many of the manifestations may appear atypical. Up to 1.3% of short term psychiatric admissions may be attributable to neurosyphilis, with a much higher rate in the general psychiatric population. (Ritchie, M Perdigao J,)

● Dysautonomia: a wide variety of autonomic nervous system (ANS) disorders may cause a wide variety of psychiatric symptoms including anxiety, panic attacks and depression. Dysautonomia usually involves failure of sympathetic or parasympathetic components of the ANS system but may also include excessive ANS activity. Dysautonomia can occur in conditions such as diabetes and alcoholism.

Differential Diagnoses (Psychological Disorders)

Psychological disorders which may be confused with an eating disorder, or be co-morbid with one:

● Emetophobia is an anxiety disorder characterized by an intense fear of vomiting. A person so afflicted may develop rigorous standards of food hygiene, such as not touching food with their hands. They may become socially withdrawn to avoid situations which in their perception may make them vomit. Many who suffer from emetophobia are diagnosed with anorexia or self-starvation. In severe cases of emetophobia they may drastically reduce their food intake.

● Phagophobia is an anxiety disorder characterized by a fear of eating, it is usually initiated by an adverse experience while eating such as choking or vomiting. Persons with this disorder may present with complaints of pain while swallowing.

● Body dysmorphic disorder (BDD) is listed as a somatoform disorder that affects up to 2% of the population. BDD is characterized by excessive rumination over an actual or perceived physical flaw. BDD has been diagnosed equally among men and women. While BDD has been misdiagnosed as anorexia nervosa, it also occurs comorbidly in 39% of eating disorder cases. BDD is a chronic and debilitating condition which may lead to social isolation, major depression and suicidal ideation and attempts. Neuroimaging studies to measure response to facial recognition have shown activity predominately in the left hemisphere in the left lateral prefrontal cortex, lateral temporal lobe and left parietal lobe showing hemispheric imbalance in information processing.

Prevention

Prevention aims to promote a healthy development before the occurrence of eating disorders. It also intends early identification of an eating disorder before it is too late to treat. Children as young as ages 5–7 are aware of the cultural messages regarding body image and dieting. Prevention comes in bringing these issues to the light. The following topics can be discussed with young children (as well as teens and young adults). Internet and modern technologies provide new opportunities for prevention. On-line programs have the potential to increase the use of prevention programs. The development and practice of prevention programs via on-line sources make it possible to reach a wide range of people at minimal cost. Such an approach can also make prevention programs to be sustainable.

● Emotional Bites: a simple way to discuss emotional eating is to ask children about why they might eat besides being hungry. Talk about more effective ways to cope with emotions, emphasizing the value of sharing feelings with a trusted adult.

● Say No to Teasing: another concept is to emphasize that it is wrong to say hurtful things about other people's body sizes.

● Body Talk: emphasize the importance of listening to one's body. That is, eating when you are hungry (not starving) and stopping when you are satisfied (not stuffed). Children intuitively grasp these concepts.

● Fitness Comes in All Sizes: educate children about the genetics of body size and the normal changes occurring in the body. Discuss their fears and hopes about growing bigger. Focus on fitness and a balanced diet.

Treatment

Treatment varies according to type and severity of eating disorder, and usually more than one treatment option is utilized. Family doctors play an important role in early treatment of people with eating disorders by encouraging those who are also reluctant to see a psychiatrist. Treatment can take place in a variety of different settings such as community programs, hospitals, day programs, and groups. The American Psychiatric Association (APA) recommends a team approach to treatment of eating disorders. The members of the team are usually a psychiatrist, therapist, and registered dietitian, but other clinicians may be included. That said, some treatment methods are:

● Cognitive behavioural therapy (CBT), which postulates that an individual's feelings and behaviours are caused by their own thoughts instead of external stimuli such as other people, situations or events; the idea is to change how a person thinks and reacts to a situation even if the situation itself does not change. See Cognitive behavioural treatment of eating disorders.

● Acceptance and commitment therapy: a type of CBT

● Cognitive Remediation Therapy (CRT), a set of cognitive drills or compensatory interventions designed to enhance cognitive functioning.

● Dialectical Behaviour Therapy

● Family Therapy including "conjoint family therapy" (CFT), "separated family therapy" (SFT) and Maudsley Family Therapy.

● Behavioural Therapy: focuses on gaining control and changing unwanted behaviours.

● Interpersonal psychotherapy (IPT)

There are few studies on the cost-effectiveness of the various treatments. Treatment can be expensive; due to limitations in health care coverage, people hospitalized with anorexia nervosa may be discharged while still underweight, resulting in relapse and rehospitalisation. For children with anorexia, the only well-established treatment is the family treatment-behaviour. For other eating disorders in children, however, there is no well-established treatments, though family treatment-behaviour has been used in treating bulimia.

- Cognitive Emotional Behaviour Therapy (CEBT)
- Music Therapy
- Recreation Therapy
- Art Therapy
- Nutrition counselling and Medical nutrition therapy
- Medication: Orlistat is used in obesity treatment. Olanzapine seems to promote weight gain as well as the ability to ameliorate obsessional behaviours concerning weight gain. zinc supplements have been shown to be helpful, and cortisol is also being investigated.
- Self-help and guided self-help have been shown to be helpful in AN, BN and BED; this includes support groups and self-help groups such as Eating Disorders Anonymous and Overeaters Anonymous.
- Psychoanalysis
- Inpatient Care

There are few studies on the cost-effectiveness of the various treatments. Treatment can be expensive; due to limitations in health care coverage, people hospitalized with anorexia nervosa may be discharged while still underweight, resulting in relapse and rehospitalisation. For children with anorexia, the only well-established treatment is the family treatment-behaviour. For other eating disorders in children, however, there is no well-established treatments, though family treatment-behaviour has been used in treating bulimia.

Outcomes

Outcome estimates are complicated by non-uniform criteria used by various studies, but for anorexia nervosa, bulimia nervosa, and binge eating disorder, there seems to be general agreement that full recovery rates are in the 50% to 85% range, with larger proportions of people experiencing at least partial remission. The outcomes of eating disorders (ED) vary among the cases. For many, it can be a lifelong struggle or it can be overcome within months. In the United States, twenty million women and ten million men have an eating disorder at least once in their lifetime.

The mortality rate for those with anorexia nervosa is 5.4 per 1000 individuals per year. Roughly 1.3 deaths were due to suicide. A person who is or had been in an inpatient setting had a rate of 4.6 deaths per 1000. Of individuals with bulimia nervosa about 2 persons per 1000 persons die per year and among those with EDNOS about 3.3 per 1000 people die per year.

- Miscarriages: Pregnant women with a Binge Eating Disorder have shown to have a greater chance of having a miscarriage compared to pregnant women with any other eating disorders. According to a study done, out of a group of pregnant women being evaluated, 46.7% of the pregnancies ended with a miscarriage in women that were diagnosed with BED, with 23.0% in the control. In the same study, 21.4% of women diagnosed with Bulimia Nervosa had their pregnancies end with miscarriages and only 17.7% of the controls.
- Relapse: An individual who is in remission from BN and EDNOS (Eating Disorder Not Otherwise Specified) is at a high risk of falling back into the habit of self-harm. Factors such as high stress regarding their job, pressures from society, as well as other occurrences that inflict stress on a person, can push a person back to what they feel will ease the pain. A study tracked a group of selected people that were either diagnosed with BN or EDNOS for 60 months. After the 60 months were complete, the researchers recorded whether or not the patients were suffering from a relapse. The results found that the probability of a person previously diagnosed with EDNOS had a 41% chance of relapsing; a person with BN had a 47% chance.
- Attachment insecurity: People who are showing signs of attachment anxiety will most likely have trouble communicating their emotional status as well as having trouble seeking effective social support. Signs that a person has adopted this symptom include not showing recognition to their caregiver or when he/she is feeling pain. In a clinical sample, it is clear that at the pre-treatment step of a patient's recovery, more severe eating disorder symptoms directly corresponds to higher attachment anxiety. The more this symptom increases, the more difficult it is to achieve eating disorder reduction prior to treatment.

Anorexia Nervosa symptoms include the increasing chance of getting osteoporosis. This disease causes the bones of an individual to become brittle, weak, and low in density. Thinning of the hair as well as dry hair and skin are also very common. The muscles of the heart will also start to change if no treatment is inflicted on the patient. This causes the heart to have an abnormally slow heart rate along with low blood pressure. Heart failure becomes a major consideration when this begins to occur. Muscles throughout the body begin to lose their strength. This will cause the individual to begin feeling faint, drowsy, and weak. Along with these symptoms, the body will begin to grow a layer of hair called lanugo. The human body does this in response to the lack of heat and insulation due to the low percentage of body fat.

Bulimia nervosa symptoms include heart problems like an irregular heartbeat that can lead to heart failure and death may occur. This occurs because of the electrolyte imbalance that is a result of the constant binge and purge process. The probability of a gastric rupture increases. A gastric rupture is when there is a sudden rupture of the stomach lining that can be fatal. The acids that are contained in the vomit can cause a rupture in the oesophagus as well as tooth decay. As a result, to laxative abuse, irregular bowel movements may occur along with constipation. Sores along the lining of the stomach called peptic ulcers begin to appear and the chance of developing pancreatitis increases.

Binge eating symptoms include high blood pressure, which can cause heart disease if it is not treated. Many patients recognize an increase in the levels of cholesterol. The chance of being diagnosed with gallbladder disease increases, which affects an individual's digestive tract.

Epidemiology

Eating disorders result in about 7,000 deaths a year as of 2010, making them the mental illnesses with the highest mortality rate. One study in the United States found a higher rate in college students who are transgender.

- Total costs in USA for hospital stays involving eating disorders rose from $165 million in 1999–2000 to $277 million in 2008–2009; this was a 68% increase. The mean cost per discharge of a person with an eating disorder rose by 29% over the decade, from $7,300 to $9,400.
- Over the decade, hospitalizations involving eating disorders increased among all age groups. The greatest increases occurred among those 45 to 65 years of age (an 88% increase), followed by hospitalizations among people younger than 12 years of age (a 72% increase).
- The majority of eating disorder inpatients were female. During 2008–2009, 88% of cases involved females, and 12% were males. The report also showed a 53% increase in hospitalizations for males with a principal diagnosis of an eating disorder, from 10% to 12% over the decade.

9 Obesity

Obesity is a medical condition in which excess body fat has accumulated to an extent that it may have a negative effect on health. People are generally considered obese when their body mass index (BMI), a measurement obtained by dividing a person's weight by the square of the person's height, is over 30 kg/m2; the range 25–30 kg/m2 is defined as overweight. Some East Asian countries use lower values. Obesity increases the likelihood of various diseases and conditions, particularly cardiovascular diseases, type 2 diabetes, obstructive sleep apnea, certain types of cancer, osteoarthritis, and depression. Obesity is most commonly caused by a combination of excessive food intake, lack of physical activity, and genetic susceptibility.

A few cases are caused primarily by genes, endocrine disorders, medications, or mental disorder. The view that obese people eat little yet gain weight due to a slow metabolism is not medically supported. On average, obese people have a greater energy expenditure than their normal counterparts due to the energy required to maintain an increased body mass. Obesity is mostly preventable through a combination of social changes and personal choices.

Changes to diet and exercising are the main treatments. Diet quality can be improved by reducing the consumption of energy-dense foods, such as those high in fat or sugars, and by increasing the intake of dietary fibre. Medications can be used, along with a suitable diet, to reduce appetite or decrease fat absorption. If diet, exercise, and medication are not effective, a gastric balloon or surgery may be performed to reduce stomach volume or length of the intestines, leading to feeling full earlier or a reduced ability to absorb nutrients from food. Obesity is a leading preventable cause of death worldwide, with increasing rates in adults and children.

In 2015, 600 million adults (12%) and 100 million children were obese in 195 countries. Obesity is more common in women than men. Authorities view it as one of the most serious public health problems of the 21st century. Obesity is stigmatized in much of the modern world (particularly in the Western world), though it was seen as a symbol of wealth and fertility at other times in history and still is in some parts of the world. In 2013, the American Medical Association classified obesity as a disease.

Classification

Obesity is a medical condition in which excess body fat has accumulated to the extent that it may have an adverse effect on health. It is defined by body mass index (BMI) and further evaluated in terms of fat distribution via the waist–hip ratio and total cardiovascular risk factors. BMI is closely related to both percentage body fat and total body fat. In children, a healthy weight varies with age and sex. Obesity in children and adolescents is defined not as an absolute number but in relation to a historical normal group, such that obesity is a BMI greater than the 95th percentile. The reference data on which these percentiles were based date from 1963 to 1994, and thus have not been affected by the recent increases in weight. BMI is defined as the subject's weight divided by the square of their height and is calculated as follows.

BMI = m / h²

m = Weight
h = Height

BMI is usually expressed in kilograms of weight per metre squared of height. To convert from pounds per inch squared multiply by 703 (kg/m2)/(lb/sq in). The most commonly used definitions, established by the World Health Organization (WHO) in 1997 and published in 2000, provide the values listed in the table. Some modifications to the WHO definitions have been made by particular organizations. The surgical literature breaks down class II and III obesity into further categories whose exact values are still disputed.

BMI Classification
<18.5 - Underweight
18.5-25 - Normal Weight
25-30 - Overweight
30-35 - Class I Obesity
35-40 - Class II Obesity
>40 - Class III Obesity

- Any BMI ≥ 35 or 40 kg/m2 is severe obesity.
- A BMI of ≥ 35 kg/m2 and experiencing obesity-related health conditions or ≥40–44.9 kg/m2 is morbid obesity.
- A BMI of ≥ 45 or 50 kg/m2 is super obesity.

As Asian populations develop negative health consequences at a lower BMI than Caucasians, some nations have redefined obesity; Japan has defined obesity as any BMI greater than 25 kg/m2 while China uses a BMI of greater than 28 kg/m2.

Effects on Health

Excessive body weight is associated with various diseases and conditions, particularly cardiovascular diseases, diabetes mellitus type 2, obstructive sleep apnea, certain types of cancer, osteoarthritis, and asthma. As a result, obesity has been found to reduce life expectancy.

Mortality
Obesity is one of the leading preventable causes of death worldwide. A number of reviews have found that mortality risk is lowest at a BMI of 20–25 kg/m2 in non-smokers and at 24–27 kg/m2 in current smokers, with risk increasing along with changes in either direction. This appears to apply in at least four continents. In contrast, a 2013 review found that grade 1 obesity (BMI 30–35) was not associated with higher mortality than normal weight, and that overweight (BMI 25–30) was associated with "lower" mortality than was normal weight (BMI 18.5–25). Other evidence suggests that the association of BMI and waist circumference with mortality is U- or J-shaped, while the association between waist-to-hip ratio and waist-to-height ratio with mortality is more positive. In Asians the risk of negative health effects begins to increase between 22–25 kg/m2. A BMI above 32 kg/m2 has been associated with a doubled mortality rate among women over a 16-year period. In the United States, obesity is estimated to cause 111,909 to 365,000 deaths per year, while 1 million (7.7%) of deaths in Europe are attributed to excess weight. On average, obesity reduces life expectancy by six to seven years, a BMI of 30–35 kg/m2 reduces life expectancy by two to four years, while severe obesity (BMI > 40 kg/m2) reduces life expectancy by ten years.

Morbidity
Obesity increases the risk of many physical and mental conditions. These comorbidities are most commonly shown in metabolic syndrome, a combination of medical disorders which includes: diabetes mellitus type 2, high blood pressure, high blood cholesterol, and high triglyceride levels. Complications are either directly caused by obesity or indirectly related through mechanisms sharing a common cause such as a poor diet or a sedentary lifestyle. The strength of the link between obesity and specific conditions varies. One of the strongest is the link with type 2 diabetes. Excess body fat underlies 64% of cases of diabetes in men and 77% of cases in women. Health consequences fall into two broad categories: those attributable to the effects of increased fat mass (such as osteoarthritis, obstructive sleep apnea, social stigmatization) and those due to the increased number of fat cells (diabetes, cancer, cardiovascular disease, non-alcoholic fatty liver disease). Increases in body fat alter the body's response to insulin, potentially leading to insulin resistance. Increased fat also creates a proinflammatory state, and a prothrombotic state.

Medical Field	Condition
Cardiology	• Coronary heart disease: angina and myocardial infarction • Congestive heart failure • High blood pressure • Abnormal cholesterol levels • Deep vein thrombosis and pulmonary embolism
Dermatology	• Stretch marks • Acanthosis nigricans lymphedema • Cellulitis • Hirsutism • Intertrigo
Endocrinology and Reproductive medicine	• Diabetes mellitus • Polycystic ovarian syndrome • Menstrual disorders infertility • Complications during pregnancy • Birth defects • Intrauterine fetal death

Gastroenterology	• Gastroesophageal reflux disease • Fatty liver disease • Cholelithiasis (gallstones)
Neurology	• Stroke • Meralgia paresthetica • Migraines • Carpal tunnel syndrome • Dementia • Idiopathic intracranial hypertension • Multiple sclerosis
Oncology	• Oesophageal • Colorectal • Pancreatic • Gallbladder • Endometrial • Kidney • Leukaemia • Hepatocellular carcinoma • Malignant melanoma
Psychiatry	• Depression in women • Social Stigmatization
Respirology	• Obstructive sleep apnea • Obesity hypoventilation syndrome • Asthma • Increased complications during general anaesthesia
Rheumatology and Orthopedics	• Gout • Poor mobility • Osteoarthritis • Low back pain
Urology and Nephrology	• Erectile dysfunction • Urinary incontinence • Chronic renal failure • Hypogonadism • Buried Penis

Causes

At an individual level, a combination of excessive food energy intake and a lack of physical activity is thought to explain most cases of obesity. A limited number of cases are due primarily to genetics, medical reasons, or psychiatric illness. In contrast, increasing rates of obesity at a societal level are felt to be due to an easily accessible and palatable diet, increased reliance on cars, and mechanized manufacturing. A 2006 review identified ten other possible contributors to the recent increase of obesity:

1. Insufficient sleep
2. Endocrine disruptors (environmental pollutants that interfere with lipid metabolism)
3. Decreased variability in ambient temperature
4. Decreased rates of smoking, because smoking suppresses appetite,
5. Increased use of medications that can cause weight gain (e.g., atypical antipsychotics)
6. Proportional increases in ethnic and age groups that tend to be heavier,
7. Pregnancy at a later age (which may cause susceptibility to obesity in children)
8. Epigenetic risk factors passed on generationally,
9. Natural selection for higher BMI
10. Assortative mating leading to increased concentration of obesity risk factors (this would increase the number of obese people by increasing population variance in weight).

While there is evidence supporting the influence of these mechanisms on the increased prevalence of obesity, the evidence is still inconclusive, and the authors state that these are probably less influential than the ones discussed in the previous paragraph.

Diet

A 2016 review supported excess food as the primary factor. Dietary energy supply per capita varies markedly between different regions and countries. It has also changed significantly over time. From the early 1970s to the late 1990s the average food energy available per person per day (the amount of food bought) increased in all parts of the world except Eastern Europe. The United States had the highest availability with 3,654 calories (15,290 kJ) per person in 1996. This increased further in 2003 to 3,754 calories (15,710 kJ). During the late 1990s Europeans had 3,394 calories (14,200 kJ) per person, in the developing areas of Asia there were 2,648 calories (11,080 kJ) per person, and in sub-Saharan Africa people had 2,176 calories (9,100 kJ) per person. Total food energy consumption has been found to be related to obesity. The widespread availability of nutritional guidelines has done little to address the problems of overeating and poor dietary choice. From 1971 to 2000, obesity rates in the United States increased from 14.5% to 30.9%. During the same period, an increase occurred in the average amount of food energy consumed. For women, the average increase was 335 calories (1,400 kJ) per day (1,542 calories (6,450 kJ) in 1971 and 1,877 calories (7,850 kJ) in 2004), while for men the average increase was 168 calories (700 kJ) per day (2,450 calories (10,300 kJ) in 1971 and 2,618 calories (10,950 kJ) in 2004). Most of this extra food energy came from an increase in carbohydrate consumption rather than fat consumption. The primary sources of these extra carbohydrates are sweetened beverages, which now account for almost 25 percent of daily food energy in young adults in America, and potato chips.

Consumption of sweetened drinks such as soft drinks, fruit drinks, iced tea, and energy and vitamin water drinks is believed to be contributing to the rising rates of obesity and to an increased risk of metabolic syndrome and type 2 diabetes. Vitamin D deficiency is related to diseases associated with obesity. As societies become increasingly reliant on energy-dense, big-portions, and fast-food meals, the association between fast-food consumption and obesity becomes more concerning. In the United States consumption of fast-food meals tripled and food energy intake from these meals quadrupled between 1977 and 1995. Agricultural policy and techniques in the United States and Europe have led to lower food prices. In the United States, subsidization of corn, soy, wheat, and rice through the U.S. farm bill has made the main sources of processed food cheap compared to fruits and vegetables. Calorie count laws and nutrition facts labels attempt to steer people toward making healthier food choices, including awareness of how much food energy is being consumed. Obese people consistently under-report their food consumption as compared to people of normal weight. This is supported both by tests of people carried out in a calorimeter room and by direct observation.

Sedentary Lifestyle

A sedentary lifestyle plays a significant role in obesity. Worldwide there has been a large shift towards less physically demanding work, and currently at least 30% of the world's population gets insufficient exercise. This is primarily due to increasing use of mechanized transportation and a greater prevalence of labour-saving technology in the home. In children, there appear to be declines in levels of physical activity due to less walking and physical education. World trends in active leisure time physical activity are less clear. The World Health Organization indicates people worldwide are taking up less active recreational pursuits, while a study from Finland found an increase and a study from the United States found leisure-time physical activity has not changed significantly. A 2011 review of physical activity in children found that it may not be a significant contributor. In both children and adults, there is an association between television viewing time and the risk of obesity. A review found 63 of 73 studies (86%) showed an increased rate of childhood obesity with increased media exposure, with rates increasing proportionally to time spent watching television.

Genetics

Like many other medical conditions, obesity is the result of an interplay between genetic and environmental factors. Polymorphisms in various genes controlling appetite and metabolism predispose to obesity when sufficient food energy is present. As of 2006, more than 41 of these sites on the human genome have been linked to the development of obesity when a favourable environment is present. People with two copies of the FTO gene (fat mass and obesity associated gene) have been found on average to weigh 3–4 kg more and have a 1.67-fold greater risk of obesity compared with those without the risk allele.

The differences in BMI between people that are due to genetics varies depending on the population examined from 6% to 85%. Obesity is a major feature in several syndromes, such as Prader–Willi syndrome, Bardet–Biedl syndrome, Cohen syndrome, and MOMO syndrome. (The term "non-syndromic obesity" is sometimes used to exclude these conditions.) In people with early-onset severe obesity (defined by an onset before 10 years of age and body mass index over three standard deviations above normal), 7% harbour a single point DNA mutation.

Studies that have focused on inheritance patterns rather than on specific genes have found that 80% of the offspring of two obese parents were also obese, in contrast to less than 10% of the offspring of two parents who were of normal weight. Different people exposed to the same environment have different risks of obesity due to their underlying genetics. The thrifty gene hypothesis postulates that, due to dietary scarcity during human evolution, people are prone to obesity.

Their ability to take advantage of rare periods of abundance by storing energy as fat would be advantageous during times of varying food availability, and individuals with greater adipose reserves would be more likely to survive famine. This tendency to store fat, however, would be maladaptive in societies with stable food supplies. This theory has received various criticisms, and other evolutionarily-based theories such as the drifty gene hypothesis and the thrifty phenotype hypothesis have also been proposed.

Other Illnesses

Certain physical and mental illnesses and the pharmaceutical substances used to treat them can increase risk of obesity. Medical illnesses that increase obesity risk include several rare genetic syndromes (listed above) as well as some congenital or acquired conditions: hypothyroidism, Cushing's syndrome, growth hormone deficiency, and some eating disorders such as binge eating disorder and night eating syndrome. However, obesity is not regarded as a psychiatric disorder, and therefore is not listed in the DSM-IVR as a psychiatric illness.

The risk of overweight and obesity is higher in patients with psychiatric disorders than in persons without psychiatric disorders. Certain medications may cause weight gain or changes in body composition; these include insulin, sulfonylureas, thiazolidinediones, atypical antipsychotics, antidepressants, steroids, certain anticonvulsants (phenytoin and valproate), pizotifen, and some forms of hormonal contraception.

Social Determinants

While genetic influences are important to understanding obesity, they cannot explain the current dramatic increase seen within specific countries or globally. Though it is accepted that energy consumption in excess of energy expenditure leads to obesity on an individual basis, the cause of the shifts in these two factors on the societal scale is much debated. There are a number of theories as to the cause but most believe it is a combination of various factors. The correlation between social class and BMI varies globally. A review in 1989 found that in developed countries women of a high social class were less likely to be obese. No significant differences were seen among men of different social classes.

In the developing world, women, men, and children from high social classes had greater rates of obesity. An update of this review carried out in 2007 found the same relationships, but they were weaker. The decrease in strength of correlation was felt to be due to the effects of globalization. Among developed countries, levels of adult obesity, and percentage of teenage children who are overweight, are correlated with income inequality. A similar relationship is seen among US states: more adults, even in higher social classes, are obese in more unequal states.

Many explanations have been put forth for associations between BMI and social class. It is thought that in developed countries, the wealthy are able to afford more nutritious food, they are under greater social pressure to remain slim, and have more opportunities along with greater expectations for physical fitness. In undeveloped countries the ability to afford food, high energy expenditure with physical labour, and cultural values favouring a larger body size are believed to contribute to the observed patterns. Attitudes toward body weight held by people in one's life may also play a role in obesity. A correlation in BMI changes over time has been found among friends, siblings, and spouses. Stress and perceived low social status appear to increase risk of obesity. Smoking has a significant effect on an individual's weight. Those who quit smoking gain an average of 4.4 kilograms (9.7 lb) for men and 5.0 kilograms (11.0 lb) for women over ten years. However, changing rates of smoking have had little effect on the overall rates of obesity.

In the United States the number of children a person has is related to their risk of obesity. A woman's risk increases by 7% per child, while a man's risk increases by 4% per child. This could be partly explained by the fact that having dependent children decreases physical activity in Western parents. In the developing world urbanization is playing a role in increasing rate of obesity. In China overall rates of obesity are below 5%; however, in some cities rates of obesity are greater than 20%. Malnutrition in early life is believed to play a role in the rising rates of obesity in the developing world. Endocrine changes that occur during periods of malnutrition may promote the storage of fat once more food energy becomes available. Consistent with cognitive epidemiological data, numerous studies confirm that obesity is associated with cognitive deficits. Whether obesity causes cognitive deficits, or vice versa is unclear at present.

Other Factors

A number of reviews have found an association between short duration of sleep and obesity. Whether one causes the other is unclear. Even if shorts sleep does increase weight gain it is unclear if this is to a meaningful degree or increasing sleep would be of benefit. Certain aspects of personality are associated with being obese. Neuroticism, impulsivity, and sensitivity to reward are more common in people who are obese while conscientiousness and self-control are less common in people who are obese.

Management

The main treatment for obesity consists of dieting and physical exercise. Diet programs may produce weight loss over the short term, but maintaining this weight loss is frequently difficult and often requires making exercise and a lower food energy diet a permanent part of a person's lifestyle. Intensive behavioural interventions are recommended by the United States Preventive Services Task Force. In the short-term low carbohydrate diets appear better than low fat diets for weight loss. In the long term; however, all types of low-carbohydrate and low-fat diets appear equally beneficial. A 2014 review found that the heart disease and diabetes risks associated with different diets appear to be similar.

Promotion of the Mediterranean diets among the obese may lower the risk of heart disease. Decreased intake of sweet drinks is also related to weight-loss. Success rates of long-term weight loss maintenance with lifestyle changes are low, ranging from 2–20%. Dietary and lifestyle changes are effective in limiting excessive weight gain in pregnancy and improve outcomes for both the mother and the child.

Intensive behavioural counselling is recommended in those who are both obese and have other risk factors for heart disease. Five medications have evidence for long-term use orlistat, lorcaserin, liraglutide, phentermine–topiramate, and naltrexone–bupropion. They result in weight loss after one year ranged from 3.0 to 6.7 kg (6.6-14.8 lbs) over placebo. Orlistat, liraglutide, and naltrexone–bupropion are available in both the United States and Europe, whereas lorcaserin and phentermine–topiramate are available only in the United States.

European regulatory authorities rejected the latter two drugs in part because of associations of heart valve problems with lorcaserin and more general heart and blood vessel problems with phentermine–topiramate. Orlistat use is associated with high rates of gastrointestinal side effects and concerns have been raised about negative effects on the kidneys. There is no information on how these drugs affect longer-term complications of obesity such as cardiovascular disease or death.

Epidemiology

In earlier historical periods obesity was rare, and achievable only by a small elite, although already recognised as a problem for health. But as prosperity increased in the Early Modern period, it affected increasingly larger groups of the population. In 1997 the WHO formally recognized obesity as a global epidemic. As of 2008 the WHO estimates that at least 500 million adults (greater than 10%) are obese, with higher rates among women than men. The percentage of adults affected in the United States as of 2015–2016 is about 39.6% overall (37.9% of males and 41.1% of females).

The rate of obesity also increases with age at least up to 50 or 60 years old and severe obesity in the United States, Australia, and Canada is increasing faster than the overall rate of obesity. The OECD has projected an increase in obesity rates until at least 2030, especially in the United States, Mexico and England with rates reaching 47%, 39% and 35% respectively. Once considered a problem only of high-income countries, obesity rates are rising worldwide and affecting both the developed and developing world. These increases have been felt most dramatically in urban settings. The only remaining region of the world where obesity is not common is sub-Saharan Africa.

10 Starvation

Starvation is a severe deficiency in caloric energy intake, below the level needed to maintain an organism's life. It is the most extreme form of malnutrition. In humans, prolonged starvation can cause permanent organ damage and eventually, death. The term inanition refers to the symptoms and effects of starvation. Starvation may also be used as a means of torture or execution. According to the World Health Organization, hunger is the single gravest threat to the world's public health. The WHO also states that malnutrition is by far the biggest contributor to child mortality, present in half of all cases. Undernutrition is a contributory factor in the death of 3.1 million children under five every year.

Figures on actual starvation are difficult to come by, but according to the Food and Agriculture Organization, the less severe condition of undernourishment currently affects about 842 million people, or about one in eight (12.5%) people in the world population. The bloated stomach represents a form of malnutrition called kwashiorkor. The exact pathogenesis of kwashiorkor is not clear, as initially it was thought to relate to diets high in carbohydrates (e.g. maize) but low in protein. While many patients have low albumin, this is thought to be a consequence of the condition. Possible causes such as alfatoxin poisoning, oxidative stress, immune dysregulation and altered gut microbiota have been suggested. Treatment can help mitigate symptoms such as the pictured weight loss and muscle wasting, however prevention is of utmost importance.

Signs and Symptoms

Early symptoms include impulsivity, irritability, and hyperactivity. Atrophy (wasting away) of the stomach weakens the perception of hunger, since the perception is controlled by the volume of the stomach that is empty. Individuals experiencing starvation lose substantial fat (adipose tissue) and muscle mass as the body breaks down these tissues for energy.

Catabolysis is the process of a body breaking down its own muscles and other tissues in order to keep vital systems such as the nervous system and heart muscle (myocardium) functioning. The energy deficiency inherent in starvation causes fatigue and renders the victim more apathetic over time. As the starving person becomes too weak to move or even eat, their interaction with the surrounding world diminishes. In females, menstruation ceases when the body fat percentage is too low to support a fetus.

Victims of starvation are often too weak to sense thirst, and therefore become dehydrated. All movements become painful due to muscle atrophy and dry, cracked skin that is caused by severe dehydration. With a weakened body, diseases are commonplace. Fungi, for example, often grow under the oesophagus, making swallowing painful. Vitamin deficiency is also a common result of starvation, often leading to anaemia, beriberi, pellagra, and scurvy. These diseases collectively can also cause diarrhoea, skin rashes, edema, and heart failure.

Individuals are often irritable and lethargic as a result. There is insufficient scientific data on exactly how long people can live without food. Although the length of time varies with an individual's percentage of body fat and general health, one medical study estimates that in adults complete starvation leads to death within 8 to 12 weeks. Starvation begins when an individual has lost about 30%, or about a third, of their normal body weight. Once the loss reaches 40% death is almost inevitable.

Causes

Starvation is an imbalance between energy intake and energy expenditure. The body expends more energy than it takes in. This imbalance can arise from one or more medical conditions or circumstantial situations, which can include:

Medical Reasons
- Anorexia nervosa
- Bulimia nervosa
- Eating disorder, not otherwise specified
- Celiac disease
- Coma
- Major depressive disorder
- Diabetes mellitus
- Digestive disease
- Constant vomiting

Circumstantial Causes
- Child, elder or dependent abuse
- Famine – for any reason, such as political strife and war
- Hunger striking
- Excessive fasting
- Poverty

Biochemistry

With a typical high-carbohydrate diet, the human body relies on free blood glucose as its primary energy source. The level of blood sugar is tightly regulated; as blood glucose is consumed, the pancreas releases glucagon, a hormone that stimulates the liver to convert stored glycogen into glucose. The glycogen stores are ordinarily replenished after every meal, but if the store is depleted before it can be replenished, the body enters hypoglycemia, and begins the starvation response.

After the exhaustion of the glycogen reserve, and for the next 2–3 days, fatty acids become the principal metabolic fuel. At first, the brain continues to use glucose. If a non-brain tissue is using fatty acids as its metabolic fuel, the use of glucose in the same tissue is switched off. Thus, when fatty acids are being broken down for energy, all of the remaining glucose is made available for use by the brain.

After 2 or 3 days of fasting, the liver begins to synthesize ketone bodies from precursors obtained from fatty acid breakdown. The brain uses these ketone bodies as fuel, thus cutting its requirement for glucose. After fasting for 3 days, the brain gets 30% of its energy from ketone bodies. After 4 days, this may go upwards to 70% or more. Thus, the production of ketone bodies cuts the brain's glucose requirement from 80 g per day to 30 g per day, about 35% of normal, with 65% derived from ketone bodies.

But of the brain's remaining 30 g requirement, 20 g per day can be produced by the liver from glycerol (itself a product of fat breakdown). But this still leaves a deficit of about 10 g of glucose per day that must be supplied from some other source. This other source will be the body's own proteins.

After exhaustion of fat stores, the cells in the body begin to break down protein. This releases alanine and lactate produced from pyruvate into the bloodstream, which can be converted into glucose by the liver. Since much of human muscle mass is protein, this phenomenon is responsible for the wasting away of muscle mass seen in starvation. However, the body is able to selectively decide which cells will break down protein and which will not. About 2–3 g of protein has to be broken down to synthesize 1 g of glucose; about 20–30 g of protein is broken down each day to make 10 g of glucose to keep the brain alive. However, this number may decrease the longer the fasting period is continued in order to conserve protein.

Starvation ensues when the fat reserves are completely exhausted and protein is the only fuel source available to the body. Thus, after periods of starvation, the loss of body protein affects the function of important organs, and death results, even if there are still fat reserves left unused. In a leaner person, the fat reserves are depleted faster, the protein depletion occurs sooner, and therefore death occurs sooner. The ultimate cause of death is, in general, cardiac arrhythmia or cardiac arrest brought on by tissue degradation and electrolyte imbalances. Alternatively, things like metabolic acidosis may also cause death in starving people.

Prevention

Starvation can be caused by factors, other than illness, outside of the control of the individual. The Rome Declaration on World Food Security outlines several policies aimed at increasing food security and, consequently, preventing starvation. These include:	• Poverty reduction • Prevention of wars and political instability • Food aid • Agricultural sustainability • Reduction of economic inequality	Supporting farmers in areas of food insecurity through such measures as free or subsidized fertilizers and seeds increases food harvest and reduces food prices.

Treatment

Starving patients can be treated, but this must be done cautiously to avoid refeeding syndrome. Rest and warmth must be provided and maintained. Small sips of water mixed with glucose should be given in regular intervals. Fruit juices can also be given. Later, food can be given gradually in small quantities. The quantity of food can be increased over time. Proteins may be administered intravenously to raise the level of serum proteins.

11 Global Nutrition Challenges

The challenges facing global nutrition are disease, child malnutrition, obesity, and vitamin deficiency.

Disease
The most common non-infectious diseases worldwide, that contribute most to the global mortality rate, are cardiovascular diseases, various cancers, diabetes, and chronic respiratory problems, all of which are linked to poor nutrition. Nutrition and diet are closely associated with the leading causes of death, including cardiovascular disease and cancer. Obesity and high sodium intake can contribute to ischemic heart disease, while consumption of fruits and vegetables can decrease the risk of developing cancer. Food-borne and infectious diseases can result in malnutrition, and malnutrition exacerbates infectious disease. Poor nutrition leaves children and adults more susceptible to contracting life-threatening diseases such as diarrheal infections and respiratory infections. According to the WHO, in 2011, 6.9 million children died of infectious diseases like pneumonia, diarrhoea, malaria, and neonatal conditions, of which at least one third were associated with undernutrition.

Child Malnutrition
According to UNICEF, in 2011, 101 million children across the globe were underweight and one in four children, 165 million, were stunted in growth. Simultaneously, there are 43 million children under five who are overweight or obese. Nearly 20 million children under 5 suffer from severe acute malnutrition, a life-threatening condition requiring urgent treatment. According to estimations at UNICEF, hunger will be responsible for 5.6 million deaths of children under the age of five this year. These all represent significant public health emergencies. This is because proper maternal and child nutrition has immense consequences for survival, acute and chronic disease incidence, normal growth, and economic productivity of individuals. Childhood malnutrition is common and contributes to the global burden of disease. Childhood is a particularly important time to achieve good nutrition status, because poor nutrition has the capability to lock a child in a vicious cycle of disease susceptibility and recurring sickness, which threatens cognitive and social development. Undernutrition and bias in access to food and health services leaves children less likely to attend or perform well in school.

Undernutrition
UNICEF defines undernutrition “as the outcome of insufficient food intake (hunger) and repeated infectious diseases. Under nutrition includes being underweight for one’s age, too short for one’s age (stunted), dangerously thin (wasted), and deficient in vitamins and minerals (micronutrient malnutrient). Under nutrition causes 53% of deaths of children under five across the world. It has been estimated that undernutrition is the underlying cause for 35% of child deaths.

The Maternal and Child Nutrition Study Group estimate that under nutrition, “including fetal growth restriction, stunting, wasting, deficiencies of vitamin A and zinc along with suboptimum breastfeeding- is a cause of 3.1 million child deaths and infant mortality, or 45% of all child deaths in 2011”. When humans are undernourished, they no longer maintain normal bodily functions, such as growth, resistance to infection, or have satisfactory performance in school or work.

Major causes of under nutrition in young children include lack of proper breast feeding for infants and illnesses such as diarrhoea, pneumonia, malaria, and HIV/AIDS. According to UNICEF 146 million children across the globe, that one out of four under the age of five, are underweight. The amount of underweight children has decreased since 1990, from 33 percent to 28 percent between 1990 and 2004.

Underweight and stunted children are more susceptible to infection, more likely to fall behind in school, more likely to become overweight and develop non-infectious diseases, and ultimately earn less than their non-stunted co-workers. Therefore, undernutrition can accumulate deficiencies in health which results in less productive individuals and societies.

Many children are born with the inherent disadvantage of low birth weight, often caused by intrauterine growth restriction and poor maternal nutrition, which results in worse growth, development, and health throughout the course of their lifetime. Children born at low birthweight (less than 5.5 pounds or 2.5 kg), are less likely to be healthy and are more susceptible to disease and early death. Those born at low birthweight also are likely to have a depressed immune system, which can increase their chances of heart disease and diabetes later on in life.

Because 96% of low birthweight occurs in the developing world, low birthweight is associated with being born to a mother in poverty with poor nutritional status that has had to perform demanding labour. Stunting and other forms of undernutrition reduces a child’s chance of survival and hinders their optimal growth and health.

Stunting has demonstrated association with poor brain development, which reduces cognitive ability, academic performance, and eventually earning potential. Important determinants of stunting include the quality and frequency of infant and child feeding, infectious disease susceptibility, and the mother’s nutrition and health status.

Undernourished mothers are more likely to birth stunted children, perpetuating a cycle of undernutrition and poverty. Stunted children are more likely to develop obesity and chronic diseases upon reaching adulthood. Therefore, malnutrition resulting in stunting can further worsen the obesity epidemic, especially in low and middle income countries. This creates even new economic and social challenges for vulnerable impoverished groups.

Data on global and regional food supply shows that consumption rose from 2011-2012 in all regions. Diets became more diverse, with a decrease in consumption of cereals and roots and an increase in fruits, vegetables, and meat products. However, this increase masks the discrepancies between nations, where Africa, in particular, saw a decrease in food consumption over the same years. This information is derived from food balance sheets that reflect national food supplies, however, this does not necessarily reflect the distribution of micro and macronutrients. Often inequality in food access leaves distribution which uneven, resulting in undernourishment for some and obesity for others.

According to FAO, 868 million people (12% of the global population) were undernourished in 2012. This has decreased across the world since 1990, in all regions except for Africa, where undernourishment has steadily increased. The global financial, economic, and food price crisis in 2008 drove many people to hunger, especially women and children. The spike in food prices prevented many people from escaping poverty, because the poor spend a larger proportion of their income on food and farmers are net consumers of food. High food prices cause consumers to have less purchasing power and to substitute more-nutritious foods with low-cost alternatives.

Adult Overweight and Obesity

Malnutrition in industrialized nations is primarily due to excess calories and non-nutritious carbohydrates, which has contributed to the obesity epidemic affecting both developed and some developing nations. In 2008, 35% of adults above the age of 20 years were overweight (BMI 25 kg/m2), a prevalence that has doubled worldwide between 1980 and 2008. Also 10% of men and 14% of women were obese, with a BMI greater than 30. Rates of overweight and obesity vary across the globe, with the highest prevalence in the Americas, followed by European nations, where over 50% of the population is overweight or obese.

Obesity is more prevalent amongst high income and higher middle income groups than lower divisions of income. Women are more likely than men to be obese, where the rate of obesity in women doubled from 8% to 14% between 1980 and 2008. Being overweight as a child has become an increasingly important indicator for later development of obesity and non-infectious diseases such as heart disease. In several western European nations, the prevalence of overweight and obese children rose by 10% from 1980 to 1990, a rate that has begun to accelerate recently.

Vitamin and Mineral Malnutrition

Vitamins and minerals are essential to the proper functioning and maintenance of the human body. Globally, particularly in developing nations, deficiencies in iodine, iron, and zinc among others are said to impair human health when these minerals are not ingested in an adequate quantity. There are 20 trace elements and minerals that are essential in small quantities to body function and overall human health. Iron deficiency is the most common inadequate nutrient worldwide, affecting approximately 2 billion people.

Globally, anaemia affects 1.6 billion people, and represents a public health emergency in mothers and children under five. The World Health Organization estimates that there exists 469 million women of reproductive age and approximately 600 million preschool and school-age children worldwide who are anemic. Anaemia, especially iron-deficient anaemia, is a critical problem for cognitive developments in children, and its presence leads to maternal deaths and poor brain and motor development in children.

The development of anaemia affects mothers and children more because infants and children have higher iron requirements for growth. Health consequences for iron deficiency in young children include increased perinatal mortality, delayed mental and physical development, negative behavioural consequences, reduced auditory and visual function, and impaired physical performance. The harm caused by iron deficiency during child development cannot be reversed and result in reduced academic performance, poor physical work capacity, and decreased productivity in adulthood.

Mothers are also very susceptible to iron-deficient anaemia because women lose iron during menstruation, and rarely supplement it in their diet. Maternal iron deficiency anaemia increases the chances of maternal mortality, contributing to at least 18% of maternal deaths in low and middle income countries.

Vitamin A plays an essential role in developing the immune system in children, therefore, it is considered an essential micronutrient that can greatly affect health. However, because of the expense of testing for deficiencies, many developing nations have not been able to fully detect and address vitamin A deficiency, leaving vitamin A deficiency considered a silent hunger. According to estimates, subclinical vitamin A deficiency, characterized by low retinol levels, affects 190 million pre-school children and 19 million mothers worldwide.

The WHO estimates that 5.2 million of these children under 5 are affected by night blindness, which is considered clinical vitamin A deficiency. Severe vitamin A deficiency (VAD) for developing children can result in visual impairments, anaemia and weakened immunity, and increase their risk of morbidity and mortality from infectious disease.

This also presents a problem for women, with WHO estimating that 9.8 million women are affected by night blindness. Clinical vitamin A deficiency is particularly common among pregnant women, with prevalence rates as high as 9.8% in South-East Asia. Estimates say that 28.5% of the global population is iodine deficient, representing 1.88 billion individuals. Although salt iodization programs have reduced the prevalence of iodine deficiency, this is still a public health concern in 32 nations.

Moderate deficiencies are common in Europe and Africa, and over consumption is common in the Americas. Iodine-deficient diets can interfere with adequate thyroid hormone production, which is responsible for normal growth in the brain and nervous system. This ultimately leads to poor school performance and impaired intellectual capabilities.

Infant and Young Child Feeding

Improvement of breast feeding practices, like early initiation and exclusive breast feeding for the first two years of life, could save the lives of 1.5 million children annually. Nutrition interventions targeted at infants aged 0–5 months first encourages early initiation of breastfeeding. Though the relationship between early initiation of breast feeding and improved health outcomes has not been formally established, a recent study in Ghana suggests a causal relationship between early initiation and reduced infection-caused neo-natal deaths.

Also, experts promote exclusive breastfeeding, rather than using formula, which has shown to promote optimal growth, development, and health of infants. Exclusive breastfeeding often indicates nutritional status because infants that consume breast milk are more likely to receive all adequate nourishment and nutrients that will aid their developing body and immune system. This leaves children less likely to contract diarrheal diseases and respiratory infections.

Besides the quality and frequency of breastfeeding, the nutritional status of mothers affects infant health. When mothers do not receive proper nutrition, it threatens the wellness and potential of their children. Well-nourished women are less likely to experience risks of birth and are more likely to deliver children who will develop well physically and mentally.

Maternal undernutrition increases the chances of low-birth weight, which can increase the risk of infections and asphyxia in fetuses, increasing the probability of neonatal deaths. Growth failure during intrauterine conditions, associated with improper mother nutrition, can contribute to lifelong health complications. Approximately 13 million children are born with intrauterine growth restriction annually.

12 Int. Food Insecurity and Malnutrition

According to UNICEF, South Asia has the highest levels of underweight children under five, followed by sub-Saharan Africans nations, with Industrialized countries and Latin nations having the lowest rates.

United States
In the United States, 2% of children are underweight, with under 1% stunted and 6% are wasting. In the US, dietitians are registered (RD) or licensed (LD) with the Commission for Dietetic Registration and the American Dietetic Association, and are only able to use the title "dietitian," as described by the business and professions codes of each respective state, when they have met specific educational and experiential prerequisites and passed a national registration or licensure examination, respectively.

Anyone may call themselves a nutritionist, including unqualified dietitians, as this term is unregulated. Some states, such as the State of Florida, have begun to include the title "nutritionist" in state licensure requirements. Most governments provide guidance on nutrition, and some also impose mandatory disclosure/labelling requirements for processed food manufacturers and restaurants to assist consumers in complying with such guidance.

In the US, nutritional standards and recommendations are established jointly by the US Department of Agriculture and US Department of Health and Human Services. Dietary and physical activity guidelines from the USDA are presented in the concept of a plate of food which in 2011 superseded the MyPyramid food pyramid that had replaced the Four Food Groups.

The Senate committee currently responsible for oversight of the USDA is the Agriculture, Nutrition and Forestry Committee. Committee hearings are often televised on C-SPAN. The U.S. Department of Health and Human Services provides a sample week-long menu which fulfils the nutritional recommendations of the government. Canada's Food Guide is another governmental recommendation.

Industrialized Countries
According to UNICEF, the Commonwealth of Independent States has the lowest rates of stunting and wasting, at 14 percent and 3 percent. The nations of Estonia, Finland, Iceland, Lithuania and Sweden have the lowest prevalence of low birthweight children in the world- at 4%. Proper prenatal nutrition is responsible for this small prevalence of low birthweight infants. However, low birthweight rates are increasing, due to the use of fertility drugs, resulting in multiple births, women bearing children at an older age, and the advancement of technology allowing more pre-term infants to survive. Industrialized nations more often face malnutrition in the form of over-nutrition from excess calories and non-nutritious carbohydrates, which has contributed greatly to the public health epidemic of obesity. Disparities, according to gender, geographic location and socio-economic position, both within and between countries, represent the biggest threat to child nutrition in industrialized countries. These disparities are a direct product of social inequalities and social inequalities are rising throughout the industrialized world, particularly in Europe.

South Asia
South Asia has the highest percentage and number of underweight children under five in the world, at approximately 78 million children. Patterns of stunting and wasting are similar, where 44% have not reached optimal height and 15% are wasted, rates much higher than any other regions. This region of the world has extremely high rates of underweight children. According to a 2006 Unicef study, 46% of its child population under five is underweight. The same study indicates India, Bangladesh, and Pakistan combined account for half the globe's underweight child population.

South Asian nations have made progress towards the MDGs, considering the rate has decreased from 53% since 1990, however, a 1.7% decrease of underweight prevalence per year will not be sufficient to meet the 2015 goal. Some nations, such as Afghanistan, Bangladesh, and Sri Lanka, on the other hand, have made significant improvements, all decreasing their prevalence by half in ten years.

While India and Pakistan have made modest improvements, Nepal has made no significant improvement in underweight child prevalence. Other forms of undernutrition have continued to persist with high resistance to improvement, such as the prevalence of stunting and wasting, which has not changed significantly in the past 10 years. Causes of this poor nutrition include energy-insufficient diets, poor sanitation conditions, and the gender disparities in educational and social status.

Girls and women face discrimination especially in nutrition status, where South Asia is the only region in the world where girls are more likely to be underweight than boys. In South Asia, 60% of children in the lowest quintile are underweight, compared to only 26% in the highest quintile, and the rate of reduction of underweight is slower amongst the poorest.

Eastern/South Africa
The Eastern and Southern African nations have shown no improvement since 1990 in the rate of underweight children under five. They have also made no progress in halving hunger by 2015, the most prevalent Millennium Development Goal. This is due primarily to the prevalence of famine, declined agricultural productivity, food emergencies, drought, conflict, and increased poverty. This, along with HIV/AIDS, has inhibited the nutrition development of nations such as Lesotho, Malawi, Mozambique, Swaziland, Zambia and Zimbabwe. Botswana has made remarkable achievements in reducing underweight prevalence, dropping 4% in 4 years, despite its place as the second leader in HIV prevalence amongst adults in the globe. South Africa, the wealthiest nation in this region, has the second lowest proportion of underweight children at 12%, but has been steadily increasing in underweight prevalence since 1995. Almost half of Ethiopian children are underweight, and along with Nigeria, they account for almost one-third of the underweight under five in all of Sub-Saharan Africa.

West/Central Africa
West/Central Africa has the highest rate of children under five underweight in the world. Of the countries in this region, the Congo has the lowest rate at 14%, while the nations of Democratic Republic of the Congo, Ghana, Guinea, Mali, Nigeria, Senegal and Togo are improving slowly. In Gambia, rates decreased from 26% to 17% in four years, and their coverage of vitamin A supplementation reaches 91% of vulnerable populations. This region has the next highest proportion of wasted children, with 10% of the population under five not at optimal weight. Little improvement has been made between the years of 1990 and 2004 in reducing the rates of underweight children under five, whose rate stayed approximately the same. Sierra Leone has the highest child under five mortality rate in the world, due predominantly to its extreme infant mortality rate, at 238 deaths per 1000 live births. Other contributing factors include the high rate of low birthweight children (23%) and low levels of exclusive breast feeding (4%). Anaemia is prevalent in these nations, with unacceptable rates of iron deficient anaemia. The nutritional status of children is further indicated by its high rate of child wasting - 10%. Wasting is a significant problem in Sahelian countries – Burkina Faso, Chad, Mali, Mauritania and Niger – where rates fall between 11% and 19% of under fives, affecting more than 1 million children.

Middle East/North Africa
Six countries in the Middle East and North Africa region are on target to meet goals for reducing underweight children by 2015, and 12 countries have prevalence rates below 10%. However, the nutrition of children in the region as a whole has degraded for the past ten years due to the increasing portion of underweight children in three populous nations – Iraq, Sudan, and Yemen. Forty six percent of all children in Yemen are underweight, a percentage that has worsened by 4% since 1990. In Yemen, 53% of children under five are stunted and 32% are born at low birth weight. Sudan has an underweight prevalence of 41%, and the highest proportion of wasted children in the region at 16%. One percent of households in Sudan consume iodized salt. Iraq has also seen an increase in child underweight since 1990. Djibouti, Jordan, the Occupied Palestinian Territory (OPT), Oman, the Syrian Arab Republic and Tunisia are all projected to meet minimum nutrition goals, with OPT, Syrian AR, and Tunisia the fastest improving regions. This region demonstrates that undernutrition does not always improve with economic prosperity, where the United Arab Emirates, for example, despite being a wealthy nation, has similar child death rates due to malnutrition to those seen in Yemen.

East Asia/Pacific
The East Asia/Pacific region has reached its goals on nutrition, in part due to the improvements contributed by China, the region's most populous country. China has reduced its underweight prevalence from 19 percent to 8 percent between 1990 and 2002. China played the largest role in the world in decreasing the rate of children under five underweight between 1990 and 2004, halving the prevalence. This reduction of underweight prevalence has aided in the lowering of the under 5 mortality rate from 49 to 31 of 1000. They also have a low birthweight rate at 4%, a rate comparable to industrialized countries, and over 90% of households receive adequate iodized salts. However, large disparities exist between children in rural and urban areas, where 5 provinces in China leave 1.5 million children iodine deficient and susceptible to diseases. Singapore, Vietnam, Malaysia, and Indonesia are all projected to reach nutrition MDGs. Singapore has the lowest under five mortality rate of any nation, besides Iceland, in the world, at 3%. Cambodia has the highest rate of child mortality in the region (141 per 1,000 live births), while still its proportion of underweight children increased by 5 percent to 45% in 2000. Further nutrient indicators show that only 12 per cent of Cambodian babies are exclusively breastfed and only 14 per cent of households consume iodized salt.

Latin America/Caribbean
This region has undergone the fastest progress in decreasing poor nutrition status of children in the world. The Latin American region has reduced underweight children prevalence by 3.8% every year between 1990 and 2004, with a current rate of 7% underweight. They also have the lowest rate of child mortality in the developing world, with only 31 per 1000 deaths, and the highest iodine consumption. Cuba has seen improvement from 9 to 4 percent underweight under 5 between 1996 and 2004. The prevalence has also decreased in the Dominican Republic, Jamaica, Peru, and Chile. Chile has a rate of underweight under 5, at merely 1%. The most populous nations, Brazil and Mexico, mostly have relatively low rates of underweight under 5, with only 6% and 8%. Guatemala has the highest percentage of underweight and stunted children in the region, with rates above 45%. There are disparities amongst different populations in this region. For example, children in rural areas have twice the prevalence of underweight at 13%, compared to urban areas at 5%.

13 Nutrition Policy

Nutrition Interventions
Nutrition directly influences progress towards meeting the Millennium Goals of eradicating hunger and poverty through health and education. Therefore, nutrition interventions take a multi-faceted approach to improve the nutrition status of various populations. Policy and programming must target both individual behavioural changes and policy approaches to public health.

While most nutrition interventions focus on delivery through the health-sector, non-health sector interventions targeting agriculture, water and sanitation, and education are important as well. Global nutrition micro-nutrient deficiencies often receive large-scale solution approaches by deploying large governmental and non-governmental organizations. For example, in 1990, iodine deficiency was particularly prevalent, with one in five households, or 1.7 billion people, not consuming adequate iodine, leaving them at risk to develop associated diseases.

Therefore, a global campaign to iodize salt to eliminate iodine deficiency successfully boosted the rate to 69% of households in the world consuming adequate amounts of iodine. Emergencies and crises often exacerbate undernutrition, due to the aftermath of crises that include food insecurity, poor health resources, unhealthy environments, and poor healthcare practices. Therefore, the repercussions of natural disasters and other emergencies can exponentially increase the rates of macro and micronutrient deficiencies in populations. Disaster relief interventions often take a multi-faceted public health approach.

UNICEF's programming targeting nutrition services amongst disaster settings include nutrition assessments, measles immunization, vitamin A supplementation, provision of fortified foods and micronutrient supplements, support for breastfeeding and complementary feeding for infants and young children, and therapeutic and supplementary feeding. For example, during Nigeria's food crisis of 2005, 300,000 children received therapeutic nutrition feeding programs through the collaboration of UNICEF, the Niger government, the World Food Programme, and 24 NGOs utilizing community and facility based feeding schemes. Interventions aimed at pregnant women, infants, and children take a behavioural and program-based approach.

Behavioural intervention objectives include promoting proper breast-feeding, the immediate initiation of breastfeeding, and its continuation through 2 years and beyond. UNICEF recognizes that to promote these behaviours, healthful environments must be established conducive to promoting these behaviours, like healthy hospital environments, skilled health workers, support in the public and workplace, and removing negative influences. Finally, other interventions include provisions of adequate micro and macro nutrients such as iron, anaemia, and vitamin A supplements and vitamin-fortified foods and ready-to-use products.

Programs addressing micro-nutrient deficiencies, such as those aimed at anaemia, have attempted to provide iron supplementation to pregnant and lactating women. However, because supplementation often occurs too late, these programs have had little effect. Interventions such as women's nutrition, early and exclusive breastfeeding, appropriate complementary food and micronutrient supplementation have proven to reduce stunting and other manifestations of undernutrition. A Cochrane review of community-based maternal health packages showed that this community-based approach improved the initiation of breastfeeding within one hour of birth. Some programs have had adverse effects. One example is the "Formula for Oil" relief program in Iraq, which resulted in the replacement of breastfeeding for formula, which has negatively affected infant nutrition.

14 Macronutrients

Macronutrients	Deficiency	Toxicity	Sources	RDI
Energy			All Foods.	8700 kj
Total Fat (Sat. / Monosat. / Polysat.)	Dry skin, deficiencies for vitamin A, D, E, K, night blindness, infection susceptibility.	Cardiovascular disease.	Meats, nuts, oil, sweets, dairy products.	78 g
Saturated Fat			Dairy products, meats, sweets, nuts oils.	20 g
Cholesterol			Meat, poultry, full-fat dairy products.	300 mg
Carbohydrates				275 g
Sugars				50 g
Dietary Fibre				28 g
Protein				50 g

15 Micronutrients

Micronutrients are essential nutrients that the human body needs in very small amounts to function properly, maintain overall health, and prevent disease. Unlike macronutrients (carbohydrates, proteins, and fats), which provide energy and building blocks for the body in large quantities, micronutrients do not provide calories.

Vitamins: These are organic compounds that the body generally cannot synthesize on its own (with the exception of Vitamin D, which can be produced in the skin through sunlight exposure) and must be obtained through diet. Vitamins play a crucial role in various metabolic processes, including energy production, immune function, blood clotting, and maintaining healthy tissues. They are further classified as:

Fat-soluble vitamins: Vitamins A, D, E, and K. These dissolve in fat and can be stored in the body's fatty tissues and liver for longer periods.

Water-soluble vitamins: B vitamins (B1, B2, B3, B5, B6, B7, B9/folate, B12) and Vitamin C. These dissolve in water and are not stored in the body for long, meaning they need to be consumed more regularly.

Minerals: These are inorganic elements that the body needs for various functions, including bone health, fluid balance, nerve function, and enzyme activity. Minerals are obtained from the soil and water, which are then absorbed by plants or animals that we consume. Minerals are typically divided into:

Macrominerals: Needed in larger quantities (e.g., calcium, phosphorus, magnesium, sodium, potassium, chloride).
Trace minerals (or microminerals): Needed in smaller quantities (e.g., iron, zinc, iodine, selenium, copper, manganese, fluoride).

Despite being required in small amounts, micronutrients are critical for a vast array of bodily functions. Deficiencies in certain micronutrients can lead to severe health problems, impacting growth, development, immune response, cognitive function, and overall well-being. For example, iron deficiency can cause anemia, vitamin A deficiency can lead to blindness, and iodine deficiency can impair cognitive development. A diverse and balanced diet rich in fruits, vegetables, whole grains, and lean proteins is essential to ensure adequate intake of these vital micronutrients.

3 Vitamins

A vitamin is an organic molecule (or related set of molecules) that is an essential micronutrient that an organism needs in small quantities for the proper functioning of its metabolism. Essential nutrients cannot be synthesized in the organism, either at all or not in sufficient quantities, and therefore must be obtained through the diet. Vitamin C can be synthesized by some species but not by others; it is not a vitamin in the first instance but is in the second.

The term vitamin does not include the three other groups of essential nutrients: minerals, essential fatty acids, and essential amino acids. Most vitamins are not single molecules, but groups of related molecules called vitamers. For example, vitamin E consists of four tocopherols and four tocotrienols.

The thirteen vitamins required by human metabolism are: vitamin A (as all-trans-retinol, all-trans-retinyl-esters, as well as all-trans-beta-carotene and other provitamin A carotenoids), vitamin B1 (thiamine), vitamin B2 (riboflavin), vitamin B3 (niacin), vitamin B5 (pantothenic acid), vitamin B6 (pyridoxine), vitamin B7 (biotin), vitamin B9 (folic acid or folate), vitamin B12 (cobalamins), vitamin C (ascorbic acid), vitamin D (calciferols), vitamin E (tocopherols and tocotrienols), and vitamin K (quinones).

Vitamins have diverse biochemical functions. Vitamin A acts as a regulator of cell and tissue growth and differentiation. Vitamin D provides a hormone-like function, regulating mineral metabolism for bones and other organs. The B complex vitamins function as enzyme cofactors (coenzymes) or the precursors for them. Vitamins C and E function as antioxidants. Both deficient and excess intake of a vitamin can potentially cause clinically significant illness, although excess intake of water-soluble vitamins is less likely to do so.

Water Soluble Vitamins

Water Soluble Vitamins	Deficiency	Toxicity	Sources	RDI
Vitamin B1 (Thiamine)	Burning feet, weak extremities, rapid heart rate, swelling, anorexia, nausea, fatigue, gastrointestinal problems.	None.	Sunflower seeds, asparagus, lettuce, mushrooms, black beans, navy beans, lentils, spinach, peas, eggplant, tomato, tuna, whole wheat, soybeans.	1.2 mg
Vitamin B2 (Riboflavin)	Cracks and sores at corner of mouth and lips, dermatitis, conjunctivitis, photophobia, glossitis of tongue, anxiety, loss of appetite, fatigue.	Harmless intensification of urine colour.	Almonds, soybeans, mushrooms, spinach, whole wheat, yoghurt, mackerel, eggs, liver.	1.3 mg
Vitamin B3 (Niacin)	Dermatitis, diarrhoea, dementia, stomatitis.	No adverse affects known. May cause liver damage in amounts over 750mg over 3 months.	Mushrooms, asparagus, peanuts, brown rice, corn, leafy green veges, potato, lentil, barley, carrots, almonds, celery, turnips, peaches, chicken, tuna, salmon.	16 mg
Vitamin B4 (Choline)	Fatigue, memory loss, cognitive decline, learning disabilities, muscle aches, nerve damage, mood changes.	Vomiting, salivation, sweating, fishy body odour, dizziness, light-headedness.	Eggs, liver, peanuts, meat, poultry, dairy foods, pasta, rice, spinach, wheat, beets.	550 mg
Vitamin B5 (Pantothenic Acid)	Very unlikely.	Nausea, heartburn, diarrhoea.	Broccoli, lentils, split peas, avocado, whole wheat, mushrooms, sweet potato, sunflower seeds, cauliflower, leafy green veges, eggs, strawberries, liver.	5 mg
Vitamin B6 (Pyridoxine)	Chelosis, glossitis, stomatitis, dermatitis, sleeplessness, confusion, nervousness, depression, irritability, anaemia.	Painful neurological symptoms.	Whole wheat, brown rice, leafy green veges, potato, beans, banana, trout, spinach, tomato, avocado, walnuts, peanut butter, tuna, salmon, chicken.	1.7 mg
Vitamin B9 (Folate)	Anaemia, sprue, leukopenia, thrombocytopenia, weakness, weight loss, cracking and red tongue and mouth, diarrhoea.	None from food.	Leafy green veges, asparagus, broccoli, brussels sprouts, citrus fruits, spinach, whole grains, baked beans, green peas, avocado, peanuts, lettuce, tomato juice, banana.	400 µg
Vitamin B12 (Cobalamin)	Pernicious anaemia, neurological problems, sprue.	None.	Fortified cereals, liver, trout, salmon, tuna, haddock, egg.	2.4 µg
Vitamin B17 (Amygdalin)	Cancer.	None Known.	Apple, apricot, peach, pear, prune and plum stones, wheat sprouts, sprouted lentils, apple seeds, common beans, grains, lentil sprout, lima beans, almonds, mulberries, sesame seeds, linseeds, flax seeds, oats, barley.	?
Vitamin H (Biotin)	Very rare.	None.	Leafy green veges, most nuts, whole grain breads, avocado, raspberries, cauliflower, carrots, papaya, banana, salmon, eggs.	30 µg

Vitamin C (Ascorbic Acid)	Bruising, gum infections, lethargy, dental cavities, tissue swelling, dry hair + eyes + skin, bleeding gums, hair loss, joint pain, pitting edema, anaemia, slow healing wounds, bone fragility, scurvy.	Possible kidney stones, excess iron absorption, vitamin B12 deficiency, erosion of dental enamel.	Guava, bell pepper, kiwi, orange, grapefruit, strawberry, brussels sprouts, papaya, broccoli, sweet potato, pineapple, cauliflower, lemon juice, parsley.	90 mg

Fat Soluble Vitamins

Fat Soluble Vitamins	Deficiency	Toxicity	Sources	RDI
Vitamin A	Blindness, risk of infections, night blindness, dry eyes + skin, spots in eyeball.	Blurry vision, bone swelling, bone pain, poor appetite, dizziness, nausea, vomiting, sunlight sensitivity, dry skin.	Liver and fish oils, milk, eggs, leafy green veges, orange, yellow vegetables, tomato, fruits.	900 µg
Vitamin D (Cholecalciferol)	Often no symptoms, difficulty thinking clearly, bone pain, muscle weakness, soft bones, fatigue.	Calcium build-up in blood causing poor appetite, nausea, vomiting, weakness, frequent urination, kidney problems.	Sunlight on skin (Ultraviolet B rays), mushrooms, tuna, trout, sardines, mackerel, salmon, beef liver, cheese, egg yolk.	20 µg
Vitamin E (Tocopherol)	Anaemia, neurological deficits, reproduction and infertility disorders, age spots, cataracts, neurological damage, muscle + liver + brain function abnormalities.	Rarely has adverse effects, possible bleeding, fatigue, muscle weakness, nausea, diarrhoea.	Almonds, spinach, sweet potato, avocado, wheat germ, sunflower seeds, palm oil, trout, olive oil.	15 mg
Vitamin K	Easy bruising, excessive bleeding from wounds, gastrointestinal tract bleeding, blood in urine or stool.	None - Has a limited storage space for the vitamin.	Bacteria in intestinal tract, green leafy veges, brussels sprouts, broccoli, cauliflower, cabbage, fish, liver, meat, eggs.	120 µg

Anti-Vitamins

Anti-vitamins are chemical compounds that inhibit the absorption or actions of vitamins. For example, avidin is a protein in raw egg whites that inhibits the absorption of biotin; it is deactivated by cooking. Pyrithiamine, a synthetic compound, has a molecular structure similar to thiamine, vitamin B1, and inhibits the enzymes that use thiamine.

Examples:
Anti-Vitamin K:

Warfarin (and other coumarins like dicumarol): This is a well-known example used therapeutically as an anticoagulant (blood thinner). Warfarin works by inhibiting vitamin K epoxide reductase, an enzyme crucial for reactivating vitamin K. By blocking this enzyme, it prevents vitamin K from participating in the synthesis of essential blood clotting factors.

Sweet Clover Poisoning: Livestock consuming spoiled sweet clover containing dicumarol can suffer from severe bleeding due to its anti-vitamin K activity.

Anti-Vitamin B1 (Thiamine):

Thiaminases: These are enzymes that specifically break down thiamine, rendering it inactive. They are found in certain raw foods, particularly raw fish (like carp, clams, or some freshwater fish) and some ferns. Cooking usually inactivates thiaminases.
Pyrithiamine and Oxythiamine: These are synthetic compounds that structurally resemble thiamine and act as antagonists, competitively inhibiting enzymes that use thiamine. They are primarily used in research to induce thiamine deficiency.
2'-methoxy-thiamine (MTh): A naturally occurring antivitamin produced by some bacteria to kill competing bacteria by interfering with their B1 function.

Anti-Vitamin B2 (Riboflavin):

Roseoflavin (RoF): A naturally occurring antivitamin of riboflavin, produced by certain microorganisms.

Anti-Vitamin B6 (Pyridoxine):

Ginkgotoxin (GT): A naturally occurring antivitamin of pyridoxine, found in ginkgo seeds.
Desoxypyridoxine: A synthetic antagonist used in research.
Isoniazid: An antitubercular drug that can interfere with vitamin B6 metabolism, sometimes leading to B6 deficiency symptoms.

Anti-Vitamin B9 (Folate/Folic Acid):

Methotrexate: This is a potent antifolate drug widely used in chemotherapy to treat certain cancers and autoimmune diseases. It inhibits dihydrofolate reductase, an enzyme critical for converting folate into its active form, thereby blocking DNA synthesis and cell division in rapidly growing cells (like cancer cells).

Sulfonamides: These are a class of antibiotics that act as antifolates in bacteria. They interfere with the bacterial synthesis of folic acid, which is essential for bacterial growth.

Anti-Vitamin B12 (Cobalamin):

There are various synthetic analogues of Vitamin B12 that are designed to interfere with its metabolic functions, primarily used in research to study B12 deficiency.

Intake

Sources
For the most part, vitamins are obtained from the diet, but some are acquired by other means: for example, microorganisms in the gut flora produce vitamin K and biotin; and one form of vitamin D is synthesized in skin cells when they are exposed to a certain wavelength of ultraviolet light present in sunlight. Humans can produce some vitamins from precursors they consume: for example, vitamin A is synthesized from beta carotene; and niacin is synthesized from the amino acid tryptophan. The Food Fortification Initiative lists countries which have mandatory fortification programs for vitamins folic acid, niacin, vitamin A and vitamins B1, B2 and B12.

Deficient Intake
The body's stores for different vitamins vary widely; vitamins A, D, and B12 are stored in significant amounts, mainly in the liver, and an adult's diet may be deficient in vitamins A and D for many months and B12 in some cases for years, before developing a deficiency condition. However, vitamin B3 (niacin and niacinamide) is not stored in significant amounts, so stores may last only a couple of weeks. For vitamin C, the first symptoms of scurvy in experimental studies of complete vitamin C deprivation in humans have varied widely, from a month to more than six months, depending on previous dietary history that determined body stores.

Deficiencies of vitamins are classified as either primary or secondary. A primary deficiency occurs when an organism does not get enough of the vitamin in its food. A secondary deficiency may be due to an underlying disorder that prevents or limits the absorption or use of the vitamin, due to a "lifestyle factor", such as smoking, excessive alcohol consumption, or the use of medications that interfere with the absorption or use of the vitamin.

People who eat a varied diet are unlikely to develop a severe primary vitamin deficiency, but may be consuming less than the recommended amounts; a national food and supplement survey conducted in the US over 2003-2006 reported that over 90% of individuals who did not consume vitamin supplements were found to have inadequate levels of some of the essential vitamins, notably vitamins D and E.

Well-researched human vitamin deficiencies involve thiamine (beriberi), niacin (pellagra), vitamin C (scurvy), folate (neural tube defects) and vitamin D (rickets). In much of the developed world these deficiencies are rare; this is due to A) an adequate supply of food and B) the addition of vitamins to common foods (fortification). In addition to these classical vitamin deficiency diseases, some evidence has also suggested links between vitamin deficiency and a number of different disorders.

Excess Intake
Some vitamins have documented acute or chronic toxicity at larger intakes, which is referred to as hypertoxicity. The European Union and the governments of several countries have established Tolerable upper intake levels (ULs) for those vitamins which have documented toxicity (see table). The likelihood of consuming too much of any vitamin from food is remote, but excessive intake (vitamin poisoning) from dietary supplements does occur. In 2016, overdose exposure to all formulations of vitamins and multi-vitamin/mineral formulations was reported by 63,931 individuals to the American Association of Poison Control Centres with 72% of these exposures in children under the age of five. In the US, analysis of a national diet and supplement survey reported that about 7% of adult supplement users exceeded the UL for folate and 5% of those older than age 50 years exceeded the UL for vitamin A.

Effects of Cooking
The USDA has conducted extensive studies on the percentage losses of various nutrients from different food types and cooking methods. Some vitamins may become more "bio-available" – that is, usable by the body – when foods are cooked. The table below shows whether various vitamins are susceptible to loss from heat—such as heat from boiling, steaming, frying, etc. The effect of cutting vegetables can be seen from exposure to air and light. Water-soluble vitamins such as B and C dissolve into the water when a vegetable is boiled, and are then lost when the water is discarded.

Vitamin	Soluble in Water	Stable to Air Exposure	Stable to Light Exposure	Stable to Heat Exposure
Vitamin A	No	Partially	Partially	Relatively Stable
Vitamin C	Very Unstable	Yes	No	No
Vitamin D	No	No	No	No
Vitamin E	No	Yes	Yes	No
Vitamin K	No	No	Yes	No
Thiamine (B1)	Highly	No	?	> 100°C
Riboflavin (B2)	Slightly	No	In Solution	No
Niacin (B3)	Yes	No	No	No
Pantothenic Acid (B5)	Quite Stable	No	No	Yes
Vitamin (B6)	Yes	?	Yes	?
Biotin (B7)	Somewhat	?	?	No
Folic Acid (B9)	Yes	?	When Dry	At High Temp
Cobalamin (B12)	Yes	?	Yes	No

Multivitamins

In those who are otherwise healthy, there is little evidence that supplements have any benefits with respect to cancer or heart disease. Vitamin A and E supplements not only provide no health benefits for generally healthy individuals, but they may increase mortality, though the two large studies that support this conclusion included smokers for whom it was already known that beta-carotene supplements can be harmful.

A 2018 meta-analysis found no evidence that intake of vitamin D or calcium for community-dwelling elderly people reduced bone fractures. In Europe are regulations that define limits of vitamin (and mineral) dosages for their safe use as dietary supplements. Most vitamins that are sold as dietary supplements are not supposed to exceed a maximum daily dosage referred to as the tolerable upper intake level (UL).

Vitamin products above these regulatory limits are not considered supplements and should be registered as prescription or non-prescription (over-the-counter drugs) due to their potential side effects. The European Union, United States, Japan establish recommended upper intake levels. Dietary supplements often contain vitamins, but may also include other ingredients, such as minerals, herbs, and botanicals. Scientific evidence supports the benefits of dietary supplements for persons with certain health conditions.

In some cases, vitamin supplements may have unwanted effects, especially if taken before surgery, with other dietary supplements or medicines, or if the person taking them has certain health conditions. They may also contain levels of vitamins many times higher, and in different forms, than one may ingest through food.

This is the typical contents of a multivitamin:	• Vitamin A - 1250 IU • Vitamin B1 - 10 mg • Vitamin B2 - 10 mg • Vitamin B3 - 25 mg • Vitamin B6 - 2 mg • Vitamin B12 - 2 mcg • Vitamin C - 75 mg • Vitamin D3 - 400IU • Vitamin E - 10 IU • Calcium - 10 mg	• Phosphorous - 7.7 mg • Vitamin B5 - 8 mg • Copper - 1 mg • Iron - 5 mg • Magnesium - 36 mg • Manganese - 1 mg • Iodine - 145 mcg • Potassium - 5 mg • Zinc - 1.5 mg			

Multivitamin Tips
- Take 1 multivitamin every week in a survival condition to keep healthy.
- Wrap bottles of vitamins in duct tape to prevent light entering and destroying the nutrients and store in a cool, dry place.

4 Minerals

In the context of nutrition, a mineral is a chemical element required as an essential nutrient by organisms to perform functions necessary for life. However, the four major structural elements in the human body by weight (oxygen, hydrogen, carbon, and nitrogen), are usually not included in lists of major nutrient minerals (nitrogen is considered a "mineral" for plants, as it often is included in fertilizers). These four elements compose about 96% of the weight of the human body, and major minerals (macrominerals) and minor minerals (also called trace elements) compose the remainder.

Minerals, being elements, cannot be synthesized biochemically by living organisms Plants get minerals from soil Most of the minerals in a human diet come from eating plants and animals or from drinking water. As a group, minerals are one of the four groups of essential nutrients, the others of which are vitamins, essential fatty acids, and essential amino acids The five major minerals in the human body are calcium, phosphorus, potassium, sodium, and magnesium All of the remaining elements in a human body are called "trace elements". The trace elements that have a specific biochemical function in the human body are sulphur, iron, chlorine, cobalt, copper, zinc, manganese, molybdenum, iodine and selenium.

Most chemical elements that are ingested by organisms are in the form of simple compounds. Plants absorb dissolved elements in soils, which are subsequently ingested by the herbivores and omnivores that eat them, and the elements move up the food chain. Larger organisms may also consume soil (geophagia) or use mineral resources, such as salt licks, to obtain limited minerals unavailable through other dietary sources.

Bacteria and fungi play an essential role in the weathering of primary elements that results in the release of nutrients for their own nutrition and for the nutrition of other species in the ecological food chain. One element, cobalt, is available for use by animals only after having been processed into complex molecules (e.g., vitamin B12) by bacteria. Minerals are used by animals and microorganisms for the process of mineralizing structures, called "biomineralization", used to construct bones, seashells, eggshells, exoskeletons and mollusc shells.

Roles in Biological Processes

Dietary Element	RDA (US) (mg)	UL (US and EU) (mg)	Category	High Nutrient Density Dietary Sources	Term for Deficiency	Term for Excess
Potassium	4700	Not Established	A systemic electrolyte and is essential in coregulating ATP with sodium	Sweet potato, tomato, potato, beans, lentils, dairy products, seafood, banana, prune, carrot, orange	Hypokalemia	Hyperkalemia
Chlorine	2300	3600	Needed for production of hydrochloric acid in the stomach and in cellular pump functions	Table salt (sodium chloride) is the main dietary source.	Hypochloremia	Hyperchloremia
Sodium	1500	2300	A systemic electrolyte and is essential in coregulating ATP with potassium	Table salt (sodium chloride, the main source), sea vegetables, milk, and spinach.	Hyponatremia	Hypernatremia
Calcium	1200	2500; 2500	Needed for muscle, heart and digestive system health, builds bone, supports synthesis and function of blood cells	Dairy products, eggs, canned fish with bones (salmon, sardines), green leafy vegetables, nuts, seeds, tofu, thyme, oregano, dill, cinnamon.	Hypocalcaemia	Hypercalcaemia
Phosphorus	700	4000; 4000	A component of bones, cells, in energy processing, in DNA and ATP (as phosphate) and many other functions	Red meat, dairy foods, fish, poultry, bread, rice, oats. In biological contexts, usually seen as phosphate	Hypophosphatemia	Hyperphosphatemia
Magnesium	420	350; 250	Required for processing ATP and for bones	Spinach, legumes, nuts, seeds, whole grains, peanut butter, avocado	Hypomagnesemia, Magnesium Deficiency	Hypermagnesemia
Iron	18	45	Required for many proteins and enzymes, notably hemoglobin to prevent anaemia	Meat, seafood, nuts, beans, dark chocolate	Iron Deficiency	Iron Overload Disorder
Zinc	11	40; 25	Pervasive and required for several enzymes such as carboxypeptidase, liver alcohol dehydrogenase, and carbonic anhydrase.	Oysters*, red meat, poultry, nuts, whole grains, dairy products	Zinc Deficiency	Zinc Toxicity
Manganese	2.3	11	A cofactor in enzymefunctions	Grains, legumes, seeds, nuts, leafy vegetables, tea, coffee	Manganese Deficiency	Manganism
Iodine	0.15	1.1; 0.6	Required for synthesis of thyroid hormones, thyroxine andtriiodothyronine and to prevent goiter	Seaweed (kelp or kombu)*, grains, eggs, iodized salt	Iodine Deficiency	IodismHyperthyroidism
Chromium	0.035	Not Established	Involved in glucose and lipid metabolism, although its mechanisms of action in the body and the amounts needed for optimal health are not well-defined	Broccoli, grape juice (especially red), meat, whole grain products	Chromium Deficiency	Chromium Toxicity

HEALTH Minerals Roles in Biologi

Molybdenum	0.045	2; 0.6	The oxidases xanthine oxidase, aldehyde oxidase, and sulphite oxidase	Legumes, whole grains, nuts	Molybdenum Deficiency	Molybdenum Toxicity
Selenium	0.055	0.4; 0.3	Essential to activity ofantioxidant enzymes likeglutathione peroxidase	Brazil nuts, seafoods, organ meats, meats, grains, dairy products, eggs	Selenium Deficiency	Selenosis
RDA = Recommended Dietary Allowance			UL = Tolerable upper intake level; Figures shown are for adults age 31-50, male or female neither pregnant nor lactating		* One serving of seaweed exceeds the US UL of 1100 µg but not the 3000 µg UL set by Japan.	

Possibly Essential

Many ultratrace elements have been suggested as essential, but such claims have usually not been confirmed. Definitive evidence for efficacy comes from the characterization of a biomolecule containing the element with an identifiable and testable function. One problem with identifying efficacy is that some elements are innocuous at low concentrations and are pervasive (examples: silicon and nickel in solid and dust), so proof of efficacy is lacking because deficiencies are difficult to reproduce. Ultratrace elements of some minerals such as silicon and boron are known to have a role but the exact biochemical nature is unknown, and others such as arsenic are suspected to have a role in health, but with weaker evidence.

Element	Description	Excess
Bromine	Possibly important to basement membrane architecture and tissue development, as a needed catalyst to make collagen IV.	Bromism
Arsenic	Essential in rat, hamster, goat and chicken models, but no biochemical mechanism known in humans.	Arsenic Poisoning
Nickel	Nickel is an essential component of several enzymes, including urease and hydrogenase. Although not required by humans, some are thought to be required by gut bacteria, such as urease required by some varieties of Bifidobacterium. In humans, nickel may be a cofactor or structural component of certain metalloenzymes involved inhydrolysis, redox rections, and gene expression. Nickel deficiency depressed growth in goats, pigs, and sheep, and diminished circulating thyroid hormone concentration in rats.	Nickel Toxicity
Fluorine	Fluorine (as fluoride) is not considered an essential element because humans do not require it for growth or to sustain life. Research indicates that the primary dental benefit from fluoride occurs at the surface from topical exposure. Of the minerals in this table, fluoride is the only one for which the U.S. Institute of Medicine has established an adequate Intake.	Fluoride Poisoning
Boron	Boron is an essential plant nutrient, required primarily for maintaining the integrity of cell walls. Boron has been shown to be essential to complete the life cycle in representatives of all phylogenetic kingdoms, including the model species Danio rerio (zebrafish) and Xenopus laevis (African clawed frog). In animals, supplemental boron has been shown to reduce calcium excretion and activate vitamin D.	Nontoxic
Lithium	It is not known whether lithium has a physiological role in any species, but nutritional studies in mammals have indicated its importance to health, leading to a suggestion that it be classed as an essential trace element.	Lithium toxicity
Strontium	Strontium has been found to be involved in the utilization of calcium in the body. It has promoting action on calcium uptake into bone at moderate dietary strontium levels, but a rachitogenic (rickets-producing) action at higher dietary levels.	Rachitogenic (Causing Rickets)
Other	Silicon and vanadium have established, albeit specialized, biochemical roles as structural or functional cofactors in other organisms, and are possibly, even probably, used by mammals (including humans). By contrast, tungsten, the early lanthanides, and cadmium have specialized biochemical uses in certain lower organisms, but these elements appear not to be utilized by humans. Other elements considered to be possibly essential include aluminium, germanium, lead, rubidium, and tin.	Multiple

Macro-Minerals

Macro-Minerals	Deficiency	Toxicity	Sources	RDI
Calcium	Low bone mineral density, rickets, osteomalacia, osteoporosis.	Nausea, vomiting, constipation, dry mouth, thirst, increased urination, kidney stones.	Leafy green veges, legumes, molasses, sardines, trout, rhubarb, sesame seeds.	1.3 g
Phosphorus	Very rare.	Very Rare, soft tissue calcification.	Legumes, nuts, seeds, whole grains, eggs, fish, seafood, corn, wild rice.	1.25 g
Potassium	Not a result of insufficient dietary intake.	Occurs when kidneys can't deal with it, >18g, tingling of extremities, muscle weakness, nausea, vomiting, diarrhoea.	Sweet potato, tomato, leafy green veges, carrots, prunes, beans, molasses, fish, bananas, peaches, apricots, melon, potato, dates, raisins, mushrooms.	4.7 g
Magnesium	Very Rare.	None, supplements result in diarrhoea, low blood pressure, muscle weakness, cardiac arrest.	Legumes, nuts, seeds, whole grains, fruits, avocado.	420 mg
Salt (Sodium Chloride)	Increased fluid retention, nausea, vomiting, headache, cramps, fatigue, disorientation.	Increased fluid volume, nausea, vomiting, diarrhoea, abdominal cramps.	Any processed foods, whole grains, legumes, nuts, seeds, vegetables.	2.3 g

Micro-Minerals

Micro-Mineral	Deficiency	Toxicity	Sources	RDI
Iron	Anaemia	Poisoning in children, increased chronic disease risk, cardiovascular disease, cancer, neurodegenerative diseases.	Almonds, apricot, baked beans, dates, raisins, brown rice, leafy green veges, broccoli, pumpkin seeds, tuna, flounder, chicken, pork.	18 mg

Zinc	Decreased immunity, susceptible to infection, reduced incidents of infection.	Abdominal pain, diarrhoea, nausea, vomiting.	Mushrooms, spinach, sesame seeds, pumpkin seeds, peas, baked beans, cashews, whole grains, flounder, oats, chicken.	11 mg
Copper	Uncommon.	Rare, abdominal pain, nausea, vomiting, diarrhoea.	Mushrooms, leafy green veges, barley, sunflower seeds, navy beans, cashews, molasses, liver.	900 µg
Chromium	Impaired glucose tolerance and elevated circulating insulin.	DNA damage, possible kidney failure.	Lettuce, onion, tomato, whole grains, potatoes, mushrooms, oats, prunes, nuts.	35 µg
Fluoride	Increased dental caries.	Nausea, Abdominal pain, vomiting.	Water, tea, fish.	10 mg
Iodine	Impairs growth, decreased production of thyroid hormones.	Rare, burning mouth, throat and stomach, fever, diarrhoea.	Sea vegetables, iodized salt, eggs, strawberries, asparagus, leafy green veges.	150 µg
Selenium	Juvenile cardiomyopathy and chondrodystrophy.	Dermatologic lesions, brittle hair and nails, gastrointestinal disturbances, skin rash, fatigue.	Brazil Nuts, mushrooms, barley, salmon, whole grains, walnuts, eggs.	55 µg
Manganese	Rarely Observed.	From industrial exposure.	Leafy green veges, berries, lettuce, oats, brown rice.	2.3 mg
Molybdenum	Never Observed.	Very Rare.	Legumes, whole grains.	45 µg

5 Fitness

Fitness helps you to determine your current level of fitness with regards to your age, gender and culture and to help you maintain a proper level of fitness with regards to muscular strength, muscular endurance, cardiovascular endurance and flexibility. It also covers to a lesser extent your mental fitness, emotional fitness and spiritual fitness. Being fit and healthy is vital to maintaining your strength and vigour in stressful situations. This section details fitness levels, workout routines, muscle groups and endurance.

Subheadings

1. Fitness Level	**2. Muscular Strength**	**3. Muscular Endurance**	**4. Endurance**
5. Flexibility	**6. Exercises**	**7. Mental Fitness**	**8. Emotional Fitness**
9. Spiritual Fitness			

1 Fitness Level

Physical fitness is a state of health and well-being and, more specifically, the ability to perform aspects of sports, occupations and daily activities. Physical fitness is generally achieved through proper nutrition, moderate-vigorous physical exercise, and sufficient rest.

Before the industrial revolution, fitness was defined as the capacity to carry out the day's activities without undue fatigue. However, with automation and changes in lifestyles physical fitness is now considered a measure of the body's ability to function efficiently and effectively in work and leisure activities, to be healthy, to resist hypokinetic diseases, and to meet emergency situations.

	Ideal BMI Height (m²) / Weight (kg) (1.88 x 1.88) / 73 = 20.65 BMI Underweight: < 18.5 Ideal: 18.5 to 24.9 Overweight: 25-29.9 Obese: 30+	**Aerobic Fitness** Heart rate at rest. A healthy heart rate is 60-100 bpm. Target Heart Rate Zone during intense workouts is - 50-75% more. **Target Heart Rates** 25yo - 98-146 bpm 35yo - 93-138 bpm 45yo - 88-131 bpm 55yo - 83-123 bpm 65yo - 78-116 bpm		

Body fat composition refers to the amount of fat on your body. A 45kg (100 pound) person with a 25% body fat composition will have a lean body mass of 34kg (75 pounds).

Fit	Men must have a body fat composition lower than 17 percent. Women must have a body fat composition lower than 24 percent. The average man tends to have about 18 to 24 percent body fat, while the average woman has 25 to 31 percent body fat.
Workout Routine	

2 Muscular Strength

This is the "power" that helps you to lift and carry heavy objects. Without muscular strength, your body would be weak and unable to keep up with the demands placed upon it.

Muscle Groups	

HEALTH | Fitness | Muscular

3 Muscular Endurance

Endurance is the ability of your muscles to perform contractions for extended periods of time. Rather than just lifting or carrying something for a few seconds, the muscles are used for minutes.

Travel Fitness	Practice carrying the BOB to get used to the weight, lighten the load if you can't travel very far at a time.

4 Cardiovascular Endurance

Cardiovascular endurance is your body's ability to keep up with exercise like running, jogging, swimming, cycling, and anything that forces your cardiovascular system (lungs, heart, blood vessels) to work for extended periods of time. Together, the heart and lungs fuel your body with the oxygen needed by your muscles, ensuring that they have the oxygen needed for the work they are doing.

5 Flexibility

Flexibility is one of the most important, yet often overlooked, components of physical fitness. Without flexibility, the muscles and joints would grow stiff and movement would be limited. Flexibility training ensures that your body can move through its entire range of motion without pain or stiffness.

6 Exercises

7 Mental Fitness

8 Emotional Fitness

9 Spiritual Fitness

6 Hygiene

Keeping clean will not only ward away illnesses but help you to feel refreshed and fairly normal in your day to day routine. Good hygiene will also discourage vermin and other parasites that feast on faeces and food.

Hygiene Items

This is a list of common hygiene items you should have handy.

Soap

Fatty acid content should be > 70%. Moisture content should be < 20%.

Toilet Paper

Imperative to stock unless you use a rag and water. The average person uses 8 sheets of toilet paper per trip or about 22 rolls per year.

Towel

For drying off when you become wet to prevent hypothermia.

HEALTH Hygiene Hygiene Items

Toothbrush

For cleaning your teeth to prevent dental conditions which can be some of the most painful.

Toothpaste

Toothpaste is a paste or gel used with a toothbrush to clean teeth, remove dental plaque, and improve oral hygiene.

Razor / Trimmer

For trimming body hair, trimming hair around wounds and cutting facial hair to help masks fit better.

Shampoo

Shampoo is used for cleaning hair and scalp.

Facewasher

A facewasher is used for washing the face and gentle skin cleansing.

Tampons

Tampons are used for absorbing menstrual flow internally during menstruation.

Quick Lime

Quick Line in a composting toilet covers excrement to avoid smells and scavengers. Spread at regular intervals over waste where covering with earth or ash isn't possible. Dangerous for eyes and respiratory tract, also reacts with water generating high temperatures and may explode.

Sawdust

Sawdust, in a composting toilet, is used to cover waste, absorb moisture, and facilitate the composting process.

House Hygiene

Hygiene methods that should be undertaken in a house during a disaster.

Dish Washing

Vacuuming

Clean Floors

Having clean floors can be the difference between survival and dying without access to medicine. You may have to get out of the house fast which is difficult when there's gear all over the floors, not to mention you could trip and fall on it. Clean floors will deter hiding places for pests and make it easier to stay healthy.

House Waste Discipline

Camp Hygiene

Hygiene methods that should be undertaken when bugging out or when outside.

Clothing Hygiene

Change clothes every few days and underwear everyday. Put clothes near the fire if they develop mould.

Food Hygiene

Tie food up away from the ground if keeping it another day. Never leave scraps near the campsite which could attract vermin. Gut and clean meat at least 100m from camp. Always wash hands before cooking and handling food.

Washing Dishes	
Toilet Hygiene	

Camp Waste Discipline

Waste Discipline	Waste discipline and sanitation are complementary actions that aid in preventative health and hygiene. Waste materials include grey water (sullage water, such as greasy and soapy water from kitchens and ablutions), human waste (faeces, urine), organic waste (kitchen food waste) and hazardous materials (lithium batteries, lead-acid vehicle batteries and POL). All human activity produces waste and if these are not disposed of correctly, the incidence of disease will increase and adversely affect efficiency.
Waste Disposal	Bury waste at least 20cm (8 in) deep and 100 metres (328ft) from water and camp. All categories of waste should be disposed of in a manner which avoids pollution of water supplies, prevents breeding of flies and rodents, and keep odours to an absolute minimum. Careful planning of camp sites and the types and duration of deployments provide a guide to waste disposal measures. There must be careful sitting of latrines and the deep burial of human waste to avoid the breeding of flies. Kitchen washing-up facilities, ablutions, showers, and facilities to dry clothing and aids to kitchen hygiene must all be kept clean and free of residues that can collect bacteria or create pollution.

Body Care

This section details how to keep various parts of your body clean in a disaster situation.

Washing	Wash regularly and keep clothes clean to keep diseases at bay. Removes the sweat worked up over the duration of the day. Check body during washing for ticks, parasites and bites. In snowy environments where water bathing isn't possible, build a sweat lodge to get clean.
Hair Maintenance	Hair can become a real knotty mess if long enough and not maintained properly. Poor hair hygiene can cause dandruff from the build-up of oil and can lead to skin infections such as Tinea Capitis.
Face Cleaning	After sleeping we often have a build up of Rheum around the eyes which should be removed.
Nose Cleaning	
Ear Cleaning	
Teeth Cleaning	Rinse mouth after every meal to remove some food debris. Brush teeth with a fluoride paste if possible, if no paste is available brush them simple to remove any food particles.
Armpit Cleaning	
Hand Hygiene	Wash your hands constantly when preparing food and after every toilet visit.
Fingernail Hygiene	Germs can hide under your nails so be sure to clean them thoroughly particularly when working with food.
Genital Cleaning	
Female Hygiene	
Bottom Cleaning	
Foot Care	
Toenail Hygiene	Toenails as with fingernails can trap dirt between them and the skin and being on the foot it's prone to more dirt than usual.

Blood & Bone Hygiene

Blood & Bone

Blood Cleaning	
Bone Removal	

Corpse Removal

Collect
Collect bodies and move them to the body holding area for storage ensuring mapping and records of the burial as well as the grave's contents. Separate body parts should be treated as individual bodies.

HEALTH | Hygiene | Blood & Bone Hygiene | Corpse Removal

Protect
Bodies should be stored individually in body bags. Where unavailable use plastic sheets or bed sheets to protect the dignity of the remains. Refrigerated storage is best. Personal documents shouldn't be separated from the remains.

Record
Keep a detailed record of every body.
- Unique Body Number
- Brought/Recorded by (name)
- From (exact location)
- Date
- Place the body is stored or buried
- Situation, taking pictures is recommended for identification

Track
Track each body/body bag and any related evidence. The burial site should be tagged and marked indelibly with the assigned body number. Ensure the number is visible to allow tracking of the remains. Ensure chain of custody is recorded about all movements.

Medical

General medical routines, tips and advice

"Whatever you do, always give 100%. Unless you're donating blood."
Bill Murray

Introduction

This category is for any generic medical knowledge such as blood groups, triage and medical equipment. The medical category is split up into 5 different sections as it would have been too big if it was left as one. The categories are: MEDICAL (This Category), MEDICATION, ILLNESS, INJURY and EMOTIONAL.

Purpose	The aim of MEDICAL is to provide a quick triage point for those who are sick or injured to be able to find the correct section quickly. It also goes into details about the human body and bodily systems to provide an overview of how it works. There is a section for the recommended medical items to have stored away for a disaster before finishing the section with information on quitting addictions and preparing to die.
Lost?	***** **QUICK TRIAGE (If you're injured or sick and looking for the correct section)** ***** ● **Sections under ILLNESS:** Radiation Sickness, Parasitic Infections, Bacterial Infections, Viral Infections, Fungal Infections, Altitude Sickness, Poisoning, Chemical Agents, Biological Agents. ● **Sections under INJURY:** Surface Wound & Bruises, Internal Injuries (Back Pain, Cerebral Hemorrhage, Bone Fractures, Dislocation, Concussion) Open Wounds, Avulsion, Burns, Environmental (Anaphylaxis, Heat Stroke, Hypothermia, Hyperthermia, Motion Sickness, Aero-otitis Media), Atmosphere (Asphyxiation, Drowning, Choking, Hypoxia, Carbon Monoxide Poisoning), Animal & Plant (Bites and Stings), Childbirth, Toothaches. ● **Sections under EMOTIONAL:** Depression, Anxiety, Stress, Confidence, Relaxation, Memory & Dementia, Grief & Loss, Postnatal Depression, New Parents, Body Image, Family & Friends and Healthy Living.

● For medications and recommended doses, see the MEDICATION section.
● For curing ailments naturally and herbal remedies, see the NATURAL REMEDIES section.
● For eating disorders, see the HEALTH > Nutrients section.
● See the GEAR > Household Gear > Home Clinic section for another list of medical supplies.

Contents

1 Medical Basics

This is basic medical advice and facts such as blood groups and triage.

Red Blood Cell Compatibility

Blood Type Rarities (Below)		O- Donor (Universal Donor)	O+ Donor	A- Donor	A+ Donor	B- Donor	B+ Donor	AB- Donor	AB+ Donor
6.6% Can receive blood from 6.6% of donors	O- Recipient	Compatible	Not Compatible	Not Compatible	Not Compatible	Not Compatible	Not Compatible	Not Compatible	Not Compatible

3.4% Can receive blood from 100% of donors	AB+ Recipient (Universal Recipient)	Compatible	Compatible	Compatible	Compatible	Compatible	Compatible	Compatible	Compatible

Triage

Triage is the process of determining the priority of patients' treatments based on the severity of their condition. This rations patient treatment efficiently when resources are insufficient for all to be treated immediately.

- Those who are likely to live, regardless of what care they receive;
- Those who are unlikely to live, regardless of what care they receive;
- Those for whom immediate care might make a positive difference in outcome.

Black / Expectant	They are so severely injured that they will die of their injuries, possibly in hours or days (large-area burns, severe trauma, lethal radiation dose), or in life-threatening medical crisis that they are unlikely to survive given the care available (cardiac arrest, septic shock, severe head or chest wounds); their treatment is usually palliative, such as being given painkillers, to reduce suffering.
Red / Immediate	They require immediate surgery or other life-saving intervention, and have first priority for surgical teams or transport to advanced facilities; they "cannot wait" but are likely to survive with immediate treatment.
Yellow / Observation	Their condition is stable for the moment but requires watching by trained persons and frequent re-triage, will need hospital care (and would receive immediate priority care under "normal" circumstances). Their condition is stable for the moment but requires watching by trained persons and frequent re-triage, will need hospital care (and would receive immediate priority care under "normal" circumstances).
Green / Wait (Walking Wounded)	They will require a doctor's care in several hours or days but not immediately, may wait for a number of hours or be told to go home and come back the next day (broken bones without compound fractures, many soft tissue injuries).
White / Dismiss (Walking Wounded)	They have minor injuries; first aid and home care are sufficient, a doctor's care is not required. Injuries are along the lines of cuts and scrapes, or minor burns.

Tool Sterilization

Sterilization of equipment is vital prior to performing any medical operations - even minor ones. Equipment should be cleaned after every use to remove organic and inorganic matter from the surfaces.

Clean Yourself	Ensure you are clean before attempting to sterilize any equipment or it will be in vain. Use gloves where possible.
Oven Sterilization	Put equipment into sterile sealable bags. Heat in the oven at 300°F for 150 minutes+ or 340°F for an hour+.
Microwave Sterilization	The non-ionizing radiation destroys the microorganisms on the surface of the tools. The microwave stream process is performed on the tools and the heat is used to kill the organisms. It can be used quickly and reliably.
Hydrogen Peroxide	Sterilizing tools with hydrogen peroxide typically involves a specialized low-temperature process called Vaporized Hydrogen Peroxide (VHP) or gas plasma sterilization. Tools are first meticulously cleaned and dried. Then, they are placed in a sealed chamber where a hydrogen peroxide solution is vaporized and introduced under vacuum. This hydrogen peroxide vapor permeates the instruments, chemically oxidizing and destroying microorganisms. Finally, the vapor is vented and broken down into harmless water and oxygen, leaving no toxic residue on the now-sterile tools. This method is used for heat-sensitive instruments and cannot be replicated by simply soaking tools in household hydrogen peroxide.
Ozone Gas Sterilization	Ozone gas sterilization, used for heat-sensitive medical tools, begins with thoroughly cleaning and drying the instruments. They are then placed inside a sealed chamber where an ozone generator produces ozone (O3) gas from medical-grade oxygen or ambient air. This ozone gas fills the chamber, acting as a powerful oxidizing agent that penetrates and destroys microorganisms on the tool surfaces. After a specific exposure time, the ozone is safely converted back into oxygen, leaving no toxic residues and making the instruments ready for use.
Chemical Sterilization	• Peracetic Acid • Formaldehyde • Gluaraldehyde

Boiling Water	Gently boil the instruments for 30 minutes. May not kill all spores however and could rust instruments.
Bleach Soak	Make a 0.1% bleach solution using Bleach or Calcium Hypochlorite and let it sit for 15-30 minutes. Keep to the time or rusting will occur.
Isopropyl Alcohol	Soak in 70-100% isopropyl alcohol for 30 minutes. You an also ignite the solution. The flame and alcohol will sterilize the instruments but eventually causes damage to them.
Pressure Cooker	Clean equipment in a pressure cooker for a canning cycle length to kill all germs and bacteria. It's recommended to have a specific cooker set aside for this purpose.

Death Diagnosis

This section assists in identifying if someone is still alive or has passed away.

The three main signs of death or strong indications that a warm-blooded animal is no longer alive is:
- Respiratory arrest (no breathing)
- Cardiac arrest (no pulse)
- Brain death (no neuronal activity)

The stages that follow after death are:
- Pallor mortis, paleness which happens in the 15–120 minutes after death
- Algor mortis, the reduction in body temperature following death. This is generally a steady decline until matching the ambient temperature
- Rigor mortis, the limbs of the corpse become stiff (Latin rigor) and difficult to move or manipulate
- Livor mortis, a settling of the blood in the lower (dependent) portion of the body
- Putrefaction, the beginning signs of decomposition
- Decomposition, the reduction into simpler forms of matter, accompanied by a strong, unpleasant odor.
- Skeletonization, the end of decomposition, where all soft tissues have decomposed, leaving only the skeleton.
- Fossilization, the natural preservation of the skeletal remains formed over a very long period

The concept of death is a key to human understanding of the phenomenon. There are many scientific approaches and various interpretations of the concept. Additionally, the advent of life-sustaining therapy and the numerous criteria for defining death from both a medical and legal standpoint, have made it difficult to create a single unifying definition.

One of the challenges in defining death is in distinguishing it from life. As a point in time, death would seem to refer to the moment at which life ends. Determining when death has occurred is difficult, as cessation of life functions is often not simultaneous across organ systems. Such determination therefore requires drawing precise conceptual boundaries between life and death. This is difficult, due to there being little consensus on how to define life.

Today, where a definition of the moment of death is required, doctors and coroners usually turn to "brain death" or "biological death" to define a person as being dead; people are considered dead when the electrical activity in their brain ceases. It is presumed that an end of electrical activity indicates the end of consciousness. Suspension of consciousness must be permanent, and not transient, as occurs during certain sleep stages, and especially a coma. In the case of sleep, EEGs can easily tell the difference.

2 Supplies

A list of ideal recommended medical supplies covering medical, trauma and dental supplies.

Medical Supplies

A list of recommended medical supplies for a long-haul disaster.

First Aid Manual	Provides instructions and guidance for responding to medical emergencies and injuries.
Oral antibiotics	Medications taken by mouth to treat bacterial infections throughout the body.
Antibiotic Ointment and/or Antibacterial Herbal Salves	Topical preparations applied to skin wounds to prevent or treat bacterial infections.
Ace Bandages	Elastic wraps used to provide compression and support for sprains, strains, or to secure dressings. Have multiple sizes.
Kerlix or Rolled Gauze	Absorbent cotton rolls used for wound dressing, padding, or securing splints.
Steri Strips, Bandaids and Butterfly Bandages	Adhesive strips used to close small wounds, protect minor cuts, and approximate skin edges respectively. You should have hundreds of them in all different shapes and sizes.
Gauze/Dressings	Sterile or clean pads used to cover wounds, absorb exudate, and protect injuries. Heaps of sterile and non-sterile 4x4s. Include lots of non-adherent “telfa” pads so healing wounds won’t stick to the dressing
ABD pads	Large, thick, absorbent dressings used for heavy bleeding wounds or to cushion injuries.
Tapes	Adhesive strips used to secure dressings, bandages, or splints to the skin. Include duct tape and paper tape.
Quality Bandage Scissor/Trauma Shears	Specialized scissors designed to safely cut through clothing or bandages in emergency situations.
Pliable Splinting Material (“Sam” Splints)	Flexible, moldable splints used to immobilize injured limbs or suspected fractures. You should have everything from finger splints to 36 inch rolls that you can cut to size.
Moleskin with Padding	Adhesive material used to protect skin from friction, prevent blisters, or cushion painful areas.
Scalpels	Extremely sharp surgical blades used for precise cutting of skin or tissue in medical procedures. Blades #10, #11, #15 are the most popular

CPR Masks	Barrier devices used to safely deliver rescue breaths during cardiopulmonary resuscitation (CPR).
Paracord	Strong cordage that can be repurposed in medical emergencies for splinting, securing dressings, or creating slings.
Nitrile Gloves	Disposable, latex-free gloves worn as a barrier to protect both the caregiver and patient from contamination. Buy hypoallergenic to help prevent reactions.
Antibacterial Soap	Soap containing antibacterial agents used to cleanse skin and reduce bacterial load, especially before or after wound care.
Syringes	For wound irrigation, cleaning and precise measurement of liquids.
Antiseptics	Chemical agents applied to living tissue (skin) to reduce the possibility of infection. Hibiclens is excellent.
Universal Cervical Collar	A rigid device used to immobilize the neck and stabilize the cervical spine following suspected neck injuries.
OPAs (Oral Airways)	Devices inserted into the mouth to maintain an open airway by preventing the tongue from obstructing the throat. It prevents occlusion of an airway due to an allergic reaction while waiting for the epi-pen or Benadryl to kick in.
Alcohol Pads	Small pads saturated with alcohol used to disinfect skin prior to injections or to clean small wounds. It also makes a great firestarter.
N-95s Masks	Respirator masks designed to filter out airborne particles, including infectious agents, protecting the wearer's respiratory system.
Dermabond (Rx) / Super Glue	Medical-grade tissue adhesive (Dermabond) or household super glue (in emergency situations) used to close small, clean skin wounds.
Sutures	Threads used to surgically close wounds or to ligate blood vessels. 2-0 nylon (don't bother with 3-0 or smaller unless working with delicate skin on the face, eyelids, etc.)
Skin Stapler/Remover and 2 Adson Forceps	Tools used to quickly close skin wounds with surgical staples and to remove them, with forceps assisting in tissue manipulation.
Curved and Straight Kelly Clamps	Surgical instruments used to clamp blood vessels or grasp tissue, particularly for hemostasis. Also used to remove foreign objects from wounds.
Safety Pins	Simple pins used to secure bandages, slings, or clothing.
Magnifying Glass	Used to closely examine small wounds, splinters, or skin conditions. Can also be used to start fires.
Light Source	Provides illumination for examining injuries, performing procedures, or navigating in low-light conditions. Get a pen light, head lamp, glow stick and flashlight.
Fire Starter	Used to create fire, which can provide warmth, purify water, or sterilize small metal instruments. Include a container for boiling water in your supplies.
Mylar Blankets	Lightweight, reflective blankets used to retain body heat and prevent hypothermia in emergency situations.
Wool Blankets	Provide warmth and insulation to prevent or treat hypothermia, especially in cold environments.
Thermometer	Device used to measure body temperature to assess for fever or hypothermia.
Ammonia Inhalants	Small crushable ampules that release ammonia fumes, used to revive someone who has fainted or is lightheaded.
Cotton Sheets	Clean fabric used for covering patients, creating temporary bandages, or for general hygiene.
Clotting Powders	Topical agents applied to wounds to help stop bleeding by promoting blood coagulation. Quikclot, Celox – (cayenne pepper powder may help minor bleeding)
Tourniquet	A device used to compress a limb to stop severe arterial or venous bleeding, typically as a last resort. An example is the CAT Tourniquet, only use in severe bleeding that will not stop with direct pressure or clotting agents.
Snake Bite Kit	Contains items (like compression bandages or an extractor device) to administer first aid for snakebites, although modern protocols emphasize pressure immobilization over extraction. It must use within 30 seconds of the bite or it is useless.
Tweezers	Small forceps used for removing splinters, ticks, or foreign objects from wounds.
Re-useable GEL packs	Flexible packs that can be heated or cooled to apply thermotherapy for pain, swelling, or muscle aches.
Instant Ice Packs	Break the interior bag and shake to have instant cold.
Hand Warmers	Chemical packs that provide localized heat to warm hands and prevent frostbite in cold conditions. Expose the iron filings to oxygen to begin the reaction. They typically reach 55°c at their hottest.
Flashlight	Provides essential illumination for examining injuries, performing procedures such as gauging alertness, or moving safely in low light.
Pocket Defibrillator	A portable automated external defibrillator (AED) used to deliver an electric shock to restore normal heart rhythm in sudden cardiac arrest.
Aquatabs	Tablets containing a disinfectant (like sodium dichloroisocyanurate) used to purify drinking water in emergency situations.
Athlete's Foot Powder	Antifungal powder used to treat and prevent fungal infections on the feet. The powder lasts longer than creams.
Monistat Cream (or equivalent)	Antifungal cream used to treat yeast infections, commonly vaginal yeast infections in women.
Salt	Can be used medically as an antiseptic rinse for wounds, a gargle for sore throats, or for rehydration solutions.

Prescription Medications	Drugs prescribed by a medical professional to treat specific conditions, ranging from pain relief to chronic disease management.

Dental Care

Medical items to assist with dental care and toothaches.

Dental Mirror	Allows you to see around the mouth much easier.
Dental Extractors/Elevator	Used to loosen and remove teeth from their sockets.
Dental Filling Material	Substances like amalgam or composite resin used to restore the structure and function of teeth damaged by decay or trauma. You can buy commercial or mix your own from zinc oxide powder and 2 drops clove oil.
Baking soda, Hydrogen Peroxide and 2 drops of Peppermint Oil	A homemade mixture sometimes used as a mouth rinse for general gum hygiene or temporary relief of minor mouth irritation.
Hydrogen Peroxide	Makes a great oral mouthwash/gargle for gum swelling and irritations. Do not use on open skin wounds after the initial wound cleaning! Hydrogen peroxide may damage healing cells inside an open skin wound.
Extra Essential Clove Bud Oil	A natural analgesic and antiseptic used topically to temporarily relieve toothache pain due to its eugenol content. Apply to the offending gum directly.
Toothbrush and Toothpaste	To keep the teeth clean and prevent future problems.
Dental Floss	A thin thread used to remove plaque and food particles from between teeth and under the gumline where a toothbrush cannot reach.

Misc Items

Any other medical items which may be of use.

Eye Cup	A small, cup-shaped device used to rinse or apply medication to the eye.
Eye Wash	A sterile solution used to rinse irritants, foreign bodies, or chemicals from the eyes.
Eye Pads / Eye Patch	Helps to prevent further infection of the eye and allows an infected eye to heal.
Claritin (Non-Drowsy Antihistamine)	An oral medication used to relieve allergy symptoms like sneezing, runny nose, and itching without causing drowsiness.
Benadryl (Drowsy Antihistamine)	An oral medication primarily used to relieve allergy symptoms, stings, reduce itching, or as a sleep aid, with a common side effect of drowsiness.
Epi-pen (Rx)	A pre-filled auto-injector of epinephrine used to treat severe allergic reactions (anaphylaxis) as an emergency measure.
Aspirin, Tylenol, and Ibuprofen	Common over-the-counter medications used to reduce pain, fever, and inflammation (Aspirin and Ibuprofen also have anti-inflammatory properties).
Imodium	An oral medication used to treat diarrhea by slowing down bowel movements.
Hydro-Cortisone Cream	A topical corticosteroid cream used to reduce skin inflammation, itching, and irritation from conditions like rashes, insect bites, or eczema.
Vaseline/Petroleum Jelly	A topical ointment used to protect and moisturize skin, aid in wound healing, and prevent friction. Great to make non-stick dressings.
Aloe Vera	A gel derived from the aloe plant used topically to soothe minor burns, skin irritations, and promote healing.
Gatorade or Rehydration Tablets/Powders	Oral solutions or mixes used to replenish electrolytes and fluids lost due to dehydration from vomiting, diarrhea, or intense physical activity.
Multi-vitamins / Vitamin C	Dietary supplements used to ensure adequate intake of essential vitamins for overall health or to boost the immune system. Include zinc, and other supplements to strengthen the immune system

3 First Aid

First aid is the first and immediate assistance given to any person suffering from either a minor or serious illness or injury, with care provided to preserve life, prevent the condition from worsening, or to promote recovery. It includes initial intervention in a serious condition prior to professional medical help being available, such as performing cardiopulmonary resuscitation (CPR) while waiting for an ambulance, as well as the complete treatment of minor conditions, such as applying a plaster to a cut. First aid is generally performed by someone with basic medical training.

ABC

ABC and its variations (DRSABCD) are initialism mnemonics for essential steps used by both medical professionals and lay persons (such as first aiders) when dealing with a patient. In its original form it stands for Airway, Breathing, and Circulation. The protocol was originally developed as a memory aid for rescuers performing cardiopulmonary resuscitation, and the most widely known use of the initialism is in the care of the unconscious or unresponsive patient, although it is also used as a reminder of the priorities for assessment and treatment of patients in many acute medical and trauma situations, from first-aid to hospital medical treatment. Airway, breathing, and circulation are all vital for life, and each is required, in that order, for the next to be effective.

A Airway	**Airway** Open their mouth - if foreign material is present Place them in the recovery position. Clear their airway with your fingers
B Breathing	**Breathing** Check for breathing - look, listen and feel. **Normal Breathing:** Place in the recovery position. **Not Normal Breathing:** If they aren't breathing normally, check the circulation (medical experts) or begin CPR (below).
C Circulation	**Circulation (In trained medical personnel, otherwise it can stand for CPR for the lay-person)** Once oxygen can be delivered to the lungs by a clear airway and efficient breathing, there needs to be a circulation to deliver it to the rest of the body.

DRSABCD

DRSABCD incorporates the additional S for "shout" (in the UK) or "send for help" (in Australia), and D for "defibrillation".

D Danger	**Danger** Ensure the area is safe for yourself, others and the patient.
R Response	**Response** Check for a response - ask their name - squeeze their shoulders. **Response** - Make them comfortable and monitor their response. **No Response** - Continue below
S Send for Help	**Send for Help** Call '911' (America) or '000' (Australia) for an ambulance or ask another person the make the call. Request them to find you an AED if available. Remember the relevant number for your country.
A Airway	**Airway** Open their mouth - if foreign material is present Place them in the recovery position. Clear their airway with your fingers

- Airway management takes precedence over any other injury including spinal.
- Ideally leave the victim in the position they are found unless they are demonstrating signs of an obstructed airway – gentle handling at all times if they must be moved.
- To clear the airway – open mouth and turn head to allow drainage
- If airway becomes compromised in resuscitation roll onto side to allow clearance and then reassess for responsiveness.
- Remember your airway opening manoeuvres – head tilt chin lift in adults, neutral position in infants.

B Breathing	**Breathing** Check for breathing - look, listen and feel. **Normal Breathing:** Place in the recovery position. **Not Normal Breathing:** If they aren't breathing normally, start CPR (below).

Causes of ineffective breathing include – central causes (e.g. opiates, brainstem injury)/ acute upper airway obstruction / chest wall paralysis or diaphragmatic paralysis / intrapulmonary cause / drowning / suffocation.
Principles in BLS – Look, listen and feel for effective breathing for 10 seconds – if absent declare cardiac arrest. Caution with agonal breaths or see saw breathing where there is a partial obstruction.

Rescue breath technique:
- Open the airway using head tilt chin lift manoeuvre or jaw thrust
- Place mouth over open mouth with nostrils pinched (with care not to lose tilt).
- Give one breath of 1 second duration to give adequate volume to give chest rise
- Causes of failure – obstruction, insufficient air or poor seal
- Alternative methods include: mouth to nose (operator choice, infants, trismus), mouth to mask, mouth to neck stoma.

C CPR	**CPR** Start CPR - 30 chest compressions : 2 breaths Continue CPR until help arrives or the patient recovers.

- Compressions should be started in BLS protocol if victim is unresponsive and has abnormal breathing including agonal respirations. Pulse check is no longer required though it can be done if trained and comfortable to do so.
- Bystander CPR is actively encouraged and should be coached
- Recommended ration remains 30:2 – ARC recommends for all ages though other resources suggest 15:2 in paediatrics. This is a BLS recommendation for simplification. If an expert is present do a ratio of 15:2 in children.
- Compression only CPR is also an option – see links below demonstrating
- All rescuers should perform compressions and if trained and willing, they should be encouraged to provide rescue breaths.
- Paediatric arrests are often hypoxic therefore if there are two people 15:2 should be encouraged and rescue breaths should in particular be encouraged. Consider further rescue breaths prior to going for help
- Location: lower half of the sternum – consensus for simplicity (lower ineffective with risk of visceral injury, higher will be ineffective)
- Rate: 100-120 BPM "Staying alive"

MEDICAL First Aid DRSABCD

- Depth: Adult: 5cm (2inches) to max of 6cm. Paediatric: 1/3rd of depth or 4cm infants, 5cm children
- Allow for chest recoil and avoid leaning on the chest
- Minimise interruptions
- Multiple rescuers – rotate roles – evidence would suggest fatigue of compressor at around 1 minute though only realised by compressor at 5 minutes. Guidelines suggest rotation every 2 minutes. Ensure early help and early access to AED as priority.
- Early defibrillation remains a priority: Defibrillation within 3-5 minutes can produce survival rates as high as 50-70%.
- Continue compressions post defibrillation – the AED will generally prompt you.
- Pulse checks in BLS are not recommended. Rescuers can look for signs of life every 2 minutes / rhythm check if AED prompts you (AED generally has a 2 minute timer between rhythm checks)

D **Defibrillator**	**Defibrillator** Apply defibrilator if available and follow the voice prompts.

AED training is generally required. The machine verbally talks the rescuer through the process of its use when the power button is activated. Pads placement is demonstrated in pictures on the back of them. The end cable from the pads is inserted into the AED. The AED will announce that it is analysing the rhythm and will request hands off the patient i.e. to cease compressions and to stand clear. It will advise if a shock is required or not.

Should a shock be required the AED will charge and deliver this shock. The rescuer's priority is to maintain scene safety and to ensure all other parties stand clear of the activated shocking defibrillator. Chest compressions must be resumed after a shock is delivered or if no shock is advised.

Continue until the patient responds OR you are unable to continue OR a health care professional arrives and takes over care or directs cessation

Risks

- Is there a risk to the victim if they are not in cardiac arrest and they receive chest compressions? The consensus guideline was based on low quality evidence but a high level recommendation. ILCOR argue on a risk benefit basis that the risk of omitting CPR to those in cardiac arrest is greater than causing injury to the non-arrested patient. Observational studies on those who received CPR in the absence of cardiac arrest report a low degree of complications.
- Is there a risk to the rescuer? There is a documented low-risk of disease transmission based on a systematic review done in training and clinical scenarios. However there is some suggestion that using barriers such as face mask reduce bacterial transmission to the rescuer therefore if available this is recommended.

CPR

The basic application of the ABC principle is in first aid, and is used in cases of unconscious patients to start treatment and assess the need for, and then potentially deliver, cardiopulmonary resuscitation.

In this simple usage, the rescuer is required to open the airway (using a technique such as "head tilt - chin lift"), then check for normal breathing. These two steps should provide the initial assessment of whether the patient will require CPR or not.

In the event that the patient is not breathing normally, the current international guidelines (set by the International Liaison Committee on Resuscitation or ILCOR) indicate that chest compressions should be started.

Previously, the guidelines indicated that a pulse check should be performed after the breathing was assessed, and this made up the 'circulation' part of the initialism, but this pulse check is no longer recommended for lay rescuers. Some trainers continue to use circulation as the label for the third step in the process, since performing chest compressions is effectively artificial circulation, and when assessing patients who are breathing, assessing 'circulation' is still important. However, some trainers now use the C to mean Compressions in their basic first aid training.

Mouth-to-Mouth Resuscitation

Mouth-to-mouth resuscitation, a form of artificial ventilation, is the act of assisting or stimulating respiration in which a rescuer presses their mouth against that of the victim and blows air into the person's lungs. Artificial respiration takes many forms, but generally entails providing air for a person who is not breathing or is not making sufficient respiratory effort on their own. It is used on a patient with a beating heart or as part of cardiopulmonary resuscitation (CPR) to achieve the internal respiration.

Pulmonary ventilation (and hence external respiration) is achieved through manual insufflation of the lungs either by the rescuer blowing into the patient's lungs, or by using a mechanical device to do so. This method of insufflation has been proved more effective than methods which involve mechanical manipulation of the patient's chest or arms, such as the Silvester method. It is also known as expired air resuscitation (EAR), expired air ventilation (EAV), rescue breathing, or colloquially the kiss of life. It was introduced as a life saving measure in 1950.

Insufflation, also known as 'rescue breaths' or 'ventilations', is the act of mechanically forcing air into a patient's respiratory system. This can be achieved via a number of methods, which will depend on the situation and equipment available. All methods require good airway management to perform, which ensures that the method is effective. These methods include:

- Mouth-to-mouth - This involves the rescuer making a seal between his or her mouth and the patient's mouth and 'blowing', to pass air into the patient's body
- Mouth-to-nose - In some instances, the rescuer may need or wish to form a seal with the patient's nose. Typical reasons for this include maxillofacial injuries, performing the procedure in water or the remains of vomit in the mouth
- Mouth-to-mouth and nose - Used on infants (usually up to around 1 year old), as this forms the most effective seal
- Mouth-to-mask – Most organisations recommend the use of some sort of barrier between rescuer and patient to reduce cross infection risk. One popular type is the 'pocket mask'. This may be able to provide higher tidal volumes than a Bag Valve Mask.

Most training organisations recommend that in any of the methods involving mouth-to-patient, that a protective barrier is used, to minimise the possibility of cross infection (in either direction). Barriers available include pocket masks and keyring-sized face shields. These barriers are an example of Personal Protective Equipment to guard the face against splashing, spraying or splattering of blood or other potentially infectious materials.

Mouth-to-Mouth on Children Under 8

Mouth-to-Mouth-and-Nose Resuscitation on a Child Under Age 8 or on an Infant

1	Place the child on a hard, flat surface.
2	Look into the mouth and throat to ensure that the airway is clear. If an object is present, try to sweep it out with your fingers. If unsuccessful and the object is blocking the airway, apply the Heimlich maneuver. If vomiting occurs, turn the child onto his or her side and sweep out the mouth with two fingers.
3	Tilt the head back slightly to open the airway.
4	Place your mouth tightly over the nose and mouth. Blow two quick, shallow breaths (smaller breaths than you would give to an adult). Watch for the chest to rise.
5	Remove your mouth. Look for the chest to fall as the child exhales.

6	Listen for the sounds of breathing. Feel for the child's breath on your cheek. If breathing does not start on its own, repeat the procedure.

Mouth-to-Mouth on Adults and Children 8+

Mouth-to-Mouth Resuscitation on a Child Age 8 or Older or on an Adult

1	Make sure the person is lying on a hard, flat surface. Look into the mouth and throat to ensure that the airway is clear. If an object is present, try to sweep it out with your fingers (wear disposable surgical gloves if they are available). Apply the Heimlich maneuver if unsuccessful and the object is blocking the airway. If vomiting occurs, turn the person on his or her side and sweep out the mouth with two fingers. Do not place your finger in the mouth if the person is rigid or is having a seizure.
2	Tilt the head back slightly to open the airway. Put upward pressure on the jaw to pull it forward.
3	Pinch the nostrils closed with thumb and index finger. Place your mouth tightly over the person's mouth. Use a mouthpiece if one is available. Blow two quick breaths and watch for the person's chest to rise.
4	Release the nostrils. Look for the person's chest to fall as he or she exhales. Listen for the sounds of breathing. Feel for the person's breath on your cheek. If the person does not start breathing on his or her own, repeat the procedure.

AED

An AED, or Automated External Defibrillator, is used to help those experiencing sudden cardiac arrest. It's a sophisticated, yet easy-to-use, medical device that can analyze the heart's rhythm and, if necessary, deliver an electrical shock, or defibrillation, to help the heart re-establish an effective rhythm.

Sudden cardiac arrest is among the leading causes of death in the United States. More than 350,000 people will suffer a cardiac arrest this year. Currently, the only way to restore a regular heart rhythm during cardiac arrest is to use an AED. Of course, you can – and should – request the assistance of trained medical professionals. However, because the average response time for first responders once 911 / 000 is called is 8-12 minutes, and for each minute defibrillation is delayed, the odds of survival are reduced by approximately 10%, having access to and AED and knowing how to use one, is critical.

Using an AED

1	Complete the CHECK and CALL steps.
2	As soon as an AED is available, turn it on and follow the voice prompts.
3	Remove clothing and attach pads correctly ● Remove all clothing covering the chest. If necessary, wipe the chest dry ● Place one pad on the upper right side of the chest ● Place the other pad on the lower left side of the chest, a few inches below the left armpit Note: If the pads may touch, place one pad in the middle of the chest and the other pad on the back, between the shoulder blades
4	Plug the pad connector cable into the AED, if necessary
5	Prepare to let the AED analyze the heart's rhythm ● Make sure no one is touching the person ● Say, "CLEAR!" in a loud, commanding voice
6	Deliver a shock, if the AED determines one is needed ● Make sure no one is touching the person ● Say, "CLEAR!" in a loud, commanding voice ● Push the "shock" button to deliver the shock
7	After the AED delivers the shock, or if no shock is advised, immediately start CPR, beginning with compressions.

4 Body Systems

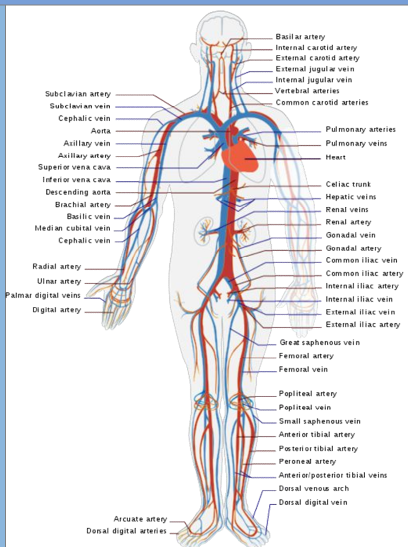
Details of the main systems of the human body. Each system is covered in greater detail below.

Circulatory System	Circulates blood around the body via the heart, arteries and veins, delivering oxygen and nutrients to organs and cells and carrying their waste products away.
Digestive System	System to absorb nutrients and remove waste via the gastrointestinal tract, including the mouth, oesophagus, stomach and intestines.
Excretory System	Eliminates waste from the body.
Endocrine System	Influences the function of the body using hormones.
Integumentary System	Skin, hair, nails, sweat and other exocrine glands.
Exocrine System	Skin, hair, nails, sweat and other exocrine glands.
Immune System	Defends the body against pathogens that may endanger the body.
Lymphatic System	The system comprising a network of lymphatic vessels that carry a clear fluid called lymph.
Muscular System	Enables the body to move using muscles.
Nervous System	Collects and processes information from the senses via nerves and the brain and tells the muscles to contract to cause physical actions.
Urinary System	The system where the kidneys filter blood to produce urine.
Reproductive System	The sex organs required for the production of offspring.
Respiratory System	Brings air into and out of the lungs to absorb oxygen and remove carbon dioxide.

Skeletal System	Bones maintain the structure of the body and its organs.
Hematopoietic System	Creates the cells that travel in blood.

Subheadings

1 Circulatory System



The circulatory system, also called the cardiovascular system or the vascular system, is an organ system that permits blood to circulate and transport nutrients (such as amino acids and electrolytes), oxygen, carbon dioxide, hormones, and blood cells to and from the cells in the body to provide nourishment and help in fighting diseases, stabilize temperature and pH, and maintain homeostasis.

The circulatory system includes the lymphatic system, which circulates lymph. The passage of lymph takes much longer than that of blood. Blood is a fluid consisting of plasma, red blood cells, white blood cells, and platelets that is circulated by the heart through the vertebrate vascular system, carrying oxygen and nutrients to and waste materials away from all body tissues.

Lymph is essentially recycled excess blood plasma after it has been filtered from the interstitial fluid (between cells) and returned to the lymphatic system. The cardiovascular (from Latin words meaning "heart" and "vessel") system comprises the blood, heart, and blood vessels. The lymph, lymph nodes, and lymph vessels form the lymphatic system, which returns filtered blood plasma from the interstitial fluid (between cells) as lymph.

The circulatory system of the blood is seen as having two components, a systemic circulation and a pulmonary circulation. While humans, as well as other vertebrates, have a closed cardiovascular system (meaning that the blood never leaves the network of arteries, veins and capillaries), some invertebrate groups have an open cardiovascular system.

The lymphatic system, on the other hand, is an open system providing an accessory route for excess interstitial fluid to be returned to the blood. The more primitive, diploblastic animal phyla lack circulatory systems. Many diseases affect the circulatory system. This includes cardiovascular disease, affecting the cardiovascular system, and lymphatic disease affecting the lymphatic system. Cardiologists are medical professionals which specialise in the heart, and cardiothoracic surgeons specialise in operating on the heart and its surrounding areas. Vascular surgeons focus on other parts of the circulatory system.

Cardiovascular System

The essential components of the human cardiovascular system are the heart, blood and blood vessels. It includes the pulmonary circulation, a "loop" through the lungs where blood is oxygenated; and the systemic circulation, a "loop" through the rest of the body to provide oxygenated blood. The systemic circulation can also be seen to function in two parts – a macrocirculation and a microcirculation. An average adult contains five to six quarts (roughly 4.7 to 5.7 litres) of blood, accounting for approximately 7% of their total body weight. Blood consists of plasma, red blood cells, white blood cells, and platelets. Also, the digestive system works with the circulatory system to provide the nutrients the system needs to keep the heart pumping. The cardiovascular systems of humans are closed, meaning that the blood never leaves the network of blood vessels. In contrast, oxygen and nutrients diffuse across the blood vessel layers and enter interstitial fluid, which carries oxygen and nutrients to the target cells, and carbon dioxide and wastes in the opposite direction. The other component of the circulatory system, the lymphatic system, is open.

Arteries
Oxygenated blood enters the systemic circulation when leaving the left ventricle, through the aortic semilunar valve. The first part of the systemic circulation is the aorta, a massive and thick-walled artery. The aorta arches and gives branches supplying the upper part of the body after passing through the aortic opening of the diaphragm at the level of thoracic ten vertebra, it enters the abdomen. Later it descends down and supplies branches to abdomen, pelvis, perineum and the lower limbs. The walls of aorta are elastic. This elasticity helps to maintain the blood pressure throughout the body. When the aorta receives almost five litres of blood from the heart, it recoils and is responsible for pulsating blood pressure. Moreover, as aorta branches into smaller arteries, their elasticity goes on decreasing and their compliance goes on increasing.

Capillaries
Arteries branch into small passages called arterioles and then into the capillaries. The capillaries merge to bring blood into the venous system.

Veins
Capillaries merge into venules, which merge into veins. The venous system feeds into the two major veins: the superior vena cava – which mainly drains tissues above the heart – and the inferior vena cava – which mainly drains tissues below the heart. These two large veins empty into the right atrium of the heart.

Portal Veins
The general rule is that arteries from the heart branch out into capillaries, which collect into veins leading back to the heart. Portal veins are a slight exception to this. In humans the only significant example is the hepatic portal vein which combines from capillaries around the gastrointestinal tract where the blood absorbs the various products of digestion; rather than leading directly back to the heart, the hepatic portal vein branches into a second capillary system in the liver.

Heart
The heart pumps oxygenated blood to the body and deoxygenated blood to the lungs. In the human heart there is one atrium and one ventricle for each circulation, and with both a systemic and a pulmonary circulation there are four chambers in total: left atrium, left ventricle, right atrium and right ventricle. The right atrium is the upper chamber of the right side of the heart. The blood that is returned to the right atrium is deoxygenated (poor in oxygen) and passed into the right ventricle to be pumped through the pulmonary artery to the lungs for re-oxygenation and removal of carbon dioxide. The left atrium receives newly oxygenated blood from the lungs as well as the pulmonary vein which is passed into the strong left ventricle to be pumped through the aorta to the different organs of the body.

Coronary Vessels
The heart itself is supplied with oxygen and nutrients through a small "loop" of the systemic circulation and derives very little from the blood contained within the four chambers. The coronary circulation system provides a blood supply to the heart muscle itself. The coronary circulation begins near the origin of the aorta by two coronary arteries: the right coronary artery and the left coronary artery. After nourishing the heart muscle, blood returns through the coronary veins into the coronary sinus and from this one into the right atrium. Back flow of blood through its opening during atrial systole is prevented by the Thebesian valve. The smallest cardiac veins drain directly into the heart chambers.

Lungs
The circulatory system of the lungs is the portion of the cardiovascular system in which oxygen-depleted blood is pumped away from the heart, via the pulmonary artery, to the lungs and returned, oxygenated, to the heart via the pulmonary vein. Oxygen deprived blood from the superior and inferior vena cava enters the right atrium of the heart and flows through the tricuspid valve (right atrioventricular valve) into the right ventricle, from which it is then pumped through the pulmonary semilunar valve into the pulmonary artery to the lungs. Gas exchange occurs in the lungs, whereby CO_2 is released from the blood, and oxygen is absorbed. The pulmonary vein returns the now oxygen-rich blood to the left atrium. A separate system known as the bronchial circulation supplies blood to the tissue of the larger airways of the lung.

Systemic Circulation
Systemic circulation is the portion of the cardiovascular system which transports oxygenated blood away from the heart through the aorta from the left ventricle where the blood has been previously deposited from pulmonary circulation, to the rest of the body, and returns oxygen-depleted blood back to the heart.

Brain
The brain has a dual blood supply that comes from arteries at its front and back. These are called the "anterior" and "posterior" circulation respectively. The anterior circulation arises from the internal carotid arteries and supplies the front of the brain. The posterior circulation arises from the vertebral arteries, and supplies the back of the brain and brainstem. The circulation from the front and the back join together (anastomise) at the Circle of Willis.

Kidneys
The renal circulation receives around 20% of the cardiac output. It branches from the abdominal aorta and returns blood to the ascending vena cava. It is the blood supply to the kidneys, and contains many specialized blood vessels.

Lymphatic System
The lymphatic system is part of the circulatory system. It is a network of lymphatic vessels and lymph capillaries, lymph nodes and organs, and lymphatic tissues and circulating lymph. One of its major functions is to carry the lymph, draining and returning interstitial fluid back towards the heart for return to the cardiovascular system, by emptying into the lymphatic ducts. Its other main function is in the adaptive immune system.

Function

About 98.5% of the oxygen in a sample of arterial blood in a healthy human, breathing air at sea-level pressure, is chemically combined with hemoglobin molecules. About 1.5% is physically dissolved in the other blood liquids and not connected to hemoglobin. The hemoglobin molecule is the primary transporter of oxygen in mammals and many other species.

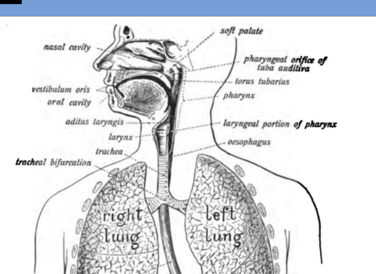
Clinical Significance

Many diseases affect the circulatory system. These include a number of cardiovascular diseases, affecting the cardiovascular system, and lymphatic diseases affecting the lymphatic system. Cardiologists are medical professionals which specialise in the heart, and cardiothoracic surgeons specialise in operating on the heart and its surrounding areas. Vascular surgeons focus on other parts of the circulatory system.

Cardiovascular Disease
Diseases affecting the cardiovascular system are called cardiovascular disease. Many of these diseases are called "lifestyle diseases" because they develop over time and are related to a person's exercise habits, diet, whether they smoke, and other lifestyle choices a person makes. Atherosclerosis is the precursor to many of these diseases. It is where small atheromatous plaques build up in the walls of medium and large arteries. This may eventually grow or rupture to occlude the arteries. It is also a risk factor for acute coronary syndromes, which are diseases which are characterised by a sudden deficit of oxygenated blood to the heart tissue. Atherosclerosis is also associated with problems such as aneurysm formation or splitting ("dissection") of arteries. Another major cardiovascular disease involves the creation of a clot, called a "thrombus". These can originate in veins or arteries. Deep venous thrombosis, which mostly occurs in the legs, is one cause of clots in the veins of the legs, particularly when a person has been stationary for a long time. These clots may embolise, meaning travel to another location in the body. The results of this may include pulmonary embolus, transient ischaemic attacks, or stroke. Cardiovascular diseases may also be congenital in nature, such as heart defects or persistent fetal circulation, where the circulatory changes that are supposed to happen after birth do not. Not all congenital changes to the circulatory system are associated with diseases, a large number are anatomical variations.

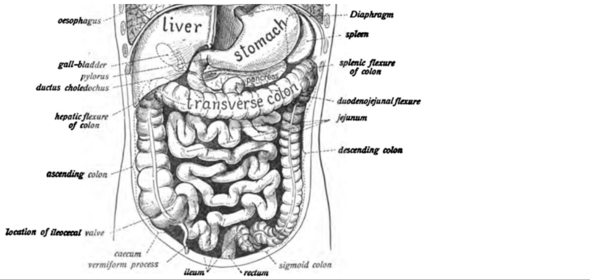
Investigations
The function and health of the circulatory system and its parts are measured in a variety of manual and automated ways. These include simple methods such as those that are part of the cardiovascular examination, including the taking of a person's pulse as an indicator of a person's heart rate, the taking of blood pressure through a sphygmomanometer or the use of a stethoscope to listen to the heart for murmurs which may indicate problems with the heart's valves. An electrocardiogram can also be used to evaluate the way in which electricity is conducted through the heart. Other more invasive means can also be used. A cannula or catheter inserted into an artery may be used to measure pulse pressure or pulmonary wedge pressures. Angiography, which involves injecting a dye into an artery to visualise an arterial tree, can be used in the heart (coronary angiography) or brain. At the same time as the arteries are visualised, blockages or narrowings may be fixed through the insertion of stents, and active bleeds may be managed by the insertion of coils. An MRI may be used to image arteries, called an MRI angiogram. For evaluation of the blood supply to the lungs a CT pulmonary angiogram may be used.

2 Digestive System



The human digestive system consists of the gastrointestinal tract plus the accessory organs of digestion (the tongue, salivary glands, pancreas, liver, and gallbladder). Digestion involves the breakdown of food into smaller and smaller components, until they can be absorbed and assimilated into the body.

The process of digestion has three stages. The first stage is the cephalic phase of digestion which begins with gastric secretions in response to the sight and smell of food. This stage includes the mechanical breakdown of food by chewing, and the chemical breakdown by digestive enzymes, that takes place in the mouth. 'Saliva contains digestive enzymes called amylase, and lingual lipase, secreted by the salivary glands and serous glands on the tongue.



The enzymes start to break down the food in the mouth. Chewing, in which the food is mixed with saliva, begins the mechanical process of digestion. This produces a bolus which can be swallowed down the oesophagus to enter the stomach. In the stomach the gastric phase of digestion takes place.

The food is further broken down by mixing with gastric acid until it passes into the duodenum, in the third intestinal phase of digestion, where it is mixed with a number of enzymes produced by the pancreas. Digestion is helped by the chewing of food carried out by the muscles of mastication, the tongue, and the teeth, and also by the contractions of peristalsis, and segmentation. Gastric acid, and the production of mucus in the stomach, are essential for the continuation of digestion.

Peristalsis is the rhythmic contraction of muscles that begins in the oesophagus and continues along the wall of the stomach and the rest of the gastrointestinal tract. This initially results in the production of chyme which when fully broken down in the small intestine is absorbed as chyle into the lymphatic system. Most of the digestion of food takes place in the small intestine. Water and some minerals are reabsorbed back into the blood in the colon of the large intestine. The waste products of digestion (faeces) are defecated from the anus via the rectum.

Components

There are several organs and other components involved in the digestion of food. The organs known as the accessory digestive organs are the liver, gall bladder and pancreas. Other components include the mouth, salivary glands, tongue, teeth and epiglottis. The largest structure of the digestive system is the gastrointestinal tract (GI tract). This starts at the mouth and ends at the anus, covering a distance of about nine (9) metres. The largest part of the GI tract is the colon or large intestine. Water is absorbed here and the remaining waste matter is stored prior to defecation. Most of the digestion of food takes place in the small intestine which is the longest part of the GI tract.

A major digestive organ is the stomach. Within its mucosa are millions of embedded gastric glands. Their secretions are vital to the functioning of the organ. There are many specialised cells of the GI tract. These include the various cells of the gastric glands, taste cells, pancreatic duct cells, enterocytes and microfold cells. Some parts of the digestive system are also part of the excretory system, including the large intestine.

Mouth

The mouth is the first part of the upper gastrointestinal tract and is equipped with several structures that begin the first processes of digestion. These include salivary glands, teeth and the tongue. The mouth consists of two regions; the vestibule and the oral cavity proper. The vestibule is the area between the teeth, lips and cheeks, and the rest is the oral cavity proper. Most of the oral cavity is lined with oral mucosa, a mucous membrane that produces a lubricating mucus, of which only a small amount is needed. Mucous membranes vary in structure in the different regions of the body but they all produce a lubricating mucus, which is either secreted by surface cells or more usually by underlying glands. The mucous membrane in the mouth continues as the thin mucosa which lines the bases of the teeth. The main component of mucus is a glycoprotein called mucin and the type secreted varies according to the region involved. Mucin is viscous, clear, and clinging. Underlying the mucous membrane in the mouth is a thin layer of smooth muscle tissue and the loose connection to the membrane gives it its great elasticity.

It covers the cheeks, inner surfaces of the lips, and floor of the mouth, and the mucin produced is highly protective against tooth decay. The roof of the mouth is termed the palate and it separates the oral cavity from the nasal cavity. The palate is hard at the front of the mouth since the overlying mucosa is covering a plate of bone; it is softer and more pliable at the back being made of muscle and connective tissue, and it can move to swallow food and liquids. The soft palate ends at the uvula. The surface of the hard palate allows for the pressure needed in eating food, to leave the nasal passage clear. The opening between the lips is termed the oral fissure, and the opening into the throat is called the fauces. At either side of the soft palate are the palatoglossus muscles which also reach into regions of the tongue. These muscles raise the back of the tongue and also close both sides of the fauces to enable food to be swallowed. Mucus helps in the mastication of food in its ability to soften and collect the food in the formation of the bolus.

Mouth - Salivary Glands

There are three pairs of main salivary glands and between 800 and 1,000 minor salivary glands, all of which mainly serve the digestive process, and also play an important role in the maintenance of dental health and general mouth lubrication, without which speech would be impossible. The main glands are all exocrine glands, secreting via ducts. All of these glands terminate in the mouth. The largest of these are the parotid glands—their secretion is mainly serous. The next pair are underneath the jaw, the submandibular glands, these produce both serous fluid and mucus.

The serous fluid is produced by serous glands in these salivary glands which also produce lingual lipase. They produce about 70% of the oral cavity saliva. The third pair are the sublingual glands located underneath the tongue and their secretion is mainly mucous with a small percentage of saliva. Within the oral mucosa, and also on the tongue, palates, and floor of the mouth, are the minor salivary glands; their secretions are mainly mucous and they are innervated by the facial nerve (CN7).

The glands also secrete amylase a first stage in the breakdown of food acting on the carbohydrate in the food to transform the starch content into maltose. There are other serous glands on the surface of the tongue that encircle taste buds on the back part of the tongue and these also produce lingual lipase. Lipase is a digestive enzyme that catalyses the hydrolysis of lipids (fats).

These glands are termed Von Ebner's glands which have also been shown to have another function in the secretion of histatins which offer an early defence (outside of the immune system) against microbes in food, when it makes contact with these glands on the tongue tissue. Sensory information can stimulate the secretion of saliva providing the necessary fluid for the tongue to work with and also to ease swallowing of the food.

Mouth - Saliva

Saliva moistens and softens food, and along with the chewing action of the teeth, transforms the food into a smooth bolus. The bolus is further helped by the lubrication provided by the saliva in its passage from the mouth into the oesophagus. Also of importance is the presence in saliva of the digestive enzymes amylase and lipase. Amylase starts to work on the starch in carbohydrates, breaking it down into the simple sugars of maltose and dextrose that can be further broken down in the small intestine. Saliva in the mouth can account for 30% of this initial starch digestion. Lipase starts to work on breaking down fats. Lipase is further produced in the pancreas where it is released to continue this digestion of fats. The presence of salivary lipase is of prime importance in young babies whose pancreatic lipase has yet to be developed. As well as its role in supplying digestive enzymes, saliva has a cleansing action for the teeth and mouth. It also has an immunological role in supplying antibodies to the system, such as immunoglobulin A. This is seen to be key in preventing infections of the salivary glands, importantly that of parotitis. Saliva also contains a glycoprotein called haptocorrin which is a binding protein to vitamin B12. It binds with the vitamin in order to carry it safely through the acidic content of the stomach. When it reaches the duodenum, pancreatic enzymes break down the glycoprotein and free the vitamin which then binds with intrinsic factor.

Mouth - Tongue

Food enters the mouth where the first stage in the digestive process takes place, with the action of the tongue and the secretion of saliva. The tongue is a fleshy and muscular sensory organ, and the very first sensory information is received via the taste buds in the papillae on its surface. If the taste is agreeable, the tongue will go into action, manipulating the food in the mouth which stimulates the secretion of saliva from the salivary glands. The liquid quality of the saliva will help in the softening of the food and its enzyme content will start to break down the food whilst it is still in the mouth. The first part of the food to be broken down is the starch of carbohydrates (by the enzyme amylase in the saliva). The tongue is attached to the floor of the mouth by a ligamentous band called the frenum and this gives it great mobility for the manipulation of food (and speech); the range of manipulation is optimally controlled by the action of several muscles and limited in its external range by the stretch of the frenum. The tongue's two sets of muscles, are four intrinsic muscles that originate in the tongue and are involved with its shaping, and four extrinsic muscles originating in bone that are involved with its movement.

Mouth - Taste
Taste is a form of chemoreception that takes place in the specialised taste receptors, contained in structures called taste buds in the mouth. Taste buds are mainly on the upper surface (dorsum) of the tongue. The function of taste perception is vital to help prevent harmful or rotten foods from being consumed. There are also taste buds on the epiglottis and upper part of the oesophagus. The taste buds are innervated by a branch of the facial nerve the chorda tympani, and the glossopharyngeal nerve. Taste messages are sent via these cranial nerves to the brain. The brain can distinguish between the chemical qualities of the food. The five basic tastes are referred to as those of saltiness, sourness, bitterness, sweetness, and umami. The detection of saltiness and sourness enables the control of salt and acid balance. The detection of bitterness warns of poisons—many of a plant's defences are of poisonous compounds that are bitter. Sweetness guides to those foods that will supply energy; the initial breakdown of the energy-giving carbohydrates by salivary amylase creates the taste of sweetness since simple sugars are the first result. The taste of umami is thought to signal protein-rich food. Sour tastes are acidic which is often found in bad food. The brain has to decide very quickly whether the food should be eaten or not. It was the findings in 1991, describing the first olfactory receptors that helped to prompt the research into taste. The olfactory receptors are located on cell surfaces in the nose which bind to chemicals enabling the detection of smells. It is assumed that signals from taste receptors work together with those from the nose, to form an idea of complex food flavours.

Mouth - Teeth
Teeth are complex structures made of materials specific to them. They are made of a bone-like material called dentin, which is covered by the hardest tissue in the body—enamel. Teeth have different shapes to deal with different aspects of mastication employed in tearing and chewing pieces of food into smaller and smaller pieces. This results in a much larger surface area for the action of digestive enzymes. The teeth are named after their particular roles in the process of mastication—incisors are used for cutting or biting off pieces of food; canines, are used for tearing, premolars and molars are used for chewing and grinding. Mastication of the food with the help of saliva and mucus results in the formation of a soft bolus which can then be swallowed to make its way down the upper gastrointestinal tract to the stomach. The digestive enzymes in saliva also help in keeping the teeth clean by breaking down any lodged food particles.

Mouth - Epiglottis
The epiglottis is a flap of elastic cartilage attached to the entrance of the larynx. It is covered with a mucous membrane and there are taste buds on its lingual surface which faces into the mouth. Its laryngeal surface faces into the larynx. The epiglottis functions to guard the entrance of the glottis, the opening between the vocal folds. It is normally pointed upward during breathing with its underside functioning as part of the pharynx, but during swallowing, the epiglottis folds down to a more horizontal position, with its upper side functioning as part of the pharynx. In this manner it prevents food from going into the trachea and instead directs it to the oesophagus, which is behind. During swallowing, the backward motion of the tongue forces the epiglottis over the glottis' opening to prevent any food that is being swallowed from entering the larynx which leads to the lungs; the larynx is also pulled upwards to assist this process. Stimulation of the larynx by ingested matter produces a strong cough reflex in order to protect the lungs.

Pharynx
The pharynx is a part of the conducting zone of the respiratory system and also a part of the digestive system. It is the part of the throat immediately behind the nasal cavity at the back of the mouth and above the oesophagus and larynx. The pharynx is made up of three parts. The lower two parts—the oropharynx and the laryngopharynx are involved in the digestive system. The laryngopharynx connects to the oesophagus and it serves as a passageway for both air and food. Air enters the larynx anteriorly but anything swallowed has priority and the passage of air is temporarily blocked. The pharynx is innervated by the pharyngeal plexus of the vagus nerve. Muscles in the pharynx push the food into the oesophagus. The pharynx joins the oesophagus at the oesophageal inlet which is located behind the cricoid cartilage.

Oesophagus
The oesophagus, commonly known as the foodpipe or gullet, consists of a muscular tube through which food passes from the pharynx to the stomach. The oesophagus is continuous with the laryngopharynx. It passes through the posterior mediastinum in the thorax and enters the stomach through a hole in the thoracic diaphragm—the oesophageal hiatus, at the level of the tenth thoracic vertebra (T10). Its length averages 25 cm, varying with an individual's height. It is divided into cervical, thoracic and abdominal parts.

The pharynx joins the oesophagus at the oesophageal inlet which is behind the cricoid cartilage. At rest the oesophagus is closed at both ends, by the upper and lower oesophageal sphincters. The opening of the upper sphincter is triggered by the swallowing reflex so that food is allowed through. The sphincter also serves to prevent back flow from the oesophagus into the pharynx.

The oesophagus has a mucous membrane and the epithelium which has a protective function is continuously replaced due to the volume of food that passes inside the oesophagus. During swallowing, food passes from the mouth through the pharynx into the oesophagus. The epiglottis folds down to a more horizontal position to direct the food into the oesophagus, and away from the trachea. Once in the oesophagus, the bolus travels down to the stomach via rhythmic contraction and relaxation of muscles known as peristalsis.

The lower oesophageal sphincter is a muscular sphincter surrounding the lower part of the oesophagus. The gastroesophageal junction between the oesophagus and the stomach is controlled by the lower oesophageal sphincter, which remains constricted at all times other than during swallowing and vomiting to prevent the contents of the stomach from entering the oesophagus. As the oesophagus does not have the same protection from acid as the stomach, any failure of this sphincter can lead to heartburn.

Diaphragm
The diaphragm is an important part of the body's digestive system. The muscular diaphragm separates the thoracic cavity from the abdominal cavity where most of the digestive organs are located. The suspensory muscle attaches the ascending duodenum to the diaphragm. This muscle is thought to be of help in the digestive system in that its attachment offers a wider angle to the duodenojejunal flexure for the easier passage of digesting material. The diaphragm also attaches to, and anchors the liver at its bare area. The oesophagus enters the abdomen through a hole in the diaphragm at the level of T10.

Stomach
The stomach is a major organ of the gastrointestinal tract and digestive system. It is a consistently J-shaped organ joined to the oesophagus at its upper end and to the duodenum at its lower end. Gastric acid (informally gastric juice), produced in the stomach plays a vital role in the digestive process, and mainly contains hydrochloric acid and sodium chloride. A peptide hormone, gastrin, produced by G cells in the gastric glands, stimulates the production of gastric juice which activates the digestive enzymes. Pepsinogen is a precursor enzyme (zymogen) produced by the gastric chief cells, and gastric acid activates this to the enzyme pepsin which begins the digestion of proteins. As these two chemicals would damage the stomach wall, mucus is secreted by innumerable gastric glands in the stomach, to provide a slimy protective layer against the damaging effects of the chemicals on the inner layers of the stomach. At the same time that protein is being digested, mechanical churning occurs through the action of peristalsis, waves of muscular contractions that move along the stomach wall. This allows the mass of food to further mix with the digestive enzymes. Gastric lipase secreted by the chief cells in the fundic glands in the gastric mucosa of the stomach, is an acidic lipase, in contrast with the alkaline pancreatic lipase. This breaks down fats to some degree though is not as efficient as the pancreatic lipase. The pylorus, the lowest section of the stomach which attaches to the duodenum via the pyloric canal, contains countless glands which secrete digestive enzymes including gastrin. After an hour or two, a thick semi-liquid called chyme is produced.
When the pyloric sphincter, or valve opens, chyme enters the duodenum where it mixes further with digestive enzymes from the pancreas, and then passes through the small intestine, where digestion continues. When the chyme is fully digested, it is absorbed into the blood. 95% of absorption of nutrients occurs in the small intestine. Water and minerals are reabsorbed back into the blood in the colon of the large intestine, where the environment is slightly acidic. Some vitamins, such as biotin and vitamin K produced by bacteria in the gut flora of the colon are also absorbed. The parietal cells in the fundus of the stomach, produce a glycoprotein called intrinsic factor which is essential for the absorption of vitamin B12. Vitamin B12 (cobalamin), is carried to, and through the stomach, bound to a glycoprotein secreted by the salivary glands - transcobalamin I also called haptocorrin, which protects the acid-sensitive vitamin from the acidic stomach contents. Once in the more neutral duodenum, pancreatic enzymes break down the protective glycoprotein. The freed vitamin B12 then binds to intrinsic factor which is then absorbed by the enterocytes in the ileum. The stomach is a distensible organ and can normally expand to hold about one litre of food. This expansion is enabled by a series of gastric folds in the inner walls of the stomach. The stomach of a newborn baby will only be able to expand to retain about 30 ml.

Spleen
The spleen is the largest lymphoid organ in the body but has other functions. It breaks down both red and white blood cells that are spent. This is why it is sometimes known as the 'graveyard of red blood cells'. A product of this digestion is the pigment bilirubin, which is sent to the liver and secreted in the bile. Another product is iron, which is used in the formation of new blood cells in the bone marrow. Medicine treats the spleen solely as belonging to the lymphatic system, though it is acknowledged that the full range of its important functions is not yet understood.

Liver
The liver is the second largest organ (after the skin) and is an accessory digestive gland which plays a role in the body's metabolism. The liver has many functions some of which are important to digestion. The liver can detoxify various metabolites; synthesise proteins and produce biochemicals needed for digestion. It regulates the storage of glycogen which it can form from glucose (glycogenesis). The liver can also synthesise glucose from certain amino acids. Its digestive functions are largely involved with the breaking down of carbohydrates. It also maintains protein metabolism in its synthesis and degradation. In lipid metabolism it synthesises cholesterol. Fats are also produced in the process of lipogenesis. The liver synthesises the bulk of lipoproteins. The liver is located in the upper right quadrant of the abdomen and below the diaphragm to which it is attached at one part, the bare area of the liver. This is to the right of the stomach and it overlies the gall bladder. The liver synthesises bile acids and lecithin to promote the digestion of fat.

Liver - Bile
Bile produced by the liver is made up of water (97%), bile salts, mucus and pigments, 1% fats and inorganic salts. Bilirubin is its major pigment. Bile acts partly as a surfactant which lowers the surface tension between either two liquids or a solid and a liquid and helps to emulsify the fats in the chyme. Food fat is dispersed by the action of bile into smaller units called micelles. The breaking down into micelles creates a much larger surface area for the pancreatic enzyme, lipase to work on. Lipase digests the triglycerides which are broken down into two fatty acids and a monoglyceride. These are then absorbed by villi on the intestinal wall. If fats are not absorbed in this way in the small intestine problems can arise later in the large intestine which is not equipped to absorb fats. Bile also helps in the absorption of vitamin K from the diet. Bile is collected and delivered through the common hepatic duct. This duct joins with the cystic duct to connect in a common bile duct with the gallbladder. Bile is stored in the gallbladder for release when food is discharged into the duodenum and also after a few hours.

Liver - Gallbladder
The gallbladder is a hollow part of the biliary tract that sits just beneath the liver, with the gallbladder body resting in a small depression. It is a small organ where the bile produced by the liver is stored, before being released into the small intestine. Bile flows from the liver through the bile ducts and into the gall bladder for storage. The bile is released in response to cholecystokinin (CCK) a peptide hormone released from the duodenum. The production of CCK (by endocrine cells of the duodenum) is stimulated by the presence of fat in the duodenum.

It is divided into three sections, a fundus, body and neck. The neck tapers and connects to the biliary tract via the cystic duct, which then joins the common hepatic duct to form the common bile duct. At this junction is a mucosal fold called Hartmann's pouch, where gallstones commonly get stuck. The muscular layer of the body is of smooth muscle tissue that helps the gallbladder contract, so that it can discharge its bile into the bile duct.

The gallbladder needs to store bile in a natural, semi-liquid form at all times. Hydrogen ions secreted from the inner lining of the gallbladder keep the bile acidic enough to prevent hardening. To dilute the bile, water and electrolytes from the digestion system are added. Also, salts attach themselves to cholesterol molecules in the bile to keep them from crystallising. If there is too much cholesterol or bilirubin in the bile, or if the gallbladder doesn't empty properly the systems can fail.

This is how gallstones form when a small piece of calcium gets coated with either cholesterol or bilirubin and the bile crystallises and forms a gallstone. The main purpose of the gallbladder is to store and release bile, or gall. Bile is released into the small intestine in order to help in the digestion of fats by breaking down larger molecules into smaller ones. After the fat is absorbed, the bile is also absorbed and transported back to the liver for reuse.

Pancreas
The pancreas is a major organ functioning as an accessory digestive gland in the digestive system. It is both an endocrine gland and an exocrine gland. The endocrine part secretes insulin when the blood sugar becomes high; insulin moves glucose from the blood into the muscles and other tissues for use as energy. The endocrine part releases glucagon when the blood sugar is low; glucagon allows stored sugar to be broken down into glucose by the liver in order to re-balance the sugar levels. The pancreas produces and releases important digestive enzymes in the pancreatic juice that it delivers to the duodenum. The pancreas lies below and at the back of the stomach. It connects to the duodenum via the pancreatic duct which it joins near to the bile duct's connection where both the bile and pancreatic juice can act on the chyme that is released from the stomach into the duodenum. Aqueous pancreatic secretions from pancreatic duct cells contain bicarbonate ions which are alkaline and help with the bile to neutralise the acidic chyme that is churned out by the stomach.

The pancreas is also the main source of enzymes for the digestion of fats and proteins. Some of these are released in response to the production of CKK in the duodenum. (The enzymes that digest polysaccharides, by contrast, are primarily produced by the walls of the intestines.) The cells are filled with secretory granules containing the precursor digestive enzymes. The major proteases, the pancreatic enzymes which work on proteins, are trypsinogen and chymotrypsinogen. Elastase is also produced. Smaller amounts of lipase and amylase are secreted. The pancreas also secretes phospholipase A2, lysophospholipase, and cholesterol esterase. The precursor zymogens, are inactive variants of the enzymes; which avoids the onset of pancreatitis caused by autodegradation. Once released in the intestine, the enzyme enteropeptidase present in the intestinal mucosa activates trypsinogen by cleaving it to form trypsin; further cleavage results in chymotripsin.

Lower Gastrointestinal Tract
The lower gastrointestinal tract (GI), includes the small intestine and all of the large intestine. The intestine is also called the bowel or the gut. The lower GI starts at the pyloric sphincter of the stomach and finishes at the anus. The small intestine is subdivided into the duodenum, the jejunum and the ileum. The cecum marks the division between the small and large intestine. The large intestine includes the rectum and anal canal.

Lower GT - Small Intestine
Partially digested food starts to arrive in the small intestine as semi-liquid chyme, one hour after it is eaten. After two hours the stomach has emptied. In the small intestine, the pH becomes crucial; it needs to be finely balanced in order to activate digestive enzymes. The chyme is very acidic, with a low pH, having been released from the stomach and needs to be made much more alkaline. This is achieved in the duodenum by the addition of bile from the gall bladder combined with the bicarbonate secretions from the pancreatic duct and also from secretions of bicarbonate-rich mucus from duodenal glands known as Brunner's glands. The chyme arrives in the intestines having been released from the stomach through the opening of the pyloric sphincter. The resulting alkaline fluid mix neutralises the gastric acid which would damage the lining of the intestine. The mucus component lubricates the walls of the intestine. When the digested food particles are reduced enough in size and composition, they can be absorbed by the intestinal wall and carried to the bloodstream.

The first receptacle for this chyme is the duodenal bulb. From here it passes into the first of the three sections of the small intestine, the duodenum. (The next section is the jejunum and the third is the ileum). The duodenum is the first and shortest section of the small intestine. It is a hollow, jointed C-shaped tube connecting the stomach to the jejunum. It starts at the duodenal bulb and ends at the suspensory muscle of duodenum. The attachment of the suspensory muscle to the diaphragm is thought to help the passage of food by making a wider angle at its attachment. Most food digestion takes place in the small intestine. Segmentation contractions act to mix and move the chyme more slowly in the small intestine allowing more time for absorption (and these continue in the large intestine). In the duodenum, pancreatic lipase is secreted together with a co-enzyme, colipase to further digest the fat content of the chyme. From this breakdown, smaller particles of emulsified fats called chylomicrons are produced.

There are also digestive cells called enterocytes lining the intestines (the majority being in the small intestine). They are unusual cells in that they have villi on their surface which in turn have innumerable microvilli on their surface. All these villi make for a greater surface area, not only for the absorption of chyme but also for its further digestion by large numbers of digestive enzymes present on the microvilli. The chylomicrons are small enough to pass through the enterocyte villi and into their lymph capillaries called lacteals.

A milky fluid called chyle, consisting mainly of the emulsified fats of the chylomicrons, results from the absorbed mix with the lymph in the lacteals. Chyle is then transported through the lymphatic system to the rest of the body. The suspensory muscle marks the end of the duodenum and the division between the upper gastrointestinal tract and the lower GI tract. The digestive tract continues as the jejunum which continues as the ileum.

The jejunum, the midsection of the small intestine contains circular folds, flaps of doubled mucosal membrane which partially encircle and sometimes completely encircle the lumen of the intestine. These folds together with villi serve to increase the surface area of the jejunum enabling an increased absorption of digested sugars, amino acids and fatty acids into the bloodstream. The circular folds also slow the passage of food giving more time for nutrients to be absorbed. The last part of the small intestine is the ileum.

This also contains villi and vitamin B12; bile acids and any residue nutrients are absorbed here. When the chyme is exhausted of its nutrients the remaining waste material changes into the semi-solids called faeces, which pass to the large intestine, where bacteria in the gut flora further break down residual proteins and starches.

Lower GT - Cecum
The cecum is a pouch marking the division between the small intestine and the large intestine. It lies below the ileocecal valve in the lower right quadrant of the abdomen. The cecum receives chyme from the last part of the small intestine, the ileum, and connects to the ascending colon of the large intestine. At this junction there is a sphincter or valve, the ileocecal valve which slows the passage of chyme from the ileum, allowing further digestion. It is also the site of the appendix attachment.

Lower GT - Large Intestine
In the large intestine, the passage of the digesting food in the colon is a lot slower, taking from 12 to 50 hours until it is removed by defecation. The colon mainly serves as a site for the fermentation of digestible matter by the gut flora. The time taken varies considerably between individuals. The remaining semi-solid waste is termed feces and is removed by the coordinated contractions of the intestinal walls, termed peristalsis, which propels the excreta forward to reach the rectum and exit via defecation from the anus. The wall has an outer layer of longitudinal muscles, the taeniae coli, and an inner layer of circular muscles. The circular muscle keeps the material moving forward and also prevents any back flow of waste. Also of help in the action of peristalsis is the basal electrical rhythm that determines the frequency of contractions. The taeniae coli can be seen and are responsible for the bulges (haustra) present in the colon. Most parts of the GI tract are covered with serous membranes and have a mesentery. Other more muscular parts are lined with adventitia.

Blood Supply
The digestive system is supplied by the celiac artery. The celiac artery is the first major branch from the abdominal aorta, and is the only major artery that nourishes the digestive organs. There are three main divisions – the left gastric artery, the common hepatic artery and the splenic artery. The celiac artery supplies the liver, stomach, spleen and the upper 1/3 of the duodenum (to the sphincter of Oddi) and the pancreas with oxygenated blood. Most of the blood is returned to the liver via the portal venous system for further processing and detoxification before returning to the systemic circulation via the hepatic veins. The next branch from the abdominal aorta is the superior mesenteric artery, which supplies the regions of the digestive tract derived from the midgut, which includes the distal 2/3 of the duodenum, jejunum, ileum, cecum, appendix, ascending colon, and the proximal 2/3 of the transverse colon. The final branch which is important for the digestive system is the inferior mesenteric artery, which supplies the regions of the digestive tract derived from the hindgut, which includes the distal 1/3 of the transverse colon, descending colon, sigmoid colon, rectum, and the anus above the pectinate line.

Nerve Supply
The enteric nervous system consists of some one hundred million neurons that are embedded in the peritoneum, the lining of the gastrointestinal tract extending from the esophagus to the anus. These neurons are collected into two plexuses - the myenteric (or Auerbach's) plexus that lies between the longitudinal and the smooth muscle layers, and the submucosal (or Meissner's) plexus that lies between the circular smooth muscle layer and the mucosa. Parasympathetic innervation to the ascending colon is supplied by the vagus nerve. Sympathetic innervation is supplied by the splanchnic nerves that join the celiac ganglia. Most of the digestive tract is innervated by the two large celiac ganglia, with the upper part of each ganglion joined by the greater splanchnic nerve and the lower parts joined by the lesser splanchnic nerve. It is from these ganglia that many of the gastric plexuses arise.

Clinical Significance
Each part of the digestive system is subject to a wide range of disorders many of which can be congenital. Mouth diseases can also be caused by pathogenic bacteria, viruses, fungi and as a side effect of some medications. Mouth diseases include tongue diseases and salivary gland diseases. A common gum disease in the mouth is gingivitis which is caused by bacteria in plaque.

The most common viral infection of the mouth is gingivostomatitis caused by herpes simplex. A common fungal infection is candidiasis commonly known as thrush which affects the mucous membranes of the mouth. There are a number of esophageal diseases such as the development of Schatzki rings that can restrict the passageway, causing difficulties in swallowing. They can also completely block the esophagus.

Stomach diseases are often chronic conditions and include gastroparesis, gastritis, and peptic ulcers. A number of problems including malnutrition and anemia can arise from malabsorption, the abnormal absorption of nutrients in the GI tract. Malabsorption can have many causes ranging from infection, to enzyme deficiencies such as exocrine pancreatic insufficiency.

It can also arise as a result of other gastrointestinal diseases such as coeliac disease. Coeliac disease is an autoimmune disorder of the small intestine. This can cause vitamin deficiencies due to the improper absorption of nutrients in the small intestine. The small intestine can also be obstructed by a volvulus, a loop of intestine that becomes twisted enclosing its attached mesentery. This can cause mesenteric ischemia if severe enough.

A common disorder of the bowel is diverticulitis. Diverticula are small pouches that can form inside the bowel wall, which can become inflamed to give diverticulitis. This disease can have complications if an inflamed diverticulum bursts and infection sets in. Any infection can spread further to the lining of the abdomen (peritoneum) and cause potentially fatal peritonitis.

Crohn's disease is a common chronic inflammatory bowel disease (IBD), which can affect any part of the GI tract, but it mostly starts in the terminal ileum. Ulcerative colitis an ulcerative form of colitis, is the other major inflammatory bowel disease which is restricted to the colon and rectum. Both of these IBDs can give an increased risk of the development of colorectal cancer. Ulcerative colitis is the most common of the IBDs. Irritable bowel syndrome (IBS) is the most common of the functional gastrointestinal disorders.

These are idiopathic disorders that the Rome process has helped to define. Giardiasis is a disease of the small intestine caused by a protist parasite Giardia lamblia. This does not spread but remains confined to the lumen of the small intestine. It can often be asymptomatic, but as often can be indicated by a variety of symptoms. Giardiasis is the most common pathogenic parasitic infection in humans. There are diagnostic tools mostly involving the ingestion of barium sulphate to investigate disorders of the GI tract. These are known as upper gastrointestinal series that enable imaging of the pharynx, larynx, oesophagous, stomach and small intestine and lower gastrointestinal series for imaging of the colon.

3 Excretory System

The excretory system is a passive biological system that removes excess, unnecessary materials from the body fluids of an organism, so as to help maintain internal chemical homeostasis and prevent damage to the body. The dual function of excretory systems is the elimination of the waste products of metabolism and to drain the body of used up and broken down components in a liquid and gaseous state. In humans and other amniotes (mammals, birds and reptiles) most of these substances leave the body as urine and to some degree exhalation, mammals also expel them through sweating. Only the organs specifically used for the excretion are considered a part of the excretory system.

In the narrow sense, the term refer to the urinary system. However, as excretion involves several functions that are only superficially related, it is not usually used in more formal classifications of anatomy or function. As most healthy functioning organs produce metabolic and other wastes, the entire organism depends on the function of the system. Breaking down of one of more of the systems is a serious health condition, for example renal failure.

Urinary System

The kidneys are bean-shaped organs which are present on each side of the vertebral column in the abdominal cavity. Humans have two kidneys and each kidney is supplied with blood from the renal artery. The kidneys remove from the blood the nitrogenous wastes such as urea, as well as salts and excess water, and excrete them in the form of urine. This is done with the help of millions of nephrons present in the kidney. The filtrated blood is carried away from the kidneys by the renal vein (or kidney vein). The urine from the kidney is collected by the ureter (or excretory tubes), one from each kidney, and is passed to the urinary bladder. The urinary bladder collects and stores the urine until urination. The urine collected in the bladder is passed into the external environment from the body through an opening called the urethra.

Kidneys
The kidney's primary function is the elimination of waste from the bloodstream by production of urine. They perform several homeostatic functions such as:
1. Maintain volume of extracellular fluid
2. Maintain ionic balance in extracellular fluid
3. Maintain pH and osmotic concentration of the extracellular fluid.
4. Excrete toxic metabolic by-products such as urea, ammonia, and uric acid.

The way the kidneys do this is with nephrons. There are over 1 million nephrons in each kidney; these nephrons act as filters inside the kidneys. The kidneys filter needed materials and waste, the needed materials go back into the bloodstream, and unneeded materials becomes urine and is gotten rid of. In some cases, excess wastes crystallize as kidney stones. They grow and can become painful irritants that may require surgery or ultrasound treatments. Some stones are small enough to be forced into the urethra.

Ureter
The ureters are muscular ducts that propel urine from the kidneys to the urinary bladder. In the human adult, the ureters are usually 25–30 cm (10–12 in) long. In humans, the ureters arise from the renal pelvis on the medial aspect of each kidney before descending towards the bladder on the front of the psoas major muscle. The ureters cross the pelvic brim near the bifurcation of the iliac arteries (which they run over). This "pelviureteric junction" is a common site for the impaction of kidney stones (the other being the uteterovesical valve). The ureters run posteriorly on the lateral walls of the pelvis. They then curve anteriormedially to enter the bladder through the back, at the vesicoureteric junction, running within the wall of the bladder for a few centimeters. The backflow of urine is prevented by valves known as ureterovesical valves. In the female, the ureters pass through the mesometrium on the way to the bladder.

Urinary Bladder
The urinary bladder is the organ that collects waste excreted by the kidneys prior to disposal by urination. It is a hollow muscular, and distensible (or elastic) organ, and sits on the pelvic floor. Urine enters the bladder via the ureters and exits via the urethra. Embryologically, the bladder is derived from the urogenital sinus, and it is initially continuous with the allantois. In human males, the base of the bladder lies between the rectum and the pubic symphysis. It is superior to the prostate, and separated from the rectum by the rectovesical excavation. In females, the bladder sits inferior to the uterus and anterior to the vagina. It is separated from the uterus by the vesicouterine excavation. In infants and young children, the urinary bladder is in the abdomen even when empty.

Urethra
In anatomy, the (from Greek – ourethra) is a tube which connects the urinary bladder to the outside of the body. In humans, the urethra has an excretory function in both genders to pass.

Gastrointestinal Tract
The large intestine's main function is to transport food particles through the body and expel the indigestible parts at the other end, but it also collects waste from throughout the body. The typical brown colour of mammal waste is due to bilirubin, a breakdown product of normal heme catabolism. The lower part of the large intestine also extracts any remaining usable water and then removes solid waste. At about 10 feet long in humans, it transports the wastes through the tubes to be excreted.

Biliary System
The liver detoxifies and breaks down chemicals, poisons and other toxins that enter the body. For example, the liver transforms ammonia (which is poisonous) into urea in fish, amphibians and mammals, and into uric acid in birds and reptiles. Urea is filtered by the kidney into urine or through the gills in fish and tadpoles. Uric acid is paste-like and expelled as a semi-solid waste (the "white" in bird excrements). The liver also produces bile, and the body uses bile to break down fats into usable fats and unusable waste. Invertebrates lack a liver, but most terrestrial groups, like insects, possesses a number of blind guts that serve the similar functions. Marine invertebrates do not need the ammonia conversion of the liver, as they can usually expel ammonia directly by diffusion through the skin.

Integumentary System

Skin
Sweat glands in the skin secrete a fluid waste called sweat or perspiration; however, its primary functions are temperature control and pheromone release. Therefore, its role as a part of the excretory system is minimal. Sweating also maintains the level of salt in the body. In mammals, the skin excretes sweat through sweat glands throughout the body. The sweat, helped by salt, evaporates and helps to keep the body cool when it is warm. In amphibians, the lungs are very simple, and they lack the necessary means to the exhale like other tetrapods can. The moist, scale-less skin is therefore essential in helping to rid the blood of carbon dioxide, and also allows for urea to be expelled through diffusion when submerged. In small-bodied marine invertebrates, the skin is the most important excretory organ. That is particularly true for acoelomate groups like cnidarians, flatworms and nemerteans, who have no body cavities and hence no body fluid that can be drained or purified by nephrons, which is the reason acoelomate animals are thread-like (nemertans), flat (flatworms) or only consist of a thin layer of cells around a gelatinous non-cellular interior (cnidarians).

Eccrine
Like sweat glands, eccrine glands allow excess water to leave the body. The majority of eccrine glands are located mainly on the forehead, the bottoms of the feet, and the palms, although the glands are everywhere throughout the body. They help the body to maintain temperature control. Eccrine glands in the skin are unique to mammals. Secretions of sweat from the eccrine glands play a large role in controlling the body temperature of humans. Regulation of body temperature, also known as thermoregulation, is very important when it comes to instances that bring the body's temperature outside of the homeostatic temperature such as with a fever or even exercise. Together these glands make up the size of about one kidney and in one day a human can perspire amounts as much as 10 liters. The two functions consist of secretion of a filtrate in response to acetylcholine and reabsorption of sodium near the duct when there is water in excess so that a sweat can be surfacing the skin. There are three parts to the eccrine sweat gland and these are the pore, the duct, and the gland. The pore is the portion that goes through the outermost layer of the skin and is typically 5-10 microns in diameter. The duct is the part of the sweat gland that connects dermis cells to the epidermis. It is composed by two layers of cells and is between 10 and 20 microns in diameter. The gland does the actual secretion and it lies deep within the dermis. The cells that make up the gland are larger in size than the duct cells and its lumen is around 20 microns in diameter.

Substances

Bile
After bile is produced in the liver, it is stored in the gall bladder. It is then secreted within the small intestine where it helps to emulsify fats in the same manner as a soap. Bile also contains bilirubin, which is a waste product. Bile salts can be considered waste that is useful for the body given that they have a role in fat absorption from the stomach. They are excreted from the liver and along with blood flow they help to form the shape of the liver where they are excreted. For instance, if biliary drainage is impaired than that part of the liver will end up wasting away. Biliary obstruction is typically due to masses blocking the ducts of the system such as tumors. The consequences of this depend on the site of blockage and how long it goes on for. There is inflammation of the ducts due to the irritation from the bile acids and this can cause infections. If rupture of the duct takes place it is very traumatic and even fatal.

Urine
Within the kidney, blood first passes through the afferent artery to the capillary formation called a glomerulus and is collected in the Bowman's capsule, which filters the blood from its contents—primarily food and wastes. After the filtration process, the blood then returns to collect the food nutrients it needs, while the wastes pass into the collecting duct, to the renal pelvis, and to the ureter, and are then secreted out of the body via the urinary bladder.

Faeces
Feces (or faeces) are the solid or semisolid remains of food that could not be digested in the small intestine. Bacteria in the large intestine further break down the material. Feces contain a relatively small amount of metabolic waste products such as bacterially altered bilirubin, and the dead epithelial cells from the lining of the gut. Feces are discharged through the anus or cloaca during defecation. Feces can be used as fertilizer or soil conditioner in agriculture. It can also be burned as fuel or dried and used for construction. Some medicinal uses have been found. In the case of human feces, fecal transplants or fecal bacteriotherapy are in use. Urine and feces together are called excreta. Feces are discharged through the anus or cloaca during defecation. This process requires pressures that may reach 100 mm Hg in humans and 450 mm Hg in penguins. The forces required to expel the feces are generated through muscular contractions and a build-up of gases inside the gut, prompting the sphincter to relieve the pressure and to release the feces. The distinctive odor of feces is due to bacterial action. Gut flora produces compounds such as indole, skatole, and thiols (sulfur-containing compounds), as well as the inorganic gas hydrogen sulfide. These are the same compounds responsible for the odor of flatulence. Consumption of spicy foods may result in the spices being undigested and adding to the odor. The perceived bad odor of feces has been hypothesized to be a deterrent for humans, as consuming or touching it may result in sickness or infection. Human perception of the odor may be contrasted by a non-human animal's perception of it; for example, an animal who eats feces may be attracted to its odor.

Sweat
Perspiration, also known as sweating, is the production of fluids secreted by the sweat glands in the skin of mammals. Two types of sweat glands can be found in humans: eccrine glands and apocrine glands. The eccrine sweat glands are distributed over much of the body. In humans, sweating is primarily a means of thermoregulation, which is achieved by the water-rich secretion of the eccrine glands. Maximum sweat rates of an adult can be up to 2–4 liters per hour or 10–14 liters per day (10–15 g/min·m2), but is less in children prior to puberty. Evaporation of sweat from the skin surface has a cooling effect due to evaporative cooling. Hence, in hot weather, or when the individual's muscles heat up due to exertion, more sweat is produced. Animals with few sweat glands, such as dogs, accomplish similar temperature regulation results by panting, which evaporates water from the moist lining of the oral cavity and pharynx. Although sweating is found in a wide variety of mammals, relatively few (exceptions include humans and horses) produce large amounts of sweat in order to cool down. Sweat contributes to body odor when it is metabolized by bacteria on the skin. Medications that are used for other treatments and diet also affect odor. Some medical conditions, such as kidney failure and diabetic ketoacidosis, can also affect sweat odor. Areas that produce excessive sweat usually appear pink or white, but, in severe cases, may appear cracked, scaly, and soft.

Breath
Breathing (or ventilation) is the process of moving air into and out of the lungs to facilitate gas exchange with the internal environment, mostly by bringing in oxygen and flushing out carbon dioxide. All aerobic creatures need oxygen for cellular respiration, which uses the oxygen to break down foods for energy and produces carbon dioxide as a waste product. Breathing, or "external respiration", brings air into the lungs where gas exchange takes place in the alveoli through diffusion. The body's circulatory system transports these gases to and from the cells, where "cellular respiration" takes place.

The breathing of all vertebrates with lungs consists of repetitive cycles of inhalation and exhalation through a highly branched system of tubes or airways which lead from the nose to the alveoli. The number of respiratory cycles per minute is the breathing or respiratory rate, and is one of the four primary vital signs of life. Under normal conditions the breathing depth and rate is automatically, and unconsciously, controlled by several homeostatic mechanisms which keep the partial pressures of carbon dioxide and oxygen in the arterial blood constant.

Keeping the partial pressure of carbon dioxide in the arterial blood unchanged under a wide variety of physiological circumstances, contributes significantly to tight control of the pH of the extracellular fluids (ECF). Over-breathing (hyperventilation) and under-breathing (hypoventilation), which decrease and increase the arterial partial pressure of carbon dioxide respectively, cause a rise in the pH of ECF in the first case, and a lowering of the pH in the second. Both cause distressing symptoms.

Breathing has other important functions. It provides a mechanism for speech, laughter and similar expressions of the emotions. It is also used for reflexes such as yawning, coughing and sneezing. Animals that cannot thermoregulate by perspiration, because they lack sufficient sweat glands, may lose heat by evaporation through panting.

Clinical Signifiance

Kidney Stones
Scientifically, masses referred to as a renal calculus or nephrolith, or more commonly, "kidney stones," are solid masses of crystals that may be a variety of shapes, sizes, and textures, that can reside within one or both of the kidneys. Kidney stones form when the balance is off between the concentration of substances that pass through urine, and the substances that are supposed to dissolve them. When substances are not properly dissolved, they have the ability to build up, and form these kidney stones. These stones are most commonly made up of substances such as calcium, cystine, oxalate, and uric acid, as these are the substances that normally would dissolve within the urine. When they do not dissolve correctly and further build up, they will commonly lodge themselves in the urinary tract and in this case, are usually small enough to pass through urine. In extreme situations, however, these stones may lodge themselves within the tube that connects the kidney and the bladder, called the ureter. In this case, they become very large in size and will most likely cause great pain, bleeding, and possibly even block the flow of urine. These can occur in both men and women, and studies show that around 12% of men, and 8% of women in America will develop kidney stones within their lifetime.

In those extreme situations, in which kidney stones are too large to pass on their own, patients may seek removal. Most of these treatments involving kidney stone removal are done by a urologist; a physician who specializes in the organs of the Urinary system. A common way of removal is shock wave lithotripsy, in which the urologist will shock the kidney stone into smaller pieces via laser, allowing these pieces to further pass through the urine on their own, as a normal case of kidney stones. Larger, more serious cases may demand Cystoscopy, Ureteroscopy, or Percutaneous Nephrolithotomy, in which the doctor will use a viewing tool or camera to locate the stone, and based on the size or situation, may either chose to continue with surgical removal, or use the shock wave lithotripsy treatment. Once the kidney stone(s) are successfully eliminated, the urologist will commonly suggest medication to prevent future recurrences.

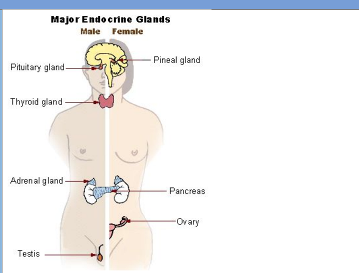
Pyelonephritis
Pyelonephritis is a type of urinary tract infection that occurs when bacteria enters the body through the urinary tract. It causes an inflammation of the renal parenchyma, calyces, and pelvis. There are three main classifications of pyelonephritis: acute, chronic and xanthogranulomatous.

Acute Pyelonephritis	In acute pyelonephritis, the patient experiences high fever, abdominal pain and pain while passing urine. Treatment for acute pyelonephritis is provided via antibiotics and an extensive urological investigation is conducted to find any abnormalities and prevent recurrence.
Chronic Pyelonephritis	In chronic pyelonephritis, patients experience persistent abdominal and flank pain, high fever, decreased appetite, weight loss, urinary tract symptoms and blood in the urine. Chronic pyelonephritis can also lead to scarring of the renal parenchyma caused by recurrent kidney infections.
Xanthogranulomatous Pyelonephritis	Xanthogranulomatous pyelonephritis is an unusual form of chronic pyelonephritis. It results in severe destruction of the kidney and causes granulomatous abscess formation. Patients infected with Xanthogranulomatous pyelonephritis experience recurrent fevers, anemia, kidney stones and loss of function in the affected kidney.

Treatment
A urine culture and antibiotics sensitivity test is issued for patients who are believed to have pyelonephritis. Since most cases of pyelonephritis are caused from bacterial infections, antibiotics are a common treatment option. Depending on the species of the infecting organism and the antibiotics sensitivity profile of the organism, treatments may include fluoroquinolones, cephalosporins, aminoglycosides, or trimethoprim individually or in combination. For patients with xanthogranulomatous pyelonephritis, treatment might include antibiotics as well as surgery. Nephrectomy is the most common surgical treatment for a majority of cases involving xanthogranulomatous pyelonephritis.

Epidemiology
In men, roughly 2-3 cases per 10,000 are treated as outpatients and 1 in 10,000 cases require admission to the hospital. In women, approximately 12-13 in 10,000 cases are treated as outpatients and 3-4 cases are admitted to a hospital. The most common age group affected by Xanthogranulomatous pyelonephritis is middle-aged women. Infants and elderly are also at an increased risk because of hormonal and anatomical changes.

4 Endocrine System



The endocrine system is a chemical messenger system comprising feedback loops of hormones released by internal glands of an organism directly into the circulatory system, regulating distant target organs. In humans, the major endocrine glands are the thyroid gland and the adrenal glands. In vertebrates, the hypothalamus is the neural control center for all endocrine systems. The study of the endocrine system and its disorders is known as endocrinology. Endocrinology is a branch of internal medicine. A number of glands that signal each other in sequence are usually referred to as an axis, for example, the hypothalamic-pituitary-adrenal axis.

In addition to the specialized endocrine organs mentioned above, many other organs that are part of other body systems, including bone, kidney, liver, heart and gonads, have secondary endocrine functions. For example, the kidney secretes endocrine hormones such as erythropoietin and renin. Hormones can consist of either amino acid complexes, steroids, eicosanoids, leukotrienes, or prostaglandins. The endocrine system can be contrasted to both exocrine glands, which secrete hormones to the outside of the body using ducts and paracrine signalling between cells over a relatively short distance.

Structure

Major Endocrine Systems
The human endocrine system consists of several systems that operate via feedback loops. Several important feedback systems are mediated via the hypothalamus and pituitary.

- TRH – TSH – T3/T4
- GnRH – LH/FSH – sex hormones
- CRH – ACTH – cortisol
- Renin – angiotensin – aldosterone
- Leptin vs. Insulin

Glands
Endocrine glands are glands of the endocrine system that secrete their products, hormones, directly into interstitial spaces and then absorbed into blood rather than through a duct. The major glands of the endocrine system include the pineal gland, pituitary gland, pancreas, ovaries, testes, thyroid gland, parathyroid gland, hypothalamus and adrenal glands. The hypothalamus and pituitary gland are neuroendocrine organs.

Cells
There are many types of cells that comprise the endocrine system and these cells typically make up larger tissues and organs that function within and outside of the endocrine system.

- Hypothalamus
- Anterior pituitary gland
- Pineal gland
- Posterior pituitary gland
- Thyroid gland
- Parathyroid gland
- Adrenal glands
  - Adrenal cortex
  - Adrenal medulla
- Pancreas
  - Alpha cells
  - Beta cells
  - Delta cells
  - F Cells
- Ovaries
  - Granulosa cells
- Testis
  - Leydig cells

Function

Hormones
A hormone is any of a class of signaling molecules produced by glands in multicellular organisms that are transported by the circulatory system to target distant organs to regulate physiology and behaviour. Hormones have diverse chemical structures, mainly of 3 classes: eicosanoids, steroids, and amino acid/protein derivatives (amines, peptides, and proteins). The glands that secrete hormones comprise the endocrine system. The term hormone is sometimes extended to include chemicals produced by cells that affect the same cell (autocrine or intracrine signalling) or nearby cells (paracrine signalling). Hormones are used to communicate between organs and tissues for physiological regulation and behavioral activities, such as digestion, metabolism, respiration, tissue function, sensory perception, sleep, excretion, lactation, stress, growth and development, movement, reproduction, and mood. Hormones affect distant cells by binding to specific receptor proteins in the target cell resulting in a change in cell function. This may lead to cell type-specific responses that include rapid changes to the activity of existing proteins, or slower changes in the expression of target genes. Amino acid–based hormones (amines and peptide or protein hormones) are water-soluble and act on the surface of target cells via signal transduction pathways; steroid hormones, being lipid-soluble, move through the plasma membranes of target cells to act within their nuclei.

Cell Signalling
The typical mode of cell signalling in the endocrine system is endocrine signaling, that is, using the circulatory system to reach distant target organs. However, there are also other modes, i.e., paracrine, autocrine, and neuroendocrine signaling. Purely neurocrine signaling between neurons, on the other hand, belongs completely to the nervous system.

Autocrine	Autocrine signaling is a form of signaling in which a cell secretes a hormone or chemical messenger (called the autocrine agent) that binds to autocrine receptors on the same cell, leading to changes in the cells.
Paracrine	Some endocrinologists and clinicians include the paracrine system as part of the endocrine system, but there is not consensus. Paracrines are slower acting, targeting cells in the same tissue or organ. An example of this is somatostatin which is released by some pancreatic cells and targets other pancreatic cells.

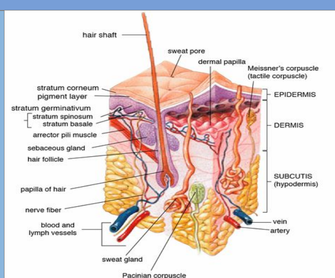
Juxtacrine	Juxtacrine signaling is a type of intercellular communication that is transmitted via oligosaccharide, lipid, or protein components of a cell membrane, and may affect either the emitting cell or the immediately adjacent cells. It occurs between adjacent cells that possess broad patches of closely opposed plasma membrane linked by transmembrane channels known as connexons. The gap between the cells can usually be between only 2 and 4 nm.

Disease

Diseases of the endocrine system are common, including conditions such as diabetes mellitus, thyroid disease, and obesity. Endocrine disease is characterized by misregulated hormone release (a productive pituitary adenoma), inappropriate response to signaling (hypothyroidism), lack of a gland (diabetes mellitus type 1, diminished erythropoiesis in chronic renal failure), or structural enlargement in a critical site such as the thyroid (toxic multinodular goitre). Hypofunction of endocrine glands can occur as a result of loss of reserve, hyposecretion, agenesis, atrophy, or active destruction. Hyperfunction can occur as a result of hypersecretion, loss of suppression, hyperplastic or neoplastic change, or hyperstimulation. Endocrinopathies are classified as primary, secondary, or tertiary. Primary endocrine disease inhibits the action of downstream glands. Secondary endocrine disease is indicative of a problem with the pituitary gland. Tertiary endocrine disease is associated with dysfunction of the hypothalamus and its releasing hormones. As the thyroid, and hormones have been implicated in signaling distant tissues to proliferate, for example, the estrogen receptor has been shown to be involved in certain breast cancers. Endocrine, paracrine, and autocrine signaling have all been implicated in proliferation, one of the required steps of oncogenesis.

Other common diseases that result from endocrine dysfunction include Addison's disease, Cushing's disease and Graves' disease. Cushing's disease and Addison's disease are pathologies involving the dysfunction of the adrenal gland. Dysfunction in the adrenal gland could be due to primary or secondary factors and can result in hypercortisolism or hypocortisolism. Cushing's disease is characterized by the hypersecretion of the adrenocorticotropic hormone (ACTH) due to a pituitary adenoma that ultimately causes endogenous hypercortisolism by stimulating the adrenal glands. Some clinical signs of Cushing's disease include obesity, moon face, and hirsutism. Addison's disease is an endocrine disease that results from hypocortisolism caused by adrenal gland insufficiency. Adrenal insufficiency is significant because it is correlated with decreased ability to maintain blood pressure and blood sugar, a defect that can prove to be fatal. Graves' disease involves the hyperactivity of the thyroid gland which produces the T3 and T4 hormones. Graves' disease effects range from excess sweating, fatigue, heat intolerance and high blood pressure to swelling of the eyes that causes redness, puffiness and in rare cases reduced or double vision.

5 Integumentary System



The integumentary system comprises the skin and its appendages acting to protect the body from various kinds of damage, such as loss of water or damages from outside. The integumentary system includes hair, scales, feathers, hooves, and nails. It has a variety of additional functions; it may serve to waterproof, and protect the deeper tissues, excrete wastes, and regulate body temperature, and is the attachment site for sensory receptors to detect pain, sensation, pressure, and temperature. In most land vertebrates with significant exposure to sunlight, the integumentary system also provides for vitamin D synthesis.

Skin

The skin is the largest organ of the body. In humans, it accounts for about 12 to 15 percent of total body weight and covers 1.5-2m2 of surface area. The human skin (integument) is composed of at least two major layers of tissue: the epidermis and dermis. (The hypodermis or subcutaneous layer is not part of the skin.) The epidermis is the outermost layer, providing the initial barrier to the external environment.It is separated from the dermis by the basement membrane. The epidermis contains melanocytes and gives color to the skin. The deepest layer of epidermis also contains nerve endings. Beneath this, the dermis comprises two sections, the papillary and reticular layers, and contains connective tissues, vessels, glands, follicles, hair roots, sensory nerve endings, and muscular tissue. The deepest layer, the hypodermis, is primarily made up of adipose tissue. Substantial collagen bundles anchor the dermis to the hypodermis in a way that permits most areas of the skin to move freely over the deeper tissue layers.

Epidermis
The epidermis is the top layer of skin made up of epithelial cells. It does not contain blood vessels. Its main functions are protection, absorption of nutrients, and homeostasis. In structure, it consists of a keratinized stratified squamous epithelium; four types of cells: keratinocytes, melanocytes, Merkel cells, and Langerhans cells. The major cell of the epidermis is the keratinocyte, which produces keratin, a fibrous protein that aids in skin protection. An overwhelming amount of keratin can cause disease by giving rise to eruptions from the skin that will protrude outwards and lead to infection. Keratin is also a waterproofing protein. Millions of dead keratinocytes rub off daily. The majority of the skin on the body is keratinized. The only skin on the body that is non-keratinized is the lining of mucous membranes, such as the inside of the mouth. Non-keratinized cells allow water to "stay" atop the structure. The protein keratin stiffens epidermal tissue to form fingernails. Nails grow from a thin area called the nail matrix at an average of 1 mm per week. The lunula is the crescent-shape area at the base of the nail, lighter in color as it mixes with the matrix cells. Also, the stratum corneum is the top part of the epidermis.

Dermis
The dermis is the middle layer of skin, composed of dense irregular connective tissue and areolar connective tissue such as a collagen with elastin arranged in a diffusely bundled and woven pattern. The dermis has two layers. One is the papillary layer which is the superficial layer and consists of the areolar connective tissue. The other is the reticular layer which is the deep layer of the dermis and consists of the dense irregular connective tissue. These layers serve to give elasticity to the integument, allowing stretching and conferring flexibility, while also resisting distortions, wrinkling, and sagging. The dermal layer provides a site for the endings of blood vessels and nerves. Many chromatophores are also stored in this layer, as are the bases of integumental structures such as hair, feathers, and glands.

Hypodermis
The hypodermis, otherwise known as the subcutaneous layer, is a layer beneath the skin. It invaginates into the dermis and is attached to the latter, immediately above it, by collagen and elastin fibers. It is essentially composed of a type of cell known as adipocytes specialized in accumulating and storing fats. These cells are grouped together in lobules separated by connective tissue. The hypodermis acts as an energy reserve. The fats contained in the adipocytes can be put back into circulation, via the venous route, during intense effort or when there is a lack of energy-providing substances, and are then transformed into energy. The hypodermis participates, passively at least, in thermoregulation since fat is a heat insulator.

Functions

The integumentary system has multiple roles in homeostasis. All body systems work in an interconnected manner to maintain the internal conditions essential to the function of the body. The skin has an important job of protecting the body and acts as the body's first line of defense against infection, temperature change, and other challenges to homeostasis. Functions include:

Functions

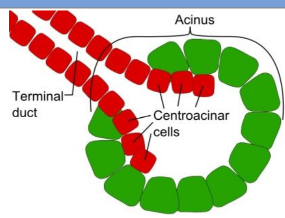
● Protect the body's internal living tissues and organs ● Protect against invasion by infectious organisms ● Protect the body from dehydration ● Protect the body against abrupt changes in temperature, maintain homeostasis ● Help excrete waste materials through perspiration ● Act as a receptor for touch, pressure, pain, heat, and cold (see Somatosensory system)	● Protect the body against sunburns by secreting melanin ● Generate vitamin D through exposure to ultraviolet light ● Store water, fat, glucose, vitamin D ● Maintenance of the body form ● Formation of new cells from stratum germanium to repair minor injuries ● Protect from UV rays. ● Regulates body temperature

It distinguishes, separates, and protects the organism from its surroundings. Small-bodied invertebrates of aquatic or continually moist habitats respire using the outer layer (integument). This gas exchange system, where gases simply diffuse into and out of the interstitial fluid, is called integumentary exchange.

Diseases / Injuries

Possible diseases and injuries to the human integumentary system include:	● Rash ● Yeast ● Athlete's Foot ● Infection ● Sunburn ● Skin Cancer	● Albinism ● Acne ● Herpes ● Herpes labialis, commonly called cold sores ● Impetigo ● Rubella	● Cancer ● Psoriasis ● Rabies ● Rosacea ● Atopic Dermatitis ● Eczema

6 Exocrine System



Exocrine glands are glands that produce and secrete substances onto an epithelial surface by way of a duct. Examples of exocrine glands include sweat, salivary, mammary, ceruminous, lacrimal, sebaceous, and mucous. Exocrine glands are one of two types of glands in the human body, the other being endocrine glands, which secrete their products directly into the bloodstream.

The liver and pancreas are both exocrine and endocrine glands; they are exocrine glands because they secrete products—bile and pancreatic juice—into the gastrointestinal tract through a series of ducts, and endocrine because they secrete other substances directly into the bloodstream.

Structure Exocrine glands contain a glandular portion and a duct portion, the structures of which can be used to classify the gland.	● The duct portion may be branched (called compound) or unbranched (called simple). ● The glandular portion may be tubular or acinar, or may be a mix of the two (called tubuloacinar). If the glandular portion branches, then the gland is called a branched gland.
Method of Secretion Exocrine glands are named apocrine glands, holocrine glands, or merocrine glands based on how their products are secreted.	● Merocrine secretion – cells excrete their substances by exocytosis; for example, pancreatic acinar cells. ● Apocrine secretion – a portion of the cell membrane that contains the excretion buds off. ● Holocrine secretion – the entire cell disintegrates to excrete its substance; for example, sebaceous glands of the skin and nose.

Product Secreted
● Serous cells secrete proteins, often enzymes. Examples include gastric chief cells and Paneth cells
● Mucous cells secrete mucus. Examples include Brunner's glands, esophageal glands, and pyloric glands
● Mixed glands secrete both protein and mucus. Examples include the salivary glands: although the parotid gland 20%is predominantly serous, the sublingual gland 5% mainly mucous gland, and the submandibular gland 70%is a mixed, mainly serous gland.
● Sebaceous glands secrete Sebum, a lipid product. These glands are also known as oil glands, e.g. Fordyce spots and Meibomian glands.

7 Immune System

The immune system is a host defense system comprising many biological structures and processes within an organism that protects against disease. To function properly, an immune system must detect a wide variety of agents, known as pathogens, from viruses to parasitic worms, and distinguish them from the organism's own healthy tissue. In many species, there are two major subsystems of the immune system: the innate immune system and the adaptive immune system. Both subsystems use humoral immunity and cell-mediated immunity to perform their functions. In humans, the blood–brain barrier, blood–cerebrospinal fluid barrier, and similar fluid–brain barriers separate the peripheral immune system from the neuroimmune system, which protects the brain.

Pathogens can rapidly evolve and adapt, and thereby avoid detection and neutralization by the immune system; however, multiple defense mechanisms have also evolved to recognize and neutralize pathogens. Even simple unicellular organisms such as bacteria possess a rudimentary immune system in the form of enzymes that protect against bacteriophage infections. Other basic immune mechanisms evolved in ancient eukaryotes and remain in their modern descendants, such as plants and invertebrates. These mechanisms include phagocytosis, antimicrobial peptides called defensins, and the complement system.

Jawed vertebrates, including humans, have even more sophisticated defense mechanisms, including the ability to adapt over time to recognize specific pathogens more efficiently. Adaptive (or acquired) immunity creates immunological memory after an initial response to a specific pathogen, leading to an enhanced response to subsequent encounters with that same pathogen. This process of acquired immunity is the basis of vaccination. Disorders of the immune system can result in autoimmune diseases, inflammatory diseases and cancer. Immunodeficiency occurs when the immune system is less active than normal, resulting in recurring and life-threatening infections.

In humans, immunodeficiency can either be the result of a genetic disease such as severe combined immunodeficiency, acquired conditions such as HIV/AIDS, or the use of immunosuppressive medication. In contrast, autoimmunity results from a hyperactive immune system attacking normal tissues as if they were foreign organisms. Common autoimmune diseases include Hashimoto's thyroiditis, rheumatoid arthritis, diabetes mellitus type 1, and systemic lupus erythematosus. Immunology covers the study of all aspects of the immune system.

Layered Defence

The immune system protects organisms from infection with layered defenses of increasing specificity. In simple terms, physical barriers prevent pathogens such as bacteria and viruses from entering the organism. If a pathogen breaches these barriers, the innate immune system provides an immediate, but non-specific response. Innate immune systems are found in all plants and animals. If pathogens successfully evade the innate response, vertebrates possess a second layer of protection, the adaptive immune system, which is activated by the innate response. Here, the immune system adapts its response during an infection to improve its recognition of the pathogen. This improved response is then retained after the pathogen has been eliminated, in the form of an immunological memory, and allows the adaptive immune system to mount faster and stronger attacks each time this pathogen is encountered.

Components of the immune system
Innate immune system
- Response is non-specific
- Exposure leads to immediate maximal response
- Cell-mediated and humoral components
- No immunological memory
- Found in nearly all forms of life

Components of the immune system
Adaptive immune system
- Pathogen and antigen specific response
- Lag time between exposure and maximal response
- Cell-mediated and humoral components
- Exposure leads to immunological memory
- Found only in jawed vertebrates

Both innate and adaptive immunity depend on the ability of the immune system to distinguish between self and non-self molecules. In immunology, self molecules are those components of an organism's body that can be distinguished from foreign substances by the immune system. Conversely, non-self molecules are those recognized as foreign molecules. One class of non-self molecules are called antigens (short for antibody generators) and are defined as substances that bind to specific immune receptors and elicit an immune response. Newborn infants have no prior exposure to microbes and are particularly vulnerable to infection. Several layers of passive protection are provided by the mother.

During pregnancy, a particular type of antibody, called IgG, is transported from mother to baby directly through the placenta, so human babies have high levels of antibodies even at birth, with the same range of antigen specificities as their mother. Breast milk or colostrum also contains antibodies that are transferred to the gut of the infant and protect against bacterial infections until the newborn can synthesize its own antibodies. This is passive immunity because the fetus does not actually make any memory cells or antibodies—it only borrows them. This passive immunity is usually short-term, lasting from a few days up to several months. In medicine, protective passive immunity can also be transferred artificially from one individual to another via antibody-rich serum.

Innate Immune System

Microorganisms or toxins that successfully enter an organism encounter the cells and mechanisms of the innate immune system. The innate response is usually triggered when microbes are identified by pattern recognition receptors, which recognize components that are conserved among broad groups of microorganisms, or when damaged, injured or stressed cells send out alarm signals, many of which (but not all) are recognized by the same receptors as those that recognize pathogens. Innate immune defenses are non-specific, meaning these systems respond to pathogens in a generic way. This system does not confer long-lasting immunity against a pathogen. The innate immune system is the dominant system of host defense in most organisms.

Pattern Recognition by Cells
Cells in the innate immune system use pattern recognition receptors (PRRs) to recognize molecular structures that are produced by microbial pathogens. PRRs are germline-encoded host sensors, which detect molecules typical for the pathogens. They are proteins expressed, mainly, by cells of the innate immune system, such as dendritic cells, macrophages, monocytes, neutrophils and epithelial cells, to identify two classes of molecules: pathogen-associated molecular patterns (PAMPs), which are associated with microbial pathogens, and damage-associated molecular patterns (DAMPs), which are associated with components of host's cells that are released during cell damage or death.

Toll-like Receptors
Recognition of extracellular or endosomal pathogen-associated molecular patterns is mediated by transmembrane proteins known as toll-like receptors (TLRs). TLRs share a typical structural motif, the Leucine rich repeats (LRR), which give them their specific appearance and are also responsible for TLR functionality. Toll-like receptors were first discovered in Drosophila and trigger the synthesis and secretion of cytokines and activation of other host defense programs that are necessary for both innate or adaptive immune responses. To date, ten functional members of the TLR family have been described in humans.

Cytosolic Receptors
Cells in the innate immune system have pattern recognition receptors that detect infection or cell damage in the cytosol. Three major classes of these cytosolic receptors are NOD–like receptors, RIG (retinoic acid-inducible gene)-like receptors, and cytosolic DNA sensors.

Inflammasomes
Inflammasomes are multiprotein complexes (consist of an NLR, the adaptor protein ASC, and the effector molecule pro-caspase-1) that form in response to cytosolic PAMPs and DAMPs, whose function is to generate active forms of the inflammatory cytokines IL-1β and IL-18.

Surface Barriers
Several barriers protect organisms from infection, including mechanical, chemical, and biological barriers. The waxy cuticle of most leaves, the exoskeleton of insects, the shells and membranes of externally deposited eggs, and skin are examples of mechanical barriers that are the first line of defense against infection. However, as organisms cannot be completely sealed from their environments, other systems act to protect body openings such as the lungs, intestines, and the genitourinary tract. In the lungs, coughing and sneezing mechanically eject pathogens and other irritants from the respiratory tract. The flushing action of tears and urine also mechanically expels pathogens, while mucus secreted by the respiratory and gastrointestinal tract serves to trap and entangle microorganisms. Chemical barriers also protect against infection. The skin and respiratory tract secrete antimicrobial peptides such as the β-defensins. Enzymes such as lysozyme and phospholipase A2 in saliva, tears, and breast milk are also antibacterials. Vaginal secretions serve as a chemical barrier following menarche, when they become slightly acidic, while semen contains defensins and zinc to kill pathogens. In the stomach, gastric acid serves as a powerful chemical defense against ingested pathogens.

Within the genitourinary and gastrointestinal tracts, commensal flora serve as biological barriers by competing with pathogenic bacteria for food and space and, in some cases, by changing the conditions in their environment, such as pH or available iron. As a result of the symbiotic relationship between commensals and the immune system, the probability that pathogens will reach sufficient numbers to cause illness is reduced. However, since most antibiotics non-specifically target bacteria and do not affect fungi, oral antibiotics can lead to an "overgrowth" of fungi and cause conditions such as a vaginal candidiasis (a yeast infection). There is good evidence that re-introduction of probiotic flora, such as pure cultures of the lactobacilli normally found in unpasteurized yogurt, helps restore a healthy balance of microbial populations in intestinal infections in children and encouraging preliminary data in studies on bacterial gastroenteritis, inflammatory bowel diseases, urinary tract infection and post-surgical infections.

Cellular Components
Leukocytes (white blood cells) act like independent, single-celled organisms and are the second arm of the innate immune system. The innate leukocytes include the phagocytes (macrophages, neutrophils, and dendritic cells), innate lymphoid cells, mast cells, eosinophils, basophils, and natural killer cells. These cells identify and eliminate pathogens, either by attacking larger pathogens through contact or by engulfing and then killing microorganisms. Innate cells are also important mediators in lymphoid organ development and the activation of the adaptive immune system. Phagocytosis is an important feature of cellular innate immunity performed by cells called phagocytes that engulf, or eat, pathogens or particles. Phagocytes generally patrol the body searching for pathogens, but can be called to specific locations by cytokines. Once a pathogen has been engulfed by a phagocyte, it becomes trapped in an intracellular vesicle called a phagosome, which subsequently fuses with another vesicle called a lysosome to form a phagolysosome. The pathogen is killed by the activity of digestive enzymes or following a respiratory burst that releases free radicals into the phagolysosome. Phagocytosis evolved as a means of acquiring nutrients, but this role was extended in phagocytes to include engulfment of pathogens as a defense mechanism. Phagocytosis probably represents the oldest form of host defense, as phagocytes have been identified in both vertebrate and invertebrate animals.

Inflammation
Inflammation is one of the first responses of the immune system to infection. The symptoms of inflammation are redness, swelling, heat, and pain, which are caused by increased blood flow into tissue. Inflammation is produced by eicosanoids and cytokines, which are released by injured or infected cells. Eicosanoids include prostaglandins that produce fever and the dilation of blood vessels associated with inflammation, and leukotrienes that attract certain white blood cells (leukocytes). Common cytokines include interleukins that are responsible for communication between white blood cells; chemokines that promote chemotaxis; and interferons that have anti-viral effects, such as shutting down protein synthesis in the host cell. Growth factors and cytotoxic factors may also be released. These cytokines and other chemicals recruit immune cells to the site of infection and promote healing of any damaged tissue following the removal of pathogens.

MEDICAL Body Systems Immune System

Complement System
The complement system is a biochemical cascade that attacks the surfaces of foreign cells. It contains over 20 different proteins and is named for its ability to "complement" the killing of pathogens by antibodies. Complement is the major humoral component of the innate immune response. Many species have complement systems, including non-mammals like plants, fish, and some invertebrates. In humans, this response is activated by complement binding to antibodies that have attached to these microbes or the binding of complement proteins to carbohydrates on the surfaces of microbes. This recognition signal triggers a rapid killing response. The speed of the response is a result of signal amplification that occurs after sequential proteolytic activation of complement molecules, which are also proteases. After complement proteins initially bind to the microbe, they activate their protease activity, which in turn activates other complement proteases, and so on. This produces a catalytic cascade that amplifies the initial signal by controlled positive feedback. The cascade results in the production of peptides that attract immune cells, increase vascular permeability, and opsonize (coat) the surface of a pathogen, marking it for destruction. This deposition of complement can also kill cells directly by disrupting their plasma membrane.

Physiological Regulation

The immune system is involved in many aspects of physiological regulation in the body. The immune system interacts intimately with other systems, such as the endocrine and the nervous systems. The immune system also plays a crucial role in embryogenesis (development of the embryo), as well as in tissue repair and regeneration.

Hormones
Hormones can act as immunomodulators, altering the sensitivity of the immune system. For example, female sex hormones are known immunostimulators of both adaptive and innate immune responses. Some autoimmune diseases such as lupus erythematosus strike women preferentially, and their onset often coincides with puberty. By contrast, male sex hormones such as testosterone seem to be immunosuppressive. Other hormones appear to regulate the immune system as well, most notably prolactin, growth hormone and vitamin D.

Vitamin D
When a T-cell encounters a foreign pathogen, it extends a vitamin D receptor. This is essentially a signaling device that allows the T-cell to bind to the active form of vitamin D, the steroid hormone calcitriol. T-cells have a symbiotic relationship with vitamin D. Not only does the T-cell extend a vitamin D receptor, in essence asking to bind to the steroid hormone version of vitamin D, calcitriol, but the T-cell expresses the gene CYP27B1, which is the gene responsible for converting the pre-hormone version of vitamin D, calcidiol into the steroid hormone version, calcitriol. Only after binding to calcitriol can T-cells perform their intended function. Other immune system cells that are known to express CYP27B1 and thus activate vitamin D calcidiol, are dendritic cells, keratinocytes and macrophages. It is conjectured that a progressive decline in hormone levels with age is partially responsible for weakened immune responses in aging individuals. Conversely, some hormones are regulated by the immune system, notably thyroid hormone activity. The age-related decline in immune function is also related to decreasing vitamin D levels in the elderly. As people age, two things happen that negatively affect their vitamin D levels. First, they stay indoors more due to decreased activity levels. This means that they get less sun and therefore produce less cholecalciferol via UVB radiation. Second, as a person ages the skin becomes less adept at producing vitamin D.

Sleep and Rest
The immune system is affected by sleep and rest, and sleep deprivation is detrimental to immune function. Complex feedback loops involving cytokines, such as interleukin-1 and tumor necrosis factor-a produced in response to infection, appear to also play a role in the regulation of non-rapid eye movement (REM) sleep Thus the immune response to infection may result in changes to the sleep cycle, including an increase in slow-wave sleep relative to REM sleep. When suffering from sleep deprivation, active immunizations may have a diminished effect and may result in lower antibody production, and a lower immune response, than would be noted in a well-rested individual. Additionally, proteins such as NFIL3, which have been shown to be closely intertwined with both T-cell differentiation and our circadian rhythms, can be affected through the disturbance of natural light and dark cycles through instances of sleep deprivation, shift work, etc. As a result, these disruptions can lead to an increase in chronic conditions such as heart disease, chronic pain, and asthma.

In addition to the negative consequences of sleep deprivation, sleep and the intertwined circadian system have been shown to have strong regulatory effects on immunological functions affecting both the innate and the adaptive immunity. First, during the early slow-wave-sleep stage, a sudden drop in blood levels of cortisol, epinephrine, and norepinephrine induce increased blood levels of the hormones leptin, pituitary growth hormone, and prolactin. These signals induce a pro-inflammatory state through the production of the pro-inflammatory cytokines interleukin-1, interleukin-12, TNF-alpha and IFN-gamma.

These cytokines then stimulate immune functions such as immune cells activation, proliferation, and differentiation. It is during this time that undifferentiated, or less differentiated, like naïve and central memory T cells, peak (i.e. during a time of a slowly evolving adaptive immune response). In addition to these effects, the milieu of hormones produced at this time (leptin, pituitary growth hormone, and prolactin) support the interactions between APCs and T-cells, a shift of the Th1/Th2 cytokine balance towards one that supports Th1, an increase in overall Th cell proliferation, and naïve T cell migration to lymph nodes.

This milieu is also thought to support the formation of long-lasting immune memory through the initiation of Th1 immune responses. In contrast, during wake periods differentiated effector cells, such as cytotoxic natural killer cells and CTLs (cytotoxic T lymphocytes), peak in order to elicit an effective response against any intruding pathogens. As well during awake active times, anti-inflammatory molecules, such as cortisol and catecholamines, peak. There are two theories as to why the pro-inflammatory state is reserved for sleep time.

First, inflammation would cause serious cognitive and physical impairments if it were to occur during wake times. Second, inflammation may occur during sleep times due to the presence of melatonin. Inflammation causes a great deal of oxidative stress and the presence of melatonin during sleep times could actively counteract free radical production during this time.

Nutrition and Diet
Overnutrition is associated with diseases such as diabetes and obesity, which are known to affect immune function. More moderate malnutrition, as well as certain specific trace mineral and nutrient deficiencies, can also compromise the immune response. Foods rich in certain fatty acids may foster a healthy immune system. Likewise, fetal undernourishment can cause a lifelong impairment of the immune system.

Repair and Regeneration
The immune system, particularly the innate component, plays a decisive role in tissue repair after an insult. Key actors include macrophages and neutrophils, but other cellular actors, including γδ T cells, innate lymphoid cells (ILCs), and regulatory T cells (Tregs), are also important. The plasticity of immune cells and the balance between pro-inflammatory and anti-inflammatory signals are crucial aspects of efficient tissue repair. Immune components and pathways are involved in regeneration as well, for example in amphibians. According to one hypothesis, organisms that can regenerate could be less immunocompetent than organisms that cannot regenerate.

Disorders

The immune system is a remarkably effective structure that incorporates specificity, inducibility and adaptation. Failures of host defense do occur, however, and fall into three broad categories: immunodeficiencies, autoimmunity, and hypersensitivities.

Immunodeficiencies

Immunodeficiencies occur when one or more of the components of the immune system are inactive. The ability of the immune system to respond to pathogens is diminished in both the young and the elderly, with immune responses beginning to decline at around 50 years of age due to immunosenescence. In developed countries, obesity, alcoholism, and drug use are common causes of poor immune function. However, malnutrition is the most common cause of immunodeficiency in developing countries. Diets lacking sufficient protein are associated with impaired cell-mediated immunity, complement activity, phagocyte function, IgA antibody concentrations, and cytokine production. Additionally, the loss of the thymus at an early age through genetic mutation or surgical removal results in severe immunodeficiency and a high susceptibility to infection. Immunodeficiencies can also be inherited or 'acquired'. Chronic granulomatous disease, where phagocytes have a reduced ability to destroy pathogens, is an example of an inherited, or congenital, immunodeficiency. AIDS and some types of cancer cause acquired immunodeficiency.

Autoimmunity

Overactive immune responses comprise the other end of immune dysfunction, particularly the autoimmune disorders. Here, the immune system fails to properly distinguish between self and non-self, and attacks part of the body. Under normal circumstances, many T cells and antibodies react with "self" peptides. One of the functions of specialized cells (located in the thymus and bone marrow) is to present young lymphocytes with self antigens produced throughout the body and to eliminate those cells that recognize self-antigens, preventing autoimmunity.

Hypersensitivity

Hypersensitivity is an immune response that damages the body's own tissues. They are divided into four classes (Type I – IV) based on the mechanisms involved and the time course of the hypersensitive reaction. Type I hypersensitivity is an immediate or anaphylactic reaction, often associated with allergy. Symptoms can range from mild discomfort to death. Type I hypersensitivity is mediated by IgE, which triggers degranulation of mast cells and basophils when cross-linked by antigen. Type II hypersensitivity occurs when antibodies bind to antigens on the patient's own cells, marking them for destruction. This is also called antibody-dependent (or cytotoxic) hypersensitivity, and is mediated by IgG and IgM antibodies. Immune complexes (aggregations of antigens, complement proteins, and IgG and IgM antibodies) deposited in various tissues trigger Type III hypersensitivity reactions. Type IV hypersensitivity (also known as cell-mediated or delayed type hypersensitivity) usually takes between two and three days to develop. Type IV reactions are involved in many autoimmune and infectious diseases, but may also involve contact dermatitis (poison ivy). These reactions are mediated by T cells, monocytes, and macrophages.

Idiopathic Inflammation

Inflammation is one of the first responses of the immune system to infection, but it can appear without known cause. Inflammation is produced by eicosanoids and cytokines, which are released by injured or infected cells. Eicosanoids include prostaglandins that produce fever and the dilation of blood vessels associated with inflammation, and leukotrienes that attract certain white blood cells (leukocytes). Common cytokines include interleukins that are responsible for communication between white blood cells; chemokines that promote chemotaxis; and interferons that have anti-viral effects, such as shutting down protein synthesis in the host cell. Growth factors and cytotoxic factors may also be released. These cytokines and other chemicals recruit immune cells to the site of infection and promote healing of any damaged tissue following the removal of pathogens.

Manipulation in Medicine

The immune response can be manipulated to suppress unwanted responses resulting from autoimmunity, allergy, and transplant rejection, and to stimulate protective responses against pathogens that largely elude the immune system (see immunization) or cancer.

Immunosuppression

Immunosuppressive drugs are used to control autoimmune disorders or inflammation when excessive tissue damage occurs, and to prevent transplant rejection after an organ transplant. Anti-inflammatory drugs are often used to control the effects of inflammation. Glucocorticoids are the most powerful of these drugs; however, these drugs can have many undesirable side effects, such as central obesity, hyperglycemia, osteoporosis, and their use must be tightly controlled. Lower doses of anti-inflammatory drugs are often used in conjunction with cytotoxic or immunosuppressive drugs such as methotrexate or azathioprine. Cytotoxic drugs inhibit the immune response by killing dividing cells such as activated T cells. However, the killing is indiscriminate and other constantly dividing cells and their organs are affected, which causes toxic side effects. Immunosuppressive drugs such as cyclosporin prevent T cells from responding to signals correctly by inhibiting signal transduction pathways. Cancer immunotherapy covers the medical ways to stimulate the immune system to attack cancer tumours.

Vaccination

Long-term active memory is acquired following infection by activation of B and T cells. Active immunity can also be generated artificially, through vaccination. The principle behind vaccination (also called immunization) is to introduce an antigen from a pathogen in order to stimulate the immune system and develop specific immunity against that particular pathogen without causing disease associated with that organism. This deliberate induction of an immune response is successful because it exploits the natural specificity of the immune system, as well as its inducibility. With infectious disease remaining one of the leading causes of death in the human population, vaccination represents the most effective manipulation of the immune system mankind has developed. Most viral vaccines are based on live attenuated viruses, while many bacterial vaccines are based on acellular components of micro-organisms, including harmless toxin components. Since many antigens derived from acellular vaccines do not strongly induce the adaptive response, most bacterial vaccines are provided with additional adjuvants that activate the antigen-presenting cells of the innate immune system and maximize immunogenicity.

Tumor Immunology

Another important role of the immune system is to identify and eliminate tumors. This is called immune surveillance. The transformed cells of tumors express antigens that are not found on normal cells. To the immune system, these antigens appear foreign, and their presence causes immune cells to attack the transformed tumor cells. The antigens expressed by tumors have several sources; some are derived from oncogenic viruses like human papillomavirus, which causes cervical cancer, while others are the organism's own proteins that occur at low levels in normal cells but reach high levels in tumor cells.

One example is an enzyme called tyrosinase that, when expressed at high levels, transforms certain skin cells (e.g. melanocytes) into tumors called melanomas. A third possible source of tumor antigens are proteins normally important for regulating cell growth and survival, that commonly mutate into cancer inducing molecules called oncogenes. The main response of the immune system to tumors is to destroy the abnormal cells using killer T cells, sometimes with the assistance of helper T cells.

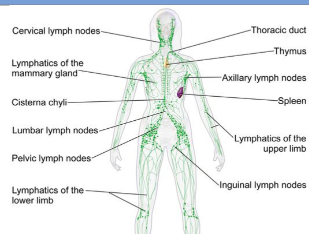
Tumor antigens are presented on MHC class I molecules in a similar way to viral antigens. This allows killer T cells to recognize the tumor cell as abnormal. NK cells also kill tumorous cells in a similar way, especially if the tumor cells have fewer MHC class I molecules on their surface than normal; this is a common phenomenon with tumors. Sometimes antibodies are generated against tumor cells allowing for their destruction by the complement system. This allows killer T cells to recognize the tumor cell as abnormal.

NK cells also kill tumorous cells in a similar way, especially if the tumor cells have fewer MHC class I molecules on their surface than normal; this is a common phenomenon with tumors. Sometimes antibodies are generated against tumor cells allowing for their destruction by the complement system. Clearly, some tumors evade the immune system and go on to become cancers. Tumor cells often have a reduced number of MHC class I molecules on their surface, thus avoiding detection by killer T cells.

Some tumor cells also release products that inhibit the immune response; for example by secreting the cytokine TGF-β, which suppresses the activity of macrophages and lymphocytes. In addition, immunological tolerance may develop against tumor antigens, so the immune system no longer attacks the tumor cells.

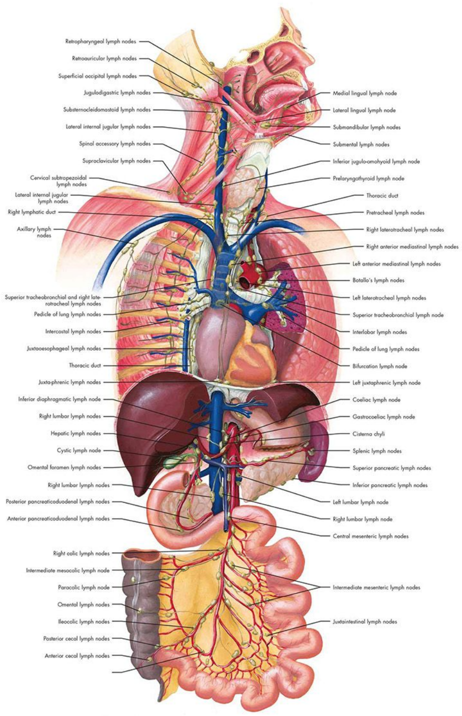
Paradoxically, macrophages can promote tumor growth when tumor cells send out cytokines that attract macrophages, which then generate cytokines and growth factors such as tumor-necrosis factor alpha that nurture tumor development or promote stem-cell-like plasticity. In addition, a combination of hypoxia in the tumor and a cytokine produced by macrophages induces tumor cells to decrease production of a protein that blocks metastasis and thereby assists spread of cancer cells.

8 Lymphatic System

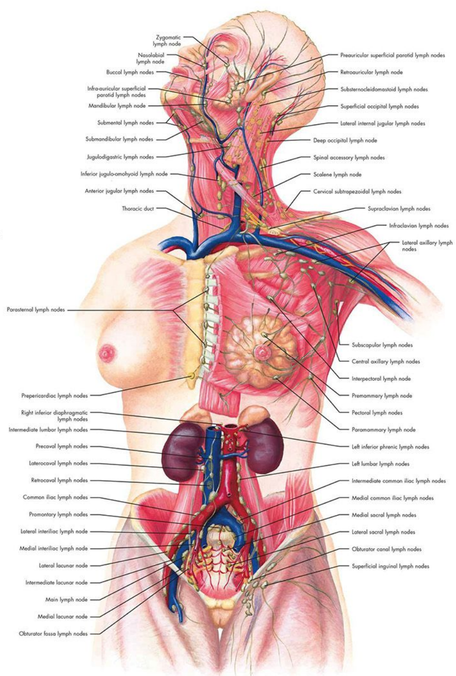


The lymphatic system is part of the vascular system and an important part of the immune system, comprising a large network of lymphatic vessels that carry a clear fluid called lymph directionally towards the heart. Unlike the circulatory system, the lymphatic system is not a closed system. The human circulatory system processes an average of 20 litres of blood per day through capillary filtration, which removes plasma while leaving the blood cells. Roughly 17 litres of the filtered plasma is reabsorbed directly into the blood vessels, while the remaining three litres remain in the interstitial fluid.

One of the main functions of the lymph system is to provide an accessory return route to the blood for the surplus three litres. The other main function is that of defense in the immune system. Lymph is very similar to blood plasma: it contains lymphocytes. It also contains waste products and cellular debris together with bacteria and proteins. Associated organs composed of lymphoid tissue are the sites of lymphocyte production.



Regional lymph nodes of head and neck (deep layer), thoracic organs, upper and lower abdominal organs



Regional lymph nodes of head and neck (superficial layer) and mammary gland. Lymph nodes of axillae, abdominal cavity, pelvis and groin

Lymphocytes are concentrated in the lymph nodes. The spleen and the thymus are also lymphoid organs of the immune system. The tonsils are lymphoid organs that are also associated with the digestive system. Lymphoid tissues contain lymphocytes, and also contain other types of cells for support. The system also includes all the structures dedicated to the circulation and production of lymphocytes (the primary cellular component of lymph), which also includes the bone marrow, and the lymphoid tissue associated with the digestive system.

The blood does not come into direct contact with the parenchymal cells and tissues in the body (except in case of an injury causing rupture of one or more blood vessels), but constituents of the blood first exit the microvascular exchange blood vessels to become interstitial fluid, which comes into contact with the parenchymal cells of the body.

Lymph is the fluid that is formed when interstitial fluid enters the initial lymphatic vessels of the lymphatic system. The lymph is then moved along the lymphatic vessel network by either intrinsic contractions of the lymphatic passages or by extrinsic compression of the lymphatic vessels via external tissue forces (e.g., the contractions of skeletal muscles), or by lymph hearts in some animals. The organization of lymph nodes and drainage follows the organization of the body into external and internal regions; therefore, the lymphatic drainage of the head, limbs, and body cavity walls follows an external route, and the lymphatic drainage of the thorax, abdomen, and pelvic cavities follows an internal route. Eventually, the lymph vessels empty into the lymphatic ducts, which drain into one of the two subclavian veins, near their junction with the internal jugular veins.

Structure

The lymphatic system consists of lymphatic organs, a conducting network of lymphatic vessels, and the circulating lymph. The primary or central lymphoid organs generate lymphocytes from immature progenitor cells. The thymus and the bone marrow constitute the primary lymphoid organs involved in the production and early clonal selection of lymphocyte tissues. Bone marrow is responsible for both the creation of T cells and the production and maturation of B cells. From the bone marrow, B cells immediately join the circulatory system and travel to secondary lymphoid organs in search of pathogens. T cells, on the other hand, travel from the bone marrow to the thymus, where they develop further. Mature T cells join B cells in search of pathogens. The other 95% of T cells begin a process of apoptosis, a form of programmed cell death. Secondary or peripheral lymphoid organs, which include lymph nodes and the spleen, maintain mature naive lymphocytes and initiate an adaptive immune response. The peripheral lymphoid organs are the sites of lymphocyte activation by antigens. Activation leads to clonal expansion and affinity maturation. Mature lymphocytes recirculate between the blood and the peripheral lymphoid organs until they encounter their specific antigen.

Secondary lymphoid tissue provides the environment for the foreign or altered native molecules (antigens) to interact with the lymphocytes. It is exemplified by the lymph nodes, and the lymphoid follicles in tonsils, Peyer's patches, spleen, adenoids, skin, etc. that are associated with the mucosa-associated lymphoid tissue (MALT). In the gastrointestinal wall the appendix has mucosa resembling that of the colon, but here it is heavily infiltrated with lymphocytes. Tertiary lymphoid organs (TLO) are abnormal lymph node–like structures that form in peripheral tissues at sites of chronic inflammation, such as chronic infection, transplanted organs undergoing graft rejection, some cancers, and autoimmune and autoimmune-related diseases. TLOs are regulated differently from the normal process whereby lymphoid tissues are formed during ontogeny, being dependent on cytokines and hematopoietic cells, but still drain interstitial fluid and transport lymphocytes in response to the same chemical messengers and gradients. TLOs typically contains far fewer lymphocytes, and assumes an immune role only when challenged with antigens that result in inflammation. It achieves this by importing the lymphocytes from blood and lymph.

Thymus

The thymus is a primary lymphoid organ and the site of maturation for T cells, the lymphocytes of the adaptive immune system. The thymus increases in size from birth in response to postnatal antigen stimulation, then to puberty and regresses thereafter. The loss or lack of the thymus results in severe immunodeficiency and subsequent high susceptibility to infection. In most species, the thymus consists of lobules divided by septa which are made up of epithelium and is therefore an epithelial organ. T cells mature from thymocytes, proliferate and undergo selection process in the thymic cortex before entering the medulla to interact with epithelial cells. The thymus provides an inductive environment for development of T cells from hematopoietic progenitor cells. In addition, thymic stromal cells allow for the selection of a functional and self-tolerant T cell repertoire. Therefore, one of the most important roles of the thymus is the induction of central tolerance. The thymus is largest and most active during the neonatal and pre-adolescent periods. By the early teens, the thymus begins to atrophy and thymic stroma is mostly replaced by adipose tissue. Nevertheless, residual T lymphopoiesis continues throughout adult life.

Spleen
The main functions of the spleen are:
● to produce immune cells to fight antigens
● to remove particulate matter and aged blood cells, mainly red blood cells.
● to produce blood cells during fetal life

The spleen synthesizes antibodies in its white pulp and removes antibody-coated bacteria and antibody-coated blood cells by way of blood and lymph node circulation. A study published in 2009 using mice found that the spleen contains, in its reserve, half of the body's monocytes within the red pulp. These monocytes, upon moving to injured tissue (such as the heart), turn into dendritic cells and macrophages while promoting tissue healing. The spleen is a center of activity of the mononuclear phagocyte system and can be considered analogous to a large lymph node, as its absence causes a predisposition to certain infections. Like the thymus, the spleen has only efferent lymphatic vessels. Both the short gastric arteries and the splenic artery supply it with blood. The germinal centers are supplied by arterioles called penicilliary radicles. Up to the fifth month of prenatal development the spleen creates red blood cells. After birth the bone marrow is solely responsible for hematopoiesis. As a major lymphoid organ and a central player in the reticuloendothelial system, the spleen retains the ability to produce lymphocytes. The spleen stores red blood cells and lymphocytes. It can store enough blood cells to help in an emergency. Up to 25% of lymphocytes can be stored at any one time.

Lymphoid Tissue (Lymph Nodes)
A lymph node is an organized collection of lymphoid tissue, through which the lymph passes on its way back to the blood. Lymph nodes are located at intervals along the lymphatic system. Several afferent lymph vessels bring in lymph, which percolates through the substance of the lymph node, and is then drained out by an efferent lymph vessel. There are between five and six hundred lymph nodes in the human body, many of which are grouped in clusters in different regions as in the underarm and abdominal areas.

Lymph node clusters are commonly found at the base of limbs (groin, armpits) and in the neck, where lymph is collected from regions of the body likely to sustain pathogen contamination from injuries. The substance of a lymph node consists of lymphoid follicles in an outer portion called the cortex. The inner portion of the node is called the medulla, which is surrounded by the cortex on all sides except for a portion known as the hilum.

The hilum presents as a depression on the surface of the lymph node, causing the otherwise spherical lymph node to be bean-shaped or ovoid. The efferent lymph vessel directly emerges from the lymph node at the hilum. The arteries and veins supplying the lymph node with blood enter and exit through the hilum. The region of the lymph node called the paracortex immediately surrounds the medulla. Unlike the cortex, which has mostly immature T cells, or thymocytes, the paracortex has a mixture of immature and mature T cells. Lymphocytes enter the lymph nodes through specialised high endothelial venules found in the paracortex.

A lymph follicle is a dense collection of lymphocytes, the number, size and configuration of which change in accordance with the functional state of the lymph node. For example, the follicles expand significantly when encountering a foreign antigen. The selection of B cells, or B lymphocytes, occurs in the germinal centre of the lymph nodes. Lymph nodes are particularly numerous in the mediastinum in the chest, neck, pelvis, axilla, inguinal region, and in association with the blood vessels of the intestines.

Other Lymphoid Tissue
Lymphoid tissue associated with the lymphatic system is concerned with immune functions in defending the body against infections and the spread of tumours. It consists of connective tissue formed of reticular fibers, with various types of leukocytes, (white blood cells), mostly lymphocytes enmeshed in it, through which the lymph passes. Regions of the lymphoid tissue that are densely packed with lymphocytes are known as lymphoid follicles. Lymphoid tissue can either be structurally well organized as lymph nodes or may consist of loosely organized lymphoid follicles known as the mucosa-associated lymphoid tissue. The central nervous system also has lymphatic vessels, as discovered by the University of Virginia Researchers. The search for T-cell gateways into and out of the meninges uncovered functional meningeal lymphatic vessels lining the dural sinuses, anatomically integrated into the membrane surrounding the brain.

Lymphatic Vessels
The lymphatic vessels, also called lymph vessels, conduct lymph between different parts of the body. They include the tubular vessels of the lymph capillaries, and the larger collecting vessels–the right lymphatic duct and the thoracic duct (the left lymphatic duct). The lymph capillaries are mainly responsible for the absorption of interstitial fluid from the tissues, while lymph vessels propel the absorbed fluid forward into the larger collecting ducts, where it ultimately returns to the bloodstream via one of the subclavian veins. These vessels are also called the lymphatic channels or simply lymphatics. The lymphatics are responsible for maintaining the balance of the body fluids. Its network of capillaries and collecting lymphatic vessels work to efficiently drain and transport extravasated fluid, along with proteins and antigens, back to the circulatory system. Numerous intraluminal valves in the vessels ensure a unidirectional flow of lymph without reflux. Two valve systems are used to achieve this one directional flow—a primary and a secondary valve system. The capillaries are blind-ended, and the valves at the ends of capillaries use specialised junctions together with anchoring filaments to allow a unidirectional flow to the primary vessels. The collecting lymphatics, however, act to propel the lymph by the combined actions of the intraluminal valves and lymphatic muscle cells.

Development
Lymphatic tissues begin to develop by the end of the fifth week of embryonic development. Lymphatic vessels develop from lymph sacs that arise from developing veins, which are derived from mesoderm. The first lymph sacs to appear are the paired jugular lymph sacs at the junction of the internal jugular and subclavian veins. From the jugular lymph sacs, lymphatic capillary plexuses spread to the thorax, upper limbs, neck and head. Some of the plexuses enlarge and form lymphatic vessels in their respective regions.

Each jugular lymph sac retains at least one connection with its jugular vein, the left one developing into the superior portion of the thoracic duct. The next lymph sac to appear is the unpaired retroperitoneal lymph sac at the root of the mesentery of the intestine. It develops from the primitive vena cava and mesonephric veins. Capillary plexuses and lymphatic vessels spread from the retroperitoneal lymph sac to the abdominal viscera and diaphragm.

The sac establishes connections with the cisterna chyli but loses its connections with neighbouring veins. The last of the lymph sacs, the paired posterior lymph sacs, develop from the iliac veins. The posterior lymph sacs produce capillary plexuses and lymphatic vessels of the abdominal wall, pelvic region, and lower limbs. The posterior lymph sacs join the cisterna chyli and lose their connections with adjacent veins.

With the exception of the anterior part of the sac from which the cisterna chyli develops, all lymph sacs become invaded by mesenchymal cells and are converted into groups of lymph nodes. The spleen develops from mesenchymal cells between layers of the dorsal mesentery of the stomach. The thymus arises as an outgrowth of the third pharyngeal pouch.

Function

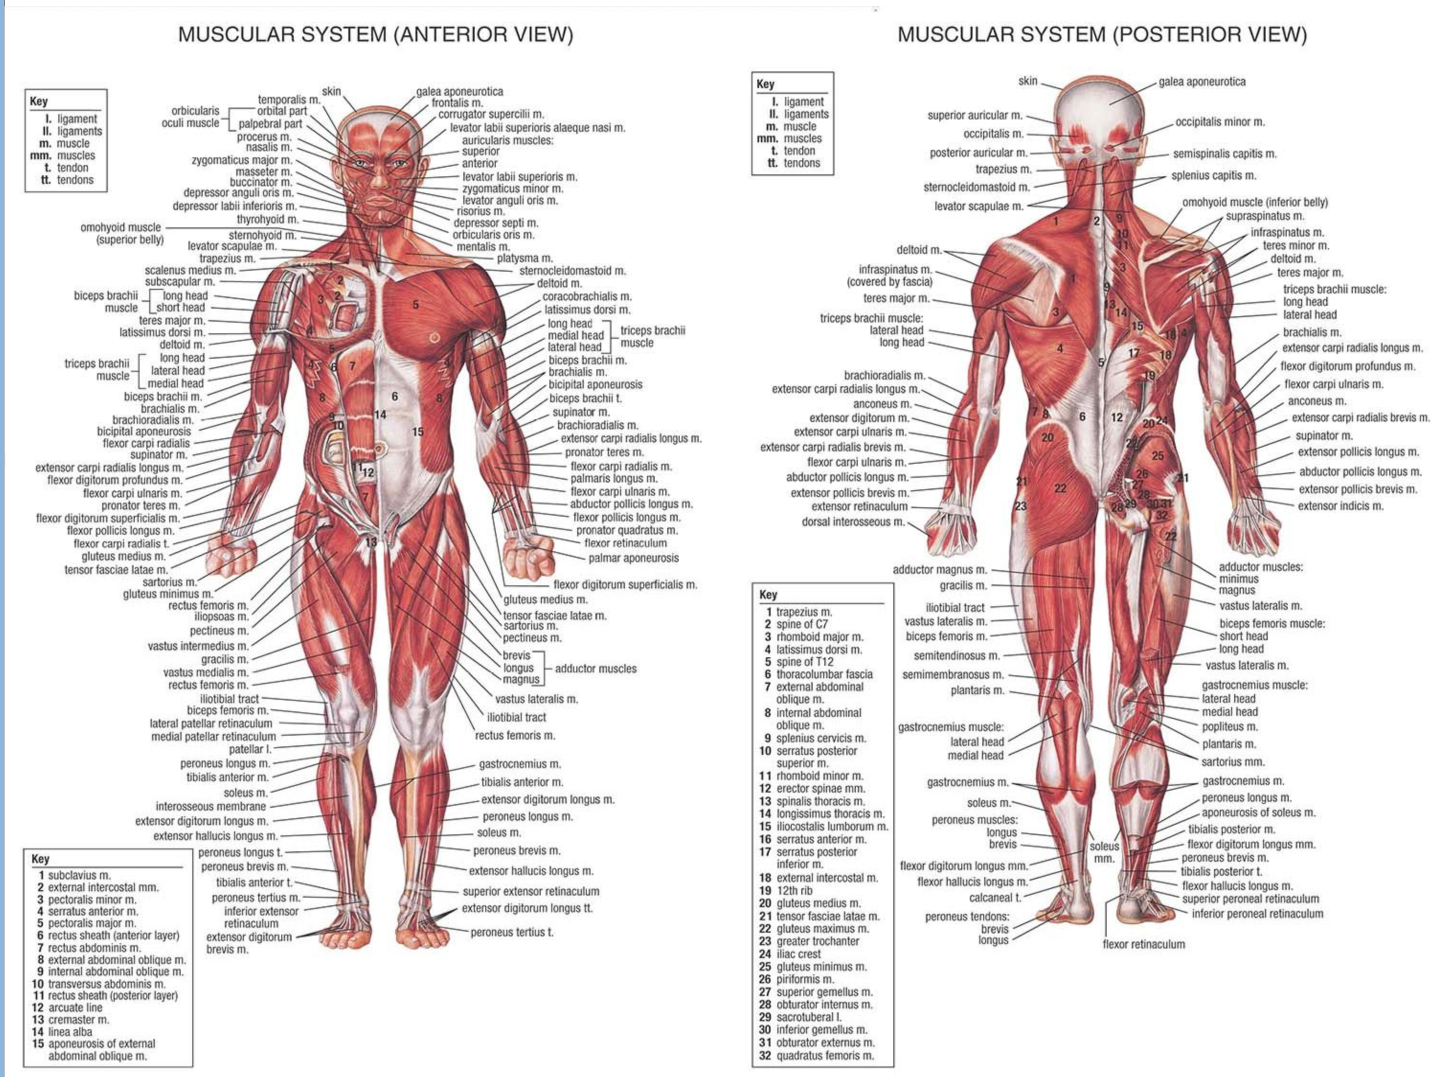
The lymphatic system has multiple interrelated functions:
● It is responsible for the removal of interstitial fluid from tissues
● It absorbs and transports fatty acids and fats as chyle from the digestive system
● It transports white blood cells to and from the lymph nodes into the bones
● The lymph transports antigen-presenting cells, such as dendritic cells, to the lymph nodes where an immune response is stimulated.

Fat Absorption
Lymph vessels called lacteals are at the beginning of the gastrointestinal tract, predominantly in the small intestine. While most other nutrients absorbed by the small intestine are passed on to the portal venous system to drain via the portal vein into the liver for processing, fats (lipids) are passed on to the lymphatic system to be transported to the blood circulation via the thoracic duct. (There are exceptions, for example medium-chain triglycerides are fatty acid esters of glycerol that passively diffuse from the GI tract to the portal system.) The enriched lymph originating in the lymphatics of the small intestine is called chyle. The nutrients that are released into the circulatory system are processed by the liver, having passed through the systemic circulation.

Immune Function
The lymphatic system plays a major role in the body's immune system, as the primary site for cells relating to adaptive immune system including T-cells and B-cells. Cells in the lymphatic system react to antigens presented or found by the cells directly or by other dendritic cells. When an antigen is recognized, an immunological cascade begins involving the activation and recruitment of more and more cells, the production of antibodies and cytokines and the recruitment of other immunological cells such as macrophages.

9 Muscular System

The muscular system is an organ system consisting of skeletal, smooth and cardiac muscles. It permits movement of the body, maintains posture and circulates blood throughout the body. The muscular systems in vertebrates are controlled through the nervous system although some muscles (such as the cardiac muscle) can be completely autonomous. Together with the skeletal system, it forms the musculoskeletal system, which is responsible for movement of the human body.



Muscular System

There are three distinct types of muscles: skeletal muscles, cardiac or heart muscles, and smooth (non-striated) muscles. Muscles provide strength, balance, posture, movement and heat for the body to keep warm.

Skeletal Muscle
Skeletal muscles, like other striated muscles, are composed of myocytes, or muscle fibers, which are in turn composed of myofibrils, which are composed of sarcomeres, the basic building block of striated muscle tissue. Upon stimulation by an action potential, skeletal muscles perform a coordinated contraction by shortening each sarcomere. The best proposed model for understanding contraction is the sliding filament model of muscle contraction. Within the sarcomere, actin and myosin fibers overlap in a contractile motion towards each other. Myosin filaments have club-shaped heads that project toward the actin filaments. Larger structures along the myosin filament called myosin heads are used to provide attachment points on binding sites for the actin filaments. The myosin heads move in a coordinated style; they swivel toward the center of the sarcomere, detach and then reattach to the nearest active site of the actin filament. This is called a ratchet type drive system. This process consumes large amounts of adenosine triphosphate (ATP), the energy source of the cell. ATP binds to the cross bridges between myosin heads and actin filaments. The release of energy powers the swiveling of the myosin head.

When ATP is used, it becomes adenosine diphosphate (ADP), and since muscles store little ATP, they must continuously replace the discharged ADP with ATP. Muscle tissue also contains a stored supply of a fast acting recharge chemical, creatine phosphate, which when necessary can assist with the rapid regeneration of ADP into ATP. Calcium ions are required for each cycle of the sarcomere. Calcium is released from the sarcoplasmic reticulum into the sarcomere when a muscle is stimulated to contract. This calcium uncovers the actin binding sites. When the muscle no longer needs to contract, the calcium ions are pumped from the sarcomere and back into storage in the sarcoplasmic reticulum. There are approximately 639 skeletal muscles in the human body.

Cardiac Muscle
Heart muscles are distinct from skeletal muscles because the muscle fibers are laterally connected to each other. Furthermore, just as with smooth muscles, their movement is involuntary. Heart muscles are controlled by the sinus node influenced by the autonomic nervous system.

Smooth Muscle
Smooth muscles are controlled directly by the autonomic nervous system and are involuntary, meaning that they are incapable of being moved by conscious thought. Functions such as heartbeat and lungs (which are capable of being willingly controlled, be it to a limited extent) are involuntary muscles but are not smooth muscles.

Physiology

Contraction
Neuromuscular junctions are the focal point where a motor neuron attaches to a muscle. Acetylcholine, (a neurotransmitter used in skeletal muscle contraction) is released from the axon terminal of the nerve cell when an action potential reaches the microscopic junction called a synapse. A group of chemical messengers cross the synapse and stimulate the formation of electrical changes, which are produced in the muscle cell when the acetylcholine binds to receptors on its surface. Calcium is released from its storage area in the cell's sarcoplasmic reticulum. An impulse from a nerve cell causes calcium release and brings about a single, short muscle contraction called a muscle twitch. If there is a problem at the neuromuscular junction, a very prolonged contraction may occur, such as the muscle contractions that result from tetanus. Also, a loss of function at the junction can produce paralysis. Skeletal muscles are organized into hundreds of motor units, each of which involves a motor neuron, attached by a series of thin finger-like structures called axon terminals. These attach to and control discrete bundles of muscle fibers. A coordinated and fine tuned response to a specific circumstance will involve controlling the precise number of motor units used. While individual muscle units contract as a unit, the entire muscle can contract on a predetermined basis due to the structure of the motor unit. Motor unit coordination, balance, and control frequently come under the direction of the cerebellum of the brain. This allows for complex muscular coordination with little conscious effort, such as when one drives a car without thinking about the process.

Aerobic and Anaerobic Muscle Activity
At rest, the body produces the majority of its ATP aerobically in the mitochondria without producing lactic acid or other fatiguing byproducts. During exercise, the method of ATP production varies depending on the fitness of the individual as well as the duration and intensity of exercise. At lower activity levels, when exercise continues for a long duration (several minutes or longer), energy is produced aerobically by combining oxygen with carbohydrates and fats stored in the body. During activity that is higher in intensity, with possible duration decreasing as intensity increases, ATP production can switch to anaerobic pathways, such as the use of the creatine phosphate and the phosphagen system or anaerobic glycolysis. Aerobic ATP production is biochemically much slower and can only be used for long-duration, low-intensity exercise, but produces no fatiguing waste products that can not be removed immediately from the sarcomere and the body, and it results in a much greater number of ATP molecules per fat or carbohydrate molecule. Aerobic training allows the oxygen delivery system to be more efficient, allowing aerobic metabolism to begin quicker. Anaerobic ATP production produces ATP much faster and allows near-maximal intensity exercise, but also produces significant amounts of lactic acid which renders high-intensity exercise unsustainable for more than several minutes. The phosphagen system is also anaerobic. It allows for the highest levels of exercise intensity, but intramuscular stores of phosphocreatine are very limited and can only provide energy for exercises lasting up to ten seconds. Recovery is very quick, with full creatine stores regenerated within five minutes.

Disease

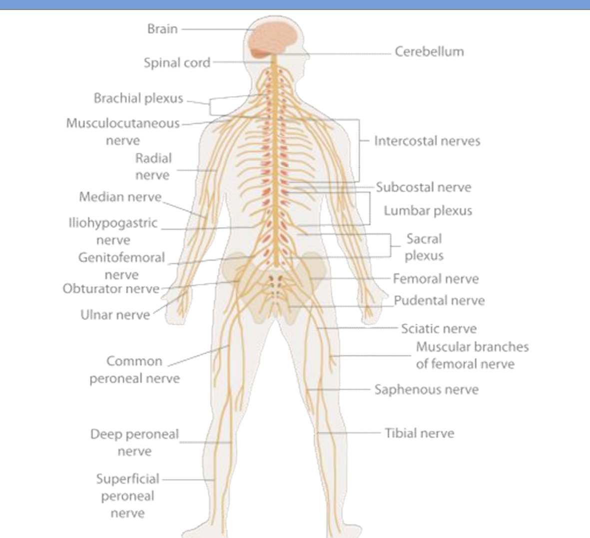
Myopathy
Myopathy is a disease of the muscle in which the muscle fibers do not function properly. This results in muscular weakness. Myopathy means muscle disease. This meaning implies that the primary defect is within the muscle, as opposed to the nerves ("neuropathies" or "neurogenic" disorders) or elsewhere (e.g., the brain). Muscle cramps, stiffness, and spasm can also be associated with myopathy. Muscular disease can be classified as neuromuscular or musculoskeletal in nature. Some conditions, such as myositis, can be considered both neuromuscular and musculoskeletal.

Signs and Symptoms
Common symptoms include muscle weakness, cramps, stiffness, and tetany.

Systemic Diseases
Myopathies in systemic disease results from several different disease processes including endocrine, inflammatory, paraneoplastic, infectious, drug- and toxin-induced, critical illness myopathy, metabolic, collagen related, and myopathies with other systemic disorders. Patients with systemic myopathies often present acutely or sub acutely. On the other hand, familial myopathies or dystrophies generally present in a chronic fashion with exceptions of metabolic myopathies where symptoms on occasion can be precipitated acutely. Most of the inflammatory myopathies can have a chance association with malignant lesion; the incidence appears to be specifically increased only in patients with dermatomyositis.

Treatments
Because different types of myopathies are caused by many different pathways, there is no single treatment for myopathy. Treatments range from treatment of the symptoms to very specific cause-targeting treatments. Drug therapy, physical therapy, bracing for support, surgery, and massage are all current treatments for a variety of myopathies.

10 Nervous System



The nervous system is a highly complex part of an animal that coordinates its actions and sensory information by transmitting signals to and from different parts of its body. The nervous system detects environmental changes that impact the body, then works in tandem with the endocrine system to respond to such events. In vertebrates it consists of two main parts, the central nervous system (CNS) and the peripheral nervous system (PNS). The CNS consists of the brain and spinal cord.

The PNS consists mainly of nerves, which are enclosed bundles of the long fibers or axons, that connect the CNS to every other part of the body. Nerves that transmit signals from the brain are called motor or efferent nerves, while those nerves that transmit information from the body to the CNS are called sensory or afferent.

Spinal nerves serve both functions and are called mixed nerves. The PNS is divided into three separate subsystems, the somatic, autonomic, and enteric nervous systems. Somatic nerves mediate voluntary movement. The autonomic nervous system is further subdivided into the sympathetic and the parasympathetic nervous systems.

The sympathetic nervous system is activated in cases of emergencies to mobilize energy, while the parasympathetic nervous system is activated when organisms are in a relaxed state. The enteric nervous system functions to control the gastrointestinal system. Both autonomic and enteric nervous systems function involuntarily. Nerves that exit from the cranium are called cranial nerves while those exiting from the spinal cord are called spinal nerves.

At the cellular level, the nervous system is defined by the presence of a special type of cell, called the neuron, also known as a "nerve cell". Neurons have special structures that allow them to send signals rapidly and precisely to other cells. They send these signals in the form of electrochemical waves traveling along thin fibers called axons, which cause chemicals called neurotransmitters to be released at junctions called synapses. A cell that receives a synaptic signal from a neuron may be excited, inhibited, or otherwise modulated. The connections between neurons can form neural pathways, neural circuits, and larger networks that generate an organism's perception of the world and determine its behavior.

Along with neurons, the nervous system contains other specialized cells called glial cells (or simply glia), which provide structural and metabolic support. Nervous systems are found in most multicellular animals, but vary greatly in complexity. The only multicellular animals that have no nervous system at all are sponges, placozoans, and mesozoans, which have very simple body plans.

The nervous systems of the radially symmetric organisms ctenophores (comb jellies) and cnidarians (which include anemones, hydras, corals and jellyfish) consist of a diffuse nerve net. All other animal species, with the exception of a few types of worm, have a nervous system containing a brain, a central cord (or two cords running in parallel), and nerves radiating from the brain and central cord. The size of the nervous system ranges from a few hundred cells in the simplest worms, to around 300 billion cells in African elephants. The central nervous system functions to send signals from one cell to others, or from one part of the body to others and to receive feedback.

Malfunction of the nervous system can occur as a result of genetic defects, physical damage due to trauma or toxicity, infection or simply of ageing. The medical specialty of neurology studies disorders of the nervous system and looks for interventions that can prevent or treat them. In the peripheral nervous system, the most common problem is the failure of nerve conduction, which can be due to different causes including diabetic neuropathy and demyelinating disorders such as multiple sclerosis and amyotrophic lateral sclerosis. Neuroscience is the field of science that focuses on the study of the nervous system.

Structure

The nervous system derives its name from nerves, which are cylindrical bundles of fibers (the axons of neurons), that emanate from the brain and spinal cord, and branch repeatedly to innervate every part of the body. Nerves are large enough to have been recognized by the ancient Egyptians, Greeks, and Romans, but their internal structure was not understood until it became possible to examine them using a microscope. A microscopic examination shows that nerves consist primarily of axons, along with different membranes that wrap around them and segregate them into fascicles. The neurons that give rise to nerves do not lie entirely within the nerves themselves—their cell bodies reside within the brain, spinal cord, or peripheral ganglia.

All animals more advanced than sponges have nervous systems. However, even sponges, unicellular animals, and non-animals such as slime molds have cell-to-cell signalling mechanisms that are precursors to those of neurons. In radially symmetric animals such as the jellyfish and hydra, the nervous system consists of a nerve net, a diffuse network of isolated cells. In bilaterian animals, which make up the great majority of existing species, the nervous system has a common structure that originated early in the Ediacaran period, over 550 million years ago.

Cells
The nervous system contains two main categories or types of cells: neurons and glial cells.

Neurons	The nervous system is defined by the presence of a special type of cell—the neuron (sometimes called "neurone" or "nerve cell"). Neurons can be distinguished from other cells in a number of ways, but their most fundamental property is that they communicate with other cells via synapses, which are membrane-to-membrane junctions containing molecular machinery that allows rapid transmission of signals, either electrical or chemical. Many types of neuron possess an axon, a protoplasmic protrusion that can extend to distant parts of the body and make thousands of synaptic contacts; axons typically extend throughout the body in bundles called nerves. Even in the nervous system of a single species such as humans, hundreds of different types of neurons exist, with a wide variety of morphologies and functions. These include sensory neurons that transmute physical stimuli such as light and sound into neural signals, and motor neurons that transmute neural signals into activation of muscles or glands; however in many species the great majority of neurons participate in the formation of centralized structures (the brain and ganglia) and they receive all of their input from other neurons and send their output to other neurons.
Glial Cells	Glial cells (named from the Greek for "glue") are non-neuronal cells that provide support and nutrition, maintain homeostasis, form myelin, and participate in signal transmission in the nervous system. In the human brain, it is estimated that the total number of glia roughly equals the number of neurons, although the proportions vary in different brain areas. Among the most important functions of glial cells are to support neurons and hold them in place; to supply nutrients to neurons; to insulate neurons electrically; to destroy pathogens and remove dead neurons; and to provide guidance cues directing the axons of neurons to their targets. A very important type of glial cell (oligodendrocytes in the central nervous system, and Schwann cells in the peripheral nervous system) generates layers of a fatty substance called myelin that wraps around axons and provides electrical insulation which allows them to transmit action potentials much more rapidly and efficiently. Recent findings indicate that glial cells, such as microglia and astrocytes, serve as important resident immune cells within the central nervous system.

Function
At the most basic level, the function of the nervous system is to send signals from one cell to others, or from one part of the body to others. There are multiple ways that a cell can send signals to other cells. One is by releasing chemicals called hormones into the internal circulation, so that they can diffuse to distant sites. In contrast to this "broadcast" mode of signaling, the nervous system provides "point-to-point" signals—neurons project their axons to specific target areas and make synaptic connections with specific target cells. Thus, neural signaling is capable of a much higher level of specificity than hormonal signaling. It is also much faster: the fastest nerve signals travel at speeds that exceed 100 meters per second. At a more integrative level, the primary function of the nervous system is to control the body. It does this by extracting information from the environment using sensory receptors, sending signals that encode this information into the central nervous system, processing the information to determine an appropriate response, and sending output signals to muscles or glands to activate the response. The evolution of a complex nervous system has made it possible for various animal species to have advanced perception abilities such as vision, complex social interactions, rapid coordination of organ systems, and integrated processing of concurrent signals. In humans, the sophistication of the nervous system makes it possible to have language, abstract representation of concepts, transmission of culture, and many other features of human society that would not exist without the human brain.

Neurons and Synapses
Most neurons send signals via their axons, although some types are capable of dendrite-to-dendrite communication. (In fact, the types of neurons called amacrine cells have no axons, and communicate only via their dendrites.) Neural signals propagate along an axon in the form of electrochemical waves called action potentials, which produce cell-to-cell signals at points where axon terminals make synaptic contact with other cells. Synapses may be electrical or chemical. Electrical synapses make direct electrical connections between neurons, but chemical synapses are much more common, and much more diverse in function. At a chemical synapse, the cell that sends signals is called presynaptic, and the cell that receives signals is called postsynaptic. Both the presynaptic and postsynaptic areas are full of molecular machinery that carries out the signalling process. The presynaptic area contains large numbers of tiny spherical vessels called synaptic vesicles, packed with neurotransmitter chemicals. When the presynaptic terminal is electrically stimulated, an array of molecules embedded in the membrane are activated, and cause the contents of the vesicles to be released into the narrow space between the presynaptic and postsynaptic membranes, called the synaptic cleft.

The neurotransmitter then binds to receptors embedded in the postsynaptic membrane, causing them to enter an activated state. Depending on the type of receptor, the resulting effect on the postsynaptic cell may be excitatory, inhibitory, or modulatory in more complex ways. For example, release of the neurotransmitter acetylcholine at a synaptic contact between a motor neuron and a muscle cell induces rapid contraction of the muscle cell. The entire synaptic transmission process takes only a fraction of a millisecond, although the effects on the postsynaptic cell may last much longer (even indefinitely, in cases where the synaptic signal leads to the formation of a memory trace). There are literally hundreds of different types of synapses. In fact, there are over a hundred known neurotransmitters, and many of them have multiple types of receptors. Many synapses use more than one neurotransmitter—a common arrangement is for a synapse to use one fast-acting small-molecule neurotransmitter such as glutamate or GABA, along with one or more peptide neurotransmitters that play slower-acting modulatory roles. Molecular neuroscientists generally divide receptors into two broad groups: chemically gated ion channels and second messenger systems. When a chemically gated ion channel is activated, it forms a passage that allows specific types of ions to flow across the membrane. Depending on the type of ion, the effect on the target cell may be excitatory or inhibitory.

When a second messenger system is activated, it starts a cascade of molecular interactions inside the target cell, which may ultimately produce a wide variety of complex effects, such as increasing or decreasing the sensitivity of the cell to stimuli, or even altering gene transcription. According to a rule called Dale's principle, which has only a few known exceptions, a neuron releases the same neurotransmitters at all of its synapses. This does not mean, though, that a neuron exerts the same effect on all of its targets, because the effect of a synapse depends not on the neurotransmitter, but on the receptors that it activates. Because different targets can (and frequently do) use different types of receptors, it is possible for a neuron to have excitatory effects on one set of target cells, inhibitory effects on others, and complex modulatory effects on others still. Nevertheless, it happens that the two most widely used neurotransmitters, glutamate and GABA, each have largely consistent effects. Glutamate has several widely occurring types of receptors, but all of them are excitatory or modulatory. Similarly, GABA has several widely occurring receptor types, but all of them are inhibitory. Because of this consistency, glutamatergic cells are frequently referred to as "excitatory neurons", and GABAergic cells as "inhibitory neurons".

Mirror Neurons

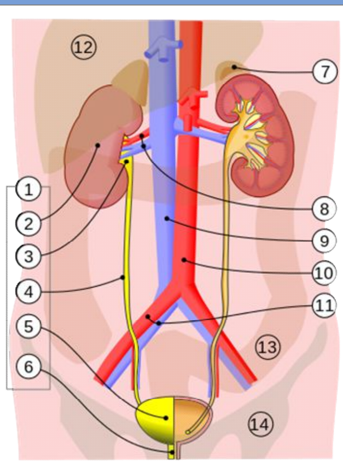
A mirror neuron is a neuron that fires both when an animal acts and when the animal observes the same action performed by another. Thus, the neuron "mirrors" the behavior of the other, as though the observer were itself acting. Such neurons have been directly observed in primate species. Birds have been shown to have imitative resonance behaviors and neurological evidence suggests the presence of some form of mirroring system. In humans, brain activity consistent with that of mirror neurons has been found in the premotor cortex, the supplementary motor area, the primary somatosensory cortex and the inferior parietal cortex. The function of the mirror system is a subject of much speculation. Many researchers in cognitive neuroscience and cognitive psychology consider that this system provides the physiological mechanism for the perception/action coupling (see the common coding theory). They argue that mirror neurons may be important for understanding the actions of other people, and for learning new skills by imitation. Some researchers also speculate that mirror systems may simulate observed actions, and thus contribute to theory of mind skills, while others relate mirror neurons to language abilities. However, to date, no widely accepted neural or computational models have been put forward to describe how mirror neuron activity supports cognitive functions such as imitation. There are neuroscientists who caution that the claims being made for the role of mirror neurons are not supported by adequate research.

Pathology

The central nervous system is protected by major physical and chemical barriers. Physically, the brain and spinal cord are surrounded by tough meningeal membranes, and enclosed in the bones of the skull and vertebral column, which combine to form a strong physical shield. Chemically, the brain and spinal cord are isolated by the blood–brain barrier, which prevents most types of chemicals from moving from the bloodstream into the interior of the CNS. These protections make the CNS less susceptible in many ways than the PNS; the flip side, however, is that damage to the CNS tends to have more serious consequences. Although nerves tend to lie deep under the skin except in a few places such as the ulnar nerve near the elbow joint, they are still relatively exposed to physical damage, which can cause pain, loss of sensation, or loss of muscle control. Damage to nerves can also be caused by swelling or bruises at places where a nerve passes through a tight bony channel, as happens in carpal tunnel syndrome. If a nerve is completely transected, it will often regenerate, but for long nerves this process may take months to complete.

In addition to physical damage, peripheral neuropathy may be caused by many other medical problems, including genetic conditions, metabolic conditions such as diabetes, inflammatory conditions such as Guillain–Barré syndrome, vitamin deficiency, infectious diseases such as leprosy or shingles, or poisoning by toxins such as heavy metals. Many cases have no cause that can be identified, and are referred to as idiopathic. It is also possible for nerves to lose function temporarily, resulting in numbness as stiffness—common causes include mechanical pressure, a drop in temperature, or chemical interactions with local anesthetic drugs such as lidocaine. Physical damage to the spinal cord may result in loss of sensation or movement. If an injury to the spine produces nothing worse than swelling, the symptoms may be transient, but if nerve fibers in the spine are actually destroyed, the loss of function is usually permanent. Experimental studies have shown that spinal nerve fibers attempt to regrow in the same way as nerve fibers, but in the spinal cord, tissue destruction usually produces scar tissue that cannot be penetrated by the regrowing nerves.

11 Urinary System (Renal System)



1. Urinary system
2. Kidney
3. Renal pelvis
4. Ureter
5. Urinary bladder
6. Urethra (Left side with frontal section)
7. Adrenal gland
8. Renal artery and vein
9. Inferior vena cava
10. Abdominal aorta
11. Common iliac artery and vein
12. Liver
13. Large intestine
14. Pelvis

The urinary system, also known as the renal system or urinary tract, consists of the kidneys, ureters, bladder, and the urethra. The purpose of the urinary system is to eliminate waste from the body, regulate blood volume and blood pressure, control levels of electrolytes and metabolites, and regulate blood pH. The urinary tract is the body's drainage system for the eventual removal of urine.

The kidneys have an extensive blood supply via the renal arteries which leave the kidneys via the renal vein. Each kidney consists of functional units called nephrons. Following filtration of blood and further processing, wastes (in the form of urine) exit the kidney via the ureters, tubes made of smooth muscle fibres that propel urine towards the urinary bladder, where it is stored and subsequently expelled from the body by urination (voiding).

The female and male urinary system are very similar, differing only in the length of the urethra. Urine is formed in the kidneys through a filtration of blood. The urine is then passed through the ureters to the bladder, where it is stored. During urination, the urine is passed from the bladder through the urethra to the outside of the body.
800–2,000 milliliters (mL) of urine are normally produced every day in a healthy human. This amount varies according to fluid intake and kidney function.

Structure

The urinary system refers to the structures that produce and transport urine to the point of excretion. In the human urinary system there are two kidneys that are located between the dorsal body wall and parietal peritoneum on both the left and right sides. The formation of urine begins within the functional unit of the kidney, the nephrons. Urine then flows through the nephrons, through a system of converging tubules called collecting ducts. These collecting ducts then join together to form the minor calyces, followed by the major calyces that ultimately join the renal pelvis. From here, urine continues its flow from the renal pelvis into the ureter, transporting urine into the urinary bladder. The anatomy of the human urinary system differs between males and females at the level of the urinary bladder. In males, the urethra begins at the internal urethral orifice in the trigone of the bladder, continues through the external urethral orifice, and then becomes the prostatic, membranous, bulbar, and penile urethra. Urine exits through the external urethral meatus. The female urethra is much shorter, beginning at the bladder neck and terminating in the vaginal vestibule. Under microscopy, the urinary system is covered in a unique lining called urothelium, a type of transitional epithelium. Unlike the epithelial lining of most organs, transitional epithelium can flatten and distend. Urothelium covers most of the urinary system, including the renal pelvis, ureters, and bladder.

Function

The main functions of the urinary system and its components are to:
- Regulate blood volume and composition (e.g. sodium, potassium and calcium)
- Regulate blood pressure.
- Regulate pH homeostasis of the blood.
- Contributes to the production of red blood cells by the kidney.
- Helps synthesize calcitrol the (active form of Vitamin D).
- Stores waste product (mainly urea and uric acid) before it and other products are removed from the body.

Urine Formation
Average urine production in adult humans is about 1–2 litres (L) per day, depending on state of hydration, activity level, environmental factors, weight, and the individual's health. Producing too much or too little urine requires medical attention. Polyuria is a condition of excessive urine production (> 2.5 L/day). Oliguria when < 400 mL (millilitres) are produced, and anuria one of < 100 mL per day. The first step in urine formation is the filtration of blood in the kidneys. In a healthy human the kidney receives between 12 and 30% of cardiac output, but it averages about 20% or about 1.25 L/min.

The basic structural and functional unit of the kidney is the nephron. Its chief function is to regulate the concentration of water and soluble substances like sodium by filtering the blood, reabsorbing what is needed and excreting the rest as urine. In the first part of the nephron, Bowman's capsule filters blood from the circulatory system into the tubules. Hydrostatic and osmotic pressure gradients facilitate filtration across a semipermeable membrane. The filtrate includes water, small molecules, and ions that easily pass through the filtration membrane.

Regulation of Concentration and Volume
The urinary system is under influence of the circulatory system, nervous system, and endocrine system.

However larger molecules such as proteins and blood cells are prevented from passing through the filtration membrane. The amount of filtrate produced every minute is called the glomerular filtration rate or GFR and amounts to 180 litres per day. About 99% of this filtrate is reabsorbed as it passes through the nephron and the remaining 1% becomes urine. The urinary system is regulated by the endocrine system by hormones such as antidiuretic hormone, aldosterone, and parathyroid hormone. Aldosterone plays a central role in regulating blood pressure through its effects on the kidney. It acts on the distal tubules and collecting ducts of the nephron and increases reabsorption of sodium from the glomerular filtrate.

Reabsorption of sodium results in retention of water, which increases blood pressure and blood volume. Antidiuretic hormone (ADH), is a neurohypophysial hormone found in most mammals. Its two primary functions are to retain water in the body and vasoconstriction. Vasopressin regulates the body's retention of water by increasing water reabsorption in the collecting ducts of the kidney nephron. Vasopressin increases water permeability of the kidney's collecting duct and distal convoluted tubule by inducing translocation of aquaporin-CD water channels in the kidney nephron collecting duct plasma membrane.

Urination
Urination is the ejection of urine from the urinary bladder through the urethra to the outside of the body. In healthy humans (and many other animals), the process of urination is under voluntary control. In infants, some elderly individuals, and those with neurological injury, urination may occur as an involuntary reflex. Physiologically, micturition involves coordination between the central, autonomic, and somatic nervous systems. Brain centers that regulate urination include the pontine micturition center, periaqueductal gray, and the cerebral cortex. In placental mammals the male ejects urine through the penis, and the female through the vulva.

Clinical Significance

Urologic disease can involve congenital or acquired dysfunction of the urinary system. As an example, urinary tract obstruction is a urologic disease that can cause urinary retention. Diseases of the kidney tissue are normally treated by nephrologists, while diseases of the urinary tract are treated by urologists. Gynecologists may also treat female urinary incontinence. Diseases of other bodily systems also have a direct effect on urogenital function. For instance, it has been shown that protein released by the kidneys in diabetes mellitus sensitizes the kidney to the damaging effects of hypertension. Diabetes also can have a direct effect in urination due to peripheral neuropathies, which occur in some individuals with poorly controlled blood sugar levels. Urinary incontinence can result from a weakening of the pelvic floor muscles caused by factors such as pregnancy, childbirth, aging, and being overweight. Pelvic floor exercises known as Kegel exercises can help in this condition by strengthening the pelvic floor. There can also be underlying medical reasons for urinary incontinence which are often treatable. In children, the condition is called enuresis. Some cancers also target the urinary system, including bladder cancer, kidney cancer, ureteral cancer, and urethral cancer. Due to the role and location of these organs, treatment is often complicated.

12 Reproductive System

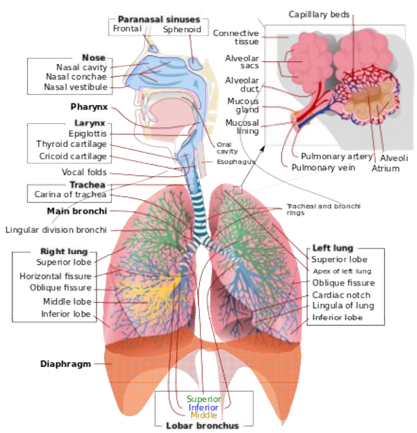
The reproductive system or genital system is a system of sex organs within an organism which work together for the purpose of sexual reproduction. Many non-living substances such as fluids, hormones, and pheromones are also important accessories to the reproductive system. Unlike most organ systems, the sexes of differentiated species often have significant differences. These differences allow for a combination of genetic material between two individuals, which allows for the possibility of greater genetic fitness of the offspring.

Human Reproduction
The human reproductive system usually involves internal fertilization by sexual intercourse. During this process, the male inserts his erect penis into the female's vagina and ejaculates semen, which contains sperm. The sperm then travels through the vagina and cervix into the uterus or fallopian tubes for fertilization of the ovum. Upon successful fertilization and implantation, gestation of the fetus then occurs within the female's uterus for approximately nine months, this process is known as pregnancy in humans. Gestation ends with birth, the process of birth is known as labor. Labor consists of the muscles of the uterus contracting, the cervix dilating, and the baby passing out the vagina (the female genital organ). Human's babies and children are nearly helpless and require high levels of parental care for many years. One important type of parental care is the use of the mammary glands in the female breasts to nurse the baby. The female reproductive system has two functions: The first is to produce egg cells, and the second is to protect and nourish the offspring until birth. The male reproductive system has one function, and it is to produce and deposit sperm. Humans have a high level of sexual differentiation. In addition to differences in nearly every reproductive organ, numerous differences typically occur in secondary sexual characteristics.

Male
The male reproductive system is a series of organs located outside of the body and around the pelvic region of a male that contribute towards the reproduction process. The primary direct function of the male reproductive system is to provide the male sperm for fertilization of the ovum. The major reproductive organs of the male can be grouped into three categories. The first category is sperm production and storage. Production takes place in the testes which are housed in the temperature regulating scrotum, immature sperm then travel to the epididymis for development and storage. The second category are the ejaculatory fluid producing glands which include the seminal vesicles, prostate, and the vas deferens. The final category are those used for copulation, and deposition of the spermatozoa (sperm) within the male, these include the penis, urethra, vas deferens, and Cowper's gland. Major secondary sexual characteristics includes: larger, more muscular stature, deepened voice, facial and body hair, broad shoulders, and development of an adam's apple. An important sexual hormone of males is androgen, and particularly testosterone. The testes release a hormone that controls the development of sperm. This hormone is also responsible for the development of physical characteristics in men such as facial hair and a deep voice.

Female
The human female reproductive system is a series of organs primarily located inside of the body and around the pelvic region of a female that contribute towards the reproductive process. The human female reproductive system contains three main parts: the vulva, which leads to the vagina, the vaginal opening, to the uterus; the uterus, which holds the developing fetus; and the ovaries, which produce the female's ova. The breasts are involved during the parenting stage of reproduction, but in most classifications they are not considered to be part of the female reproductive system. The vagina meets the outside at the vulva, which also includes the labia, clitoris and urethra; during intercourse this area is lubricated by mucus secreted by the Bartholin's glands. The vagina is attached to the uterus through the cervix, while the uterus is attached to the ovaries via the fallopian tubes. Each ovary contains hundreds of egg cells or ova (singular ovum). Approximately every 28 days, the pituitary gland releases a hormone that stimulates some of the ova to develop and grow. One ovum is released and it passes through the fallopian tube into the uterus. Hormones produced by the ovaries prepare the uterus to receive the ovum. It sita her and awaits the sperm for fertilization to occur. When this does not occur i.e. no sperm for fertilization, the lining of the uterus, called the endometrium, and unfertilized ova are shed each cycle through the process of menstruation. If the ovum is fertilized by sperm, it attaches to the endometrium and the fetus develops.

13 Respiratory System



The respiratory system (also respiratory apparatus, ventilatory system) is a biological system consisting of specific organs and structures used for gas exchange in animals and plants. The anatomy and physiology that make this happen varies greatly, depending on the size of the organism, the environment in which it lives and its evolutionary history. In land animals the respiratory surface is internalized as linings of the lungs.

Gas exchange in the lungs occurs in millions of small air sacs called alveoli in mammals and reptiles, but atria in birds. These microscopic air sacs have a very rich blood supply, thus bringing the air into close contact with the blood. These air sacs communicate with the external environment via a system of airways, or hollow tubes, of which the largest is the trachea, which branches in the middle of the chest into the two main bronchi.

These enter the lungs where they branch into progressively narrower secondary and tertiary bronchi that branch into numerous smaller tubes, the bronchioles. In birds the bronchioles are termed parabronchi. It is the bronchioles, or parabronchi that generally open into the microscopic alveoli in mammals and atria in birds. Air has to be pumped from the environment into the alveoli or atria by the process of breathing which involves the muscles of respiration.

In most fish, and a number of other aquatic animals (both vertebrates and invertebrates) the respiratory system consists of gills, which are either partially or completely external organs, bathed in the watery environment. This water flows over the gills by a variety of active or passive means. Gas exchange takes place in the gills which consist of thin or very flat filaments and lammelae which expose a very large surface area of highly vascularized tissue to the water. Other animals, such as insects, have respiratory systems with very simple anatomical features, and in amphibians even the skin plays a vital role in gas exchange. Plants also have respiratory systems but the directionality of gas exchange can be opposite to that in animals. The respiratory system in plants includes anatomical features such as stomata, that are found in various parts of the plant.

Anatomy

In humans and other mammals, the anatomy of a typical respiratory system is the respiratory tract. The tract is divided into an upper and a lower respiratory tract. The upper tract includes the nose, nasal cavities, sinuses, pharynx and the part of the larynx above the vocal folds. The lower tract includes the lower part of the larynx, the trachea, bronchi, bronchioles and the alveoli. The branching airways of the lower tract are often described as the respiratory tree or tracheobronchial tree. The intervals between successive branch points along the various branches of "tree" are often referred to as branching "generations", of which there are, in the adult human about 23. The earlier generations (approximately generations 0–16), consisting of the trachea and the bronchi, as well as the larger bronchioles which simply act as air conduits, bringing air to the respiratory bronchioles, alveolar ducts and alveoli (approximately generations 17–23), where gas exchange takes place. Bronchioles are defined as the small airways lacking any cartilagenous support. The first bronchi to branch from the trachea are the right and left main bronchi. Second only in diameter to the trachea (1.8 cm), these bronchi (1 -1.4 cm in diameter) enter the lungs at each hilum, where they branch into narrower secondary bronchi known as lobar bronchi, and these branch into narrower tertiary bronchi known as segmental bronchi.

Further divisions of the segmental bronchi (1 to 6 mm in diameter) are known as 4th order, 5th order, and 6th order segmental bronchi, or grouped together as subsegmental bronchi. Compared to the, on average, 23 number of branchings of the respiratory tree in the adult human, the mouse has only about 13 such branchings. The alveoli are the dead end terminals of the "tree", meaning that any air that enters them has to exit via the same route. A system such as this creates dead space, a volume of air (about 150 ml in the adult human) that fills the airways after exhalation and is breathed back into the alveoli before environmental air reaches them. At the end of inhalation the airways are filled with environmental air, which is exhaled without coming in contact with the gas exchanger.

Ventilatory Volumes
The lungs expand and contract during the breathing cycle, drawing air in and out of the lungs. The volume of air moved in or out of the lungs under normal resting circumstances (the resting tidal volume of about 500 ml), and volumes moved during maximally forced inhalation and maximally forced exhalation are measured in humans by spirometry. A typical adult human spirogram with the names given to the various excursions in volume the lungs can undergo is illustrated below. Not all the air in the lungs can be expelled during maximally forced exhalation. This is the residual volume of about 1.0-1.5 liters which cannot be measured by spirometry. Volumes that include the residual volume (i.e. functional residual capacity of about 2.5-3.0 liters, and total lung capacity of about 6 liters) can therefore also not be measured by spirometry. Their measurement requires special techniques. The rates at which air is breathed in or out, either through the mouth or nose, or into or out of the alveoli are tabulated below, together with how they are calculated. The number of breath cycles per minute is known as the respiratory rate.

Measurement Minute ventilation **Equation** tidal volume * respiratory rate **Description** The total volume of air entering, or leaving, the nose or mouth per minute.	**Measurement** Alveolar ventilation **Equation** (tidal volume – dead space) * respiratory rate **Description** The volume of air entering or leaving the alveoli per minute.	**Measurement** Dead space ventilation **Equation** dead space * respiratory rate **Description** The volume of air that does not reach the alveoli during inhalation, but instead remains in the airways, per minute.

Breathing Mechanics

In mammals, inhalation at rest is primarily due to the contraction of the diaphragm. This is an upwardly domed sheet of muscle that separates the thoracic cavity from the abdominal cavity. When it contracts the sheet flattens, increasing the volume of the thoracic cavity. The contracting diaphragm pushes the abdominal organs downwards. But because the pelvic floor prevents the lowermost abdominal organs moving in that direction, the pliable abdominal contents cause the belly to bulge outwards to the front and sides, because the relaxed abdominal muscles do not resist this movement. This entirely passive bulging (and shrinking during exhalation) of the abdomen during normal breathing is sometimes referred to as "abdominal breathing", although it is, in fact, "diaphragmatic breathing", which is not visible on the outside of the body. Mammals only use their abdominal muscles only during forceful exhalation (see Fig. 8, and discussion below). Never during any form of inhalation. As the diaphragm contracts, the rib cage is simultaneously enlarged by the ribs being pulled upwards by the intercostal muscles as shown in Fig. 4. All the ribs slant downwards from the rear to the front; but the lowermost ribs also slant downwards from the midline outwards. Thus the rib cage's transverse diameter can be increased in the same way as the antero-posterior diameter is increase by the so-called pump handle movement.

The enlargement of the thoracic cavity's vertical dimension by the contraction of the diaphragm, and its two horizontal dimensions by the lifting of the front and sides of the ribs, causes the intrathoracic pressure to fall. The lungs' interiors are open to the outside air, and being elastic, therefore expand to fill the increased space. The inflow of air into the lungs occurs via the respiratory airways. In health these airways (starting at the nose or mouth, and ending in the microscopic dead-end sacs called alveoli) are always open, though the diameters of the various sections can be changed by the sympathetic and parasympathetic nervous systems. The alveolar air pressure is therefore always close to atmospheric air pressure (about 100 kPa at sea level) at rest, with the pressure gradients that cause air to move in and out of the lungs during breathing rarely exceeding 2–3 kPa. During exhalation the diaphragm and intercostal muscles relax. This returns the chest and abdomen to a position determined by their anatomical elasticity. This is the "resting mid-position" of the thorax and abdomen when the lungs contain their functional residual capacity of air, which in the adult human has a volume of about 2.5–3.0 liters. Resting exhalation lasts about twice as long as inhalation because the diaphragm relaxes passively more gently than it contracts actively during inhalation.

The volume of air that moves in or out (at the nose or mouth) during a single breathing cycle is called the tidal volume. In a resting adult human it is about 500 ml per breath. At the end of exhalation the airways contain about 150 ml of alveolar air which is the first air that is breathed back into the alveoli during inhalation. This volume air that is breathed out of the alveoli and back in again is known as dead space ventilation, which has the consequence that of the 500 ml breathed into the alveoli with each breath only 350 ml (500 ml - 150 ml = 350 ml) is fresh warm and moistened air. Since this 350 ml of fresh air is thoroughly mixed and diluted by the air that remains in the alveoli after normal exhalation (i.e. the functional residual capacity of about 2.5–3.0 liters), it is clear that the composition of the alveolar air changes very little during the breathing cycle. The oxygen tension (or partial pressure) remains close to 13-14 kPa (about 100 mm Hg), and that of carbon dioxide very close to 5.3 kPa (or 40 mm Hg). This contrasts with composition of the dry outside air at sea level, where the partial pressure of oxygen is 21 kPa (or 160 mm Hg) and that of carbon dioxide 0.04 kPa (or 0.3 mmHg). The volume of air that moves in or out (at the nose or mouth) during a single breathing cycle is called the tidal volume. In a resting adult human it is about 500 ml per breath. At the end of exhalation the airways contain about 150 ml of alveolar air which is the first air that is breathed back into the alveoli during inhalation. This volume air that is breathed out of the alveoli and back in again is known as dead space ventilation, which has the consequence that of the 500 ml breathed into the alveoli with each breath only 350 ml (500 ml - 150 ml = 350 ml) is fresh warm and moistened air.

Since this 350 ml of fresh air is thoroughly mixed and diluted by the air that remains in the alveoli after normal exhalation (i.e. the functional residual capacity of about 2.5–3.0 liters), it is clear that the composition of the alveolar air changes very little during the breathing cycle. The oxygen tension (or partial pressure) remains close to 13-14 kPa (about 100 mm Hg), and that of carbon dioxide very close to 5.3 kPa (or 40 mm Hg). This contrasts with composition of the dry outside air at sea level, where the partial pressure of oxygen is 21 kPa (or 160 mm Hg) and that of carbon dioxide 0.04 kPa (or 0.3 mmHg). During heavy breathing (hyperpnea), as, for instance, during exercise, inhalation is brought about by a more powerful and greater excursion of the contracting diaphragm than at rest. In addition the "accessory muscles of inhalation" exaggerate the actions of the intercostal muscles. These accessory muscles of inhalation are muscles that extend from the cervical vertebrae and base of the skull to the upper ribs and sternum, sometimes through an intermediary attachment to the clavicles. When they contract the rib cage's internal volume is increased to a far greater extent than can be achieved by contraction of the intercostal muscles alone. Seen from outside the body the lifting of the clavicles during strenuous or labored inhalation is sometimes called clavicular breathing, seen especially during asthma attacks and in people with chronic obstructive pulmonary disease.

During heavy breathing, exhalation is caused by relaxation of all the muscles of inhalation. But now, the abdominal muscles, instead of remaining relaxed (as they do at rest), contract forcibly pulling the lower edges of the rib cage downwards (front and sides). This not only drastically decreases the size of the rib cage, but also pushes the abdominal organs upwards against the diaphragm which consequently bulges deeply into the thorax. The end-exhalatory lung volume is now well below the resting mid-position and contains far less air than the resting "functional residual capacity". However, in a normal mammal, the lungs cannot be emptied completely. In an adult human there is always still at least 1 liter of residual air left in the lungs after maximum exhalation. The automatic rhythmical breathing in and out, can be interrupted by coughing, sneezing (forms of very forceful exhalation), by the expression of a wide range of emotions (laughing, sighing, crying out in pain, exasperated intakes of breath) and by such voluntary acts as speech, singing, whistling and the playing of wind instruments. All of these actions rely on the muscles described above, and their effects on the movement of air in and out of the lungs. Although not a form of breathing, the Valsalva maneuver involves the respiratory muscles. It is, in fact, a very forceful exhalatory effort against a tightly closed glottis, so that no air can escape from the lungs. Instead abdominal contents are evacuated in the opposite direction, through orifices in the pelvic floor. The abdominal muscles contract very powerfully, causing the pressure inside the abdomen and thorax to rise to extremely high levels. The Valsalva maneuver can be carried out voluntarily, but is more generally a reflex elicited when attempting to empty the abdomen during, for instance, difficult defecation, or during childbirth. Breathing ceases during this maneuver.

Gas Exchange

The primary purpose of the respiratory system is the equilibration of the partial pressures of the respiratory gases in the alveolar air with those in the pulmonary capillary blood. This process occurs by simple diffusion, across a very thin membrane (known as the blood–air barrier), which forms the walls of the pulmonary alveoli. It consisting of the alveolar epithelial cells, their basement membranes and the endothelial cells of the alveolar capillaries (Fig. 10). This blood gas barrier is extremely thin (in humans, on average, 2.2 μm thick). It is folded into about 300 million small air sacs called alveoli (each between 75 and 300 μm in diameter) branching off from the respiratory bronchioles in the lungs, thus providing an extremely large surface area (approximately 145 m2) for gas exchange to occur. The air contained within the alveoli has a semi-permanent volume of about 2.5-3.0 liters which completely surrounds the alveolar capillary blood. This ensures that equilibration of the partial pressures of the gases in the two compartments is very efficient and occurs very quickly. The blood leaving the alveolar capillaries and is eventually distributed throughout the body therefore has a partial pressure of oxygen of 13-14 kPa (100 mmHg), and a partial pressure of carbon dioxide of 5.3 kPa (40 mmHg) (i.e. the same as the oxygen and carbon dioxide gas tensions as in the alveoli). As mentioned in the section above, the corresponding partial pressures of oxygen and carbon dioxide in the ambient (dry) air at sea level are 21 kPa (160 mmHg) and 0.04 kPa (0.3 mmHg) respectively.

This marked difference between the composition of the alveolar air and that of the ambient air can be maintained because the functional residual capacity is contained in dead-end sacs connected to the outside air by fairly narrow and relatively long tubes (the airways: nose, pharynx, larynx, trachea, bronchi and their branches down to the bronchioles), through which the air has to be breathed both in and out (i.e. there is no unidirectional through-flow as there is in the bird lung). This typical mammalian anatomy combined with the fact that the lungs are not emptied and re-inflated with each breath (leaving a substantial volume of air, of about 2.5-3.0 liters, in the alveoli after exhalation), ensures that the composition of the alveolar air is only minimally disturbed when the 350 ml of fresh air is mixed into it with each inhalation. Thus the animal is provided with a very special "portable atmosphere", whose composition differs significantly from the present-day ambient air. It is this portable atmosphere (the functional residual capacity) to which the blood and therefore the body tissues are exposed – not to the outside air. The resulting arterial partial pressures of oxygen and carbon dioxide are homeostatically controlled. A rise in the arterial partial pressure of CO2 and, to a lesser extent, a fall in the arterial partial pressure of O2, will reflexly cause deeper and faster breathing till the blood gas tensions in the lungs, and therefore the arterial blood, return to normal. The converse happens when the carbon dioxide tension falls, or, again to a lesser extent, the oxygen tension rises: the rate and depth of breathing are reduced till blood gas normality is restored.

Since the blood arriving in the alveolar capillaries has a partial pressure of O2 of, on average, 6 kPa (45 mmHg), while the pressure in the alveolar air is 13-14 kPa (100 mmHg), there will be a net diffusion of oxygen into the capillary blood, changing the composition of the 3 liters of alveolar air slightly. Similarly, since the blood arriving in the alveolar capillaries has a partial pressure of CO2 of also about 6 kPa (45 mmHg), whereas that of the alveolar air is 5.3 kPa (40 mmHg), there is a net movement of carbon dioxide out of the capillaries into the alveoli. The changes brought about by these net flows of individual gases into and out of the alveolar air necessitate the replacement of about 15% of the alveolar air with ambient air every 5 seconds or so. This is very tightly controlled by the monitoring of the arterial blood gases (which accurately reflect composition of the alveolar air) by the aortic and carotid bodies, as well as by the blood gas and pH sensor on the anterior surface of the medulla oblongata in the brain. There are also oxygen and carbon dioxide sensors in the lungs, but they primarily determine the diameters of the bronchioles and pulmonary capillaries, and are therefore responsible for directing the flow of air and blood to different parts of the lungs.

It is only as a result of accurately maintaining the composition of the 3 liters of alveolar air that with each breath some carbon dioxide is discharged into the atmosphere and some oxygen is taken up from the outside air. If more carbon dioxide than usual has been lost by a short period of hyperventilation, respiration will be slowed down or halted until the alveolar partial pressure of carbon dioxide has returned to 5.3 kPa (40 mmHg). It is therefore strictly speaking untrue that the primary function of the respiratory system is to rid the body of carbon dioxide “waste”. The carbon dioxide that is breathed out with each breath could probably be more correctly be seen as a byproduct of the body’s extracellular fluid carbon dioxide and pH homeostats. If these homeostats are compromised, then a respiratory acidosis, or a respiratory alkalosis will occur. In the long run these can be compensated by renal adjustments to the H+ and HCO3− concentrations in the plasma; but since this takes time, the hyperventilation syndrome can, for instance, occur when agitation or anxiety cause a person to breathe fast and deeply thus causing a distressing respiratory alkalosis through the blowing off of too much CO2 from the blood into the outside air.

Oxygen has a very low solubility in water, and is therefore carried in the blood loosely combined with hemoglobin. The oxygen is held on the hemoglobin by four ferrous iron-containing heme groups per hemoglobin molecule. When all the heme groups carry one O2 molecule each the blood is said to be “saturated” with oxygen, and no further increase in the partial pressure of oxygen will meaningfully increase the oxygen concentration of the blood. Most of the carbon dioxide in the blood is carried as bicarbonate ions (HCO3−) in the plasma. However the conversion of dissolved CO2 into HCO3− (through the addition of water) is too slow for the rate at which the blood circulates through the tissues on the one hand, and through alveolar capillaries on the other. The reaction is therefore catalyzed by carbonic anhydrase, an enzyme inside the red blood cells. The reaction can go in both directions depending on the prevailing partial pressure of CO2. A small amount of carbon dioxide is carried on the protein portion of the hemoglobin molecules as carbamino groups. The total concentration of carbon dioxide (in the form of bicarbonate ions, dissolved CO2, and carbamino groups) in arterial blood (i.e. after it has equilibrated with the alveolar air) is about 26 mM (or 58 ml/100 ml), compared to the concentration of oxygen in saturated arterial blood of about 9 mM (or 20 ml/100 ml blood).

Control of Ventilation

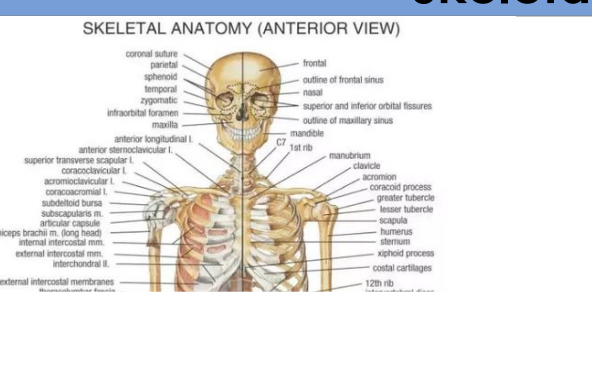
Ventilation of the lungs in mammals occurs via the respiratory centers in the medulla oblongata and the pons of the brainstem. These areas form a series of neural pathways which receive information about the partial pressures of oxygen and carbon dioxide in the arterial blood. This information determines the average rate of ventilation of the alveoli of the lungs, to keep these pressures constant. The respiratory center does so via motor nerves which activate the diaphragm and other muscles of respiration. The breathing rate increases when the partial pressure of carbon dioxide in the blood increases. This is detected by central blood gas chemoreceptors on the anterior surface of the medulla oblongata. The aortic and carotid bodies, are the peripheral blood gas chemoreceptors which are particularly sensitive to the arterial partial pressure of O2 though they also respond, but less strongly, to the partial pressure of CO2. At sea level, under normal circumstances, the breathing rate and depth, is determined primarily by the arterial partial pressure of carbon dioxide rather than by the arterial partial pressure of oxygen, which is allowed to vary within a fairly wide range before the respiratory centers in the medulla oblongata and pons respond to it to change the rate and depth of breathing. Exercise increases the breathing rate due to the extra carbon dioxide produced by the enhanced metabolism of the exercising muscles. In addition passive movements of the limbs also reflexively produce an increase in the breathing rate. Information received from stretch receptors in the lungs limits tidal volume (the depth of inhalation and exhalation).

Disorders

Disorders of the respiratory system can be classified into several general groups:
- Airway obstructive conditions (e.g., emphysema, bronchitis, asthma)
- Pulmonary restrictive conditions (e.g., fibrosis, sarcoidosis, alveolar damage, pleural effusion)
- Vascular diseases (e.g., pulmonary edema, pulmonary embolism, pulmonary hypertension)
- Infectious, environmental and other "diseases" (e.g., pneumonia, tuberculosis, asbestosis, particulate pollutants)
- Primary cancers (e.g. bronchial carcinoma, mesothelioma)
- Secondary cancers (e.g. cancers that originated elsewhere in the body, but have seeded themselves in the lungs)
- Insufficient surfactant (e.g. respiratory distress syndrome in pre-term babies)

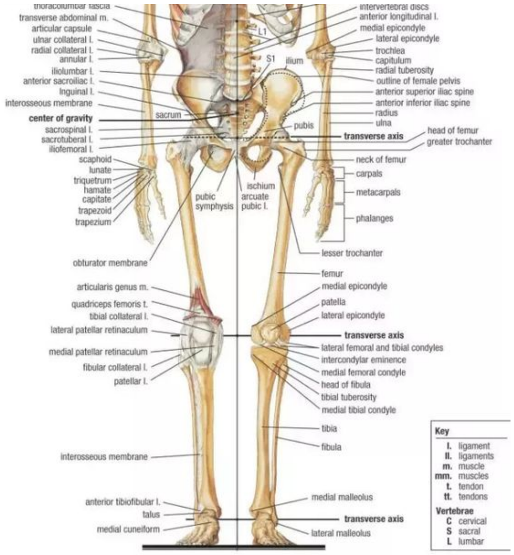
Disorders of the respiratory system are usually treated by a pulmonologist and respiratory therapist. Where there is an inability to breathe or an insufficiency in breathing a medical ventilator may be used.

14 Skeletal System



The skeleton is the body part that forms the supporting structure of an organism. It can also be seen as the bony frame work of the body which provides support, shape and protection to the soft tissues and delicate organs in animals.

There are several different skeletal types: the exoskeleton, which is the stable outer shell of an organism, the endoskeleton, which forms the support structure inside the body, the hydroskeleton, a flexible skeleton supported by fluid pressure, and the cytoskeleton present in the cytoplasm of all cells, including bacteria, and archaea.



Skeleton Types

There are two major types of skeletons: solid and fluid. Solid skeletons can be internal, called an endoskeleton, or external, called an exoskeleton, and may be further classified as pliant (elastic/movable) or rigid (hard/non-movable). Fluid skeletons are always internal.

Exoskeleton	Exoskeletons are external, and are found in many invertebrates; they enclose and protect the soft tissues and organs of the body. Some kinds of exoskeletons undergo periodic moulting or edolysis as the animal grows, as is the case in many arthropods including insects and crustaceans. The exoskeleton of insects is not only a form of protection, but also serves as a surface for muscle attachment, as a watertight protection against drying, and as a sense organ to interact with the environment. The shell of mollusks also performs all of the same functions, except that in most cases it does not contain sense organs. An external skeleton can be quite heavy in relation to the overall mass of an animal, so on land, organisms that have an exoskeleton are mostly relatively small. Somewhat larger aquatic animals can support an exoskeleton because weight is less of a consideration underwater. The southern giant clam, a species of extremely large saltwater clam in the Pacific Ocean, has a shell that is massive in both size and weight. Syrinx aruanus is a species of sea snail with a very large shell.
Endoskeleton	The endoskeleton is the internal support structure of an animal, composed of mineralized tissue and is typical of vertebrates. Endoskeletons vary in complexity from functioning purely for support (as in the case of sponges), to serving as an attachment site for muscles and a mechanism for transmitting muscular forces. A true endoskeleton is derived from mesodermal tissue. Such a skeleton is present in echinoderms and chordates.
Pliant Skeletons	Pliant skeletons are capable of movement; thus, when stress is applied to the skeletal structure, it deforms and then reverts to its original shape. This skeletal structure is used in some invertebrates, for instance in the hinge of bivalve shells or the mesoglea of cnidarians such as jellyfish. Pliant skeletons are beneficial because only muscle contractions are needed to bend the skeleton; upon muscle relaxation, the skeleton will return to its original shape. Cartilage is one material that a pliant skeleton may be composed of, but most pliant skeletons are formed from a mixture of proteins, polysaccharides, and water. For additional structure or protection, pliant skeletons may be supported by rigid skeletons. Organisms that have pliant skeletons typically live in water, which supports body structure in the absence of a rigid skeleton.
Rigid Skeletons	Rigid skeletons are not capable of movement when stressed, creating a strong support system most common in terrestrial animals. Such a skeleton type used by animals that live in water are more for protection (such as barnacle and snail shells) or for fast-moving animals that require additional support of musculature needed for swimming through water. Rigid skeletons are formed from materials including chitin (in arthropods), calcium compounds such as calcium carbonate (in stony corals and mollusks) and silicate (for diatoms and radiolarians).
Cytoskeleton	The cytoskeleton (gr. kytos = cell) is used to stabilize and preserve the form of the cells. It is a dynamic structure that maintains cell shape, protects the cell, enables cellular motion (using structures such as flagella, cilia and lamellipodia), and plays important roles in both intracellular transport (the movement of vesicles and organelles, for example) and cellular division.
Fluid Skeletons	**Hydrostatic Skeleton (Hydroskeleton)** A hydrostatic skeleton is a semi-rigid, soft tissue structure filled with liquid under pressure, surrounded by muscles. Longitudinal and circular muscles around their body sectors allow movement by alternate lengthening and contractions along their lengths. A common example of this is the earthworm.

Human Skeleton

The human skeleton consists of both fused and individual bones supported and supplemented by ligaments, tendons, muscles and cartilage. It serves as a scaffold which supports organs, anchors muscles, and protects organs such as the brain, lungs, heart and spinal cord. Although the teeth do not consist of tissue commonly found in bones, the teeth are usually considered as members of the skeletal system. The biggest bone in the body is the femur in the upper leg, and the smallest is the stapes bone in the middle ear. In an adult, the skeleton comprises around 14% of the total body weight, and half of this weight is water. Fused bones include those of the pelvis and the cranium. Not all bones are interconnected directly: There are three bones in each middle ear called the ossicles that articulate only with each other. The hyoid bone, which is located in the neck and serves as the point of attachment for the tongue, does not articulate with any other bones in the body, being supported by muscles and ligaments. There are 206 bones in the adult human skeleton, although this number depends on whether the pelvic bones (the hip bones on each side) are counted as one or three bones on each side (ilium, ischium, and pubis), whether the coccyx or tail bone is counted as one or four separate bones, and does not count the variable wormian bones between skull sutures. Similarly, the sacrum is usually counted as a single bone, rather than five fused vertebrae. There is also a variable number of small sesamoid bones, commonly found in tendons. The patella or kneecap on each side is an example of a larger sesamoid bone. The patellae are counted in the total, as they are constant.

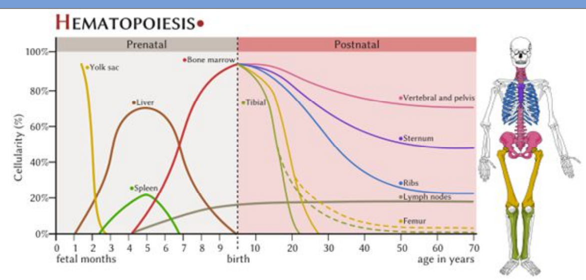
The number of bones varies between individuals and with age – newborn babies have over 270 bones some of which fuse together. These bones are organized into a longitudinal axis, the axial skeleton, to which the appendicular skeleton is attached. The human skeleton takes 20 years before it is fully developed. In many animals, the skeleton bones contain marrow, which produces blood cells. There exist several general differences between the male and female skeletons. The male skeleton, for example, is generally larger and heavier than the female skeleton. In the female skeleton, the bones of the skull are generally less angular. The female skeleton also has wider and shorter breastbone and slimmer wrists. There exist significant differences between the male and female pelvis which are related to the female's pregnancy and childbirth capabilities. The female pelvis is wider and shallower than the male pelvis. Female pelvises also have an enlarged pelvic outlet and a wider and more circular pelvic inlet. The angle between the pubic bones is known to be sharper in males, which results in a more circular, narrower, and near heart-shaped pelvis.

Bones and Cartilage

Bone
Bones are rigid organs that form part of the endoskeleton of vertebrates. They function to move, support, and protect the various organs of the body, produce red and white blood cells and store minerals. Bone tissue is a type of dense connective tissue. Bones have a variety of shapes with a complex internal and external structure they are also lightweight, yet strong and hard. One of the types of tissue that makes up bone tissue is mineralized tissue and this gives it rigidity and a honeycomb-like three-dimensional internal structure. Other types of tissue found in bones include marrow, endosteum and periosteum, nerves, blood vessels and cartilage. There are 206 bones in the adult human body and 270 in an infant.

Cartilage
During embryogenesis the precursor to bone development is cartilage. Much of this substance is then replaced by bone during the second and third trimester, after the flesh such as muscle has formed around it; forming the skeleton. Cartilage is a stiff and inflexible connective tissue found in many areas in the bodies of humans and other animals, including the joints between bones, the rib cage, the ear, the nose, the elbow, the knee, the ankle, the bronchial tubes and the intervertebral discs. It is not as hard and rigid as bone but is stiffer and less flexible than muscle. Cartilage is composed of specialized cells called chondrocytes that produce a large amount of extracellular matrix composed of Type II collagen (except Fibrocartilage which also contains type I collagen) fibers, abundant ground substance rich in proteoglycan, and elastin fibers. Cartilage is classified in three types, elastic cartilage, hyaline cartilage and fibrocartilage, which differ in the relative amounts of these three main components. Unlike other connective tissues, cartilage does not contain blood vessels. The chondrocytes are supplied by diffusion, helped by the pumping action generated by compression of the articular cartilage or flexion of the elastic cartilage. Thus, compared to other connective tissues, cartilage grows and repairs more slowly.

15 Hematopoietic System



The haematopoetic system is the system in the body involved in the creation of the cells of blood.

Structure

The haematopoetic system is the system in the body involved in the creation of the cells of blood. Haematopoietic stem cells (HSCs) reside in the medulla of the bone (bone marrow) and have the unique ability to give rise to all of the different mature blood cell types and tissues. HSCs are self-renewing cells: when they differentiate, at least some of their daughter cells remain as HSCs, so the pool of stem cells is not depleted. This phenomenon is called asymmetric division. The other daughters of HSCs (myeloid and lymphoid progenitor cells) can follow any of the other differentiation pathways that lead to the production of one or more specific types of blood cell, but cannot renew themselves. The pool of progenitors is heterogeneous and can be divided into two groups; long-term self-renewing HSC and only transiently self-renewing HSC, also called short-terms. This is one of the main vital processes in the body.

Function

Haematopoiesis is the formation of blood cellular components. All cellular blood components are derived from haematopoietic stem cells. In a healthy adult person, approximately 10^11–10^12 new blood cells are produced daily in order to maintain steady state levels in the peripheral circulation. All blood cells are divided into three lineages.
● Red blood cells, also called erythrocytes, are the oxygen-carrying cells. Erythrocytes are functional and are released into the blood. The number of reticulocytes, immature red blood cells, gives an estimate of the rate of erythropoiesis.
● Lymphocytes are the cornerstone of the adaptive immune system. They are derived from common lymphoid progenitors. The lymphoid lineage is composed of T-cells, B-cells and natural killer cells. This is lymphopoiesis.
● Cells of the myeloid lineage, which include granulocytes, megakaryocytes and macrophages, are derived from common myeloid progenitors, and are involved in such diverse roles as innate immunity and blood clotting. This is myelopoiesis.

5 Quitting Addictions

This section is about how you can quit unhealthy addictions. Not only to improve your health, but because those items may become scarce in a disaster.

Quitting Smoking

If a disaster happens you may not have the ability to buy cigarettes as readily so this guide will help you stop smoking so you don't have to suddenly deal with running out and stopping cold turkey. When you decide to quit smoking, it can help to find out what to expect as you work through the process. Some people have only a few mild symptoms when they quit but others find it harder. While withdrawal can be challenging, it can help if you look at the symptoms as signs that your body is recovering from the damage smoking has caused. Many people find withdrawal symptoms disappear completely after two to four weeks, although for some people they may last longer. Symptoms tend to come and go over that time. Remember, it will pass, and you will feel better if you hang on and quit for good. Nicotine is highly addictive. While various products can help smokers quit, there is no easy fix.

Reasons to Quit
Twelve hours after stopping, almost all nicotine is out of your system with most by-products gone within five days. After 24 hours, the level of carbon monoxide in your blood has dropped dramatically, meaning your body can take and use oxygen more efficiently. After two days, your senses of taste and smell start to return. After two months, blood flow to your hands and feet improves. After one year, your risk of heart disease rapidly drops. After 10 years, your risk of lung cancer is halved. If you smoke a pack of 20 cigarettes a day at $27, you will save around $10,000 a year. Thinking about what else you would like to do with that money can be a great motivator to stick to your quit plan. Your children will be less at risk from bronchitis, pneumonia, asthma, meningitis and ear infections.

Excuses

These are common excuses why you can't stop smoking.

Excuse 1: The damage is done	You might feel that because you smoke, you've already increased your chance of getting cancer or another smoking-related disease, so quitting now won't make any difference. In fact, as soon as you quit, your body starts to repair itself. You'll notice improvements in your breathing and sense of taste and smell just a few days after stopping. You'll also improve the health of your family and friends by not exposing them to passive smoking.

Excuse 2: I'll gain weight	Medical evidence shows that nicotine doesn't stop you getting hungry. Nicotine makes you burn calories faster, but as long as you remember that you need less food energy, quitting won't actually make you gain weight. Try eating low calorie options and take up an activity instead of replacing cigarettes with food.
Excuse 3: I'll get stressed	Despite what you may think, nicotine doesn't calm you down. Nicotine cravings between cigarettes make you feel stressed and anxious, so when you smoke the cigarette you feel calmer. But you'll feel less stressed once you quit and don't have cravings any more. If you want a cigarette, wait for 10 minutes and the craving will usually pass. Take some deep breaths or go for a walk to relieve the stress and distract you from those cravings.
Excuse 4: It's not the right time to quit smoking	Although it's true that you shouldn't try to quit during particularly stressful times, don't use this as an excuse to never try quitting. Pick a particular date, such as the beginning of a holiday or the beginning of a working week. Work out what makes you want a cigarette, such as having a cup of tea or going to the pub, and pick a day when you can avoid these triggers. Telling lots of people that you're giving up will make you more likely to quit. You won't want to let them down, and you can ask smokers not to offer you cigarettes.
Excuse 5: Quitting will ruin my social life	For many smokers, cigarettes are an important part of their social life. You may class yourself as a social smoker, who only has a cigarette when you're with friends who smoke or during nights out. You may also have bonded with colleagues during cigarette breaks. Although social smoking may seem better than smoking 40 a day, any cigarette smoking damages your health.
Excuse 6: Smoking looks good	For some people, holding a stick of tobacco wrapped in paper seems attractive and fashionable. Teenagers may think it makes them look older or cooler. But many people find the sight of a smoker unattractive. Yellow fingernails, blackened fingers and a stained tongue are not a pretty sight. Smoking also makes your complexion dull and prematurely ages your skin. If you don't want to look old before your time, it's a good idea to quit. There's also the smell — cigarette smoke sticks to your hair and clothes long after you've had your last cigarette of the day. Some people think kissing a smoker is like 'kissing an ashtray'. If you'd prefer to smell fresher, now's the time to quit.
Excuse 7: I can't quit because I'm addicted	There is some truth in this. Smoking is an addiction that's undeniably tough to quit. But it's not impossible. With a lot of determination, you can do it. To quit successfully, you need to deal with your chemical addiction to nicotine and the fact that smoking has become part of your daily routine. The chemical addiction causes physical symptoms when you quit, such as tiredness, irritability and poor concentration. Your doctor can prescribe medication to replace the nicotine. There are counselling and support groups that can give you extra motivation to help you ignore your cravings. Change your routine so that you replace smoking a cigarette with an alternative, such as a drink of water or another activity.

Ways to Quit

The different ways you can quit smoking.

Cold Turkey	For many people the most successful way to quit is going ?cold turkey?. This means stopping completely without cutting down.
Nicotine Replacement Therapy	Using nicotine gum, patches, lozenges, tablets or inhalers may be useful for heavy smokers, though most smokers quit by themselves. Your doctor or pharmacist will explain how to use these products.
Prescription Drugs to Help	Prescription medications can help to reduce withdrawal symptoms when you quit, such as cravings, irritability, and anxiety. But it may not stop them completely.
Alternative Therapies	Some people try herbal remedies, spiritual healing or other alternative therapies, but there is insufficient evidence these methods help you quit.

Symptoms

The symptoms after you quit.

Cravings	These may be strong at first, but they usually only last a few minutes. If you resist each one they will get less powerful in time
Restlessness and trouble concentrating or sleeping	These will pass as your body gets used to not smoking. Relaxation and deep breathing can help. It's also a good idea to reduce your caffeine intake because when you quit smoking your body absorbs almost twice as much caffeine as usual, which can leave you feeling anxious, irritable and restless
Irritability, anger, anxiety, depressed mood	This is all normal: don't panic. Just accept that you will be emotional for a while and that it will pass
Increase in Appetite and Weight Gain	This may last several weeks. Planning ahead can help. Better Health Channel has tips on managing weight gain when you quit.
Less Common Symptoms	● Cold symptoms such as coughing, sore throat and sneezing ● Constipation ● Dizziness or light-headedness ● Mouth ulcers.

As time passes, you will find these symptoms grow weaker, and you will think about smoking less. If you have severe or long-lasting symptoms, it might help to discuss them with a health professional or a quitline.

Coping with Cravings

- Delay acting on the urge to smoke. After five minutes, the urge to smoke weakens. Deep breathe in and out slowly and deeply, and repeat three times.
- Deep breathe in and out slowly and deeply, and repeat three times.
- Drink water, sipping slowly, holding it in the mouth a little longer to savour the taste.
- Do something else. Listen to music, exercise or talk to a friend. After quitting smoking, being more active is the best thing you can do for your general health and wellbeing.
- Remember, each time you resist that urge and do something else instead it's a victory in your quest to quit: you're helping your brain break that link between the activity and the cigarette.
- Many people find withdrawal symptoms disappear completely after two to four weeks.
- Changing your routine can help avoid those triggers that tell your brain it's time for a smoke.

Feeling Emotional
- Within six hours your heart rate will slow and your blood pressure will become more stable.
- Within one day your bloodstream will be almost nicotine free, the level of carbon monoxide in your blood will have dropped, and oxygen will be reaching your heart and muscles more easily.
- Within one week your sense of taste and smell may have improved.
- Within three months you will be coughing and wheezing less, your immune function and circulation to your hands and feet will be improving, and your lungs will be getting better at removing mucus, tar and dust.
- Within six months your stress levels are likely to have dropped, and you are less likely to be coughing up phlegm.
- After one year your lungs will be healthier and breathing will be easier than if you'd kept smoking.
- Within two to five years your risk of heart disease will have dropped significantly (and will continue to do so over time).

- Within five years, a woman's risk of cervical cancer will be the same as if she had never smoked.
- After 10 years your risk of lung cancer will be lower than if you had kept smoking.
- After 15 years your risk of heart attack and stroke will be similar to that of someone who has never smoked.

Quitting Drinking

Quitting isn't even the hardest part. It isn't even what happens to you when you quit. The hardest part of the journey to sobriety is attempting sobriety in the first place. Still, people can and do recover from alcoholism, perhaps more often than you may think. OK so you need to quit, you know it's going to be tough, but you know it's possible. Professional treatment is strongly recommended. What follows is a list of reasons and ways to stay on the path to recovery. There is no particular order of any kind. We have simply combined our knowledge of alcohol treatment to give you a guide on how to stay sober.

Admit the Problem
With drinking, we tend to think in black and white terms: are you an alcoholic or a normal drinker? Meanwhile, the large gray area in between is full of problematic drinkers who either are alcoholics, or are well on their way. If you have a drinking problem, chances are you are aware of it. As the old saying goes, the first step is admitting you have a problem. If you find yourself caught in a thought cycle – comparing your drinking to that of others, taking online assessments, or just asking yourself if you have a problem – give these three things a try:

- Ask the right question. Stop asking yourself whether or not you're an alcoholic. If you're asking yourself this, you probably are one. Sorry to be so harsh. Instead, ask yourself if drinking is preventing you from having the life you want. If yes, step one is over. You've admitted the problem.
- Stop the comparisons. They do you no good. That's not your life. You are an individual with a complicated, unique life. So what if you drink less than Billy down the street… If you have a problem, you have a problem. Comparing your drinking to that of others will only lead to self-justification.
- Think of your future self. Picture yourself five years from now with the same drinking habits. Are you okay with what you see? If not, you likely have a problem with alcohol. Now admit it, so you can begin treating it.

Quitting Reasons
Long-term benefits are rarely enough to motivate people to quit. We often prefer instant gratification. Quitting drinking is no exception. Quitting alcohol (as a drinker) is the healthiest decision you can make. Weight loss, improved liver function, lower cholesterol, stronger immune system, a clearer mind, better emotional balance, and more efficient brain activity are among the ocean of long-term benefits. The long-term benefits are only about saving your health and well-being anyway, so here are 4 short-term benefits we all can relate to:

- Reclaim lost time. Jill is a moderate drinker. She drinks three times a week, 2-3 drinks per occasion. Each time, she 'loses' about 3 hours of productive time being buzzed. Every year, Jill loses a month and a half. That's a lot of lost time that could have been spent sober and productively. Don't forget about any time Jill (or you) may spend hungover.
- Have more meaningful talks. Conversation builds character and makes us grow. Those benefits disappear when you're drunk. Alcohol prevents any meaningful change from talking. It might seem terrifying to meet new people without drinking, but the damage alcohol causes is scarier.
- Get rich quickly. It's easy to spend $150 or more per week as a drinker, especially if you go out. of drinking. After 6 months, quitting could allow you to afford backpacking around the world. Are you willing to pay $600 a month for health problems?
- Sleep better. Alcohol is a depressant, which means it will make you tired. Alcohol also disrupts sleep patterns, throwing off your body's balance.

Set Rules
Giving up alcohol must be made priority number one in your life. A partial commitment is a commitment to failure. Establish rules and do not break them. Say no to bar night, say no to the sale on six-packs, and say no to the devil on your shoulder telling you it's only one drink. Put sobriety on a pedestal and don't remove it until you know your problem is cured. Whether alcohol is a major part of your social life, or it's just something you and the gang do once in a while, it's going to be hard if and when your friends/family drink around you. Step one is telling them all you simply cannot be around drinking for a while. Step two is cutting off anyone with whom all you did was drink. Besides, if the only thing you have in common with someone is knocking them down, you might want to consider unfriending them. I've let go of people in my social circle before and I know it's not easy—but that doesn't make it unnecessary. This might be the hardest thing you do in choosing a life without alcohol. The key is to remember that true friends are an abundant resource. Having a strong social circle is purely a function of the effort you invest into it. That includes choosing to associate with people who are aligned with your purpose, avoiding the energy vampires. Tell people what you're doing. Not only does this add accountability to your goal, it also drops the hint that if your friends are planning on going out and getting wasted, you're probably not interested. Plus, if someone offers you a drink and you look at them and say, "I can't. I'm a full blown alcoholic," they probably won't ask you again.

Quitting Risks
The first 72 hours are the most painful part of recovery. As your body rids itself of alcohol, you'll experience acute withdrawal – unpleasant. Alcoholics can experience especially difficult recoveries, and professional help is recommended for them. Regardless, the benefits of quitting drinking will soon make themselves known. Even though it may not feel like it, the acute withdrawal stage of the recovery timeline is the beginning of something great. Withdrawal symptoms are evidence your body is healing. The onset of withdrawal symptoms can begin as soon as six hours after your last drink. You may experience:

- Elevated temperature
- Increased blood pressure, breathing rate, and pulse
- Excessive sweating
- Tremors
- Insomnia
- In extreme cases, one may experience seizures, sometimes life-threatening.

The body is working overtime to cleanse itself. When done correctly, detox is the most important step in the recovery process. At the same time, many recovering addicts relapse when they use drink as self-medication for the withdrawal symptoms. Ironic, but true. This is why it's crucial to seek professional treatment when necessary.

Attitude Change
Even after you admit that you have a problem, you need to change your attitude regarding your situation. Don't get mad at people when they try to help. Don't put yourself down because you have gone through a rough patch. Instead, get in the right frame of mind by realizing that you are taking the right steps on the road to recovery. Is it easy to have a good attitude when you are dealing with such a difficult situation? Of course not. That being said, when you approach the situation the right way you are going to ease the stress on yourself and make it much easier to reach your goals.

2 Weeks Later
Full detoxification from alcohol can take up to two weeks. As your body is getting rid of its last remnants, some negative symptoms may pop up, but the benefits will already be clear. As expected, recovery comes with emotional highs and lows. The negative effects may include:

- Anxiety & depression
- Decreased energy & metabolism
- Feelings of aggression or hostility
- Declined sexual interest or function
- Sleep disruption & nightmares

Don't let this deter you. The positive effects will be abundant, too many to list.

The worst part of all may be cravings for alcohol, which may last a lifetime. Even after removing all traces of alcohol from your system, the brain will still want it to help return to the balance of chemicals it has gotten used to — but knowing the source of these symptoms is key to dealing with cravings appropriately. Develop and enforce new hobbies and habits that don't include the bottle. In a treatment program, you can attend therapy, perform group work, and receive one-on-one attention from medical and clinical professionals. Building effective coping skills and getting to the root of your addiction is key to alcohol abuse recovery. Seek out a therapist. Attend some type of group meeting, such as AA or NA. It's always helpful to have a support system of counselors and people who understand what you're going through. Utilize your friends and family as well. Go to WAR with your addiction. Recovery is a lifelong process, and post-treatment maintenance is just as important as the initial treatment process.

Quitting Drugs

Developing a drug addiction isn't a character flaw or a sign of weakness, and it takes more than willpower to overcome the problem. Abusing illegal or certain prescription drugs can create changes in the brain, causing powerful cravings and a compulsion to use that makes sobriety seem like an impossible goal. But recovery is never out of reach, no matter how hopeless your situation seems. With the right treatment and support, change is possible. Don't give up—even if you've tried and failed before. The road to recovery often involves bumps, pitfalls, and setbacks.

But by examining the problem and thinking about change, you're already well on your way. For many people struggling with addiction, the toughest step toward recovery is the very first one: recognizing that you have a problem and deciding to make a change. It's normal to feel uncertain about whether you're ready to make a change, or if you have what it takes to quit. If you're addicted to a prescription drug, you may be concerned about how you're going to find an alternate way to treat a medical condition. It's okay to feel torn.

Committing to sobriety involves changing many things, including:
● The way you deal with stress
● Who you allow in your life
● What you do in your free time
● How you think about yourself
● The prescription and over-the-counter medications you take

It's also normal to feel conflicted about giving up your drug of choice, even when you know it's causing problems in your life. Recovery requires time, motivation, and support, but by making a commitment to change, you can overcome your addiction and regain control of your life.

Think About Change
● Keep track of your drug use, including when and how much you use. This will give you a better sense of the role the addiction is playing in your life
● List the pros and cons of quitting, as well as the costs and benefits of continuing your drug use
● Consider the things that are important to you, such as your partner, your kids, your pets, your career, or your health. How does your drug use affect those things?
● Ask someone you trust about their feelings on your drug use
● Ask yourself if there's anything preventing you from changing. What could help you make the change?

Preparation for Change
Remind yourself of the reasons you want to change. Think about your past attempts at recovery, if any. What worked? What didn't? Set specific, measurable goals, such as a start date or limits on your drug use. Remove reminders of your addiction from your home, workplace, and other places you frequent. Tell friends and family that you're committing to recovery, and ask for their support.

Treatment Options
Once you've committed to recovery, it's time to explore your treatment choices. While addiction treatment can vary according to the specific drug, a successful program often includes different elements, such as:
● Detoxification. Usually the first step is to purge your body of drugs and manage withdrawal symptoms.
● Behavioral counseling. Individual, group, and/or family therapy can help you identify the root causes of your drug use, repair your relationships, and learn healthier coping skills.
● Medication may be used to manage withdrawal symptoms, prevent relapse, or treat any co-occurring mental health condition such as depression or anxiety.
● Long-term follow-up can help to prevent relapse and maintain sobriety. This may include attending regular in-person support groups or online meetings to help keep your recovery on track.

Best Treatment
No treatment works for everyone. Everyone's needs are different. Whether you have a problem with illegal or prescription drugs, addiction treatment should be customized to your unique situation. It's important that you find a program that feels right. Treatment should address more than just your drug abuse. Addiction affects your whole life, including your relationships, career, health, and psychological well-being. Treatment success depends on developing a new way of living and addressing the reasons why you turned to drugs in the first place. For example, your drug dependency may have developed from a desire to manage pain or to cope with stress, in which case you'll need to find a healthier way to relieve pain or to handle stressful situations. Commitment and follow-through are key. Drug addiction treatment is not a quick and easy process. In general, the longer and more intense the drug use, the longer and more intense the treatment you'll need. And in all cases, long-term follow-up care is crucial to recovery. There are many places to turn for help. Not everybody requires medically supervised detox or an extended stint in rehab. The care you need depends on a variety of factors, including your age, drug-use history, medical or psychiatric conditions. In addition to doctors and psychologists, many clergy members, social workers, and counselors offer addiction treatment services. Substance abuse and mental health. As you seek help for drug addiction, it's also important to get treatment for any other medical or psychological issues you're experiencing. Your best chance of recovery is by getting combined mental health and addiction treatment from the same treatment provider or team.

Addiction Recovery
Don't try to go it alone—reach out for support. Whatever treatment approach you choose, having positive influences and a solid support system is essential. The more people you can turn to for encouragement, guidance, and a listening ear, the better your chances for recovery. Lean on close friends and family. Having the support of friends and family members is an invaluable asset in recovery. If you're reluctant to turn to your loved ones because you've let them down before, consider going to relationship counseling or family therapy. Build a sober social network. If your previous social life revolved around drugs, you may need to make some new connections. It's important to have sober friends who will support your recovery. Try taking a class, joining a church or a civic group, volunteering, or attending events in your community. Consider moving into a sober living home. Sober living homes provide a safe, supportive place to live while you're recovering from drug addiction. They are a good option if you don't have a stable home or a drug-free living environment. Make meetings a priority. Join a recovery support group such as a 12-step program and attend meetings regularly. Spending time with people who understand exactly what you're going through can be very healing. You can also benefit from the shared experiences of the group members and learn what others have done to stay sober.

Coping with Stress
After addressing your immediate problems with addiction and starting treatment, you'll still have to face the problems that led to your drug abuse. Did you start using to numb painful emotions, calm yourself after an argument, unwind after a bad day, or forget about your problems? Once you're sober, the negative feelings that you dampened with drugs will resurface. For treatment to be successful, you'll first need to resolve your underlying issues. Once you have resolved your underlying issues, you will, at times, continue to experience stress, loneliness, frustration, anger, shame, anxiety, and hopelessness. These emotions are all a normal part of life. Finding ways to address these feelings as they arise is an essential component to your treatment and recovery. There are healthier ways to keep your stress level in check. You can learn to manage your problems without falling back on your addiction. When you're confident in your ability to quickly de-stress, facing strong feelings isn't as intimidating or overwhelming. Different quick stress relief strategies work better for some people than others. The key is to find the one that works best for you.

● Movement. A brisk walk around the block can be enough to relieve stress. Yoga and meditation are also excellent ways to bust stress and find balance.
● Step outside and savor the warm sun and fresh air. Enjoy a beautiful view or landscape.
● Play with your dog or cat. Enjoy the relaxing touch of your pet's fur.
● Experiment with your sense of smell. Breathe in the scent of fresh flowers or coffee beans, or savor a scent that reminds you of a favorite vacation, such as sunscreen or a seashell.
● Close your eyes and picture a peaceful place. Think of a sandy beach, or a fond memory, such as your child's first steps or time spent with friends.
● Pamper yourself. Make yourself a steaming cup of tea, give yourself a neck or shoulder massage. Soak in a hot bath or shower.

Drug Triggers
Your recovery doesn't end at getting sober. Your brain still needs time to recover and rebuild connections that changed while you were addicted. During this rebuild, drug cravings can be intense. You can support your continued recovery by avoiding people, places, and situations that trigger your urge to use:

● Step away from your friends who use. Don't hang out with friends who are still doing drugs. Surround yourself with people who support your sobriety, not those who tempt you to slip back into old, destructive habits.
● Avoid bars and clubs. Even if you don't have a problem with alcohol, drinking lowers inhibitions and impairs judgment, which can easily lead to a relapse. Drugs are often readily available and the temptation to use can be overpowering. Also avoid any other environments and situations that you associate with drug use.
● Be upfront about your history of drug use when seeking medical treatment. If you need a medical or dental procedure done, be upfront and find a provider who will work with you in either prescribing alternatives or the absolute minimum medication necessary. You should never feel ashamed or humiliated about previous drug use or be denied medication for pain; if that happens, find another provider.
● Use caution with prescription drugs. If you were addicted to a prescription drug, such as an opioid painkiller, find alternate ways to manage the pain. It's important to stay away from prescription drugs with the potential for abuse. Drugs with a high abuse potential include painkillers, sleeping pills, and anti-anxiety medication.

Drug Cravings
Sometimes craving cannot be avoided, and it is necessary to find a way to cope:

● Get involved in a distracting activity. Read, see friends, go to a movie, immerse yourself in a hobby, hike, or exercise. Once you're interested in something else, you'll find the urges go away.
● Talk it through. Talk to friends or family members about craving when it occurs. Talking can be very helpful in pinpointing the source of the craving. Also, talking about craving often helps to discharge and relieve the feeling and will help restore honesty in your relationship. Craving is nothing to feel bad about.
● Challenge and change your thoughts. When experiencing a craving, many people have a tendency to remember only the positive effects of the drug and forget the negative consequences. Therefore, you may find it helpful to remind yourself that you really won't feel better if you use and that you stand to lose a lot. Sometimes it is helpful to have these consequences listed on a small card that you keep with you.
● Urge surf. Many people try to cope with their urges by toughing it out. But some cravings are too strong to ignore. When this happens, it can be useful to stay with the urge until it passes. This technique is called urge surfing. Imagine yourself as a surfer who will ride the wave of your drug craving, staying on top of it until it crests, breaks, and turns into less powerful, foamy surf.

Urge Surfing
1. Take an inventory of how you experience the craving. Do this by sitting in a comfortable chair with your feet flat on the floor and your hands in a comfortable position. Take a few deep breaths and focus your attention inward. Allow your attention to wander through your body. Notice where in your body you experience the craving and what the sensations are like. Notice each area where you experience the urge, and tell yourself what you are experiencing. For example, "My craving is in my mouth and nose and in my stomach."
2. Focus on one area where you are experiencing the urge. Notice the exact sensations in that area. For example, do you feel hot, cold, tingly, or numb? Are your muscles tense or relaxed? How large an area is involved? Notice the sensations and describe them to yourself. Notice the changes that occur in the sensation. "My mouth feels dry and parched. There is tension in my lips and tongue. I keep swallowing. As I exhale, I can imagine the tingle of using."
3. Repeat the focusing with each part of your body that experiences the craving. Describe to yourself the changes that occur in the sensations. Notice how the urge comes and goes. Many people, when they urge surf, notice that after a few minutes the craving has vanished. The purpose of this exercise, however, is not to make the craving go away but to experience the craving in a new way. If you practice urge surfing, you will become familiar with your cravings and learn how to ride them out until they go away naturally.

Drug Free Life
You can support your drug treatment and protect yourself from relapse by having activities and interests that provide meaning to your life. It's important to be involved in things that you enjoy, that make you feel needed, and add meaning to your life. When your life is filled with rewarding activities and a sense of purpose, your addiction will lose its appeal.

● Pick up an old hobby or try a new one. Do things that challenge your creativity and spark your imagination—something you've always wanted to try. Learn a musical instrument, a foreign language, or try a new sport.
● Adopt a pet. Yes, pets are a responsibility, but caring for an animal makes you feel loved and needed. Pets can also get you out of the house for exercise.
● Spend time in nature. Take a scenic hike, go fishing or camping, or enjoy regular walks in a park.
● Enjoy the arts. Visit a museum, go to a concert or a play, take an art class or write a memoir.
● Get involved in your community. Replace your addiction with drug-free groups and activities. Volunteer, become active in your church or faith community, or join a local club or neighborhood group.
● Set meaningful goals. Having goals to work toward and something to look forward to can be powerful antidotes to drug addiction. It doesn't matter what the goals are, just that they are important to you.
● Look after your health. Regular exercise, adequate sleep, and healthy eating habits help you keep your energy levels up and your stress levels down. The more you can stay healthy and feel good, the easier it will be to stay sober.

Relapse

Relapse is a common part of the recovery process from drug addiction. While relapse is frustrating and discouraging, it can be an opportunity to learn from your mistakes, identify additional triggers, and correct your treatment course. Various "triggers" can put people at risk of relapsing into old patterns of substance use. Causes of relapse can differ for each person. Some common ones include:

● Negative emotional states (such as anger, sadness, trauma or stress)
● Physical discomfort (such as withdrawal symptoms or physical pain)
● Positive emotional states (wanting to feel even better)
● Testing personal control ("I can have just one pill")
● Strong temptations or urges (cravings to use)
● Conflict with others (such as an argument with a spouse or partner)
● Social pressures to use (situations where it seems as though everyone else is using drugs)
● Good times with others (such as having fun with friends or family)

The important thing to remember is that relapse doesn't mean drug treatment failure. Don't give up. Call your sponsor, talk to your therapist, go to a meeting, or schedule an appointment with your doctor. When you're sober again and out of danger, look at what triggered the relapse, what went wrong, and what you could have done differently. You can choose to get back on the path to recovery and use the experience to strengthen your commitment.

Quitting Caffeine

The positive effects of caffeine are real and valuable, but in this case, more is not better. The mental benefits of caffeine are, for the most part, fully realized at very low doses. Consuming as little as 40 mg of caffeine can improve attention, alertness, vigilance, and reaction time. Higher doses of caffeine can actually be counterproductive from the standpoint of productivity or mental performance: after a certain point, more caffeine will cause anxiety, jitters, and brain fog, and the increase in energy level it produces can make it hard to stay still. To give you some context, here's the amount of caffeine in some common beverages, as reported by the Center for Science in the Public Interest:

- One tall (12 oz.) Starbucks coffee, Pike Place Roast: 235 mg
- One cup of Folgers ground coffee, House blend, made with 2 tablespoons of coffee: 60–80 mg
- One 8 oz. cup of brewed green tea: 29 mg
- One 20 oz. Diet Coke: 76 mg
- One 8 oz. Red Bull: 80 mg
- One 2 oz. 5-Hour Energy (or one caplet of Vivarin or NoDoze): 200 mg

Improvements in physical performance require higher doses of caffeine. Improvements in endurance start happening at dosages of 3 mg per kilogram of body weight, and sometimes even more is needed. Since most people weigh between 40 and 100 kg (1 kg = 2.2 lbs), a minimum of 120 to 300 mg of caffeine is needed to aid with distance running. Improvements in strength and power require even higher dosages, and many studies find that caffeine leads to no improvement at all.

One research review found that 11 of 17 studies found a relationship between caffeine and improvements in power, and 6 of 11 studies found that caffeine was associated with improvements in strength. Of the studies that did show a benefit of caffeine usage before resistance training (weightlifting), the minimum dosage required was always at least 3 mg per kilogram of body weight, and sometimes as high as 6 mg/kg. What most people don't realize is that the physical effects of caffeine are largely due to the placebo effect.

So strong is this effect that it actually gets stronger the more caffeine subjects believe they're consuming. In fact, there's not even a plausible physical mechanism whereby caffeine could improve strength and power—it actually works primarily by boosting your motivation so that you push yourself harder, which you could potentially train yourself to do without caffeine.

Studies also consistently find a greater benefit to caffeine usage early in the morning, when it works in part by banishing any remaining sleepiness from the night before. As you'll see in a minute, it only takes 100 mg or so per day to start getting addicted to caffeine. With that in mind, usage is best limited to very low dosages, taken early in the morning and with an eye toward mental rather than physical benefits.

Caffeine Addiction

This is really two questions: How easily can you get addicted to caffeine? and How much can excessive caffeine consumption hurt you? I'll tackle the "How addictive is it?" question first. Consuming as little as 1.5 mg per kilogram of body weight per day is enough to start building up a tolerance for caffeine. That means tolerance will start to build at a daily intake of somewhere between 70 and 150 mg per day. This amounts to roughly one cup of coffee a day or maybe two cups of relatively weak coffee or tea if you're especially big. Once you build up a tolerance, you become dependent on caffeine just to function normally. Effectively, your baseline level of physical and mental performance goes down, and your usual caffeine dose is only enough to get you up to normal. So if you normally consume 100 mg per day, for instance, after a few weeks you'll be subnormal without caffeine; 100 mg will get you functioning normally, but it will take an even higher dose to truly reap its benefits. Once your consumption rises to around 750 mg a day—the equivalent of 5 to 8 cups of coffee or 15 to 20 cups of tea—your tolerance will be complete. You'll cease to get any benefit from caffeine, even at higher intakes. And, of course, the withdrawal will be … not fun. Withdrawal can begin to occur when you're habitually consuming around 100 mg per day. On the plus side, while caffeine withdrawal is painful, it's not dangerous. Also, some of caffeine's withdrawal symptoms, just like some of its positive effects, are purely subjective—caffeine withdrawal does not significantly reduce cognitive ability, even though it almost always feels like it does.

Everyone knows that caffeine can disrupt your sleep, but most people vastly underestimate just how easily it can do so. The standard advice to stop consuming caffeine in the afternoon actually doesn't go nearly far enough, because even a single moderate dose of caffeine consumed first thing in the morning—such as a double espresso or two cups of coffee—can measurably reduce the amount of time spent in deep sleep later that night. This reduction occurs despite the fact that by nighttime, the caffeine is almost entirely gone from your bloodstream; that is, its effects seem to last beyond the active life of caffeine itself. Note that a much smaller dose of caffeine consumed in the afternoon, like a can of soda, will also have been metabolized by this time and thus could be expected to have the same effect. Caffeine also causes anxiety—in fact, this is likely a secondary mechanism behind its sleep-inhibiting effects. Even 150 mg of caffeine, usually considered a moderate dose, will significantly increase anxiety levels in most people.

Daily consumption of even lower doses of caffeine can have even worse long-term effects. If you regularly consume more than 100 mg a day, you'll experience increased anxiety and have chronically elevated cortisol levels. Cortisol, of course, is known as the body's main "stress hormone." And while it's not as bad of a hormone as it's often made out to be—you want it to be high first thing in the morning, for instance—chronically elevated cortisol levels are one of the most reliable biomarkers of poor overall health. When your cortisol levels are consistently high, you're likely to die sooner. As if that wasn't bad enough, higher cortisol levels can also cut your ability to recover from exercise in half—meaning you'll make half as much progress as you would with low cortisol and only be able to exercise half as much before experiencing symptoms of overtraining. With all that said, there is good news here. You don't need to quit caffeine forever, but habitual users should go on a one- to two-week caffeine detox every so often. Thankfully, there's a way to kick a caffeine addiction in one week with very little pain.

Withdrawl Symptoms

Typical caffeine withdrawal symptoms include the following:

- Lethargy
- Increased heart rate
- Decreased motor activity (you don't feel like moving much)
- Shakes or hand tremors
- Increased need to urinate (i.e., a diuretic effect)
- Skin flushing
- Flu-like symptoms

In addition, the following symptoms can occur, but usually only after a person has been habituated to higher dosages (several hundred milligrams per day):

- Muscle aches and stiffness
- Constipation
- Joint pain
- Abdominal pain
- Nausea and/or vomiting

Withdrawal symptoms usually set in about 12 to 24 hours after cessation of caffeine intake. Fortunately, it only takes about nine days to get over a caffeine addiction and reset your tolerance, and the worst of the withdrawal symptoms will usually be behind you after two to three days. Those first few days can be quite unpleasant, however. The good news is that there are a couple of things you can do to make the process—and particularly the first two days—easier, and in fact nearly painless. Surprisingly, a simple amino acid supplement can block the worst effects of caffeine withdrawal. Here's how that works: While caffeine's primary mechanism of action is inhibition of the depressant neurotransmitter adenosine, the most painful symptoms of caffeine withdrawal aren't linked to this process. Among other things, caffeine causes the brain to overproduce three stimulant hormones and neurotransmitters: dopamine, epinephrine (adrenaline), and norepinephrine. All three of these chemicals are synthesized by the body from the amino acid tyrosine, which in turn is synthesized from the amino acid phenylalanine. The biosynthesis pathway looks like this: Phenylalanine → tyrosine → L-Dopa → dopamine, epinephrine (adrenaline), norepinephrine

Chronic caffeine usage can therefore deplete the brain's stores of tyrosine and phenylalanine, two amino acids that act as building blocks for dopamine and adrenaline. This depletion is partly responsible for caffeine tolerance, as well as some of the more painful side effects of caffeine withdrawal - which is why research shows that phenylalanine and tyrosine depletion reduces the effectiveness of stimulants. As such, it is unsurprising that anecdotally, many people find that supplementing either tyrosine or phenylalanine can make recovery from caffeine addiction (and probably addiction to other dopamine-producing drugs) faster and easier. You might also recognize phenylalanine as an ingredient in diet sodas: a 12 oz. can of Diet Coke, for example, contains 104 mg of phenylalanine, one of the components of aspartame. Of the two recommended supplements—tyrosine and phenylalanine—I recommend phenylalanine, in the form of DL-phenylalanine (abbreviated DLPA), over tyrosine. Since each step in the synthesis pathway described above is irreversible, taking phenylalanine will restore your tyrosine levels as well, whereas taking tyrosine won't directly restore your phenylalanine levels.

DL-phenylalanine is a mixture of the left and right isomers of phenylalanine, and because your brain uses both, it's best to supplement with a mix of the two. The other thing you can do to make the withdrawal process easier is replace your caffeine habit with another habit. According to The Power of Habit, the seminal book on habit change, it's almost impossible to simply get rid of a habit without replacing it with something else. It is far more effective to replace that habit with something else that you can do at the same time and under the same circumstances as your old habit. What this means for caffeine is that you should replace your usual caffeine source with a decaffeinated version of the same thing. This decaffeinated substitute should also be available from the same sources from which you're used to getting your caffeine. So if you normally have coffee at home, instead have decaf at home. If you normally get Diet Coke from 7–11, instead get caffeine-free Diet Coke if your store has it; otherwise, go for diet root beer, which is the closest thing to decaffeinated diet cola.

Addiction Solution

Putting all this information together, here's the exact schedule you should follow to kick your addiction in one week. Before starting: Figure out what your substitute habit is going to be—decaf coffee, herbal tea, root beer, etc. If you normally make or consume your caffeine at home or the office, acquire a supply of your substitute that will last you more than a week. Also get a bottle of DL-phenylalanine capsules. The last day you consume caffeine: Throw out all your caffeine. Coffee, soda, caffeine pills - get rid of them all. You may also take 500 mg of DLPA either in the morning or around noon as desired. Be aware that taking it with or shortly before caffeine will potentiate the effects of the caffeine.

Day 1	Consume 1,000 mg of DL-phenylalanine first thing in the morning and another 1,000 mg around noon. Start consuming your substitute beverage in place of your usual caffeinated beverage at the same time and place you would normally be consuming caffeine.
Day 2	Take 1,000 mg of DLPA in the morning and 1,000 mg at noon. The morning of Day 2 is the hardest for most people—once you go without caffeine that morning, it only gets easier from there.
Day 3	Take 1,000 mg of DLPA in the morning and 500 mg at noon. By the afternoon of Day 3, if not sooner, your caffeine cravings should be all but gone.
Day 4	Take 1,000 mg of DLPA first thing in the morning and 500 mg at noon. Things will be noticeably easier by this day at the latest: withdrawal symptoms should no longer be noticeable, although you're still a few days away from completely resetting your tolerance.
Day 5-6	Take 500 mg of DLPA in the morning and 500 mg at noon.
Day 7-10	Take 500 mg of DLPA in the morning, but not at noon. By Day 7, your tolerance will probably have been completely reset and your addiction will be over, but you should keep going for 10 days just to be absolutely certain.
Day 11+	After 10 days, you can resume having one caffeinated beverage a day, in the morning, if you so choose, as long as it has less than 100 mg of caffeine. Check this list to find the caffeine content of a beverage.

Reset Your Caffeine Tolerance
This system is simple and has been proven effective time and time again. Even for an ardent tea drinker like me, it's well worth taking a week or two off from caffeine in order to once again enjoy the full benefits of the world's favorite drug. Caffeine withdrawal can be tough, but if you follow this system, you'll only experience mild discomfort for the first two days. By Day 3, you'll barely even miss caffeine. After a week or so, your tolerance will have been completely reset—it will be as if you had never had caffeine before. The even better news is that you don't have to quit caffeine forever, and your effort will not have been "wasted" if you start drinking coffee again. In fact, a one-week caffeine washout will allow you to once more experience the full benefits of caffeine from a nice, low dose while still functioning at 100 percent the rest of the time and sleeping soundly at night.

Quitting Sugar

Sugar addiction is such an integral part of our society that we don't even have a word (like "alcoholic", "chocaholic" or "workaholic") to describe people addicted to sugar. "Eaters" are addicted to sugar, but you can eat without sugar. So I'm inventing a new word for sugar addicts: "sugarholics". Sugarholics today are in the same position that smokers were in the 1950s. You used to be able to smoke any time at work. You didn't have to stop work and stand alone in the middle of a field. You weren't vilified for lighting up a cigarette in a restaurant. Quite the opposite; if you didn't smoke, you were the weirdo. Today, sugarholics rule the roost. Everybody is addicted from birth. Not eating the birthday cake in the tea room marks you out as the weirdo. Make no mistake: the task you are about to undertake will not be easy, but it is not an exercise in willpower. Despite what everybody tells you, if you are a sugarholic, you do not have a personality defect. You are not a glutton. You are not weak-willed. You are chemically addicted to a substance in the food supply called fructose. And until you treat that addiction as the powerful biochemical force that it is, you will never loosen its grip. There are five steps to breaking your addiction.

Names for Sugar

Sugar is a master of disguise: just because you don't see "sugar" on the ingredient list when scanning a nutrition label does not guarantee the item is sugar or sweetener-free. Sugar goes by a slew of different names, making it easy for manufacturers to hide how much sugar is truly in a given product.

Basic Simple Sugars • Dextrose • Fructose • Galactose • Glucose • Lactose • Maltose • Sucrose			
Solid / Granulated Sugars • Beet sugar • Brown sugar • Cane juice crystals • Cane sugar • Castor sugar • Coconut sugar • Confectioner's sugar	• Corn syrup solids • Crystalline fructose • Date sugar • Demerara sugar • Dextrin • Diastatic malt • Ethyl maltolFlorida crystals • Golden sugar	• Glucose syrup solids • Grape sugar • Icing sugar • Maltodextrin • Muscovado sugar • Panela sugar • Raw sugar	• Sugar (granulated or table) • Sucanat • Turbinado sugar • Yellow sugar
Liquid or Syrup Sugars • Agave Nectar/Syrup • Barley malt • Blackstrap molasses • Brown rice syrup • Buttered sugar/buttercream • Caramel • Carob syrup	• Corn syrup • Evaporated cane juice • Fruit juice • Fruit juice concentrate • Golden syrup • High-Fructose Corn Syrup (HFCS) • Honey	• Invert sugar • Malt syrup • Maple syrup • Molasses • Rice syrup • Refiner's syrup • Sorghum syrup • Treacle	

Sugar Elimination

Attitude
There are lots of downsides to sugar addiction and the only upside is that you feel normal when you have a hit. Do you really have cause to feel deprived? No, but willpower diets demand that you feel deprived. They ask you to "go without" and to "give up" a treat. Feeling deprived will simply drive you back into the arms of addiction. If you want to succeed, you mustn't feel you are being deprived of anything. You need to take pity on the poor hopeless addicts who are all around you ingesting poison. You need to view any off ering of sugar not as a temptation to be overcome, but as an attempt to poison you (perhaps a little extreme, but you get the idea). So, don't feel deprived. You are not giving up anything. You are simply stopping a dangerous and harmful addiction. It really is that simple to break an addiction. If you have the right attitude, staying sugar-free becomes a lot easier than you could possibly imagine.

Habits
A critical step in breaking your sugar addiction is identifying the habits associated with the addiction. For me, watching TV was a means of relaxation, and it still is. But my sugar addiction had infiltrated that pleasurable experience and made it its own. Sugar had become an integral part of the relaxation process. The pleasure I gained from watching TV was directly associated, in my mind, with the dopamine hit I got from the sugar. It's possible to disassociate the two activities, but you won't do it by abstaining from both using willpower. The trouble with addictions is that they frequently attach themselves to otherwise-pleasurable experiences and it becomes impossible to distinguish the two. Those habits will really test your resolve because of the strong association, and in some cases the strong peer group pressure (such as at birthday parties, Easter and Christmas) to conform. In many instances, the only rational way to deal with the problem is to avoid the habitual events associated with consuming sugar until you break the addiction. So, if you are in the habit of relaxing in front of the TV with a chocolate at the end of the day, stop watching TV and find some other way to relax in the evening for the next month. Or you could continue your TV habit but replace the chocolate with nuts, for example.

Elimination
This step is all about giving you the shopping strategies you need to prevent too much fructose from contaminating your food supply. You are going to need some shelf space for all your fructose-free food, so the first thing you need to do is throw out all the food in your pantry and fridge that is too high in fructose. Chocolate of any description must be sent to a happier hunting ground. The same goes for anything you picked up in the confectionery aisle at the supermarket. Sweet biscuits are slightly less bad than confectionery. To make your cupboards truly fructose-free, all the sweet biscuits should go in the bin. The only drinks you should have in your cupboard or fridge are unflavoured water and unflavoured milk. If you prefer your water with bubbles, then by all means have unflavoured mineral water or soda water. Alcoholic drinks are okay for the recovering sugarholic as long as they don't taste sweet and they are not mixed with other drinks that contain sugar. You can keep the dry wines, beers and spirits, but you need to toss out the dessert wines, ports, sweet sherries, liqueurs and mixers (unless they are diet mixers). If you see honey or sultanas in the name of a cereal, it's usually a good idea to check the sugar content carefully. Don't be fooled by the branding of new ranges of flavoured oat cereals, either. Unlike their unflavoured cousins, they are usually extremely high in sugar.

Withdraw
Walt Disney once said, "The way to get started is to quit talking and begin doing." And that is the point at which we have arrived on our mission to break your sugar addiction. There's nothing fun about the withdrawal period, but it does end. And once it does, you'll be completely free from the desire to eat sugar ever again. A plate of bikkies will hold all the attraction of a plate of raw broccoli. If you are going cold turkey, have one last supper of your favourite sugary treat. Get that Mars Bar or that can of Coke. Sit down and consciously enjoy the very last time in your life that you will eat (or drink) sugar. If you can just get past the next few weeks of danger, you will enjoy the health that sugar has sucked from your life to date. Then, all of a sudden, your desire for sugar will vanish. I know it sounds strange, but it just plain goes. Bang! And you will never want the stuff again.

Restock

Once you start the withdrawal, you'll need to re-stock your now-bare cupboard.

Fruit	Whole fruits do contain fructose (the addictive and harmful half of sugar) - in some cases, very large amounts. But they also contain a fairly large amount of fibre and water.
Vegetables	There is no such thing as a bad vegetable. All vegetables contain some level of fructose, but it is an insignificant amount and is vastly overwhelmed by the fibre content.
Nuts	Like vegetables, there's no such thing as a bad nut. Some have more fructose than others, but even the worst of them, from a fructose perspective, have huge amounts of fibre.
Meat	Meat does not contain any sugar, so knock yourself out. The only possible word of caution is around some of the fancy marinated meats. The marinade is usually very high in sugar and this type of product should generally be avoided.
Eggs, Yoghurt, Milk and Cream	Only choose the tartest of European and natural yoghurts and avoid flavoured milk or whipped cream that you buy in a can.
Cheese	Cheese will have sugar on the ingredients list, but it is all lactose, so there's no need for concern.
Bread	All breads contain some sugar. All of the standard unflavoured white breads lie somewhere between 0.5 and four per cent sugar (two per cent fructose). Multigrain and brown (wholemeal and rye) breads are low-sugar and have approximately twice as much fibre.

Quitting Gambling

Quitting gambling, especially for someone struggling with a gambling addiction, is a significant challenge that often requires professional help and a multi-faceted approach. It's a behavioral addiction, and recovery is a process that involves addressing underlying issues, changing habits, and building a strong support system.

1. Acknowledge and Talk About the Problem
The first crucial step is to admit there's a problem. Gambling addiction often thrives in secrecy. Talking openly and honestly about your gambling with a trusted friend, family member, or professional counsellor can ease the burden, reduce shame, and be the catalyst for seeking help.

2. Seek Professional Help
- Counselling and Therapy: This is often the most effective treatment.
  - Cognitive Behavioural Therapy (CBT): Helps individuals identify and challenge unhealthy thoughts and beliefs related to gambling and develop coping mechanisms.
  - Motivational Interviewing: Helps to build and strengthen motivation for change.
  - Group Therapy: Provides a supportive environment where individuals can share experiences and strategies with peers facing similar challenges.
  - Family Therapy: Addresses the impact of gambling on family relationships and helps create a more supportive home environment.
- Medication: While there are no FDA-approved medications specifically for gambling disorder, some medications (like antidepressants or mood stabilizers) may be prescribed to treat co-occurring conditions such as depression, anxiety, or bipolar disorder, which can often fuel gambling behavior.

MEDICAL Quitting Addictions Quitting Gambling

3. Implement Financial Safeguards
● Block Gambling Transactions: Contact your bank to see if they offer features to block gambling payments or transactions to gambling sites/venues.
● Give Control of Finances: Have a trusted person (e.g., family member) manage your money, pay bills, and control access to funds. This can include giving them control of credit cards and bank accounts.
● Self-Exclusion: Legally ban yourself from gambling venues (casinos, clubs, pubs, TABs) or online gambling websites. Australian gambling providers are legally required to offer this option.
● Carry Limited Cash: Avoid carrying large amounts of money that could be used for gambling.
● Seek Financial Counselling: Address any debt or financial difficulties caused by gambling.

4. Identify Triggers and Avoid High-Risk Situations
● Journaling: Keep a journal to track when, where, and why you feel the urge to gamble. Note your thoughts, feelings, and the situations that precede gambling sessions.
● Avoid Venues/People: Steer clear of places (casinos, clubs, betting shops) and people associated with your gambling. If a certain route takes you past a gambling venue, find an alternative.
● Manage Emotions: Recognize if stress, anxiety, boredom, loneliness, or depression trigger your gambling. Develop healthy coping mechanisms for these emotions (e.g., exercise, mindfulness, hobbies, talking to someone).

5. Find Healthy Alternatives and New Hobbies
● Fill the Void: Gambling often fills a significant portion of a person's time and provides a certain "rush." Find new, healthy activities, hobbies, or social engagements to replace gambling. This could include sports, arts, volunteering, learning a new skill, or spending time with loved ones.
● Set Goals: Set short-term and long-term personal goals that are unrelated to gambling to maintain focus and motivation.

MEDICAL Quitting Addictions Quitting Gambling

6. Build a Strong Support Network
● Support Groups: Join peer support groups like Gamblers Anonymous (GA), which follows a 12-step program similar to Alcoholics Anonymous. SMART Recovery meetings are another option. These groups provide a sense of community and accountability.
● Lean on Trusted Individuals: Continue to communicate openly with your trusted friends and family members. Their support is vital for recovery.

7. Prepare for Lapses (Relapses)
● Understand Relapse is Part of Recovery: A lapse (or relapse) is when you gamble again after deciding to stop. It doesn't mean you've failed completely, but rather that you need to re-evaluate your strategies.
● Learn from Lapses: Use any lapse as an opportunity to understand what triggered it and what strategies worked or didn't work. Reach out to your support person or counsellor immediately.
● Don't Give Up: Recovery is a marathon, not a sprint. Be fair to yourself and persist with your efforts.

MEDICAL

6 Preparing to Die

MEDICAL Preparing to Die

One day you will die, that's obvious enough but for some people this may occur before you expect it. If you know you're going to die or there's a very high chance of it happening soon then consider yourself lucky that you know the approximate time and can prepare for it. The section below will discuss what you should get in order before your passing, your wishes for the future and who will inherit your possessions. This section assumes that SHTF is in progress so a lot of the law and will sections have been excluded.

Questions

Questions

● Think about where/how you would like to die; in what surroundings; with what things (music? videos?); with which people present?
● Is my will up to date?
● Have I discussed my condition with my family/friends in complete honesty?
● Who will make medical decisions when you can no longer make them?
● What are my beliefs about death?
● Do I need to make peace with myself or a Higher Power?
● Do I need psychological, emotional, spiritual care, counselling or support?
● Have I left a legacy? Identify life lessons, advice, hopes and dreams that you would like to pass on to family and friends. Write or record these. Identify a person who can pass these along to the people to those whom you wish to
receive your legacy.
● Have I written my personal history? You can write it down, or record on audio or video tape, etc. Who is to get my personal history?
● Do I have anything amiss with my family/friends to fix? Can I fix them now?

MEDICAL Preparing to Die Questions

● Do I have letters to write? Calls to make? Make a list of all old grudges, enemies, etc., and attempt to settle those affairs. You may use the "6 things" as a guide.
● Have I created my "bucket list"? What am I able to accomplish with the time I have left? Use this list to help create your "goals of medical care. "
● Do I want to be buried, embalmed, cremated or something else?
● Do you have a plan for someone to take over your position, such as an apprentice?
● Who do I give my personal belongings to? If you are married, most likely all of your belongings will transfer to your spouse or family. If you are single, then you must specify what you want done with these items.
● Who gets my special items, such as photos, mementos, etc.?
● If I am single and have kids, have I set up a guardian for my children for the immediate time after my death? Short-term money for them?
● What should I sell before my death? House? Car? Furniture? Land?
● Have I made arrangements for the care of my pets?
● What unfinished projects around the house, at work, or in the community would I like to complete?

MEDICAL Preparing to Die Questions

● If I have young children, have I left letters or videos to them?
● Are all my digital photos/videos in one place?
● Who do I want notified of my death?
● Do I want to write my own obituary?
● Do I have burial plot? If cremated, where should my ashes be scattered or interned?
● Do I want/need a headstone/grave marker? Have I written out what I want inscribed on it? Design?
● Do I want a Funeral service? Program?
● Do I have special needs for my ceremony? Military? Religious?
● Who will deliver the eulogy? Ask him or her in advance.
● Do I want a wake or memorial party instead of a funeral?

Thoughts

MEDICAL

Discussing / Thoughts	Do you need to discuss with someone about the uncertainty of death? Tell family, friends and enemies anything you have kept secret up until this point. Tell someone or write down all your online passwords to make disabling accounts easier. Have a look at the different religions in the "Religion" section and try praying if you've never done it before.	**Things to Say** "I'm sorry." "I forgive you." "Thank you." "I love you." "Goodbye."

Master File	• Will • Letter of Instruction • Birth Certificates • Marriage Certificates • Citizenship Papers • Financial Assets	• Medicare Numbers • Adoption Papers • Passports • Driver Licences • Military Records • Real Estate	• Other Assets • Liabilities • Trust Documents • Buried/Hidden Assets • Income Sources • Divorce/Separation Papers	• Social worker or caseworker names/info • Passwords, websites and other digital information	• Names/phone numbers of healthcare professionals • Healthcare proxies/living wills • Medications (dosages, name of prescribing doctors, pharmacy) • Address and phone numbers of hospitals of choice

Bucket List

A bucket list is a list of things you want to do, see or experience before you die. The list below has been specially chosen to be able to be completed in a SHTF scenario. As always don't do one if it makes you uncomfortable or it risks your life. Every activity is outdoors based and can be done for free in the right circumstances.

Questions to ask yourself to gauge what sorts of activities you can do. Honestly estimate how long you may have to live. Many years, a few months, weeks? How strong are you? How good is your health? What are your financial resources?

• Make a Personalised Bucket List • Explore a Cave • Dog Sled • Go Bamboo Rafting • Go Skinny Dipping	• Walk a Suspension Bridge • Climb to the top of a Tree • Herd Cattle • Hold a Monkey • Milk a Cow
• Climb a Volcano • Rappel Down a Waterfall • Sail a Boat • Whale Watching • Snowboard	• Walk on Hot Coals • Stand Under a Waterfall • Make a Snowman • Swim in the Ocean • Ride in a Horse & Carriage
• Read the Bible • Roll in a Huge Pile of Leaves • Watch the Sunrise & Sunset in One Day • Kiss in the Rain • Relax in a Natural Hot Spring	• Sleep in a Yurt • Hug a Tree • Horseback Ride on the Beach • Make a Candle • Create a Piece of Art & Sell it
• Find the Meaning of Your Name • Write a Love Letter • Learn Another Language • Start Fire Without Lighters or Matches • Learn to Play a Song on an Instrument	• Go Ice Fishing • Do 24-Hours of Silence • Learn to Juggle • Share Your Most Embarrassing Moment • Go Kayaking
• Drink only Water for a Week • Plant a Tree • Be Grateful for 10 Things Today • Climb a Rock Wall • Shuck Oysters	• Rescue an Animal • Learn the Heimlich Manoeuvre • Feed a Homeless Person • Teach a Class • Spend the Entire Day By Myself
• Have a White Christmas • Go Canoeing • Send a Message in a Bottle • Toss Pizza Dough in the Air • Eat Cactus	• New Years Eve Kiss • Clean Up Litter • Write a Poem • Find a Pearl in an Oyster • Hit the Archery Bulls-Eye
• Sleep in a Treehouse • Throw a Dart at a Map and Just Go • Watch a Meteor Shower • Learn How to Shoot a Gun • Camp in a Storm	• Break a Bad Habit • Give a Stranger a Meal • Dance in the Rain • Sing a Campfire Song • Survive a Campout in Heavy Snow
• Learn Archery • Tell Stories by the Fire • Spear a Fish • Craft a Piece of Furniture • Navigate Using a Map and Compass	• Stealth Camp Overnight • Put a Flag at the Top of a Mountain • Sleep in a Hammock • Build your own Stick Shelter and Sleep in it • Complete a Thru-Hike
• Extract Honey from a Bee Hive • Sleep under the Stars • Play in Mud • Have a Meaningful Conversation With a Stranger • Act in a Play	• Surprise Someone • Rappel into a Cave • Witness a Solar Eclipse • Sleep in an Igloo • Make a Handmade Gift
• Cook Christmas Dinner • Make a Handmade Greeting Card • Create your Own Recipe • Make an Origami Animal • Make Paper	• Sew Something you can Wear • Be a Street Performer • Take a Mud Bath • Pray to God • Bake a Cake for Someone Special
• Make Soap • Watch a Caterpillar Turn into a Butterfly • Jump Into Water Fully Clothed • Explore a Rainforest • Eat Crickets	• Achieve your Ideal Weight • Trap and Eat an Animal • Swim in a Crystal Clear Lake/Ocean • Eat an Insect • Create an Ice Sculpture

MED	Pre	Buc			
				● Sleep in a Teepee (while reading TPE) ● Bake a Loaf of Bread ● Hunt for Wild Mushrooms ● Ride a Camel ● Go Fly-fishing	● Catch, Cook & Eat a Fish ● Eat Breakfast in Bed ● Watch an Entire Storm ● Learn to Use Chopsticks ● Make Cheese

Medication

Medications and the dosage required for treating illnesses

"We might die from medication but we sure killed all the pain."
Conor Oberst

Introduction

Modern cupboards are often packed full of medication in today's world, especially the sick and elderly. During scavenging you are likely to find a fair amount of it which may be of use to you down the track if only you knew what it was and how to use it. This section contains a description of the medication, it's use, shelf life, dosages and warnings. This section has been reduced in scope and entirely rewitten in version 11 due to the sheer size of the incompleted previous version.

Purpose	The aim of MEDICATION is to provide accurate, up-to-date information of the most common drugs and medications used today. It includes dosage recommendations based on illness type and also includes information on how the medication is supplied, the warnings involved with overdosing and how it affects the body.
Lost?	***** **QUICK TRIAGE (If you're injured or sick and looking for the correct section)** ***** ● **Sections under ILLNESS:** Radiation Sickness, Parasitic Infections, Bacterial Infections, Viral Infections, Fungal Infections, Altitude Sickness, Poisoning, Chemical Agents, Biological Agents. ● **Sections under INJURY:** Surface Wound & Bruises, Internal Injuries (Back Pain, Cerebral Hemorrhage, Bone Fractures, Dislocation, Concussion) Open Wounds, Avulsion, Burns, Environmental (Anaphylaxis, Heat Stroke, Hypothermia, Hyperthermia, Motion Sickness, Aero-otitis Media), Atmosphere (Asphyxiation, Drowning, Choking, Hypoxia, Carbon Monoxide Poisoning), Animal & Plant (Bites and Stings), Childbirth, Toothaches. ● **Sections under EMOTIONAL:** Depression, Anxiety, Stress, Confidence, Relaxation, Memory & Dementia, Grief & Loss, Postnatal Depression, New Parents, Body Image, Family & Friends and Healthy Living.

● For medications and recommended doses, see the MEDICATION section.
● For curing ailments naturally and herbal remedies, see the NATURAL REMEDIES section.
● For eating disorders, see the HEALTH > Nutrients section.
● For medication lists for your BOB, see the GEAR > Gear Descriptions > Medication section.
● For recommended medications for a home clinic over the long term, see the GEAR > Household Gear > Home Clinic > Medications section.

Contents

MEDICATION Introduction Contents

1 Medication Info

This section describes how to properly store medications.

Antibiotics

An antibiotic is a type of antimicrobial substance active against bacteria and is the most important type of antibacterial agent for fighting bacterial infections. Antibiotic medications are widely used in the treatment and prevention of such infections. They may either kill or inhibit the growth of bacteria. A limited number of antibiotics also possess antiprotozoal activity. Antibiotics are not effective against viruses such as the common cold or influenza; drugs which inhibit viruses are termed antiviral drugs or antivirals rather than antibiotics.

Antibiotic Classes

These are the different types of antibiotic classes and what they typically treat.

Name	Treats	Types	Side Effects
Penicillins Inhibits formation of bacterial cell wall	Skin infections, dental infections, ear infections, respiratory tract infections, urinary tract infections and gonorrhoea.	Natural Penicillin, Penicillinase-resistant (methicillin, oxacillin), Aminopenicillins (ampicillin, amoxicillin), Extended-spectrum (mezlocillin, piperacillin, ticarcillin)	Very safe with minimum toxicity, common side effects: Diarrhea, Nausea, vomiting, upset stomach. Rare cases: skin rashes, fever, angioedema, anaphylactic shock.
Cephalosporins Inhibits formation of bacterial cell wall	Pneumonia, strep throat, staph infections, tonsillitis, bronchitis, otitis media, various skin infections, gonorrhea, urinary tract, Cephalexin - bone infections.	**Four Generations:** **1st** - cephalothin, cefazolin, cephapirin, cephradine, cephalexin, cefadroxil. **2nd** - cefaclor, cefamandole, cefonicid, cefuroxime. **3rd** - cefditoren, cefixime, cefodizime, cefoperazone, cefotaxime, cefpodoxime, ceftibuten, ceftriaxone. **4th** - cefclidine, cefepime, cefpirome.	Very safe, causes few side effects. Diarrhoea, nausea, stomach cramps. Shouldn't be used in people with an allergic reaction to penicillins or cephalasporins.
Fluoroquinolones Synthetic and not derived from bacteria. Older - quinolones, newer - fluoroquinolones. Older gen isn't well absorbed and treat urinary tract. Newer generations are broad spectrum and have excellent oral absorption.	Urinary tract, skin infections, respiratory infections (sinusitis, pneumonia, bronchitis), pulmonary infections in cystic fibrosis.	Clinafloxacin, ciprofloxacin, gatifloxacin, levofloxacin, lomefloxacin, ofloxacin, sparfloxacin, trovafloxacin.	Well tolerated and accectable safety level. **Common Side Effects:** Nausea, vomiting, diarrhea, abdominal pain. **Less Common:** Central Nervous System disruptions (headache, confusion, dizziness, tremor), phototoxicity, tendinopathy, tendon rupture, convulsions.
Tetracyclines Bacteriostatic. Effective against microorganisms including spirochetes, atypical bacteria, rickettsia, amebic parasites.	Respiratory tract, cholera, rocky mountain spotted fever, lyme, typhus, prophylaxis of traveler's diarrhea, malaria prophylaxis. Most commonly: acne vulgaris, rosacea.	Doxycycline, minocycline, oxytetracycline, tetracycline.	Stomach cramps, diarrhea, nausea, vomiting, esophageal ulceration, sore mouth or tongue. Can cause increased sunburn risk. Rarely: Severe headaches, vision problems, both signs of secondary intercranial hypertension. Should not be used in children under 8 and may cause yellow teeth.
Macrolides Targets bacterial ribosomes and prevent protein production. Mainly bacteriostatic.	Erythromycin has a similar use to penicillin, azithromycin and clarithyromycin are useful for their excellent lung penetration. Macrolides are used to treat respiratory tract infections (pharyngitis, sinusitis, bronchitis), genital, gastrointestinal tract, skin infections.	Azithromycin, clarithromycin, dirithromycin, erythromycin, roxithromycin, troleandomycin.	Tolerated well, Commonly: nausea, vomiting, abdominal discomfort, diarrhea. Rarely: reversible deafness and allergic reactions (angioedema, anaphylaxis, dermatologic reactions) Used with caution with liver dysfunction.
Aminoglycosides Stops the bacteria making proteins.	Treats gram-negative bacteria. May be used in combination with penicillins or cephalosporins to ensure better coverage. Work well but bacteria can become resistant to them. Can only be injected.	Amikacin, gentamicin, kanamycin, neomycin, streptomycin, tobramycin.	Side Effects: Toxicity causes irreversible damage to the ear and hearing. aminoglycoside may damage kidney.

Shelf Life

The shelf life of medication is a critical aspect of pharmaceutical quality control and patient safety. It refers to the period during which a drug product is expected to remain within its approved specifications of strength, quality, and purity when stored under specified conditions.

Shelf Life
This is the length of time a drug product can be stored, under defined conditions, before its quality attributes (like potency, purity, physical appearance, and dissolution) fall outside the established acceptance criteria. It's determined through rigorous scientific testing.

Expiration Date (EXP Date)
This is the final day that the manufacturer guarantees the full potency and safety of a medication. It's the date beyond which the product should not be used, as its stability is no longer guaranteed by the manufacturer. For most over-the-counter (OTC) and prescription drugs in Australia, the expiration date is a legal requirement. If only a month and year are given (e.g., June 2025), it means the end of that given month.

Shelf Life Factors
- Temperature: Higher temperatures generally increase the rate of chemical reactions, leading to faster degradation. Freezing can also damage some liquid formulations.
- Moisture/Humidity: Water can cause hydrolysis, physical changes (softening, caking), and promote microbial growth.
- Light: UV and visible light can cause photodegradation, leading to loss of potency or formation of toxic byproducts.
- Oxygen: Exposure to oxygen in the air can lead to oxidation, degrading the active ingredients.
- pH: For liquid formulations, changes in pH can significantly affect stability.
- Dosage Form: **Solid forms (tablets, capsules):** Generally more stable due to lower moisture content and less chemical reactivity. **Liquid forms (solutions, suspensions, injections):** More prone to degradation due to the presence of water, which can facilitate hydrolysis and microbial growth. **Creams, ointments, gels:** Can be sensitive to oxidation, microbial growth, and physical separation.
- Container and Closure System: The material and integrity of the packaging play a crucial role in protecting the drug from environmental factors.
- Active Pharmaceutical Ingredient (API) Properties: The inherent chemical stability of the drug molecule itself is a primary determinant.
- Excipients and Interactions: Inactive ingredients can sometimes interact with the API or contribute to instability.

Shelf Life Extension Program (SLEP)

The Shelf Life Extension Program (SLEP) is a joint initiative primarily between the U.S. Department of Defense (DoD) and the U.S. Food and Drug Administration (FDA), established in 1986. Its main purpose is to determine if the actual shelf life of certain federally stockpiled medications and medical supplies extends beyond their manufacturer-assigned expiration dates, thereby deferring replacement costs and ensuring readiness for emergencies.

Here are the key findings and implications of SLEP:

Vast Majority of Drugs Retain Potency Beyond Expiration
One of the most significant findings is that a substantial percentage of tested drugs remain potent and safe for years, and sometimes decades, beyond their labeled expiration dates, provided they are stored under optimal conditions (controlled temperature, humidity, and light).
Studies have shown that approximately 88% of tested drug lots were extended at least one year beyond their original expiration date, with an average extension of about 66 months (5.5 years). Some specific medications have shown demonstrable stability for 4-5 years, or even up to 15 years, after their original expiry.
A notable study from 2012 even found that 86% of 14 tested drugs (multiple batches) that were 28-40 years past expiration still retained at least 90% of their labeled potency, which is generally considered within the FDA's acceptable range.

Significant Cost Savings
The program has resulted in substantial cost savings for the DoD and other participating federal agencies by reducing the need to frequently replace expensive stockpiled medications. In 2023, the DoD reported saving $1.3 billion.

Lot-to-Lot Variability
While many drugs can be extended, the actual stability beyond expiration can show considerable lot-to-lot variability. This means that periodic testing and systematic evaluation of each specific lot are required to guarantee the adequacy of the medications. A blanket extension for a drug product is generally not issued; rather, extensions are granted on a lot-by-lot basis after rigorous testing.

Optimal Storage Conditions are Crucial
The success of shelf life extension is heavily dependent on the medications being stored under controlled and optimal environmental conditions (e.g., proper temperature, protection from light and moisture). This is why SLEP is primarily applied to stockpiles housed in environmentally controlled facilities.

Not Applicable to All Drugs (or Home Use)
- Certain types of medications are generally less stable and may not be good candidates for shelf life extension. These often include:
- Liquid formulations (solutions, suspensions)
- Certain biological products (e.g., some vaccines, insulins)
- Nitroglycerin (a highly unstable medication)
- Some antibiotics (especially once reconstituted)
- Crucially, SLEP data is generally not applicable to medications stored in homes or by the general public. This is because home storage conditions are highly variable and often not controlled, meaning there's no guarantee that the drug has maintained its stability or potency.

Impact on Expiration Dating Philosophy
SLEP findings have fueled a broader discussion about how expiration dates are determined by pharmaceutical manufacturers. The program strongly suggests that for many drugs, the manufacturer's initial expiration date (typically 2-5 years) is often conservative, based on limited initial stability data, and primarily serves commercial interests and liability concerns rather than the drug's true chemical degradation point.

In essence, SLEP has provided invaluable, real-world data demonstrating that many medications, when stored properly, remain safe and effective for significantly longer than their labeled expiration dates. It highlights the often-conservative nature of drug expiration dates and has enabled the DoD to maintain critical medical stockpiles more efficiently and cost-effectively. However, it also underscores the importance of proper storage and the need for rigorous, lot-specific testing for any actual shelf life extension.

Dangerous Meds Post-Expiry

This is a list of medications which are toxic to ingest soon after expiry, or those which lose their potency quickly.

Loss of Potency Risk

Insulin
Used to control blood sugar in diabetes. Expired or improperly stored insulin can rapidly lose potency, leading to uncontrolled high blood sugar (hyperglycemia) and potentially serious complications like diabetic ketoacidosis.

Epinephrine Auto-injectors (e.g., EpiPen, Anapen)
Used for severe allergic reactions (anaphylaxis). Epinephrine degrades relatively quickly. Using an expired auto-injector may mean receiving an insufficient dose of a life-saving drug during an emergency, which could be fatal. While some potency may remain, replacement is strongly advised.

Nitroglycerin (GTN) for Angina/Chest Pain
This medication is very unstable and prone to degradation, especially once the bottle is opened and exposed to air and moisture. Expired GTN may not effectively alleviate chest pain during a heart attack, leading to critical delays in care.

Anticoagulants and Antiplatelets (Blood Thinners)
These drugs (e.g., warfarin, dabigatran, clopidogrel) require precise dosing to prevent blood clots without causing excessive bleeding. Diminished potency could lead to serious events like strokes or deep vein thromboses.

Seizure Medications (Anticonvulsants)
Consistent and adequate dosing is vital to prevent seizures. Reduced potency from expired medication could lead to breakthrough seizures.

Thyroid Medications (e.g., Levothyroxine)
Used to treat hypothyroidism. Precise dosing is crucial for maintaining proper thyroid hormone levels. Sub-potent medication can lead to under-treatment.

Certain Heart Medications (e.g., Antiarrhythmics, some Blood Pressure Meds)
For conditions where precise control is essential, using an expired drug could lead to a worsening of the underlying condition or dangerous cardiac events.

Toxicity Risk

Tetracycline Antibiotics
The older formulation of tetracycline (the parent drug) that was famously associated with Fanconi syndrome (a type of kidney damage) when degraded. While doxycycline is a tetracycline, the specific breakdown products linked to Fanconi syndrome are more associated with tetracycline itself, not generally doxycycline. The risk of toxicity from degraded tetracyclines is rare with modern formulations and storage, but it was a historical concern that contributed to the general caution around expired medications. The primary risk with expired antibiotics, including doxycycline, is often loss of potency, which can lead to:
● Ineffective treatment: The infection isn't fully cleared, allowing it to persist or worsen.
● Antibiotic Resistance: Sub-therapeutic doses can select for resistant bacteria, making future infections harder to treat.

Liquid Medications (especially once opened or reconstituted)
● Oral Liquid Antibiotics (e.g., Amoxicillin suspensions): Once reconstituted with water, these are highly susceptible to bacterial growth, even with preservatives. Their shelf life after mixing is typically very short (e.g., 7-14 days, usually refrigerated). Using them beyond this period risks ingesting contaminated medication.
● Eye Drops, Ear Drops, Nasal Sprays: These are often formulated to be sterile or contain preservatives to prevent microbial growth. Once opened, or if expired, the preservatives can degrade, making the solution vulnerable to bacterial or fungal contamination. Using contaminated drops in sensitive areas like the eyes or ears can lead to serious infections.
● Injectable Medications: Similar to oral liquids, injectables (especially multi-dose vials) can become contaminated or degrade if not used within their "beyond-use date" once punctured.

Other Considerations
● Compounded Medications: Medicines custom-prepared by a pharmacist often have much shorter expiry dates (sometimes just days or weeks) because they don't have the extensive stability testing of mass-produced drugs and may lack robust preservative systems.
● Biologics and Vaccines: These are often sensitive to temperature and time and can lose effectiveness quickly if their cold chain is broken or if they are used past expiry.

Storage

How your medications should be stored.

Temperature

Proper medication storage regarding temperature is crucial for maintaining the drug's effectiveness, stability, and safety. Exposure to temperatures outside the recommended range can degrade the active ingredients, alter the drug's chemical composition, or even make it toxic.

Controlled Room Temperature (CRT) or "Room Temperature"
Range: Generally, 15°C to 25°C (59°F to 77°F). Some manufacturers may specify slightly different ranges, sometimes allowing excursions up to 30°C (86°F) for short periods.
Examples: Many common medications, both prescription and over-the-counter, including most tablets, capsules, and some inhalers (e.g., Albuterol, Amoxicillin capsules, EpiPens).

Cool Temperature
Range: Generally, 8°C to 15°C (46°F to 59°F).
Examples: Some specific medications that need to be kept cooler than room temperature but not necessarily refrigerated. Always check the label.
Key Points: This range bridges the gap between refrigerated and controlled room temperature. Medications requiring "cool" storage are less common than those needing refrigeration or room temperature, but it's crucial to identify them to ensure proper storage.

Refrigerated Medications
Range: 2°C to 8°C (36°F to 46°F). This is often referred to as "cold chain" storage.
Examples: Many vaccines (e.g., influenza, MMR), insulins (before opening), certain antibiotics (especially suspensions after reconstitution), biological products (like monoclonal antibodies), and some eye or ear drops.

Frozen Medications
Range: Typically -20°C (-4°F) or colder.
Examples: Some vaccines (e.g., Varicella, Zoster), certain specialized biological samples, and RNA/DNA samples.
Key Points: These are less common for general home storage but are critical in healthcare settings and laboratories.

Moisture/Humidity

Beyond temperature, moisture (humidity) is a significant factor in medication storage that can drastically affect a drug's stability, potency, and safety. Many medications are sensitive to moisture and can degrade or become less effective when exposed to high humidity.

Why Moisture is a Problem for Medications
Hydrolysis: This is a chemical reaction where water molecules break down the active ingredients in a drug. Many common medications, especially those in solid forms like tablets and capsules, are susceptible to hydrolysis. Once degraded, the drug may lose its potency or even form harmful byproducts.

Physical Changes
● Softening or Sticking: Tablets and capsules can absorb moisture from the air, causing them to soften, swell, or stick together.
● Disintegration: Some medications, particularly effervescent or dispersible tablets, are designed to dissolve in water. Exposure to ambient moisture can cause them to start breaking down prematurely.
● Crystal Formation: In some liquid formulations, moisture can lead to unwanted crystal formation.
● Reduced Effectiveness: Degraded medications may not deliver the intended therapeutic effect, leading to ineffective treatment.
● Potential Toxicity: In rare cases, the breakdown products formed due to moisture exposure can be toxic. For example, aspirin exposed to moisture can break down into salicylic acid and acetic acid (vinegar), which can irritate the stomach.
● Compromised Test Strips: Items like blood glucose test strips are highly sensitive to moisture. Exposure to humidity can lead to inaccurate readings, which can have serious implications for managing conditions like diabetes.

Oxygen

Oxygen is a significant environmental factor that can lead to the degradation of many pharmaceutical products. This process is known as oxidation, and it can compromise a drug's efficacy, safety, and shelf life.

Why Oxygen is a Concern for Medications
● Oxidation Reactions: Oxygen (specifically molecular oxygen, O2, from the air) can react directly with the active pharmaceutical ingredient (API) or excipients (inactive ingredients) in a medication. This is a chemical process involving the loss of electrons from a molecule, which can lead to:
● Loss of Potency: The chemical structure of the API can be altered, rendering it less effective or completely ineffective.
● Formation of Toxic Byproducts: In some cases, the oxidation process can create new compounds that are harmful or toxic to the patient.
● Changes in Physical Appearance: Oxidation can cause discoloration, changes in odor, taste, or texture of the medication (e.g., a pill turning brown, a liquid becoming cloudy).
● Chain Reactions (Autoxidation): Oxidation can sometimes be a self-propagating chain reaction, meaning that once it starts, it can continue to degrade more of the drug even with limited oxygen exposure. This is why preventing initial exposure is crucial.
● Sensitivity Varies: Not all medications are equally susceptible to oxidation. Some classes of drugs, like certain vitamins (e.g., Vitamin C, Vitamin A), some antibiotics, biological products (like insulin or monoclonal antibodies), and drugs with specific chemical functional groups (e.g., phenols, aldehydes, unsaturated fats/oils), are highly prone to oxidation.

Pests

While temperature, moisture, and oxygen are crucial for the chemical stability of medications, pests are a major concern for the physical integrity, contamination, and overall safety of stored pharmaceutical products. This applies across the supply chain, from manufacturing and warehouses to pharmacies and even the home medicine cabinet.

Why Pests are a Problem for Medications
● Physical Damage to Packaging: Rodents (mice, rats), insects (like "drugstore beetles," "biscuit beetles," cockroaches, silverfish, ants), and even birds can chew through or damage medication packaging (boxes, bottles, blister packs, even some soft plastics or foils). This compromises the product's sterility, exposes it to light, moisture, and oxygen, and can lead to contamination.
● Contamination: Pests carry bacteria, viruses, fungi, and other pathogens on their bodies, in their droppings, or in their urine. If they come into contact with medications or their packaging, they can introduce these contaminants, making the medication unsafe for consumption.
● Direct Consumption/Spoilage: While less common for the drug itself, some pests, especially beetles, mites, and rodents, are known to feed on dried goods, including components in medications or even the medication itself if it's palatable.
● Nesting and Breeding: Storage areas can become nesting sites for pests, leading to rapid proliferation and a larger infestation problem.
● Reputation and Economic Loss: For pharmaceutical companies, pharmacies, and even individuals, a pest infestation can lead to significant financial losses due due to spoiled product, require costly remediation, and damage reputation.
● Public Health Risk: Contaminated medications pose a health risk to patients, potentially causing illness or reducing the effectiveness of treatment.

Light

Light, particularly ultraviolet (UV) and certain visible light wavelengths, can significantly degrade many medications through a process called photodegradation (or photolysis). This can lead to a loss of drug potency, altered efficacy, and even the formation of harmful byproducts.

Why Light is a Problem for Medications
● Photochemical Reactions: Light carries energy, and when absorbed by drug molecules, this energy can initiate chemical reactions.
● Oxidation: Light can catalyze oxidation reactions (as discussed previously), accelerating the breakdown of sensitive compounds.
● Isomerization: Light can cause molecules to change their spatial arrangement, potentially rendering them inactive or less effective.
● Polymerization: Light can cause drug molecules to link together, forming larger, often inactive or insoluble, complexes.
● Loss of Potency: The most common consequence of photodegradation is a reduction in the amount of active ingredient in the medication, leading to a diminished or complete loss of its therapeutic effect.
● Formation of Toxic Byproducts: In some cases, the degraded products formed due to light exposure can be toxic or cause adverse reactions.
● Changes in Physical Appearance: Visible signs of photodegradation can include:
● Discoloration: Pills or liquids changing color (e.g., turning yellow, brown, or pink).
● Cloudiness or Precipitation: Liquids becoming cloudy or forming visible particles.
● Changes in Consistency: Gels or creams becoming watery or separating.
● Catalysis: Light can act as a catalyst, speeding up other degradation processes that might occur more slowly in the dark.
● Wavelength Sensitivity: Different drugs are sensitive to different wavelengths of light. UV light (both UVA and UVB) is particularly damaging, but even visible light (especially blue light) can affect some medications.

Medication Suffixes

In pharmacology, medication suffixes are incredibly useful as they often indicate the drug class, its mechanism of action, or its therapeutic use. This helps healthcare professionals and even patients understand what a drug is likely for, even if they don't recognize the full name.

-afil	Phosphodiesterase-5 (PDE5) inhibitors. Used for erectile dysfunction and pulmonary hypertension. Examples: Sildenafil, Tadalafil, Vardenafil
-alol	Alpha and beta-blockers. Used for hypertension. Examples: Labetalol, Carvedilol
-ane	Inhaled anesthetics. Used to induce and maintain general anesthesia. Examples: Halothane, Isoflurane, Sevoflurane
-arin	Anticoagulants (blood thinners). Prevent blood clots. Examples: Heparin, Warfarin, Enoxaparin
-ase	Thrombolytics (clot busters). Break down existing blood clots. Examples: Alteplase, Streptokinase

-asone / -sone / -olone	Corticosteroids. Anti-inflammatory and immunosuppressive agents. Examples: Dexamethasone, Prednisone, Betamethasone, Prednisolone
-azepam / -zolam	Benzodiazepines. Used for anxiety, insomnia, seizures, and muscle spasms. Examples: Diazepam, Lorazepam, Alprazolam, Midazolam
-azosin	Alpha-1 blockers. Used for hypertension and benign prostatic hyperplasia (BPH). Examples: Terazosin, Doxazosin, Prazosin
-barbital	Barbiturates. Sedative-hypnotics, sometimes used for epilepsy. Examples: Phenobarbital, Secobarbital
-bicin	Antineoplastic (cytotoxic) agents / Chemotherapy. Used in cancer treatment. Examples: Doxorubicin, Idarubicin
-caine	Local anesthetics. Block nerve impulses to numb an area. Examples: Lidocaine, Bupivacaine, Procaine
-cillin	Penicillin antibiotics. Treat bacterial infections. Examples: Amoxicillin, Ampicillin, Penicillin
-coxib	COX-2 inhibitors (a type of NSAID). Anti-inflammatory drugs with fewer gastrointestinal side effects than traditional NSAIDs. Examples: Celecoxib
-cycline	Tetracycline antibiotics. Broad-spectrum antibiotics. Examples: Doxycycline, Tetracycline, Minocycline
-dipine	Dihydropyridine Calcium Channel Blockers. Used for hypertension and angina. Examples: Amlodipine, Nifedipine, Felodipine
-dronate	Bisphosphonates. Inhibit bone resorption, used for osteoporosis. Examples: Alendronate, Risedronate, Ibandronate
-fenac / -profen	NSAIDs (Nonsteroidal Anti-inflammatory Drugs). Reduce pain, inflammation, and fever. Examples: Diclofenac, Ibuprofen, Ketoprofen
-floxacin	Fluoroquinolone antibiotics. Broad-spectrum antibiotics. Examples: Ciprofloxacin, Levofloxacin, Moxifloxacin
-fungin	Echinocandin antifungals. Treat fungal infections. Examples: Caspofungin, Micafungin
-gliptin	DPP-4 inhibitors. Used to treat Type 2 diabetes. Examples: Sitagliptin, Saxagliptin
-glitazone	Thiazolidinediones. Used to treat Type 2 diabetes. Examples: Pioglitazone, Rosiglitazone
-ide	This suffix has multiple meanings depending on the class: * Loop Diuretics: Furosemide, Torsemide * Sulfonylureas (for diabetes): Glipizide, Glyburide
-ipramine / -triptyline	Tricyclic Antidepressants (TCAs). Examples: Imipramine, Amitriptyline, Nortriptyline
-mab	Monoclonal Antibodies. Biologic drugs targeting specific cellular components, used in various conditions (cancer, autoimmune diseases). Examples: Trastuzumab, Adalimumab, Rituximab
-lukast	Leukotriene Receptor Antagonists. Used for asthma and allergies. Examples: Montelukast, Zafirlukast
-mycin / -micin	Aminoglycoside antibiotics or Macrolide antibiotics. Aminoglycosides: Gentamicin, Tobramycin Macrolides: Azithromycin, Erythromycin, Clarithromycin
-navir	Protease Inhibitors. Antiviral drugs, primarily used for HIV. Examples: Ritonavir, Lopinavir, Atazanavir
-olol	Beta-blockers. Used for hypertension, angina, arrhythmias, and heart failure. Examples: Metoprolol, Atenolol, Propranolol
-oprazole	Proton Pump Inhibitors (PPIs). Reduce stomach acid, used for GERD, ulcers. Examples: Omeprazole, Lansoprazole, Pantoprazole
-parin	Anticoagulants (specifically low molecular weight heparins or heparinoids). Examples: Dalteparin, Enoxaparin
-phylline	Xanthine Derivatives. Bronchodilators for asthma and COPD. Examples: Theophylline, Aminophylline
-pram / -oxetine / -tine	SSRIs (Selective Serotonin Reuptake Inhibitors). Antidepressants. Examples: Escitalopram, Fluoxetine, Sertraline, Paroxetine
-prazin	Antipsychotics (Phenothiazines). Examples: Chlorpromazine, Fluphenazine
-pril	ACE Inhibitors (Angiotensin-Converting Enzyme Inhibitors). Used for hypertension, heart failure, and kidney protection. Examples: Lisinopril, Enalapril, Ramipril
-ridone / -apine	Atypical Antipsychotics. Treat schizophrenia and bipolar disorder. Examples: Risperidone, Olanzapine, Quetiapine
-sartan	ARBs (Angiotensin II Receptor Blockers). Used for hypertension and heart failure, alternative to ACE inhibitors. Examples: Losartan, Valsartan, Irbesartan
-statin	HMG-CoA Reductase Inhibitors (Statins). Lower cholesterol. Examples: Atorvastatin, Simvastatin, Rosuvastatin
-terol	Beta-agonists (Bronchodilators). Relax airways, used for asthma and COPD. Examples: Albuterol, Salmeterol, Formoterol
-thiazide	Thiazide Diuretics. Remove excess fluid, used for hypertension and edema. Examples: Hydrochlorothiazide, Chlorothiazide
-tidine	H2 Receptor Antagonists (H2 Blockers). Reduce stomach acid. Examples: Cimetidine, Famotidine, Ranitidine
-tinib	Tyrosine Kinase Inhibitors. Targeted cancer therapies. Examples: Imatinib, Erlotinib
-triptan	Serotonin Receptor Agonists (Triptans). Treat migraines. Examples: Sumatriptan, Zolmitriptan, Rizatriptan
-vir	Antiviral Drugs. Treat viral infections (e.g., HIV, herpes, influenza). Examples: Acyclovir, Ritonavir, Oseltamivir
-zodone	Antidepressants (specifically serotonin reuptake inhibitors/antagonists). Examples: Trazodone, Vilazodone

2 Common Drugs

A list of the most common drugs (both over the counter and prescription) and what they do. For a more comprehensive list, see the 'Medication List' section in this category.

Actiq	Actiq is the brand name for fentanyl citrate, which is a narcotic used for the treatment of pain. This particular narcotic is used primarily for cancer patients who experience pain that is not relieved by other types of medications.
Adderall	Adderall is a medication that is given to treat symptoms of attention deficit hyperactivity disorder. Adderall can be habit-forming and is usually given in conjunction with therapy or other treatment. It comes in tablet form and is taken by mouth.
Alcohol	Alcohol is an intoxicating substance made from the fermentation of sugar, starch, and yeast. Consumption of it depresses the central nervous system. Alcohol is quickly absorbed and affects the body's neurotransmitters, resulting in enhanced or depressed sensations and moods.
Alprazolam	Alprazolam is a medication used to treat anxiety and panic disorders. It can also be used to treat depression or pre-menstrual syndrome and may be habit-forming. This medication decreases levels of abnormal excitement in the brain.
Ambien	Ambien is a brand name of the drug zolpidem. It is commonly used as a short-term treatment for insomnia, and it can also be used to treat certain brain disorders. Ambien effectively initiates sleep, but does not effectively maintain sleep.
Amobarbital	Amobarbital is a barbiturate-derived medication used as an injection before anaesthesia prior to surgery, as short-term treatment for insomnia or anxiety relief. It has sedative and analgesic effects and if taken for extended periods of time, dependence can occur.
Amphetamine	Amphetamines are psychoactive drugs that stimulate the central nervous system. They increase the release of dopamine and norepinephrine in the brain while inhibiting reuptake. Amphetamines are prescribed for several conditions, but they are also abused illegally.
Amytal	Amytal is a strong sedative used to treat sleeping disorders like insomnia. It affects the nervous system by inducing drowsiness, eventually allowing the user to sleep. Because of its strength, it is prescribed only for short periods of time.
Anexsia	Anexsia is a brand name used for the combination of acetaminophen and hydrocodone. This narcotic drug is used for the relief of moderate to severe pain. Acetaminophen is used to increase the effectiveness of the hydrocodone.
Antabuse	Antabuse is a brand name of the drug disulfiram, which prevents the breakdown of dopamine. It is used to treat chronic alcoholism by causing sensitivity to alcohol. Antabuse is a possible treatment for cocaine dependence.
Ativan	Ativan is a brand name for lorazepam, which is a benzodiazepine used in the treatment of anxiety, epilepsy, IBS, and several other conditions. Low doses have sedative effects, whereas high doses can be hypnotic. It decreases activity in the brain for relaxation.
Avinza	Avinza is a morphine sulfate extended-release capsule administered once a day. It is used to relieve moderate to severe chronic, long-term, noncancerous pain in adults requiring around-the-clock pain relief. Avinza is used to treat osteoarthritis and lower-back pain.
Biocodone	Biocodone is a brand name medication that contains the narcotic opioid drug hydrocodone. It is most commonly prescribed to treat patients with moderate to severe pain. Side effects can include itching, nausea, drowsiness, and vomiting.
Buprenorphine	Buprenorphine is a drug that causes effects similar to methadone and heroin. When given at low doses, it can help individuals addicted to opioids avoid withdrawal symptoms. The drug is available as a tablet to be placed under the tongue.
Butalbital	Butalbital is a barbiturate, which reduces anxiety and promotes relation. It is combined with acetaminophen and sometimes caffeine, and it is prescribed to treat tension headaches or other serious headaches. Butalbital is not available by itself. It may cause dependency.
Butorphanol	Butorphanol is a drug most commonly used to manage pain. It is a common treatment for sufferers of migraine headaches. Studies have shown that women typically feel more pain relief from this drug than men.
Campral	Campral is a brand name for acamprosate, a medicine given to people who have formerly consumed alcohol to help them avoid drinking again. While it does not prevent withdrawal symptoms, it does help the brain function normally again.
Carisoprodol	Carisoprodol is a muscle relaxant commonly prescribed for muscle injuries such as strains or sprains. Taken as a pill by mouth, the main side effect may be an upset stomach and should be taken with food or milk.
Chlordiazepoxide	Chlordiazepoxide is used to treat the effects of alcohol withdrawal as well as the symptoms of irritable bowel syndrome. To be effective it must be taken regularly; however, it can be habit-forming. Chloridiazepoxide should not be taken for more than four months.
Clonazepam	Clonazepam is a medication used to help control seizures. It also can be prescribed to alleviate panic attacks. This drug works by decreasing electrical activity in the brain. It may take several weeks to see improvement of symptoms.
Clonidine	Clonidine is an antihypertensive used in the treatment of high blood pressure, ADHD, and dysmenorrhea, among other conditions. It relaxes blood vessels and decreases a person's heart rate. Clonidine is taken orally in tablet form and is often combined with other medications.
Cocaine	Cocaine is a stimulant drug and is very addictive. The three routes of administration for cocaine are snorting, injecting, and smoking. It stimulates the brain by releasing dopamine, which causes the user to feel pleasure.
Codeine	Codeine is a prescription pain reliever that is classified as an antitussive and opiate analgesic. This narcotic suppresses coughing, and it alters the body's perception of pain by mimicking natural endorphins. It is taken in pill or liquid form.
Concerta	Concerta is a branded version of methylphenidate. This medication is used to treat the symptoms of ADHD. It is sometimes used to treat narcolepsy. It is part of the central nervous stimulant drug family. It's available in chewable, pill, and liquid form.
Crack Cocaine	Crack cocaine is freebase cocaine. It produces an immediate high and is considered a highly addictive stimulant. Crack cocaine's effects include psychological effects like intense feelings of euphoria, increased energy, insomnia, paranoia, and more.
Crystal Meth	Crystal Meth is one of the street names for methamphetamine. It is a powerful stimulant that speeds up the central nervous system and the effects can last from 6-12 hours depending on the method of use.
Damason-P	Damason-P is a prescription pain reliever that contains a combination of aspirin and hydrocodone. The aspirin reduces fevers and inflammation while the hydrocodone alters the nervous system's response to pain. This drug is classified as a narcotic and can be habit-forming.
Darvocet	Darvocet is a combination of acetaminophen and propoxyphene. It is used to treat pain and to reduce fevers. In large doses it can be harmful or fatal. This drug was removed from the United States market in November 2010 by FDA request.

MEDICATION / Common Drugs	**Darvon**	Darvon is a pharmaceutical-grade pain reliever that contains propoxyphene, caffeine, and aspirin. The FDA withdrew approval of this opioid in 2010 due to the dangers of propoxyphene, as it can have negative effects on the heart.
	Demerol	Demerol is a brand name for meperidine, which is a pain reliever in the narcotics category. This medication is used for pain that is moderate to severe. It is similar to morphine, which can be extremely habit-forming.
	Depade	Depade is used as an addiction-recovery medication to help patients avoid taking drugs or drinking alcohol. This drug is an opiate antagonist, which means it works in the brain to prevent opiate effects and reduce the desire to take opiates.
	Desoxyn	Desoxyn is a brand name for methamphetamine hydrochloride. It is a stimulant drug that causes appetite suppression and is sometimes used to treat obesity in patients who have had unsuccessful outcomes with other treatments. Desoxyn is also used to treat ADHD.
	Dexedrine	Dexedrine is a brand name of the drug dextroamphetamine, which produces feelings of wakefulness, focus, decreased fatigue, and decreased appetite. It is commonly used to treat ADHD and narcolepsy, and it may be used to treat obesity and certain types of depression.
	Dextroamphetamine	Dextroamphetamine is used to increase alertness and focus, as well as to reduce appetite and fatigue. This drug makes up approximately 75 percent of the ADHD treatment Adderall. It also treats narcolepsy, treatment-resistant depression, and exogenous obesity.
Common Drugs	**Dextromethorphan (DXM)**	Dextromethorphan (DXM) is widely used in over-the-counter cough syrups. It works by affecting the part of the brain that controls coughing. DXM is part of the antitussive family of drugs. It can cause dizziness and stomach discomfort.
	Dextropropoxyphene	Dextropropoxyphene is a type of medication that is used to treat mild pain. This analgesic is in the opioid drug category, and is also used for its local anaesthetic and anti-tussive effects. It can be found under the brands Darvon and Darvocet.
	Dextrostat	Dextrostat is a brand name for dextroamphetamine, which is a stimulant used in the treatment of ADHD. It can increase blood pressure and depress the respiratory system while altering the brain's natural chemicals. This amphetamine has high potential for dependence and abuse.
	Di-Gesic	Di-Gesic is the trade name for the analgesic dextropropoxyphene. It is an opioid used to treat mild pain. The medication is no longer used in Europe and the United States because it was linked to arrhythmias and fatal overdoses.
MEDICATION / Common Drugs	**Diazepam**	Diazepam is used to treat muscle spasms, anxiety disorder, and seizures. It also prescribed to control agitation caused by the withdrawal of alcohol. Diazepam is taken by mouth in tablet, extended-release capsule or liquid concentrate form.
	Dicodid	Dicodid is a trade name for hydrocodone, an opioid that acts as both a narcotic analgesic and an antitussive. In addition to managing and relieving moderate to severe pain, Dicodid may also be used as a cough suppressant.
	Dilaudid	Dilaudid is a brand name for the narcotic pain reliever hydromorphone. It works in the brain by increasing tolerance to moderate or severe pain, so it is often used after surgery. Dilaudid is available in liquid or tablet form.
	Disulfiram	Disulfiram is a medication used to treat chronic alcoholism. It works by causing unpleasant side effects when alcohol is consumed, such as headache, vomiting, chest pain and anxiety. It comes in tablet form and is taken by mouth.
	Duodin	Duodin is also known as hydrocodone, which is a semi-synthetic opioid derived from codeine and thebaine. It is used to relieve pain and suppress coughs. It is administered orally in tablet, capsule or syrup form.
Common Drugs	**Duragesic**	Duragesic is an opiate analgesic applied as a skin patch. It is a brand of fentanyl patches, which are used to treat chronic and severe pain that does not lessen considerably with other narcotics. The medication can be habit forming.
	Duramorph	Duramorph is an injected form of morphine. It is a narcotic pain reliever typically given in a clinic or hospital to relieve severe pain. Some patients may be able to give themselves injections at home.
	Ecstasy and MDMA	Ecstasy is the street name for the drug MDMA. MDMA is a synthetic psychoactive drug that induces feelings of euphoria, increased energy, and emotional warmth in the user. It is taken orally as a capsule or tablet.
	Fentanyl	Fentanyl is a potent narcotic analgesic that is used to treat severe or breakthrough pain. It is approximately 50 times more potent than heroin. It is often used in operating rooms, in intensive care units, and for treatment of cancer pain.
	Fioricet	Fioricet is a combination of three active ingredients: caffeine, acetaminophen, and butalbital. This medication is taken orally and can be habit forming. It is usually used to treat migraine headaches. It can cause an upset stomach and should be taken with food.
MEDICATION / Common Drugs	**Fiorinal**	Fiorinal is a medication that contains aspirin, caffeine, and butalbital. Butalbital is a barbiturate. Fiorinal is most commonly used to treat tension headaches and is sometimes used to treat migraines. Butalbital is habit-forming and can lead to dependency.
	Flunitrazepam (Rohypnol)	Flunitrazepam is a potent hypnotic and sedative drug most commonly known as Rohypnol. It is used medically to treat severe insomnia on a short-term basis. Non-medically, it is commonly known as a date rape drug.
	GHB	GHB, which is short for gamma hydroxybutyrate, is a pharmacological substance that was approved to treat narcolepsy. The odourless powder or liquid is often used illegally for intoxication, as it affects the brain's GABA receptors and depresses the central nervous system.
	Halcion	Halcion is a brand name for triazolam, which is a benzodiazepine. This medication is generally used as a short-term treatment for insomnia. It acts as a sedative and hypnotic, and it has a calming effect on the mind and body.
	Hash	Hashish, often referred to as hash, is a product of the cannabis plant. Prepared from marijuana buds, hash is commonly burned and inhaled. The effects are often many times more potent than those of unprocessed marijuana buds.
	Heroin	Heroin is an addictive recreational drug known to induce feelings of intense relaxation and euphoria. It is an opioid derived from morphine, which is derived from the opium poppy. Heroin can be injected, smoked, snorted, or taken orally.
Common Drugs	**Hycodan**	Hycodan is a brand name version of hydrocodone bibartate that is mixed with homatropine methylbromide. This drug is an antitussive and analgesic that reduces coughing. Too much hycodan can cause breathing difficulties. This drug can be physically and mentally addictive.
	Hydrococet	Hydrococet is the brand name for the generic drug hydrocodone. Hydrococet is a narcotic pain reliever that is approximately two-thirds as powerful as oxycodone. Hydrococet is an addictive drug and is among one of the most abused drugs.
	Hydrocodone	Hydrocodone is only available as a component in other medications. It is an opiate analgesic that can control pain as well as minimize coughing. It is taken orally and is available in many forms, including as a tablet and syrup.

Hydromorphone	Hydromorphone is an opioid narcotic drug that is a derivative of morphine. It is medically used as an alternative to morphine to relieve chronic or severe pain. It is also commonly known as Palladone and Dilaudid.
Inhalant	An inhalant is a chemical vapour that is inhaled through the mouth or nose. It can be classified as volatile solvents, gases, aerosol sprays, and nitrites. The effects of inhalants range from an alcohol-like intoxication and intense euphoria to vivid hallucinations.
Kadian	Kadian is a brand name for the generic drug morphine sulfate. It is used to relieve moderate to severe pain. Kadian is classified as a narcotic pain reliever and an opioid. Kadian can be habit-forming.
Kapanol	Kapanol is made of morphine sulfate and is used to treat acute and chronic pain. It is a member of the opioid analgesic drug group. It is available in capsule form. Kapanol can cause drowsiness.
Ketamine	Originally developed as a general anaesthetic, Ketamine is a form of PCP. Ketamine causes its user to have a dissociative experience from his surroundings and himself. In controlled mediums, the drug is also used as an anaesthetic for humans and animals.
Klonopin	Klonopin, the brand name for clonazepam, is used to control certain types of seizures caused by epilepsy. It decreases abnormal electrical activity in the brain. Klonopin is also prescribed to treat panic attacks by relieving anxiety.
LSD	LSD is the abbreviation for lysergic acid diethylamide. LSD, or acid as it is usually called, is a drug that causes several psychological effects including hallucinations. It isn't addictive and is commonly taken orally, via things like sugar cubes or blotter paper.
Laudanum	Laudanum is an alcoholic narcotic mixture that generally contains 10 percent opium, or the equivalent of 1 percent morphine. Commonly available without a prescription until the early 20th century, its use is limited now to severe cases of pain and other conditions.
Levacetylmethadol (LAAM)	Levacetylmethadol (LAAM) is an opioid analgesic and used in the treatment of opioid addiction. It is administered in conjunction with counselling and other rehabilitative measures. Only treatment programs have approval to administer Levacetylmethadol in the U.S.
Librium	Librium is a brand name for chlordiazepoxide, which is used to treat the symptoms of alcohol withdrawal and IBS. It reduces anxiety and agitation by depressing the central nervous system. Librium is classified as a benzodiazepine and can be habit forming.
Lorazepam	Lorazepam is an antianxiety medication that works by slowing brain activity. Often marketed under the names Ativan and Temesta, lorazepam is also helpful in treating insomnia, epilepsy, and nausea caused by cancer treatments. This drug can be habit-forming.
Lorcet	Lorcet is a narcotic analgesic that is combined with acetaminophen, a non-narcotic pain reliever. Patients should avoid grapefruit or grapefruit juice while taking this medication as it can increase the amount of drug in the bloodstream.
Lortab	Lortab is a brand name of a pill that combines the drugs hydrocodone and acetaminophen. It is commonly given to patients to relieve moderate to severe pain. Common side effects include an upset stomach, nausea, and dizziness.
Luminal	Luminal is a brand name of the drug phenobarbital. This drug has sedative and hypnotic effects, but it is most commonly used as an anticonvulsant to treat patients who suffer from any type of seizures.
MS Contin	MS Contin is a version of morphine for oral use. It is available in liquid and tablet forms. This drug is used to control moderate to severe pain. It can be habit-forming. MS Contin should be taken with plenty of liquid.
MSIR	MSIR is the brand name for morphine sulfate immediate release. It is an opiate narcotic analgesic known as morphine. MSIR is a pain reliever often used by cancer patients to relieve long-term moderate to severe pain.
Marijuana	Marijuana, also called cannabis, is a psychoactive drug that is most often smoked. The chemical compound tetrahydrocannabinol, commonly referred to as THC, is the major psychoactive element of cannabis. Marijuana is controversially used to treat some common medical conditions.
Meperidine	Meperidine is a habit-forming narcotic pain reliever that is often compared to morphine. This medication is used to treat pain that is considered moderate to severe. It can also be found under the brand name, Demerol.
Mescaline	Mescaline is a naturally occurring psychedelic drug found in the peyote cactus. Mescaline visually distorts the user's vision. It does not cause hallucinations, and tolerance is built with continued use. Mescaline is illegal in the United States.
Methadone	Methadone is a narcotic analgesic that is prescribed to help patients with withdrawal symptoms from illegal drug use or to deal with severe pain. This medication can be habit-forming and may be prescribed in decreasing amounts to alleviate additional withdrawal.
Methadrine	Methadrine is another name for methamphetamine, an addictive stimulant. It causes brief increases in energy and feelings of euphoria, but it also leads to cognitive impairment and confusion. It has a high potential for abuse and addiction.
Methamphetamine	Methamphetamine is a stimulant that is highly addictive and has a high potential for widespread abuse. This drug affects the central nervous system and is also referred to as speed, ice, crank, meth and crystal.
Methaqualone	Methaqualone is the generic term for Quaaludes. It was initially marketed as a non-habit-forming substitute for barbiturates, but it has slightly different properties and ultimately had a high rate of abuse. This sedative-hypnotic drug can cause euphoric feelings and sleepiness.
Methylphenidate	Methylphenidate, also known under the brand name Ritalin, is a medication used to help control the symptoms of attention deficit hyperactivity disorder. It can be habit-forming and is often used in conjunction with therapy and counselling to obtain the best results.
Morphine	Morphine is an opiate analgesic classified as a narcotic. The drug is derived from opium and used to relieve severe pain. It impairs mental and physical functions, which can result in a euphoric feeling and decreased hunger, among other effects.
Mushrooms	Mushrooms, often called Magic Mushrooms, are a specific strain of fungi that contain the hallucinogens psilocybin. It causes a distortion of the senses, which can be pleasurable or terrifying, when the mushroom is consumed whole or brewed into tea.
Naltrexone	Naltrexone is an opioid receptor antagonist used in medication-assisted treatment of alcohol or drug dependency. Naltrexone is available in tablet form or in an extended-release injection format and acts by blocking the effects of opioids.
Nembutal	Nembutal is a brand name for pentobarbital sodium, which is a part of the group of barbiturate drugs. This medication is primarily used for the purpose of insomnia treatment for short-term relief. It can also be used as a sedative before surgery.

Norco	Norco is a pharmaceutical-grade pain reliever that contains hydrocodone and acetaminophen. This medication is classified as a narcotic and is used to treat moderate to severe pain. The acetaminophen boosts the effects of the hydrocodone, which is an opioid analgesic.
Opium	Opium is a street drug that is eaten, injected, or smoked. It is highly addictive and tolerance is quickly developed in the user. It has analgesic effects and severe withdrawal symptoms including nausea and chills.
Oramorph	Oramorph, most commonly known as morphine, is an opioid drug used to treat chronic or severe pain. Oramorph has the potential to be highly addictive and can cause physiological and physical dependence that can result in difficult withdrawal.
Orlaam	Orlaam is a narcotic analgesic that is prescribed as part of a treatment plan for recovery from illegal narcotic drugs. It helps prevent withdrawal symptoms. It is usually given in gradually decreasing doses until the patient is drug-free.
OxyContin	OxyContin, generically known as oxycodone, is a narcotic used for pain relief. It can be habit-forming. Side effects include fatigue, dizziness, and fainting. It is available as a liquid, tablet, extended-release tablet, and capsule. It can be taken with or without food.
Oxycodone	Oxycodone is a medication prescribed to reduce and control pain. It is a narcotic that can be addictive. An overdose of oxycodone can be fatal. Oxycodone is a class B drug, meaning that it may be safe for use during pregnancy.
PCP	PCP is the abbreviation for phencyclidine, an addictive drug with anaesthetic, sedative, and hallucinogenic effects. It is a white powder that can be dissolved in water or alcohol. PCP can be smoked, snorted, injected, or taken orally.
Palladone	Palladone, also called hydromorphone, is normally prescribed for pain relief and cough control. It is available in liquid, tablet, and suppository form. Palladone can be habit-forming. It can also cause an upset stomach; it should be taken with food.
Panacet	Panacet is a drug used as a pain medication and fever reducer. It contains hydrocodone, which is a narcotic pain reliever, and acetaminophen, which is a non-narcotic pain reliever and fever reducer. Panacet is most commonly swallowed in pill form.
Pentobarbital	Pentobarbital is a type of barbiturate that works by slowing the brain and nervous system activity. It is used to treat insomnia for short-term relief, and has been used for sedation before surgery and as a treatment for seizures in an emergency.
Percocet	Percocet is an analgesic that contains a combination of acetaminophen and oxycodon, used in the management and relief of moderate to severe pain. Percocet is typically used to deal with non-chronic pain. The drug is usually not used for breakthrough pain.
Percodan	Percodan is a mixture of aspirin and oxycodone. The aspirin reduces inflammation while the oxycodone serves as an opiate analgesic. This drug is used to relieve moderate to severe pain, and it can be habit forming.
Peyote	Peyote is a drug found in a small spineless cactus. After eating peyote, the user experiences dream-like hallucinations. The active ingredient in peyote is mescaline, and the effect varies from person to person. Indigenous Americans often used peyote for rituals.
Phenobarbital	Phenobarbital, also known as Luminal, is a barbiturate. It is commonly used as an anticonvulsant to treat patients with seizures. It can also be used to treat those experiencing acute withdrawal from benzodiazepines, which can cause tremors and seizures.
Quaalude	Quaalude is a sedative drug that was once prescribed for insomnia and as a muscle relaxant. It gained popularity in the 1960s and 1970s as a recreational drug and is currently a drug that cannot be prescribed by physicians.
ReVia	ReVia is classified as an opiate antagonist. Also known as naltrexone, this drug is used to help people avoid drinking and using drugs once they have stopped. It is available in tablet form and used in conjunction with counselling.
Ritalin	Ritalin is one of the trade names for the stimulant methylphenidate. It is commonly used for the treatment of attention deficit hyperactivity disorder and the sleep disorder narcolepsy. Ritalin is available in tablet, capsule, and liquid form.
Rohypnol	Rohypnol is used to treat patients in a pre-surgery situation and to treat insomnia. It can be used to reduce muscle tension, to induce sedation, to reduce anxiety, and to prevent convulsions. Rohyphnol causes partial amnesia.
Roxanol	Roxanol, also known as rectal morphine, is an opiate analgesic that is used to relieve moderate to severe pain. This medication comes in suppository form that must be inserted into the rectum. This drug can be habit-forming.
Roxicodone	Roxicodone is an opium-derived drug commonly used to treat patients that suffer from moderate to severe pain. This drug is commonly used in formulations with other drugs, such as acetaminophen or ibuprofen, to create brand name pharmaceuticals.
Ryzolt	Ryzolt is a brand name for tramadol, which is a prescription pain reliever. It is classified as an opiate agonist. Ryzolt is taken as a pill and mimics the effects of natural endorphins to change the body's perception of pain.
Secobarbital	Secobarbital is a barbiturate that slows the activity of your nervous system and your brain. Its main uses are as a pre-surgery sedative and as a short-term insomnia treatment to help you fall asleep and stay asleep.
Seconal	Seconal is a brand name for secobarbital, which is a prescription barbituate. It decreases activity in the brain and is used to control seizures, insomnia, and severe anxiety. This medication is taken orally as a pill.
Soma	Soma is the brand name for the drug carisoprodol, which is a muscle relaxant. It is used as treatment for acute back pain. Dependency and side effects of this drug are controversial and have caused concern in some countries.
Speed	Speed is a slang term for methamphetamine made from chemicals and over-the-counter ingredients. This synthetic drug stimulates the central nervous system, resulting in a short-lived euphoric feeling and an increased heart rate and breathing rate, among other effects.
Steroids	Steroids are a class of drugs used to stimulate certain functions in the body. Medicinally, steroids are prescribed to stimulate cell production or a patient's appetite. When combined with hormones, steroids can be used as a contraceptive.
Stilnox	Stilnox is a brand name for zolpidem, which is a drug that is used to treat insomnia for short-term relief. Additionally, it can also be used for the treatment of some brain disorders. This drug is an anticonvulsant and muscle relaxant.
Sublimaze	Sublimaze is a potent narcotic analgesic that comes in injection form. It is commonly used in or after an operative setting, such as during anaesthesia or in the recovery room. It should only be given by those trained specifically in its use.

Suboxone	Suboxone is an FDA-approved drug used to supplement additional detox treatments for pain killer addictions. It contains buprenorphine and naloxone. When used under the supervision of a physician, this medicine can help an individual overcome an opioid dependence.
Subutex	Subutex is a brand name version of buprenorphine that is used to treat an addiction to narcotics. This is an opioid and is considered addictive. It must be taken as directed to avoid the risk of serious injury or death. The effects of Subutex abuse are serious, so getting help for Subutex addiction is vital.
Symtan	Symtan is a combination medication used to treat symptoms of coughing associated with influenza or during a cold. It contains a decongestant and a narcotic cough suppressant. This medication is not recommended for patients under 6 years of age.
Temesta	Temesta is a brand name for lorazepam, which is a type of medication that is used to treat anxiety, acute seizures and insomnia. This benzodiazepine drug is a muscle relaxant, antiemetic, anticonvulsant, sedative, amnesic and anxiolytic.
Tramadol	Tramadol is a member of the opiate agonists drug family. Its primary use is pain relief, and it is administered in tablet form. Tramadol can be habit-forming. Tramadol dosage should be gradually decreased; abruptly stopping tramadol therapy can have unpleasant side effects.
Tramal	Tramal is a centrally acting analgesic. Tramal is typically used in the management of moderate to severe pain and is effective on pain of all types. The drug has a low risk of dependency and tends to provide relief quickly.
Triazolam	Triazolam is a drug that treats insomnia, so you are better able to fall asleep and stay asleep. It is a part of the benzodiazepines group, and works by affecting the unbalanced brain chemicals that cause the sleeping problems.
Tussionex	Tussionex is a prescription medication that contains a combination of hydrocodone and chlorpheniramine. The hydrocodone suppresses coughing while the other active ingredient serves as an antihistamine. It is used to relieve symptoms of colds and the flu.
Tylox	Tylox is a combination of acetaminophen and oxycodone. It is a narcotic that can become addictive. This drug is contraindicated for patients who are heavy drinkers or who suffer from liver disease. Tylox can cause drowsiness and dizziness.
Ultram	Ultram, also known as tramadol, is used as a pain reliever similar to narcotics. It can help ease moderate to severe pain and is often used to treat chronic pain. Ultram is available in tablet form.
Valium	Valium is in a class of drugs called benzodiazepines. It is used to treat anxiety, seizures and muscle spasms. It can be habit forming, so it should not be taken for an extended period of time.
Vicodin	Vicodin is a mixture of acetaminophen and hydrocodone. This pharmaceutical pain reliever is classified as a narcotic, as hydrocodone is an opioid analgesic. Vicodin depresses the central nervous system and impairs mental and physical functions.
Vicoprofen	Vicoprofen is the brand name of the combination drug that contains hydrocodone and ibuprofen. This narcotic and nonsteroidal anti-inflammatory drug combination is used for the treatment of severe pain as a short-term option for relief.
Vivitrol	Vivitrol is another name for a naltrexone injection. It is prescribed in conjunction with psychological counselling for patients recovering from drug or alcohol addiction. It reduces the urge to drink or use drugs. It cannot be taken together with drugs or alcohol.
Xanax	Xanax is the name brand of the generic drug alprazolam, which is a benzodiazepine. It is primarily used to prevent anxiety and panic attacks, as well as anxiety caused by depression in some patients, by altering the chemicals in the brain.
Xodol	Xodol is a combination of two pain relievers known as hydrocodone and acetaminophen. The presence of acetaminophen increases the effects of hydrocodone, which is classified as a narcotic pain reliever. Xodol is used to relieve moderate to severe pain.
Zolpidem	Zolpidem is a sedative-hypnotic medication used in the treatment of insomnia. It depresses the central nervous system and decreases activity in the brain to cause drowsiness. The drug is taken orally as a pill or spray.
Zydone	Zydone is an opiate that contains a mixture of Hydrocodone Bitartrate and acetaminophen. Zydone is commonly used in the management of pain ranging from moderate to moderately severe. The substance should always be used under the direction of a physician.

3 Making Drugs

This section is for making different types of drugs at home.

Making Penicillin

After SHTF, we may find ourselves in a similar situation that people faced before 1928 when penicillin wasn't freely available. It's important to note that making your own penicillin is possible but not easy. It's not something you should undertake unless you or a loved one is in a truly life-threatening survival situation and there are no other options. While it's true that growing penicillin requires basic items like bread and citrus fruit, you'll also need some equipment and chemicals that you wouldn't expect to find in your typical bug out bag or survival kit.

Warnings

- Contamination: You cannot guarantee that the mold you grow is Penicillium chrysogenum (the species that produces penicillin) and not a harmful mold. Even if it is, contamination with other bacteria or fungi is almost inevitable in a non-sterile home environment.
- Purity: Extracting and purifying penicillin from a mold culture is a complex biochemical process requiring specialized equipment, chemicals, and expertise. Homemade versions would be highly impure, potentially containing toxins from other molds, fermentation byproducts, or residual solvents.
- Potency/Dosage: You would have no way to measure the concentration or potency of the penicillin you produced. Administering an unknown and inconsistent dose is incredibly dangerous – too little could lead to antibiotic resistance and ineffective treatment, while too much could cause severe side effects or toxicity.
- Sterility: Injectable or even oral medications need to be sterile. Achieving and maintaining sterility at home is impossible, leading to a high risk of life-threatening infections if consumed.
- Allergic Reactions: Penicillin can cause severe allergic reactions (anaphylaxis) in some individuals. Without proper medical supervision and emergency care, this could be fatal.

Equipment Needed
- 1 x Citrus fruit or cantaloupe rind
- 2 x Pieces of whole wheat bread
- 1 x Gram scale
- 1 x 1 Liter glass container
- 1 x Separator funnel
- 1 x 750ml Erlenmeyer flask plus non-absorbent plug
- 1 x pH testing kit

Equipment Needed
The following chemicals (dissolved in water):
- Manganese Sulfate (0.044 gm)
- Lactose Monohydrate (44 gm)
- Corn Starch (25 gm)
- Magnesium Sulfate (0.25 gm)
- Sodium Nitrate (3 gm)
- Potassium Monophosphate (0.50 gm)
- Glucose Monohydrate (2.75 gm)
- Zinc Sulfate (0.044 gm)

On top of all that, you'll need to make sure that your culture is grown in a completely sterile environment. If the environment isn't sterile, you risk contamination which could cause bigger problems.

Procedure
1. First, set out the fruit or rind and let it mold naturally for a few days until it turns a bright bluish-green color.
2. Put the flask in an oven for an hour at 315 degrees F to sterilize it.
3. Cut the bread into small, ½-inch pieces and put them in the flask.
4. Scrape off the mold from step one and place it in with the bread.
5. Incubate the flask in a dark area for 5 days. The environment for the flask should be kept at around 70 degrees.
6. Now sterilize the 1-liter container and dissolve all the chemical ingredients in 500 ml of cold water. Once this is done, fill up the rest of the container with cold water.
7. Test the pH of the solution and use hydrochloric acid to get the pH level to 5.0.
8. Sterilize the entire solution similar to the flask in step 2.
9. Let the solution cool, then add in the mold from step 5. Allow this new solution to incubate for another 7 days.
10. Filter the mixture then adjust the pH of the solution to 2.2 with the hydrochloric acid.
11. Mix the solution with ethyl acetate and shake vigorously.
12. Let a beaker chill in an ice bath then drain the ethyl acetate into it. Combine with 1% potassium acetate and shake again.
13. Give the beaker air and let the ethyl acetate evaporate off.
14. If all the steps have been followed correctly, you'll have penicillin.

4 Drug Alternatives

These are alternative drugs that have a similar effect to the original but aren't prescription or restricted to purchase in most countries.

Animal Antibiotics

Animal Medication Equivalents
You might be able to use animal antibiotics for human consumption in an emergency depending on what type you need to cure the infection. The following is the animal equivalent antibiotic. Only use these as a last resort, and ensure you verify that it is the same product as the human version as much as possible.

Fish Antibiotics
- **Fish Cillin** - Ampicillin
- **Fish Zole** - Metronidazole
- **Fish Pen** - Penicillin
- **Fish Mox** - Amoxicillin
- **Fish Flox** - Ciprofloxacin
- **Fish Sulfa** - Sulfamethoxazole

Fish Antibiotics
- **Fish Flex** - Cephalexin
- **Fish Doxy** - Doxycycline
- **Fish Cin** - Clindamycin
- **Fish Fungus** - Ketoconazole
- **Fish Tapes** - Praziquantel
- **Fish Min** - Minocycline Hydrochloride

Bird Antibiotics
- **Bird Biotic** - Doxycycline
- **Bird Sulfa** - Sulfamethoxazole / Trimethoprim

Fish Antibiotics Labelling
This is the visual appearance and labeling of fish antibiotics so you can be sure what you're using is the correct drug.

- Fish Mox: 250mg - Labelled with 'WC 731'
- Fish Mox: 500mg - Green & White
- Fish Flox: 250mg - Labelled with 'CTI 222'
- Fish Flox: 500mg - Labelled with 'CR 500'

Natural Drug Alternatives

Head to the NATURAL MEDICATIONS section for a list of natural drug alternatives.

THE SECTIONS 5-17 BELOW CONTAIN LISTS OF MEDICATIONS BY THERAPEUTIC USE, CATEGORISED BY BODY SYSTEM. THESE SECTIONS ARE TO BE USED TO LOOK UP WHAT MEDICATIONS WORK FOR COMMON ILLNESSES.

5 Cardiovascular Meds

Cardiovascular system medications are a broad category of drugs specifically designed to treat conditions affecting the heart and blood vessels. These conditions can range from common issues like high blood pressure and high cholesterol to more severe problems such as heart failure, irregular heartbeats (arrhythmias), and the formation of dangerous blood clots.

The medications work through various mechanisms to achieve their therapeutic goals, such as relaxing blood vessels to lower blood pressure (e.g., ACE inhibitors, ARBs, calcium channel blockers), reducing the heart's workload (e.g., beta-blockers), preventing or dissolving blood clots (e.g., anticoagulants, antiplatelets, thrombolytics), or managing fluid retention (e.g., diuretics). Ultimately, these medications aim to improve the heart's pumping efficiency, ensure adequate blood flow throughout the body, reduce the risk of serious cardiovascular events like heart attacks and strokes, and alleviate symptoms to improve a patient's quality of life.

Subheadings

1 Antihypertensives

To lower high blood pressure (e.g., ACE inhibitors, ARBs, beta-blockers, calcium channel blockers, diuretics).

Lisinopril (Prinivil, Zestril)	This pharmaceutical medication blocks the enzyme that produces angiotensin II, leading to relaxation of blood vessels and reduced blood volume. It is one of the most commonly prescribed drugs for high blood pressure.
Amlodipine (Norvasc)	This pharmaceutical medication relaxes and widens blood vessels by preventing calcium from entering the muscle cells of arteries. This leads to lower blood pressure and is widely used for various types of hypertension.
Hydrochlorothiazide (HCTZ) (Microzide, Esidrix)	This pharmaceutical "water pill" helps the body eliminate excess sodium and water, reducing blood volume and thereby lowering blood pressure. It is often a first-line treatment for uncomplicated hypertension and frequently found in combination pills.
Valsartan (Diovan)	This pharmaceutical medication blocks the action of angiotensin II, a hormone that narrows blood vessels, thereby relaxing blood vessels and lowering blood pressure. It is a very commonly prescribed drug, especially when ACE inhibitors are not tolerated.
Metoprolol (Lopressor, Toprol XL)	This pharmaceutical medication blocks the effects of adrenaline, slowing the heart rate and relaxing blood vessels. It is widely used to lower blood pressure and also for conditions like angina and heart failure.
Losartan (Cozaar)	This pharmaceutical medication is an angiotensin receptor blocker that works by preventing angiotensin II from narrowing blood vessels. This results in relaxed blood vessels and a decrease in blood pressure.
Ramipril (Altace)	This pharmaceutical medication is an ACE inhibitor that helps relax blood vessels and reduce blood volume by blocking the production of a powerful vasoconstrictor called angiotensin II. It is commonly prescribed for high blood pressure and to protect the heart.
Telmisartan (Micardis)	This pharmaceutical medication is an angiotensin receptor blocker that prevents angiotensin II from constricting blood vessels. It leads to vasodilation and lower blood pressure, often used for long-term management of hypertension.
Enalapril (Vasotec)	This pharmaceutical medication is an ACE inhibitor that helps to relax blood vessels by blocking the formation of a substance that tightens them. It is widely used for hypertension and to improve outcomes in heart failure.
Perindopril (Coversyl)	This pharmaceutical ACE inhibitor helps relax blood vessels and reduce blood pressure by inhibiting the production of angiotensin II. It is commonly prescribed for hypertension and also for heart failure and coronary artery disease.
Benazepril (Lotensin)	This pharmaceutical ACE inhibitor works by blocking the formation of angiotensin II, leading to the relaxation of blood vessels and a reduction in blood pressure. It is used to treat hypertension and can also be prescribed for kidney protection in certain conditions.
Nifedipine (Procardia, Adalat)	This pharmaceutical calcium channel blocker primarily relaxes and widens blood vessels throughout the body, reducing peripheral resistance and lowering blood pressure. It is commonly used for both hypertension and angina.
Diltiazem (Cardizem, Tiazac)	This pharmaceutical calcium channel blocker works by relaxing blood vessels and slowing the heart rate, thereby lowering blood pressure. It is also used to control heart rate in certain arrhythmias.
Verapamil (Calan, Isoptin)	This pharmaceutical calcium channel blocker relaxes blood vessels and slows the heart rate, making the heart pump more easily and lowering blood pressure. It is also extensively used for managing certain heart rhythm disorders and angina.
Labetalol (Trandate, Normodyne)	This pharmaceutical medication is a unique beta-blocker that also has alpha-blocking properties, leading to both heart rate reduction and blood vessel dilation. It is often used for hypertensive emergencies and for managing high blood pressure during pregnancy.
Dietary Approaches to Stop Hypertension (DASH) Diet	This natural dietary pattern emphasizes fruits, vegetables, whole grains, and low-fat dairy, while limiting saturated fat, cholesterol, and sodium. It is a highly recommended and evidence-based non-pharmacological approach to lowering blood pressure.
Potassium-Rich Foods (Bananas, Spinach, Avocados)	Consuming foods naturally rich in potassium helps to counteract the effects of sodium in the body and relax blood vessel walls. This natural dietary adjustment is a fundamental recommendation for managing blood pressure.
Exercise (Regular Physical Activity)	Regular aerobic exercise helps strengthen the heart, making it more efficient at pumping blood, which reduces the force on arteries and lowers blood pressure. It is a cornerstone natural approach to both preventing and managing hypertension.
Hibiscus Tea	This natural herbal tea contains compounds that act as natural ACE inhibitors and diuretics, helping to relax blood vessels and increase fluid excretion. It is a popular traditional remedy and has some scientific backing for its blood pressure-lowering effects.
Garlic (Aged Garlic Extract) (Kyolic)	This natural supplement, particularly aged garlic extract, is believed to lower blood pressure by promoting nitric oxide production, which helps relax blood vessels, and by reducing arterial stiffness. It is a widely used natural remedy for cardiovascular health.
Coenzyme Q10 (CoQ10) (Qunol, Nature Made CoQ10)	This natural antioxidant and essential compound for cellular energy production may help lower blood pressure by improving blood vessel function and reducing oxidative stress. It's often used as a supplement for cardiovascular support.

2 Antiarrhythmics

To regulate irregular heart rhythms (arrhythmias).

Metoprolol (Lopressor, Toprol XL)	This pharmaceutical beta-blocker slows the heart rate and reduces the force of heart muscle contraction by blocking adrenaline's effects. It is widely used to control ventricular rate in atrial fibrillation, reduce symptoms in supraventricular tachycardias, and manage other rhythm disturbances.
Diltiazem (Cardizem, Tiazac)	This pharmaceutical calcium channel blocker slows conduction through the AV node, which helps to control the heart rate in conditions like atrial fibrillation and flutter. It also relaxes blood vessels, impacting blood pressure.
Amiodarone (Cordarone, Pacerone)	This pharmaceutical antiarrhythmic works by blocking potassium, sodium, and calcium channels, as well as alpha and beta receptors, thereby prolonging the cardiac action potential and refractory period. It is a highly effective, broad-spectrum agent used for a wide range of supraventricular and ventricular arrhythmias.
Digoxin (Lanoxin)	This pharmaceutical cardiac glycoside increases the force of heart muscle contraction and slows conduction through the AV node. It is used primarily to control ventricular rate in chronic atrial fibrillation and for heart failure.
Flecainide (Tambocor)	This pharmaceutical sodium channel blocker slows the electrical conduction in the heart, helping to restore normal rhythm and prevent episodes of atrial fibrillation, flutter, and certain ventricular tachycardias. It is often used for "pill-in-the-pocket" strategies.
Sotalol (Betapace)	This pharmaceutical beta-blocker also possesses potassium channel blocking properties, which prolongs the heart's action potential and refractory period. It is used to treat and prevent both atrial and ventricular arrhythmias.

MEDICATION 5. Cardiovascular Meds Antiarrhythmics

Propafenone (Rythmol)	This pharmaceutical sodium channel blocker slows electrical impulses in the heart, helping to maintain normal heart rhythm. It is used to treat and prevent certain supraventricular arrhythmias, including atrial fibrillation.
Verapamil (Calan, Isoptin)	This pharmaceutical calcium channel blocker slows conduction through the AV node, similar to diltiazem, to control heart rate in atrial fibrillation and supraventricular tachycardias. It also has a significant effect on blood pressure.
Adenosine (Adenocard)	This pharmaceutical medication transiently blocks conduction through the AV node, effectively interrupting re-entry pathways responsible for most supraventricular tachycardias (SVTs). It has a very rapid onset and short duration of action, making it ideal for acute SVT termination.
Magnesium (Magnesium Oxide, Magnesium Citrate)	This natural mineral plays a critical role in cardiac electrical stability and muscle function. It is often supplemented, particularly in cases of hypomagnesemia, to help stabilize heart rhythms, especially certain types of ventricular arrhythmias.
Potassium (Potassium Chloride)	This natural electrolyte is crucial for maintaining normal cardiac electrical activity and membrane potential. Supplementation is often necessary to correct hypokalemia, which can trigger or worsen various arrhythmias.
Coenzyme Q10 (CoQ10) (Qunol)	This natural antioxidant and essential compound for cellular energy production may help improve cardiac cell function and energy efficiency. It is sometimes used as a complementary therapy to support heart health, though its direct antiarrhythmic effect is not fully established.

3 Antianginal Agents

MEDICATION 5. Cardiovascular Meds Antianginal Agents

To relieve or prevent chest pain (angina) (e.g., nitrates, some beta-blockers, calcium channel blockers).

Metoprolol	This beta-blocker reduces the heart's workload by slowing the heart rate and decreasing the force of heart muscle contraction. By doing so, it reduces the heart's demand for oxygen, thereby preventing angina.
Amlodipine	This calcium channel blocker primarily works by relaxing and widening blood vessels, including those supplying the heart. This increases blood flow and oxygen supply to the heart muscle, while also reducing the heart's workload.
Nitroglycerin	This medication works by relaxing smooth muscle in blood vessels, leading to widespread vasodilation. This helps to acutely relieve angina by increasing blood flow to the heart and reducing the heart's overall workload.
Diltiazem	This calcium channel blocker not only relaxes blood vessels but also slows the heart rate and reduces the force of heart muscle contraction. These actions decrease myocardial oxygen demand and improve blood flow to the heart.
Ranolazine	This medication helps to improve the heart's efficiency by altering the flow of sodium and calcium into heart cells, which reduces the heart's oxygen demand. It is often used for chronic stable angina, particularly when other treatments are not fully effective or tolerated.
Ivabradine	This drug works by selectively slowing the heart rate without affecting blood pressure or heart muscle contraction. By reducing heart rate, it lowers the heart's oxygen demand and increases the time the heart has to fill with blood, improving oxygen supply.

4 Anticoagulants

5. Cardiovascular Meds Anticoagulants

To prevent blood clot formation (blood thinners) (e.g., warfarin, direct oral anticoagulants).

Warfarin	This oral medication works by inhibiting vitamin K epoxide reductase, an enzyme necessary for the production of several clotting factors in the liver. This reduces the blood's ability to form clots, but requires regular monitoring with INR (International Normalized Ratio) tests.
Rivaroxaban	As a direct oral anticoagulant (DOAC), rivaroxaban directly inhibits Factor Xa, a crucial enzyme in the coagulation cascade. By blocking Factor Xa, it prevents the formation of thrombin, thereby reducing blood clot formation.
Apixaban	Another direct oral anticoagulant (DOAC), apixaban also directly inhibits Factor Xa, similar to rivaroxaban. This targeted action prevents the generation of thrombin, effectively reducing the risk of blood clots.
Enoxaparin (Low Molecular Weight Heparin - LMWH)	This injectable anticoagulant works by enhancing the activity of antithrombin, which then inactivates Factor Xa and, to a lesser extent, thrombin. It is often used for preventing and treating blood clots, particularly in hospital settings or for bridge therapy.
Dabigatran	This direct oral anticoagulant (DOAC) specifically inhibits thrombin (Factor IIa), which is a key enzyme in the final steps of clot formation. By blocking thrombin, dabigatran prevents the conversion of fibrinogen to fibrin and inhibits platelet activation.
Heparin (Unfractionated Heparin - UFH)	Administered intravenously or subcutaneously, heparin works by binding to antithrombin, significantly increasing its ability to inactivate thrombin and Factor Xa. It's primarily used in acute care settings for rapid anticoagulation.

5 Antiplatelet Agents

MEDICATION 5. Cardiovascular Meds Antiplatelet Agents

To prevent platelets from sticking together and forming clots (e.g., aspirin, clopidogrel).

Aspirin	This medication works by irreversibly inhibiting an enzyme called cyclooxygenase (COX-1) in platelets, which prevents the formation of thromboxane A2, a powerful promoter of platelet aggregation. This ultimately reduces the ability of platelets to stick together and form clots.
Clopidogrel	This is a prodrug that, once metabolized, irreversibly blocks the P2Y12 receptor on platelets. By doing so, it prevents adenosine diphosphate (ADP) from binding to this receptor, which is crucial for platelet activation and aggregation.
Ticagrelor	Unlike clopidogrel, ticagrelor is a direct-acting P2Y12 receptor antagonist that reversibly binds to the receptor. This action prevents ADP-mediated platelet activation and aggregation, with a faster onset and more consistent platelet inhibition compared to clopidogrel.
Prasugrel	Similar to clopidogrel, prasugrel is a prodrug that, upon metabolism, irreversibly blocks the P2Y12 receptor on platelets. It offers more potent and consistent platelet inhibition than clopidogrel, but carries a higher risk of bleeding.
Dipyridamole	This agent works by increasing levels of cyclic AMP (cAMP) in platelets through various mechanisms, including inhibiting phosphodiesterase and blocking adenosine reuptake. Higher cAMP levels inhibit platelet aggregation and promote vasodilation.

6 Thrombolytics (Fibrinolytics)

MEDICATION | 5. Cardiovascular Meds | Thrombolytics (Fibrinolytics)

Thrombolytics, often called "clot busters," are powerful medications used in emergency situations to dissolve existing blood clots that are blocking blood flow. Their primary use is in acute, life-threatening conditions where rapid restoration of blood flow is critical.

It's important to note that the use of thrombolytics is confined to specific, acute medical emergencies and is almost exclusively administered in a hospital setting due to their potency and significant risk of bleeding. Therefore, their "common prescription" refers to their frequent use in these critical scenarios rather than outpatient prescriptions. The landscape has also shifted, with newer, more fibrin-specific agents often preferred over older ones in many developed countries.

Alteplase	This medication is a recombinant tissue plasminogen activator (tPA) that directly converts plasminogen into plasmin, an enzyme that breaks down fibrin clots. It is a highly effective clot-busting drug often used for acute ischemic stroke, pulmonary embolism, and certain types of heart attack.
Tenecteplase	This is a modified recombinant tPA that has a longer half-life and higher fibrin specificity than alteplase, allowing for a single bolus administration. It works by converting plasminogen to plasmin, thereby dissolving blood clots, and is commonly used for acute myocardial infarction and increasingly for acute ischemic stroke.
Streptokinase	This older thrombolytic is a bacterial protein that forms a complex with plasminogen, which then activates other plasminogen molecules into plasmin to break down fibrin. While effective and often more affordable, its use has decreased in some regions due to concerns about antigenicity and a higher risk of allergic reactions or re-administration issues.
Reteplase	This is another recombinant plasminogen activator that directly converts plasminogen to plasmin, similar to alteplase but with a slightly different pharmacokinetic profile. It is often administered as a double bolus and is used for acute myocardial infarction.
Urokinase	This thrombolytic directly cleaves plasminogen into plasmin, leading to clot dissolution. It is naturally produced by human kidneys and is often used for dissolving clots in catheters or for peripheral vascular thrombus.

7 Antihyperlipidemics (Lipid-lowering agents)

MEDICATION | 5. Cardiovascular Meds | Antihyperlipidemics (Lipid-lowering agents)

Antihyperlipidemics (also known as lipid-lowering agents) are a class of medications used to reduce elevated levels of lipids (fats) such as cholesterol and triglycerides in the blood. High levels of these lipids, particularly LDL ("bad") cholesterol, are major risk factors for atherosclerosis, heart attacks, and strokes.

Atorvastatin (Lipitor)	This pharmaceutical statin works by blocking an enzyme in the liver responsible for cholesterol production, thereby significantly lowering LDL ("bad") cholesterol and triglycerides, and moderately increasing HDL ("good") cholesterol. It is the most prescribed cholesterol-lowering medication globally.
Rosuvastatin (Crestor)	This pharmaceutical statin is a potent inhibitor of cholesterol synthesis in the liver, leading to substantial reductions in LDL cholesterol and triglycerides, and an increase in HDL cholesterol. It is another very commonly prescribed statin.
Simvastatin (Zocor)	This pharmaceutical statin reduces cholesterol production in the liver by inhibiting a key enzyme, resulting in lower LDL and total cholesterol levels. It is a widely used and effective medication for managing high cholesterol.
Ezetimibe (Zetia)	This pharmaceutical medication works by selectively inhibiting the absorption of cholesterol from the small intestine, leading to a reduction in the amount of cholesterol delivered to the liver and subsequently lower LDL cholesterol. It is often used in combination with statins.
Omega-3 Fatty Acids (Fish Oil/Algae Oil)	These natural/dietary supplements, rich in EPA and DHA, significantly reduce triglyceride levels by decreasing their production in the liver. They are widely consumed for cardiovascular health, with prescription-strength versions available for very high triglycerides.
Pravastatin (Pravachol)	This pharmaceutical statin lowers cholesterol by inhibiting a key enzyme in its production pathway in the liver, leading to reduced LDL and total cholesterol. It is a commonly used statin.
Fenofibrate (TriCor, Lipofen)	This pharmaceutical fibrate primarily lowers high triglyceride levels and can also increase HDL cholesterol, by activating specific receptors that regulate lipid metabolism. It is often prescribed for severe hypertriglyceridemia.
Niacin (Nicotinic Acid) (Niaspan, Niacor)	This pharmaceutical B vitamin lowers LDL cholesterol and triglycerides while increasing HDL cholesterol by reducing the liver's production of very-low-density lipoproteins (VLDL). It can also cause flushing side effects.
Plant Sterols/Stanols (CholestOff, Benecol)	These natural compounds, structurally similar to cholesterol, reduce the absorption of dietary cholesterol in the intestine. They are often found in fortified foods like margarines and yogurts, as well as supplements.
Red Yeast Rice	This natural supplement contains compounds called monacolins, including monacolin K, which is chemically identical to the statin drug lovastatin. It works by inhibiting cholesterol production in the liver, similar to statins.
Alirocumab (Praluent)	This pharmaceutical PCSK9 inhibitor is an injectable medication that blocks a protein called PCSK9, which allows the liver to remove more LDL cholesterol from the blood. It is used for patients with very high cholesterol who need additional lowering, often after maximally tolerated statins.
Evolocumab (Repatha)	This pharmaceutical PCSK9 inhibitor is an injectable medication that works by blocking the PCSK9 protein, leading to increased clearance of LDL cholesterol from the bloodstream by the liver. It is prescribed for severe hypercholesterolemia and cardiovascular risk reduction.
Colesevelam (Welchol)	This pharmaceutical bile acid sequestrant works in the intestine by binding to bile acids, preventing their reabsorption and increasing their excretion. This prompts the liver to use more cholesterol to make new bile acids, thereby lowering LDL cholesterol.
Gemfibrozil (Lopid)	This pharmaceutical fibrate reduces high triglyceride levels and can increase HDL cholesterol by enhancing the breakdown and clearance of triglyceride-rich particles from the blood. It is used to treat severe hypertriglyceridemia.
Cholestyramine (Prevalite, Questran)	This pharmaceutical bile acid sequestrant binds to bile acids in the intestine, preventing their reabsorption. This leads to increased excretion of bile acids, prompting the liver to convert more cholesterol into bile acids, thus lowering LDL cholesterol levels.

8 Diuretics

MEDICATION | 5. Cardiovascular Meds | Diuretics

Diuretics, often called "water pills," are medications that help the body get rid of excess water and salt (sodium) through increased urination. They are commonly used to treat conditions characterized by fluid retention (edema) and high blood pressure, thereby reducing the workload on the heart and improving fluid balance.

Hydrochlorothiazide (Microzide, Esidrix)	This pharmaceutical thiazide diuretic helps the body eliminate excess sodium and water, reducing blood volume and thereby lowering blood pressure and reducing fluid retention (edema). It is one of the most widely prescribed diuretics, often used alone or in combination with other blood pressure medications.
Furosemide (Lasix)	This pharmaceutical loop diuretic is very potent, working in the loop of Henle in the kidneys to remove large amounts of salt and water from the body. It is frequently used for significant fluid retention associated with heart failure, liver disease, or kidney disease, and also for hypertension.
Chlorthalidone (Thalitone, Hygroton)	This pharmaceutical thiazide-like diuretic helps the kidneys remove more fluid and salt from the blood, similar to hydrochlorothiazide. It is widely used for treating high blood pressure and edema, and some studies suggest it may offer superior cardiovascular benefits in certain populations.
Spironolactone (Aldactone)	This pharmaceutical potassium-sparing diuretic and aldosterone antagonist helps the body excrete sodium and water while retaining potassium. It is commonly used for fluid retention in heart failure, liver cirrhosis, and for resistant hypertension.
Torsemide (Demadex)	This pharmaceutical loop diuretic, similar to furosemide, increases urine output by acting on the kidneys to enhance the excretion of salt and water. It is used to treat fluid retention and swelling associated with heart failure, kidney disease, and liver disease.

Indapamide (Natrilix, Indipam)	This pharmaceutical thiazide-like diuretic works by inhibiting sodium reabsorption in the kidneys, leading to increased excretion of water and salt. It is used for the treatment of high blood pressure and edema, and may offer additional benefits in terms of vascular protection.
Bumetanide (Bumex)	This pharmaceutical loop diuretic is very potent, working in the kidneys to remove excess salt and water from the body. It is primarily used to treat fluid retention (edema) associated with heart failure, liver disease, or kidney disease.
Triamterene (Dyrenium)	This pharmaceutical potassium-sparing diuretic works by directly blocking sodium channels in the kidneys, which leads to increased sodium and water excretion while conserving potassium. It is often used in combination with other diuretics to prevent potassium loss.
Dandelion	This natural herb has traditionally been used for its diuretic properties, helping to increase urine production and promote the excretion of salts and water from the kidneys. It is sometimes consumed as a tea.
Green Tea	This natural beverage contains caffeine, which acts as a mild diuretic, promoting increased urine output. It is widely consumed globally and can contribute to fluid elimination.
Parsley	This natural herb has been traditionally used as a diuretic in folk medicine, believed to stimulate the kidneys to excrete more sodium and water. It can be added to food or brewed as a tea.
Hibiscus Tea	This natural herbal tea contains compounds that may act as mild diuretics, helping to increase fluid excretion and reduce water retention. It is also known for potential blood pressure-lowering effects.
Mannitol (Osmitrol)	This pharmaceutical osmotic diuretic is administered intravenously and works by drawing water out of tissues into the bloodstream, increasing urine output. It is primarily used in acute settings to reduce intracranial pressure (brain swelling) or intraocular pressure (eye pressure).

9 Inotropic Agents

Inotropic agents are medications that alter the force or energy of muscular contractions, particularly those of the heart. Positive inotropes strengthen the heart's contractions, increasing cardiac output, and are used to support cardiac function in conditions like acute heart failure, cardiogenic shock, and severe low cardiac output states. Negative inotropes weaken contractions and are used to decrease cardiac workload, for example, in angina or hypertrophic cardiomyopathy (though these are typically classified as beta-blockers or calcium channel blockers and not generally considered "inotropic agents" in the context of increasing contractility).

This list focuses on positive inotropic agents commonly used to enhance cardiac contractility in critical care or chronic heart conditions. Their "common prescription" refers to their frequent use in specific hospital-based situations or for long-term management of heart failure.

Digoxin (Lanoxin)	This pharmaceutical cardiac glycoside increases the force of heart muscle contractions and slows the heart rate. It is widely used orally to manage symptoms of chronic heart failure and to control the heart rate in atrial fibrillation.
Dobutamine (Dobutrex)	This pharmaceutical synthetic catecholamine stimulates beta-1 adrenergic receptors in the heart, increasing the force of heart muscle contraction and cardiac output. It is primarily administered intravenously in acute heart failure or cardiogenic shock to improve heart function.
Milrinone (Primacor)	This pharmaceutical phosphodiesterase-3 inhibitor increases the force of heart muscle contraction and causes vasodilation (widening of blood vessels). It is administered intravenously in acute heart failure to improve cardiac output and reduce systemic vascular resistance.
Dopamine (Intropin)	This pharmaceutical catecholamine acts on dopamine, beta-1, and alpha-1 adrenergic receptors depending on the dose, increasing heart rate, contractility, and blood pressure. It is used intravenously to treat various forms of shock, including cardiogenic and septic shock.
Coenzyme Q10 (CoQ10) (Qunol)	This natural antioxidant and essential compound for cellular energy production plays a vital role in the heart's energy metabolism and function. It is widely used as a dietary supplement to support cardiovascular health, though its direct inotropic effect is not as immediate or potent as pharmaceuticals.
Hawthorn	This natural herb contains flavonoids and proanthocyanidins that are believed to improve cardiac contractility, dilate blood vessels, and have antioxidant effects. It is traditionally used to support heart function, particularly in mild heart failure.
L-Carnitine	This natural amino acid is crucial for transporting fatty acids into mitochondria, where they are converted into energy, thereby supporting the heart muscle's energy production. It is used as a dietary supplement for various cardiovascular conditions.

10 Vasodilators

Vasodilators are a diverse group of medications that work by widening (dilating) blood vessels. This action improves blood flow, reduces the heart's workload, and lowers blood pressure. They are used to treat various conditions, including hypertension, heart failure, angina, and certain peripheral vascular diseases.

It's important to note that many common antihypertensives (like ACE inhibitors, ARBs, and calcium channel blockers) also function as vasodilators as a primary component of their action. This list will include some of the most prominent drugs known for their vasodilatory effects across different classes.

Amlodipine (Norvasc)	This pharmaceutical calcium channel blocker relaxes and widens blood vessels by preventing calcium from entering the muscle cells of arteries. This leads to lower blood pressure and is a cornerstone in the treatment of hypertension.
Lisinopril (Prinivil, Zestril)	This pharmaceutical ACE inhibitor blocks the enzyme that produces angiotensin II, a powerful vasoconstrictor, leading to relaxation of blood vessels and reduced blood pressure. It is one of the most widely prescribed vasodilators for hypertension and heart failure.
Valsartan (Diovan)	This pharmaceutical angiotensin receptor blocker (ARB) directly blocks the action of angiotensin II, a hormone that narrows blood vessels, thereby relaxing blood vessels and lowering blood pressure. It is a very commonly prescribed vasodilator.
Nitroglycerin (Nitrostat, Nitrolingual)	This pharmaceutical nitrate directly relaxes smooth muscle in blood vessel walls, particularly veins, leading to widespread vasodilation that reduces the heart's workload and improves blood flow to the heart muscle. It is a rapid-acting treatment for angina (chest pain).
Hydralazine (Apresoline)	This pharmaceutical direct vasodilator primarily relaxes arterial smooth muscle, leading to a decrease in peripheral vascular resistance and blood pressure. It is used to treat severe hypertension, often in combination with other medications.
Sildenafil (Viagra, Revatio)	This pharmaceutical phosphodiesterase-5 (PDE5) inhibitor increases nitric oxide activity, leading to relaxation of smooth muscle in blood vessels and increased blood flow. While famously known for erectile dysfunction, it is also used for pulmonary hypertension (Revatio).
Telmisartan (Micardis)	This pharmaceutical angiotensin receptor blocker prevents angiotensin II from constricting blood vessels, leading to vasodilation and lower blood pressure. It is a common choice for long-term management of hypertension.
Isosorbide Dinitrate (Isordil, Dilatrate-SR)	This pharmaceutical nitrate is metabolized to nitric oxide, which relaxes vascular smooth muscle, causing vasodilation in both arteries and veins. It is used to prevent and treat angina (chest pain) and manage heart failure.
Minoxidil (Loniten)	This pharmaceutical direct vasodilator works by opening potassium channels in vascular smooth muscle cells, causing profound vasodilation and a significant reduction in blood pressure. Its oral form is used for severe hypertension, while its topical form (Rogaine) stimulates hair growth.
Prazosin (Minipress)	This pharmaceutical alpha-1 adrenergic blocker relaxes both arterial and venous smooth muscle, leading to vasodilation and a reduction in blood pressure. It is used to treat hypertension and also for symptoms of benign prostatic hyperplasia (BPH) and PTSD-related nightmares.
Garlic (Aged Garlic Extract)	This natural supplement is believed to promote nitric oxide production and inhibit ACE activity, leading to relaxation of blood vessels and a modest reduction in blood pressure. It is widely used for cardiovascular health.

MEDICATION

5. Cardiovasc Vasodilators

Hibiscus Tea	This natural herbal tea contains compounds that may act as natural ACE inhibitors and have diuretic properties, helping to relax blood vessels and increase fluid excretion, contributing to blood pressure reduction.
L-Arginine	This natural amino acid is a precursor to nitric oxide, a powerful vasodilator that helps relax and widen blood vessels, improving blood flow. It is often taken as a supplement for cardiovascular health.
Coenzyme Q10 (CoQ10) (Qunol)	This natural antioxidant and essential compound for cellular energy production may help improve blood vessel function and reduce oxidative stress, which can contribute to vasodilation. It is a popular supplement for heart health.
Cayenne Pepper (Capsaicin)	This natural spice contains capsaicin, which can stimulate transient receptor potential (TRP) channels, leading to the release of vasodilating substances like nitric oxide. It is sometimes used in traditional medicine to support circulation.

6 Central Nervous System Meds

Central Nervous System (CNS) medications are a diverse group of drugs that exert their effects directly on the brain and spinal cord, which together constitute the CNS. These medications are used to treat a wide array of neurological and psychiatric conditions by influencing neurotransmitters, receptors, and neural pathways. They can broadly be categorized by their primary action as depressants (slowing down brain activity, like sedatives, hypnotics, and antianxiety agents), stimulants (increasing brain activity, like those for ADHD or narcolepsy), or those that modulate specific neurological functions (such as anticonvulsants for seizures, antipsychotics for psychosis, antidepressants for mood disorders, or pain relievers like opioids). Due to their direct impact on brain function, CNS medications often carry significant side effects and potential for dependence, requiring careful prescription and monitoring regardless of the patient's geographic location.

13. Antimigraine	**14. Antidementia**		

1 Analgesics (Non-opioid)

Non-opioid analgesics are the cornerstone of pain management for mild to moderate pain, and are often used in combination with opioids for more severe pain (multimodal analgesia). They primarily include acetaminophen (paracetamol) and nonsteroidal anti-inflammatory drugs (NSAIDs).

Paracetamol (Acetaminophen)	This widely available over-the-counter medication is highly effective for relieving mild to moderate pain and reducing fever. It works primarily in the central nervous system, though its exact mechanism is still not fully understood.
Ibuprofen (Advil, Motrin IB)	As a nonsteroidal anti-inflammatory drug (NSAID), ibuprofen reduces pain, inflammation, and fever by inhibiting the production of prostaglandins, which are substances that cause pain and inflammation in the body. It is commonly used for musculoskeletal pain, headaches, and menstrual pain.
Naproxen (Aleve, Naprosyn)	Another NSAID, naproxen works by reducing inflammation and pain through the inhibition of prostaglandin synthesis. It is known for its longer duration of action compared to ibuprofen, making it suitable for conditions requiring less frequent dosing, such as arthritis pain.
Aspirin (Acetylsalicylic Acid) (Bayer Aspirin)	While best known for its antiplatelet properties at low doses, at higher doses, this pharmaceutical NSAID functions as an anti-inflammatory and analgesic by irreversibly inhibiting cyclooxygenase enzymes. It's used for various pain and inflammatory conditions.
Diclofenac (Voltaren, Cataflam)	This NSAID effectively reduces pain and inflammation by inhibiting cyclooxygenase (COX) enzymes, thereby decreasing prostaglandin production. It is available in various forms, including oral tablets, gels, and patches, for conditions like arthritis and acute pain.
Celecoxib (Celebrex)	This is a selective COX-2 inhibitor, a type of NSAID that targets only the COX-2 enzyme, which is primarily involved in inflammation and pain. This selectivity aims to reduce gastrointestinal side effects compared to non-selective NSAIDs, making it useful for chronic inflammatory conditions.
Curcumin (from Turmeric)	This natural compound found in turmeric is well-researched for its potent anti-inflammatory and antioxidant properties, acting on multiple molecular targets to reduce inflammation pathways in the body. It is often used as a supplement for conditions like arthritis and general pain.
Ginger (Fresh Ginger, Ginger Root)	A natural remedy, ginger contains bioactive compounds like gingerols and shogaols that possess anti-inflammatory and analgesic effects by inhibiting prostaglandin and leukotriene synthesis. It is commonly used to alleviate muscle pain, menstrual pain, and reduce inflammation.
Capsaicin (Topical)	This natural compound, derived from chili peppers, works by depleting Substance P, a neurotransmitter involved in sending pain signals to the brain. It is used topically to relieve neuropathic pain, arthritis pain, and muscle soreness.
Gabapentin (Neurontin)	Although primarily an anti-epileptic, gabapentin is widely prescribed for neuropathic pain, such as nerve pain from shingles or diabetes. It is thought to work by affecting calcium channels in nerve cells, which reduces the release of pain-signaling neurotransmitters.
Pregabalin (Lyrica)	Similar to gabapentin, pregabalin also works by modulating calcium channels in nerve endings, thereby reducing the release of excitatory neurotransmitters that contribute to pain. It is used for neuropathic pain, fibromyalgia, and generalized anxiety disorder.
White Willow Bark	This natural botanical contains salicin, a compound similar to the active ingredient in aspirin, which is converted in the body to salicylic acid. It is traditionally used to reduce pain and inflammation, particularly for back pain and osteoarthritis.
Magnesium	This natural mineral plays a crucial role in muscle relaxation and nerve function. It is often supplemented to alleviate muscle cramps, headaches, and neuropathic pain, particularly when a deficiency is present.

2 Analgesics (Opioid)

Opioid analgesics are a class of powerful medications that relieve moderate to severe pain. They work by binding to opioid receptors (primarily mu, kappa, and delta) in the brain, spinal cord, and other areas of the body, which then block pain signals and produce feelings of euphoria or relaxation. Due to their potential for dependence, addiction, and serious side effects (especially respiratory depression), their prescription is carefully controlled.

Hydrocodone (Vicodin, Norco, Lortab)	Often prescribed in combination with acetaminophen, hydrocodone acts on opioid receptors in the brain and spinal cord to relieve moderate to severe pain. It is one of the most commonly dispensed opioids for pain management.
Oxycodone (OxyContin, Percocet, Roxicodone)	This potent opioid analgesic works by binding to opioid receptors in the central nervous system, effectively changing how the body perceives and responds to pain. It is used for moderate to severe acute and chronic pain.

MEDICATION | 6. Central Nervous System Meds | Analgesics (Opioid)

Tramadol (Ultram, Conzip)	This centrally acting analgesic has a dual mechanism, involving both weak opioid receptor binding and inhibition of norepinephrine and serotonin reuptake in the brain. It is used to treat moderate to moderately severe pain.
Codeine (Tylenol with Codeine, Panadeine Forte, Nurofen Plus)	Often found in combination with non-opioid analgesics, codeine is a prodrug that is metabolized into morphine, acting on opioid receptors to provide relief for mild to moderate pain. It also has cough suppressant properties.
Morphine (MS Contin, Kadian, Roxanol)	As a strong opioid, morphine acts directly on opioid receptors in the brain and spinal cord to provide powerful relief for severe pain. It is a fundamental medication for acute severe pain and chronic pain, including in palliative care.
Fentanyl (Duragesic, Actiq, Sublimaze)	This highly potent synthetic opioid acts on opioid receptors, providing rapid and strong pain relief, often used for severe chronic pain (e.g., in transdermal patches) or acute procedural pain (e.g., intravenous forms). It is significantly more potent than morphine.
Hydromorphone (Dilaudid)	This pharmaceutical semi-synthetic opioid is more potent than morphine, binding to opioid receptors to provide potent pain relief for moderate to severe pain. It is often used for acute pain management in hospital settings.
Opium (Various preparations, often historical or illicit)	This natural substance derived from the opium poppy contains a mixture of alkaloids, including morphine and codeine, which bind to opioid receptors to produce pain relief, euphoria, and sedation. Historically, it was a primary source of pain relief.
Heroin (Illicit, derived from morphine)	This semi-synthetic opioid is derived from morphine and is rapidly converted to morphine in the body after administration. It is a highly potent opioid that acts on opioid receptors, producing intense euphoria and pain relief, though its use is primarily illicit due to its high addiction potential.

MEDICATION | 6. Central Nervous System Meds | Antipyretics

3 Antipyretics

To reduce fever.

Paracetamol (Acetaminophen) (Tylenol)	This widely available medication works primarily in the central nervous system, though its exact mechanism is not fully understood, to reduce fever and mild to moderate pain. It is a cornerstone for fever management in both adults and children.
Ibuprofen (Advil)	As a nonsteroidal anti-inflammatory drug (NSAID), ibuprofen reduces fever by inhibiting the production of prostaglandins, which are key mediators of fever and inflammation in the body. It also provides pain relief and anti-inflammatory effects.
Naproxen (Aleve)	Similar to ibuprofen, naproxen is an NSAID that reduces fever by blocking the synthesis of prostaglandins. Its longer duration of action makes it suitable for sustained fever reduction.
Aspirin (Bayer Aspirin)	This older NSAID reduces fever by inhibiting cyclooxygenase enzymes, which are involved in prostaglandin synthesis in the hypothalamus, the brain's temperature-regulating center. However, its use as an antipyretic in children is generally avoided due to the risk of Reye's syndrome.
Diclofenac (Voltaren, Cataflam)	This pharmaceutical NSAID provides significant antipyretic effects by potently inhibiting prostaglandin synthesis. It is used for fever associated with inflammatory conditions, available in various formulations including oral and topical.
Metamizole (Dipyrone) (Novamin, Analgin)	This pharmaceutical pyrazolone derivative reduces fever by acting centrally on the brain's temperature-regulating centers and has anti-inflammatory properties. It is widely used for fever reduction in many parts of the world, though its use is restricted in some countries due to rare blood disorders.
Ginger (Fresh Ginger, Ginger Root)	A natural remedy, ginger contains bioactive compounds that possess anti-inflammatory properties, which may indirectly help reduce fever by addressing the underlying inflammation. It is often consumed as a tea for cold and flu symptoms.
Elderberry (Sambucol)	This natural botanical extract is believed to have antiviral and anti-inflammatory properties, which may help to reduce the severity and duration of fever associated with viral infections like colds and flu. It is commonly taken as a syrup or supplement.
Willow Bark	This natural botanical contains salicin, which is chemically similar to aspirin and is converted into salicylic acid in the body. It has traditional use for reducing fever and pain.
Peppermint	This natural herb has cooling properties due to menthol, and consumption of peppermint tea can help promote sweating, which is a natural mechanism for cooling the body and reducing fever.

MEDICATION | 6. Central Nervous System Meds | Anesthetics

4 Anesthetics

To cause loss of sensation (local) or consciousness (general) during medical procedures.

Propofol (Diprivan)	This pharmaceutical intravenous anesthetic produces rapid onset of unconsciousness with a short duration of action, making it ideal for induction and maintenance of general anesthesia, as well as sedation in critical care. It works by enhancing the activity of GABA, an inhibitory neurotransmitter in the brain.
Lidocaine (Xylocaine, Lignocaine)	This pharmaceutical local anesthetic blocks nerve signals by inhibiting sodium channels in nerve membranes, preventing pain sensation in a specific area of the body. It is widely used for local anesthesia during minor procedures, as a nerve block, and topically for pain relief.
Sevoflurane (Ultane, Sevorane)	This pharmaceutical volatile inhaled anesthetic induces and maintains general anesthesia by depressing central nervous system activity, allowing for rapid onset and recovery. It is a very commonly used inhalation agent, particularly for pediatric anesthesia due to its non-pungent odor.
Desflurane (Suprane)	This pharmaceutical volatile inhaled anesthetic provides rapid induction and emergence from general anesthesia due to its low blood solubility, allowing for precise control of anesthetic depth. It is frequently used for surgical procedures where quick recovery is desired.
Midazolam (Versed)	This pharmaceutical benzodiazepine works by enhancing the effects of GABA in the brain, leading to sedation, anxiety reduction, and amnesia. It is commonly used for conscious sedation during medical procedures and as a pre-anesthetic medication.
Fentanyl (Sublimaze, Duragesic)	This pharmaceutical synthetic opioid, when used as an anesthetic adjunct, provides strong analgesia and sedation by binding to opioid receptors in the brain and spinal cord. It is frequently used in general anesthesia to manage pain and blunt surgical responses.
Isoflurane (Forane)	This pharmaceutical volatile inhaled anesthetic induces and maintains general anesthesia by depressing central nervous system function. It is a commonly used and cost-effective inhalation agent globally.
Ketamine (Ketalar)	This pharmaceutical dissociative anesthetic produces a "dissociative state" where the patient appears awake but is unresponsive to pain and unaware of their surroundings. It is used for anesthesia, sedation, and increasingly for its rapid antidepressant effects.
Bupivacaine (Marcaine, Sensorcaine)	This pharmaceutical long-acting local anesthetic blocks nerve impulse transmission by inhibiting sodium channels. It is commonly used for regional anesthesia, such as epidurals for labor pain, nerve blocks, and for prolonged local pain relief.
Nitrous Oxide (Laughing Gas, Entonox)	This pharmaceutical inhaled anesthetic gas produces analgesia and mild sedation by acting on various neurotransmitter systems in the brain. It is commonly used for dental procedures, minor surgeries, and to provide pain relief during labor due to its rapid onset and offset.
Clove Oil	This natural essential oil contains eugenol, which has local anesthetic and antiseptic properties, numbing the area it's applied to. It is traditionally used as a natural remedy for toothache relief.
Ice/Cold Application	This natural physical method works by constricting blood vessels and slowing nerve conduction, which reduces pain sensation and inflammation in the affected area. It is a very common first-aid measure for minor injuries and localized pain.
Cannabinoids (e.g., THC, CBD)	These natural compounds, derived from the cannabis plant, interact with the body's endocannabinoid system, which plays a role in pain perception. They can provide analgesic and sedative effects, though their use as anesthetics is complementary and largely experimental.

5 Anticonvulsants (Antiepileptics)

Anticonvulsants, also known as antiepileptic drugs (AEDs) or anti-seizure medications, are a diverse group of drugs primarily used to prevent or reduce the frequency and severity of epileptic seizures. Many also have broader uses, such as treating neuropathic pain, bipolar disorder, and migraine prevention.

Valproic Acid (Depakote, Depakene)	This pharmaceutical medication works by making it harder for brain cells to "fire" too quickly, thus preventing seizures. It is effective against many types of epilepsy and is one of the most widely prescribed AEDs globally.
Lamotrigine (Lamictal)	This pharmaceutical medication slows down the abnormal electrical signals in the brain that cause seizures. It is widely used for both focal onset and generalized seizures.
Levetiracetam (Keppra, Spritam)	This pharmaceutical medication helps to lower excessive electrical signals in the brain, though its exact mechanism is not fully understood. It is a very commonly used antiepileptic drug for both focal onset and generalized seizures.
Topiramate (Topamax)	This pharmaceutical medication slows down how fast brain cells work, which helps to stop seizures from developing. It is mainly used to treat generalized epilepsy, including Lennox-Gastaut syndrome.
Gabapentin (Neurontin)	This pharmaceutical medication is thought to work similarly to GABA, a brain chemical that helps calm nerves, thereby decreasing abnormal excitement in the brain to control seizures. It is FDA approved for focal onset seizures.
Carbamazepine (Tegretol, Curatil)	This pharmaceutical sodium channel blocker works by stabilizing the electrical activity in the brain, slowing down how quickly signals are sent. It has been a long-standing treatment primarily for focal seizures.
Phenytoin (Dilantin)	This pharmaceutical medication reduces abnormal brain signals by blocking sodium ion channels in the brain, thereby stopping high-frequency electrical firing. It has been used for a long time to treat various types of seizures.
Oxcarbazepine (Trileptal, Oxtellar XR)	This pharmaceutical medication is similar to carbamazepine and works by decreasing abnormal electrical activity in the brain. It is used to control certain types of seizures, either alone or in combination with other medications.
Pregabalin (Lyrica)	This pharmaceutical medication reduces abnormal electrical activity in the brain to stop seizures, though it is also widely used for nerve pain and anxiety. It is primarily used as an add-on therapy for focal onset seizures.
Clobazam (Onfi, Sympazan)	This pharmaceutical benzodiazepine works in the brain to prevent seizures by enhancing the activity of GABA, an inhibitory neurotransmitter. It is primarily used to help control seizures associated with Lennox-Gastaut syndrome.
Cannabidiol (CBD) (Epidiolex	This natural compound derived from the cannabis plant interacts with the body's endocannabinoid system, showing promise in reducing seizure frequency and severity, particularly in certain severe forms of epilepsy like Dravet syndrome and Lennox-Gastaut syndrome. Epidiolex is the pharmaceutical-grade formulation.
Valerian Root	This natural herb is often used for its sedative and anxiolytic properties, and some traditional uses suggest it may help calm nervous system overactivity, which could potentially contribute to seizure control, though scientific evidence is limited.
Magnesium	This natural mineral is a potential modulator of seizure activity due to its ability to antagonize excitation at certain brain receptors and its role in nerve function. It is sometimes supplemented, particularly in cases of magnesium deficiency, which can lower seizure threshold.
Ketogenic Diet	This natural dietary therapy involves a very high-fat, very low-carbohydrate, and adequate-protein regimen that forces the body to burn fat for fuel, producing ketones. This metabolic state has been shown to reduce seizure frequency in some individuals, particularly children with drug-resistant epilepsy.

6 Antidepressants

Antidepressants are a class of medications used to treat major depressive disorder and other conditions such as anxiety disorders, obsessive-compulsive disorder (OCD), post-traumatic stress disorder (PTSD), chronic pain, and sometimes certain eating disorders. They work by affecting the balance of neurotransmitters (chemical messengers) in the brain, primarily serotonin, norepinephrine,

Sertraline (Zoloft)	This pharmaceutical Selective Serotonin Reuptake Inhibitor (SSRI) works by increasing the levels of serotonin in the brain, a neurotransmitter associated with mood regulation. It is one of the most widely prescribed antidepressants for major depressive disorder, anxiety, and obsessive-compulsive disorder.
Escitalopram (Lexapro, Cipralex)	This pharmaceutical SSRI specifically targets serotonin reuptake in the brain, leading to increased serotonin levels and improved mood. It is a very commonly used antidepressant for major depressive disorder and generalized anxiety disorder.
Fluoxetine (Prozac)	This pharmaceutical SSRI increases serotonin levels in the brain by blocking its reabsorption into neurons. It was one of the first SSRIs developed and remains widely used for depression, obsessive-compulsive disorder, and bulimia nervosa.
Venlafaxine (Effexor XR)	This pharmaceutical Serotonin-Norepinephrine Reuptake Inhibitor (SNRI) increases the levels of both serotonin and norepinephrine in the brain. It is used to treat major depressive disorder, generalized anxiety disorder, and panic disorder.
Duloxetine (Cymbalta)	This pharmaceutical SNRI increases the levels of serotonin and norepinephrine in the brain, helping to improve mood and reduce pain. It is prescribed for major depressive disorder, generalized anxiety disorder, and chronic pain conditions like fibromyalgia and neuropathic pain.
Bupropion (Wellbutrin, Zyban)	This pharmaceutical atypical antidepressant works primarily by increasing the levels of norepinephrine and dopamine in the brain. It is used for major depressive disorder, seasonal affective disorder, and as an aid to stop smoking.
Citalopram (Celexa)	This pharmaceutical SSRI selectively blocks the reuptake of serotonin, leading to higher concentrations of serotonin in the brain. It is a commonly prescribed medication for major depressive disorder.
Mirtazapine (Remeron)	This pharmaceutical atypical antidepressant works by blocking certain serotonin and histamine receptors, which leads to increased levels of norepinephrine and serotonin. It is often chosen for its sedative properties and potential to improve sleep and appetite alongside antidepressant effects.
Trazodone (Desyrel)	This pharmaceutical serotonin antagonist and reuptake inhibitor (SARI) primarily works by blocking certain serotonin receptors and weakly inhibiting serotonin reuptake. While also an antidepressant, it is very commonly prescribed off-label for insomnia due to its strong sedative effects.
St. John's Wort	This natural herbal supplement is believed to work by inhibiting the reuptake of several neurotransmitters, including serotonin, norepinephrine, and dopamine, similar to some pharmaceutical antidepressants. It is widely used for mild to moderate depression.
Omega-3 Fatty Acids (Fish Oil, Krill Oil)	These natural essential fatty acids, particularly EPA (eicosapentaenoic acid), are thought to influence brain function by modulating neuroinflammation, neurotransmitter pathways, and cell membrane fluidity. They are often used as a complementary supplement for mood disorders.
S-Adenosylmethionine (SAM-e)	This natural compound, which occurs naturally in the body, is involved in several biochemical processes, including the synthesis of neurotransmitters like serotonin, dopamine, and norepinephrine. It is taken as a dietary supplement for mood support.
5-Hydroxytryptophan (5-HTP)	This natural amino acid is a precursor to serotonin, meaning the body converts it into serotonin. It is used as a dietary supplement with the aim of increasing brain serotonin levels to improve mood.

7 Anxiolytics (Antianxiety Agents)

MEDICATION

6. Central Nervous System Meds

Anxiolytics (Antianxiety Agents)

Anxiolytics are medications primarily used to treat anxiety disorders and related conditions. They work by influencing neurotransmitter activity in the brain to reduce symptoms such as worry, fear, and physical tension. It's important to note that while some medications are specifically called "anxiolytics" (like benzodiazepines and buspirone), many commonly prescribed drugs for anxiety are actually antidepressants or other classes of medication used off-label.

Sertraline (Zoloft)	This pharmaceutical Selective Serotonin Reuptake Inhibitor (SSRI) increases serotonin levels in the brain, helping to regulate mood and reduce anxiety over time. It is a very commonly prescribed antidepressant that is also highly effective for various anxiety disorders.
Escitalopram (Lexapro, Cipralex)	This pharmaceutical SSRI specifically enhances serotonin activity in the brain, which helps to alleviate symptoms of generalized anxiety disorder, panic disorder, and social anxiety disorder. It is widely used for long-term anxiety management.
Alprazolam (Xanax)	This pharmaceutical benzodiazepine enhances the effect of GABA, an inhibitory neurotransmitter in the brain, producing rapid calming and sedative effects. It is widely prescribed for acute anxiety and panic attacks due to its fast action, but typically for short-term use due to addiction potential.
Lorazepam (Ativan)	This pharmaceutical benzodiazepine increases the activity of GABA in the brain, leading to a reduction in anxiety, muscle relaxation, and sedation. It is commonly used for acute anxiety, panic attacks, and preoperative sedation.
Clonazepam (Klonopin)	This pharmaceutical benzodiazepine works by increasing the activity of GABA in the brain, which helps to calm nerve activity and reduce anxiety. It has a longer duration of action compared to some other benzodiazepines, making it suitable for chronic anxiety and panic disorder.
Diazepam (Valium)	This pharmaceutical benzodiazepine enhances the effect of GABA, leading to sedative, anxiolytic, muscle relaxant, and anticonvulsant effects. It is a long-acting benzodiazepine used for anxiety disorders, alcohol withdrawal, and muscle spasms.
Buspirone (BuSpar)	This pharmaceutical non-benzodiazepine anxiolytic works by affecting serotonin and dopamine receptors in the brain, helping to reduce anxiety without causing sedation or dependence commonly associated with benzodiazepines. It is typically used for generalized anxiety disorder and takes longer to show effects.
Hydroxyzine (Vistaril, Atarax)	This pharmaceutical antihistamine has sedative properties that can reduce anxiety by blocking histamine receptors in the brain. It is used for short-term relief of anxiety, often in situations where a non-addictive option is preferred.
Pregabalin (Lyrica)	This pharmaceutical medication reduces abnormal electrical activity in the brain and modulates calcium channels, which contributes to its anxiolytic effects. It is approved for generalized anxiety disorder in some regions and also used for neuropathic pain.
Propranolol (Inderal)	This pharmaceutical beta-blocker primarily blocks the physical symptoms of anxiety, such as a racing heart, sweating, and trembling, by blocking the effects of adrenaline. It is often used for performance anxiety or situational anxiety.
Ashwagandha (Sensoril, KSM-66)	This natural adaptogenic herb is believed to help the body adapt to stress by modulating the stress response system, including cortisol levels. It is widely used as a supplement to reduce anxiety and promote calm.
Valerian Root	This natural herb contains compounds that are thought to increase GABA levels in the brain, promoting relaxation and reducing anxiety. It is commonly used as a natural sleep aid but also for general anxiety.
Chamomile	This natural herb contains apigenin, a flavonoid that binds to benzodiazepine receptors in the brain, leading to mild sedative and anxiolytic effects. Chamomile tea is a widely consumed natural remedy for calming nerves and promoting relaxation.
L-Theanine (Suntheanine)	This natural amino acid, found primarily in green tea, promotes relaxation without drowsiness by increasing alpha brain waves and affecting neurotransmitters like GABA. It is used as a supplement to reduce stress and anxiety.
Kava	This natural root extract from the South Pacific contains kavalactones, which are believed to act on GABA receptors in the brain to produce anxiolytic and sedative effects. Its use is subject to caution due to potential liver toxicity concerns.

8 Hypnotics/Sedatives

Hypnotics and sedatives are medications used to induce sleep (hypnotics) or promote calmness and reduce anxiety (sedatives). Many drugs have both sedative and hypnotic effects, depending on the dosage. Their prescription is carefully managed due to potential for dependence, tolerance, and side effects.

Zolpidem (Ambien)	This pharmaceutical non-benzodiazepine ("Z-drug") acts rapidly on specific GABA receptors in the brain to induce sleep, primarily used for short-term treatment of insomnia. It is one of the most prescribed sleep medications globally.
Temazepam (Restoril)	This pharmaceutical benzodiazepine enhances the effect of GABA, an inhibitory neurotransmitter, leading to sedative and hypnotic effects. It is commonly prescribed for short-term treatment of insomnia, particularly for difficulty staying asleep.
Alprazolam (Xanax)	While primarily an anxiolytic, this pharmaceutical benzodiazepine's strong sedative properties lead to its frequent use for acute insomnia, especially when anxiety is an underlying cause. It quickly enhances GABA's inhibitory effects in the brain.
Lorazepam (Ativan)	This pharmaceutical benzodiazepine enhances GABA activity in the brain, producing sedative effects that aid in sleep induction and maintenance. It is often used in hospital settings for acute insomnia, anxiety, and procedural sedation.
Eszopiclone (Lunesta)	This pharmaceutical non-benzodiazepine ("Z-drug") works by selectively binding to GABA receptors in the brain to promote sleep. It is approved for both short-term and long-term treatment of insomnia.
Clonazepam (Klonopin)	While mainly an anticonvulsant and anxiolytic, this pharmaceutical benzodiazepine's long half-life and sedative effects mean it is often used for chronic insomnia, particularly when associated with anxiety or restless leg syndrome.
Zaleplon (Sonata)	This pharmaceutical non-benzodiazepine ("Z-drug") has a very rapid onset and short duration of action, making it suitable for individuals who have difficulty falling asleep or who wake up in the middle of the night and need to return to sleep quickly. It also works on GABA receptors.
Melatonin (Circadin)	This natural hormone, produced by the pineal gland, regulates the body's sleep-wake cycle (circadian rhythm). It is widely used as a natural or over-the-counter supplement to help with sleep onset, jet lag, and shift work sleep disorder.
Trazodone (Desyrel)	While an antidepressant, this pharmaceutical serotonin antagonist and reuptake inhibitor (SARI) is very commonly prescribed off-label at lower doses for its strong sedative effects to help with insomnia. It primarily works by blocking certain serotonin and histamine receptors.
Diazepam (Valium)	This pharmaceutical long-acting benzodiazepine enhances GABA's inhibitory effects in the brain, providing sustained sedative, anxiolytic, and muscle relaxant properties. It is used for anxiety, alcohol withdrawal, and can aid sleep, especially in cases of agitated insomnia.
Doxepin (low dose) (Silenor)	This pharmaceutical tricyclic antidepressant (TCA) is used at very low doses specifically for insomnia, primarily by blocking histamine H1 receptors, which promotes sleep maintenance.
Valerian Root	This natural herb contains compounds that are believed to increase GABA levels in the brain, promoting relaxation and aiding in sleep. It is one of the most popular herbal remedies for insomnia.
Suvorexant (Belsomra)	This pharmaceutical orexin receptor antagonist works by blocking the wake-promoting signals of orexin neurotransmitters in the brain. It is a newer class of hypnotic specifically designed to help people fall asleep and stay asleep.
Ramelteon (Rozerem)	This pharmaceutical melatonin receptor agonist acts similarly to natural melatonin, targeting specific melatonin receptors in the brain to regulate the sleep-wake cycle. It helps with sleep onset but does not have the risk of dependence associated with benzodiazepines.
Lemborexant (Dayvigo)	This pharmaceutical orexin receptor antagonist also blocks the activity of orexin, a chemical that promotes wakefulness, thereby facilitating sleep onset and maintenance. It is a newer option for insomnia.
Chamomile	This natural herb contains apigenin, a flavonoid that binds to benzodiazepine receptors in the brain, leading to mild sedative effects and promoting relaxation and sleep. Chamomile tea is a widely consumed natural sleep aid.
Lavender	This natural plant is known for its calming aroma, and its essential oil or oral supplements containing silexan are believed to have anxiolytic and mild sedative effects that can promote relaxation and improve sleep quality.
Ashwagandha (Sensoril, KSM-66)	This natural adaptogenic herb is used to help the body manage stress and anxiety, which can often interfere with sleep. While not a direct hypnotic, by reducing stress, it can indirectly improve sleep quality and promote relaxation.

9 Antipsychotics

Antipsychotics are a class of medications primarily used to treat psychotic disorders such as schizophrenia, schizoaffective disorder, and bipolar disorder (especially manic and mixed episodes), as well as certain other conditions like severe agitation and sometimes treatment-resistant depression. They work by affecting neurotransmitters in the brain, primarily dopamine and serotonin.

Quetiapine (Seroquel)	This pharmaceutical atypical antipsychotic balances levels of dopamine and serotonin in the brain, helping to regulate mood, thoughts, and behaviors. It is widely used for schizophrenia, bipolar disorder, and as an add-on for major depressive disorder.
Aripiprazole (Abilify)	This pharmaceutical atypical antipsychotic acts as a partial agonist at dopamine D2 and serotonin 5-HT1A receptors, meaning it can both block and stimulate these receptors depending on the brain's activity. It is used for schizophrenia, bipolar disorder, and as an adjunctive treatment for depression.
Olanzapine (Zyprexa)	This pharmaceutical atypical antipsychotic works by balancing dopamine and serotonin levels in the brain to help manage mood, behaviors, and thoughts. It is commonly prescribed for schizophrenia and bipolar disorder.
Risperidone (Risperdal)	This pharmaceutical atypical antipsychotic blocks receptors for both serotonin and dopamine in the brain, helping to reduce psychotic symptoms. It is widely used for schizophrenia, bipolar disorder, and irritability associated with autism.
Lurasidone (Latuda)	This pharmaceutical atypical antipsychotic affects dopamine and serotonin receptors in the brain to improve mood and reduce psychotic symptoms. It is used for schizophrenia and bipolar depression.
Paliperidone (Invega)	This pharmaceutical atypical antipsychotic is the active metabolite of risperidone and primarily acts as an antagonist at dopamine D2 and serotonin 5-HT2A receptors. It is available in oral and long-acting injectable forms for schizophrenia and schizoaffective disorder.
Haloperidol (Haldol)	This pharmaceutical typical (first-generation) antipsychotic primarily works by blocking dopamine D2 receptors in the brain, effectively reducing positive symptoms of psychosis like hallucinations and delusions. It is a potent and widely used antipsychotic, especially in acute settings.
Ziprasidone (Geodon)	This pharmaceutical atypical antipsychotic blocks dopamine and serotonin receptors and also has some reuptake inhibition effects on serotonin and norepinephrine. It is used for schizophrenia and bipolar disorder, notable for a lower risk of weight gain.
Clozapine (Clozaril)	This pharmaceutical atypical antipsychotic has a complex mechanism, affecting multiple dopamine and serotonin receptors, and is considered highly effective for treatment-resistant schizophrenia. Due to potential serious side effects, its use requires strict monitoring.
Chlorpromazine (Largactil, Thorazine)	This pharmaceutical typical (first-generation) antipsychotic primarily blocks dopamine receptors, helping to control psychotic symptoms. It was one of the first antipsychotics developed and is still used, particularly for its sedative effects.
Lithium (Lithobid, Eskalith)	While primarily known as a mood stabilizer for bipolar disorder, lithium's ability to modulate various neurotransmitter systems can indirectly contribute to stabilizing thought processes and mood swings that may involve psychotic features in bipolar disorder.
Omega-3 Fatty Acids	These natural essential fatty acids, particularly EPA and DHA, are thought to play a role in brain cell membrane function and neurotransmitter modulation. Research suggests they may have a supportive role in reducing the risk or severity of psychotic symptoms, especially in early stages.
Ashwagandha (Sensoril, KSM-66)	This natural adaptogenic herb is believed to modulate stress pathways and neurotransmitter systems, which may indirectly support mental well-being and potentially reduce stress-induced psychotic symptoms, though its direct antipsychotic effect is not established.
Curcumin (from Turmeric)	This natural compound is recognized for its anti-inflammatory and antioxidant properties, which may address some of the inflammatory processes hypothesized in certain psychiatric disorders. Early research suggests it could be an add-on for improving negative and cognitive symptoms in schizophrenia.

10 Antiparkinsonian Agents

Antiparkinsonian agents are medications used to manage the symptoms of Parkinson's disease (PD), a progressive neurodegenerative disorder characterized by a deficit of dopamine in the brain. The goal of treatment is to improve motor symptoms (tremor, rigidity, bradykinesia, postural instability) and non-motor symptoms. These drugs work by increasing dopamine levels, mimicking dopamine's effects, or by affecting other neurotransmitter systems.

Carbidopa/Levodopa (Sinemet, Duopa)	Levodopa is a precursor to dopamine that is converted into dopamine in the brain to replace what is lost in Parkinson's disease, directly addressing motor symptoms. Carbidopa prevents the breakdown of levodopa before it reaches the brain, reducing side effects and increasing effectiveness. This combination is the most effective and widely used treatment for motor symptoms in Parkinson's disease.
Pramipexole (Mirapex)	This pharmaceutical dopamine agonist directly stimulates dopamine receptors in the brain, mimicking the effects of dopamine to improve motor symptoms. It is often used as a first-line treatment or as an add-on therapy, helping with shaking, stiffness, and slow movements.
Ropinirole (Requip)	This pharmaceutical dopamine agonist also directly stimulates dopamine receptors in the brain, helping to reduce the motor symptoms of Parkinson's disease like tremors, rigidity, and slowness of movement. It can be used alone or with levodopa.
Rasagiline (Azilect)	This pharmaceutical MAO-B inhibitor blocks the breakdown of dopamine in the brain, allowing more dopamine to be available to act on receptors. It is used to improve motor symptoms and can be taken as monotherapy in early Parkinson's or as an adjunct to levodopa.
Entacapone (Comtan)	This pharmaceutical COMT inhibitor helps levodopa last longer in the body by preventing its breakdown by the COMT enzyme, allowing more levodopa to reach the brain. It is used as an add-on therapy for patients experiencing "wearing-off" periods with levodopa.
Mucuna Pruriens (Velvet Bean)	This natural plant extract contains naturally occurring levodopa, which acts as a precursor to dopamine in the brain. It has been used traditionally and studied as a natural source of L-dopa to help alleviate Parkinson's symptoms.
Coenzyme Q10 (CoQ10) (Qunol)	This natural antioxidant and essential compound for cellular energy production is believed to support mitochondrial function, which is often impaired in Parkinson's disease. While early studies were mixed, it is widely used as a supplement for overall brain and heart health.
Creatine	This natural compound, involved in cellular energy metabolism, is thought to help improve mitochondrial function and protect neurons. It has been investigated for its potential neuroprotective effects in Parkinson's disease, though clinical trial results have not consistently shown significant symptomatic benefits.

11 CNS Stimulants

Central Nervous System (CNS) stimulants are a class of medications that enhance brain activity, leading to increased alertness, attention, energy, and sometimes elevated mood. They are primarily used to treat Attention-Deficit/Hyperactivity Disorder (ADHD) and narcolepsy, but some are also used for weight management. These medications are carefully controlled due to their potential for abuse and dependence.

Methylphenidate (Ritalin, Concerta)	This pharmaceutical stimulant works by increasing the levels of dopamine and norepinephrine in the brain, improving focus and impulse control. It is one of the most widely prescribed medications for ADHD and narcolepsy.

Amphetamine/Dextroamphetamine Salts (Adderall, Vyvanse)	These pharmaceutical stimulants increase the release of dopamine and norepinephrine in the brain, leading to increased alertness, attention, and energy. They are commonly prescribed for ADHD and narcolepsy.
Caffeine (NoDoz, Vivarin)	This natural stimulant works by blocking adenosine receptors in the brain, reducing feelings of fatigue and increasing alertness. It is the most widely consumed psychoactive substance globally.
Lisdexamfetamine (Vyvanse, Elvanse)	This pharmaceutical prodrug is converted into dextroamphetamine in the body, which then increases dopamine and norepinephrine levels in the brain. It provides a smooth, long-lasting stimulant effect and is widely used for ADHD and binge-eating disorder.
Modafinil (Provigil)	This pharmaceutical wakefulness-promoting agent is thought to affect dopamine, norepinephrine, and histamine systems in the brain to promote alertness and reduce excessive daytime sleepiness. It is used for narcolepsy, sleep apnea, and shift work sleep disorder.
Nicotine (Nicorette, NicoDerm CQ)	This natural alkaloid, primarily consumed through tobacco products or nicotine replacement therapies, acts on nicotinic acetylcholine receptors in the brain, producing stimulating and mood-modulating effects. It is highly addictive.
Armodafinil (Nuvigil)	This pharmaceutical wakefulness-promoting agent is the R-enantiomer of modafinil, having a longer half-life and similar effects in promoting alertness. It is used to treat excessive daytime sleepiness associated with narcolepsy, obstructive sleep apnea, and shift work disorder.
Dextroamphetamine (Dexedrine, Zenzedi)	This pharmaceutical stimulant increases the release of dopamine and norepinephrine in the brain, resulting in increased alertness, improved attention, and reduced impulsivity. It is used for ADHD and narcolepsy.
Coca Leaves	This natural plant, particularly when chewed or brewed as a tea, contains naturally occurring cocaine alkaloids that act as mild stimulants. It is traditionally used in certain cultures to reduce fatigue, hunger, and improve endurance.
Guarana	This natural plant extract contains a high concentration of caffeine, along with other compounds like theobromine and theophylline, providing a sustained stimulating effect. It is a popular ingredient in energy drinks and supplements.
Ephedrine (Bronkaid, Primatene Mist - OTC; Akovaz)	This pharmaceutical sympathomimetic amine stimulates alpha and beta-adrenergic receptors, leading to bronchodilation, vasoconstriction, and CNS stimulation. It is used as a decongestant, for asthma (historically), and occasionally for hypotension.

12 Muscle Relaxants

Muscle relaxants are a class of medications used to treat muscle spasms and muscle spasticity. While both conditions involve muscle stiffness and involuntary contractions, muscle spasms are typically acute and painful (e.g., from injury), while spasticity is a chronic neurological condition (e.g., from multiple sclerosis, cerebral palsy, spinal cord injury).

Cyclobenzaprine (Flexeril)	This centrally acting muscle relaxant works in the brainstem to reduce muscle spasms associated with acute, painful musculoskeletal conditions. It is believed to reduce tonic somatic motor activity, affecting both gamma and alpha motor systems.
Tizanidine (Zanaflex)	This centrally acting alpha-2 adrenergic agonist reduces muscle spasticity by inhibiting the release of excitatory amino acids in the spinal cord. It is effective for spasticity caused by conditions like multiple sclerosis or spinal cord injury.
Carisoprodol (Soma)	This medication is a central nervous system depressant that interrupts neuronal communication within the reticular formation and spinal cord, leading to sedation and alteration in pain perception, thereby providing muscle relaxation. Its primary metabolite, meprobamate, also contributes to its effects.
Methocarbamol (Robaxin)	The exact mechanism of methocarbamol is not fully understood, but it is believed to work by calming overactive nerves in the brain and spinal cord, which helps to relax muscles and alleviate pain and stiffness associated with muscle spasms.
Baclofen (Lioresal)	This medication is a gamma-aminobutyric acid (GABA)-B receptor agonist that works at the spinal cord level to reduce spasticity. It is thought to decrease the release of excitatory neurotransmitters and stimulate inhibitory signals, effectively relaxing muscles.
Diazepam (Valium)	This benzodiazepine enhances the effects of gamma-aminobutyric acid (GABA), an inhibitory neurotransmitter, in the brain and spinal cord. By increasing GABA activity, it helps to calm the central nervous system, leading to muscle relaxation and reduced spasms.

13 Antimigraine Agents

Antimigraine agents are broadly categorized into two main groups: acute (abortive) treatments taken to stop a migraine attack once it starts, and preventive (prophylactic) treatments taken regularly to reduce the frequency, severity, and duration of migraine attacks. Many commonly prescribed medications for migraine fall into established drug classes, but there are also newer, highly targeted therapies.

Sumatriptan (Imitrex, Onzetra, Tosymra)	This pharmaceutical triptan works by stimulating serotonin receptors in the brain, causing constricted blood vessels and blocking pain pathways, which helps to stop a migraine attack. It is the most prescribed triptan for acute migraine relief.
Ibuprofen (Advil, Motrin IB, Nurofen)	This pharmaceutical Non-steroidal Anti-inflammatory Drug (NSAID) reduces the inflammation and pain associated with migraines by inhibiting prostaglandin production. It is a common over-the-counter option for mild to moderate migraine attacks.
Rizatriptan (Maxalt)	This pharmaceutical triptan selectively activates serotonin receptors, leading to constriction of cranial blood vessels and inhibition of pain-signaling pathways. It is used for the acute treatment of migraine headaches with or without aura.
Zolmitriptan (Zomig)	This pharmaceutical triptan works by stimulating serotonin receptors, which constricts blood vessels around the brain and blocks pain signals. It is used for the acute treatment of migraine headaches and is available in oral and nasal spray forms.
Eletriptan (Relpax)	This pharmaceutical triptan activates serotonin receptors to constrict dilated blood vessels in the brain and block pain transmission. It is used for the acute treatment of migraine headaches with or without aura.
Naproxen (Aleve, Naprosyn)	This pharmaceutical NSAID reduces pain and inflammation by inhibiting prostaglandin synthesis, making it effective for mild to moderate migraine attacks or as an adjunct to other migraine treatments.
Topiramate (Topamax)	This pharmaceutical anticonvulsant, while initially developed for epilepsy, works to prevent migraines by stabilizing nerve activity in the brain. It is widely used as a daily preventive medication for chronic and episodic migraines.
Propranolol (Inderal)	This pharmaceutical beta-blocker is primarily used for migraine prevention by blocking the effects of adrenaline, which can help stabilize blood vessels and reduce the frequency of attacks.
Amitriptyline (Elavil, Endep)	This pharmaceutical tricyclic antidepressant is used at low doses to prevent migraines by modulating neurotransmitters like serotonin and norepinephrine in the brain, helping to reduce pain signals and improve sleep.
Aspirin (Acetylsalicylic Acid) (Bayer Aspirin)	This pharmaceutical NSAID, at appropriate doses, can alleviate mild to moderate migraine pain by reducing inflammation and blocking pain pathways. It is often combined with caffeine and acetaminophen for enhanced relief.
Magnesium	This natural mineral is thought to play a role in migraine prevention by stabilizing blood vessels, regulating neurotransmitters, and reducing cortical spreading depression. It is a commonly recommended supplement for migraine prophylaxis.
Caffeine (NoDoz, Vivarin)	This natural stimulant, when used judiciously, can help with acute migraine pain by constricting dilated blood vessels in the brain. It is often combined with other analgesics in over-the-counter migraine remedies.
Coenzyme Q10 (CoQ10)	This natural antioxidant and essential compound for cellular energy production is believed to improve mitochondrial function and reduce oxidative stress, which may contribute to migraine prevention. It is used as a supplement for prophylaxis.
Botulinum Toxin Type A (Botox)	This pharmaceutical neurotoxin works by blocking the release of pain-related neurotransmitters at nerve endings, thereby preventing chronic migraine headaches. It is administered via injections around the head and neck, specifically for chronic migraine (15 or more headache days per month).

MEDICATION
6. Central Nervous System Meds
Antimigraine Agents

Erenumab (Aimovig)	This pharmaceutical Calcitonin Gene-Related Peptide (CGRP) receptor antagonist is a monoclonal antibody that specifically blocks the CGRP receptor, preventing the activation of a key pathway involved in migraine attacks. It is an injectable preventive treatment.
Fremanezumab (Ajovy)	This pharmaceutical CGRP ligand antibody binds to the CGRP molecule itself, preventing it from attaching to its receptor and initiating a migraine attack. It is an injectable preventive treatment for episodic and chronic migraine.
Galcanezumab (Emgality)	This pharmaceutical CGRP ligand antibody also binds to CGRP, preventing it from binding to its receptor and thereby reducing migraine frequency. It is an injectable preventive treatment for migraine and episodic cluster headache.
Ginger (Fresh Ginger, Ginger Root)	This natural root has anti-inflammatory and analgesic properties that can help alleviate migraine pain and associated symptoms like nausea. It is often consumed as a tea or supplement.
Riboflavin (Vitamin B2)	This natural vitamin is involved in cellular energy production, and high doses are sometimes recommended to improve mitochondrial function and potentially reduce migraine frequency.
Rimegepant (Nurtec ODT)	This pharmaceutical calcitonin gene-related peptide (CGRP) receptor antagonist can be used for both acute treatment and preventive treatment of migraine. It works by blocking the CGRP receptor, preventing the pain signals associated with migraine.
Feverfew	This natural herb contains compounds called parthenolides, which are believed to have anti-inflammatory and vasoconstrictive properties that may help prevent migraines or reduce their severity.
Ubrogepant (Ubrelvy)	This pharmaceutical CGRP receptor antagonist is used for the acute treatment of migraine attacks. It blocks the CGRP receptor to alleviate migraine pain and associated symptoms without constricting blood vessels.
Butterbur	This natural herb contains compounds called petasins, which have anti-inflammatory and antispasmodic properties that may help reduce the frequency and severity of migraines.

14 Antidementia Agents

Antidementia Agents

Antidementia agents are medications primarily used to manage the cognitive and sometimes behavioral symptoms of dementia, most commonly Alzheimer's disease. These medications do not cure dementia or stop its progression, but they can temporarily slow the worsening of symptoms or improve quality of life for a period.

Donepezil (Aricept)	This pharmaceutical cholinesterase inhibitor increases levels of acetylcholine, a neurotransmitter important for memory and thinking, by preventing its breakdown in the brain. It is the most commonly prescribed medication for mild to moderate Alzheimer's disease.
Memantine (Namenda, Ebixa)	This pharmaceutical NMDA receptor antagonist works by blocking the activity of glutamate, a neurotransmitter that can be overactive and damage brain cells in Alzheimer's disease. It is used for moderate to severe Alzheimer's disease, often in combination with cholinesterase inhibitors.
Rivastigmine (Exelon)	This pharmaceutical cholinesterase inhibitor boosts acetylcholine levels in the brain by preventing its breakdown, helping to improve memory, thinking, and daily functioning. It is used for mild to moderate Alzheimer's disease and Parkinson's disease dementia, available in oral and transdermal patch forms.
Galantamine (Razadyne, Reminyl)	This pharmaceutical cholinesterase inhibitor increases acetylcholine in the brain and also modulates nicotinic acetylcholine receptors, enhancing nerve communication. It is prescribed for mild to moderate Alzheimer's disease.
Ginkgo Biloba	This natural herb is believed to improve blood flow to the brain and possess antioxidant properties, which may support cognitive function and memory. It is widely used as a dietary supplement for age-related cognitive decline.
Bacopa Monnieri	This natural herb, often called Brahmi, is traditionally used in Ayurvedic medicine as a nootropic, believed to enhance memory, learning, and cognitive processing. It contains compounds called bacosides that have antioxidant and neuroprotective effects.
Lion's Mane Mushroom	This natural mushroom is gaining popularity for its potential neuroprotective properties, believed to stimulate the production of nerve growth factor (NGF), which supports the health and regeneration of neurons. It is used as a supplement to support cognitive function.
Phosphatidylserine (PS)	This natural phospholipid is a crucial component of brain cell membranes and is believed to support neurotransmitter function, cell-to-cell communication, and overall cognitive health. It is used as a supplement to support memory and cognitive function, particularly with age.
Vitamin E	This natural antioxidant may help protect brain cells from damage caused by free radicals, which are implicated in neurodegenerative processes. It is sometimes used as a complementary therapy in dementia, although definitive evidence of its efficacy is still under investigation.
Huperzine A	This natural compound, derived from Chinese club moss, acts as an acetylcholinesterase inhibitor, similar to some pharmaceutical drugs, to increase acetylcholine levels in the brain. It is used as a supplement to support memory and cognitive function.

7 Respiratory Meds

MEDICATION
7. Respiratory Meds

Respiratory system medications are a class of drugs primarily used to manage conditions affecting the lungs and airways, facilitating easier breathing and reducing symptoms like shortness of breath, coughing, and wheezing. This category includes bronchodilators, which work by relaxing the muscles around the airways to open them up (e.g., short-acting and long-acting beta-agonists and anticholinergics), and anti-inflammatory agents like inhaled corticosteroids, which reduce swelling and inflammation in the airways to prevent symptom flare-ups. Additionally, other types of respiratory medications include mucolytics to thin mucus, expectorants to help expel it, decongestants for nasal congestion, and antihistamines for allergic respiratory symptoms.

For infections like bronchitis or pneumonia, antibiotics may also be prescribed. These medications are crucial for managing chronic conditions such as asthma and Chronic Obstructive Pulmonary Disease (COPD), as well as acute respiratory illnesses, often delivered directly to the lungs via inhalers or nebulizers to maximize local effect and minimize systemic side effects.

Subheadings

1. Bronchodilators	**2. Anti-inflammatory**	**3. Antihistamines**	**4. Decongestants**
5. Antitussives	**6. Expectorants**		

1 Bronchodilators

Bronchodilators are medications that relax the muscles around the airways, causing the airways to widen and making it easier to breathe. They are crucial for managing conditions like asthma and chronic obstructive pulmonary disease (COPD). They come in various forms, most commonly inhaled, and can be short-acting (for quick relief) or long-acting (for daily maintenance).

Salbutamol (Albuterol) (Ventolin HFA, ProAir HFA)	This pharmaceutical short-acting beta-2 agonist rapidly relaxes the smooth muscles around the airways, providing quick relief from sudden breathlessness, wheezing, and coughing during an asthma attack or COPD flare-up. It is a widely used "rescue inhaler."

Tiotropium (Spiriva)	This pharmaceutical long-acting anticholinergic bronchodilator blocks the action of acetylcholine, a chemical that can cause airways to constrict, leading to sustained widening of the airways. It is primarily used daily to prevent symptoms in COPD and sometimes asthma.
Formoterol (Foradil, Perforomist)	This pharmaceutical long-acting beta-2 agonist provides prolonged relaxation of airway muscles, helping to keep airways open for an extended period. It is used daily for maintenance treatment in asthma and COPD.
Ipratropium (Atrovent)	This pharmaceutical short-acting anticholinergic bronchodilator blocks acetylcholine in the airways, causing them to relax and widen. It provides quick relief from bronchospasm, particularly in COPD.
Caffeine (NoDoz, Vivarin)	This natural stimulant, a methylxanthine, can cause mild bronchodilation by inhibiting the enzyme phosphodiesterase, which leads to increased levels of cyclic AMP in airway smooth muscle cells. It is widely consumed and has a minor bronchodilatory effect.
Theophylline (Theo-Dur, Theo-24)	This pharmaceutical xanthine derivative relaxes the smooth muscles of the bronchi and also has anti-inflammatory properties, helping to improve airflow. While effective, its narrow therapeutic window and potential for side effects mean it is less commonly used than inhaled bronchodilators.
Epinephrine (Adrenaline) (EpiPen)	This pharmaceutical sympathomimetic agent is a powerful bronchodilator that rapidly relaxes airway smooth muscles by stimulating beta-2 adrenergic receptors. It is primarily used as an emergency treatment for severe allergic reactions (anaphylaxis) due to its quick and strong bronchodilatory and vasoconstrictive effects.
Ginger (Fresh Ginger, Ginger Root)	This natural root contains compounds that may have bronchodilatory and anti-inflammatory effects by modulating intracellular calcium in airway smooth muscle cells. It is often used traditionally to alleviate respiratory symptoms.
Eucalyptus Oil (often in rubs or steam inhalants)	This natural essential oil contains cineole, which has mucolytic and bronchodilatory properties, helping to clear mucus and relax airways. It is commonly used as a decongestant and to ease breathing.
Magnesium	This natural mineral can act as a bronchodilator by blocking calcium channels in airway smooth muscles, leading to relaxation. Intravenous magnesium sulfate is sometimes used in severe acute asthma exacerbations.
Licorice Root	This natural herb has traditionally been used for respiratory conditions, possessing anti-inflammatory and demulcent properties that may help soothe airways and reduce irritation, indirectly supporting bronchodilation.

2 Anti-inflammatory (Respiratory)

Bronchodilators address the airway narrowing, but for chronic respiratory conditions like asthma and COPD, inflammation is a key underlying problem. Respiratory anti-inflammatories are crucial for controlling this inflammation, preventing exacerbations, and improving long-term lung function.

Fluticasone (Flovent, Arnuity Ellipta)	This pharmaceutical inhaled corticosteroid directly reduces inflammation in the airways, making them less swollen and less sensitive to triggers. It is one of the most widely used inhaled corticosteroids for the long-term control of asthma and COPD.
Budesonide (Pulmicort, Rhinocort)	This pharmaceutical inhaled corticosteroid works by reducing inflammation and mucus production in the airways, helping to prevent asthma attacks and improve breathing in COPD. It is a very common daily maintenance treatment.
Montelukast (Singulair)	This pharmaceutical leukotriene receptor antagonist blocks the action of leukotrienes, chemicals that cause inflammation and narrowing of the airways. It is widely used to prevent asthma symptoms, exercise-induced bronchoconstriction, and to relieve symptoms of allergic rhinitis.
Mometasone (Asmanex, Nasonex	This pharmaceutical inhaled corticosteroid reduces inflammation in the airways, making them less reactive and preventing symptoms. It is used for the maintenance treatment of asthma and for nasal allergy symptoms.
Prednisone (Deltasone)	This pharmaceutical oral corticosteroid is a powerful anti-inflammatory that suppresses the immune system's inflammatory response throughout the body. It is used for short bursts to treat severe asthma exacerbations or COPD flare-ups.
Ciclesonide (Alvesco)	This pharmaceutical inhaled corticosteroid reduces inflammation in the lungs by its anti-inflammatory actions. It is used as a maintenance treatment for asthma.
Omalizumab (Xolair)	This pharmaceutical monoclonal antibody targets and blocks immunoglobulin E (IgE), a key component of the allergic inflammatory response. It is an injectable biologic used for severe allergic asthma and chronic hives that are not well controlled by other medications.
Dupilumab (Dupixent)	This pharmaceutical monoclonal antibody blocks the signaling of IL-4 and IL-13, two key cytokines involved in type 2 inflammation. It is an injectable biologic used for severe eosinophilic asthma, atopic dermatitis, and chronic rhinosinusitis with nasal polyps.
Curcumin (from Turmeric)	This natural compound is known for its potent anti-inflammatory and antioxidant properties, acting on multiple molecular targets to suppress inflammatory pathways. It is used as a supplement to support overall inflammatory balance, including respiratory health.
Ginger (Fresh Ginger, Ginger Root)	This natural root contains bioactive compounds like gingerols that possess anti-inflammatory properties, which can help reduce inflammation in the airways. It is often consumed as a traditional remedy for respiratory discomfort.
Quercetin	This natural flavonoid, found in many fruits and vegetables, has strong antioxidant and anti-inflammatory properties. It is believed to stabilize mast cells and inhibit inflammatory pathways, potentially benefiting respiratory conditions.
Vitamin D	This natural vitamin plays a crucial role in immune system modulation and has anti-inflammatory properties by affecting various immune cells and their signaling pathways. Adequate levels are associated with better respiratory health and reduced risk of exacerbations in asthma.
Omega-3 Fatty Acids (Fish Oil/Algae Oil)	These natural essential fatty acids, particularly EPA and DHA, have potent anti-inflammatory effects by modulating the production of inflammatory mediators and resolving inflammation. They are used as supplements to reduce systemic and potentially respiratory inflammation.

3 Antihistamines

Antihistamines are a class of medications that block the action of histamine, a chemical released by the immune system in response to allergens, injuries, or other triggers. Histamine plays a key role in allergic reactions, causing symptoms like itching, sneezing, watery eyes, and runny nose. Antihistamines are primarily used for allergies, but some also have properties that make them useful for insomnia, nausea, and motion sickness.

Antihistamines are generally divided into two main generations:
First-Generation Antihistamines: These are older, often sedating, and have a broader range of effects due to crossing the blood-brain barrier and affecting other receptors (e.g., anticholinergic).
Second-Generation Antihistamines: These are newer, generally less sedating, and more selective for peripheral H1 receptors, leading to fewer central nervous system side effects.
Third-Generation Antihistamines: A non-sedating antihistamine that is derived from second-generation antihistamines, designed to maintain potent antihistaminic effects while further minimizing central nervous system side effects like drowsiness.

Loratadine (Claritin)	This second-generation antihistamine works by selectively blocking histamine H1 receptors, which helps to alleviate common allergy symptoms like sneezing, runny nose, and itchy eyes without causing significant drowsiness. It is widely available over-the-counter.
Cetirizine (Zyrtec)	Another second-generation antihistamine, cetirizine effectively blocks histamine H1 receptors to relieve allergy symptoms such as itching, sneezing, and watery eyes. While generally considered non-drowsy, some individuals may experience mild sedation.
Hydroxyzine (Atarax, Vistaril)	This pharmaceutical first-generation antihistamine is a potent H1 receptor antagonist that produces significant sedative effects in addition to its antihistamine properties. It is commonly prescribed for itchiness, anxiety, and as a short-term sleep aid.
Fexofenadine (Allegra)	This third-generation antihistamine acts by blocking histamine H1 receptors, providing relief from hay fever and hives with a low incidence of drowsiness. It is known for its rapid onset of action and good tolerability profile.

MEDICATION | 7. Respiratory Meds | Antihistamines

Loratadine (Claritin, Alavert)	This pharmaceutical second-generation antihistamine blocks histamine H1 receptors to alleviate allergy symptoms such as sneezing, watery eyes, and runny nose, with minimal drowsiness. It is a popular over-the-counter choice for allergy relief.
Diphenhydramine (Benadryl)	A first-generation antihistamine, diphenhydramine blocks histamine H1 receptors in the brain and body, effectively reducing allergy symptoms like itching and sneezing. It is well-known for causing significant drowsiness, which is also why it's used as a sleep aid.
Levocetirizine (Xyzal)	This is the active isomer of cetirizine, also a third-generation antihistamine that selectively blocks histamine H1 receptors. It provides potent relief from allergy symptoms and hives, often with less drowsiness than its parent compound.
Desloratadine (Clarinex)	As the active metabolite of loratadine, desloratadine also works by blocking peripheral histamine H1 receptors. It offers effective and long-lasting relief from allergic rhinitis and chronic idiopathic urticaria with minimal sedative effects.
Chlorpheniramine (Chlor-Trimeton, ChlorTabs)	This pharmaceutical first-generation antihistamine blocks histamine H1 receptors to reduce allergy symptoms, but it can cause drowsiness and other anticholinergic side effects. It is a common ingredient in many over-the-counter cold and allergy formulations.
Quercetin	This natural flavonoid, found in many fruits and vegetables, has antioxidant and anti-inflammatory properties and is believed to act as a natural antihistamine by inhibiting the release of histamine from mast cells. It is used as a supplement to help with allergy symptoms.
Stinging Nettle	This natural herb is traditionally used to alleviate allergy symptoms, with some research suggesting it may inhibit the production and release of histamine and other inflammatory chemicals. It is commonly consumed as a tea or supplement for hay fever.
Butterbur	This natural herb contains compounds called petasins, which are thought to have anti-inflammatory and antispasmodic effects and may also inhibit histamine release. It has been studied for its effectiveness in treating allergic rhinitis and migraines.
Bromelain	This natural enzyme mixture derived from pineapple has anti-inflammatory properties and may help reduce swelling and mucus associated with allergic reactions by breaking down inflammatory proteins. It is often used as a complementary supplement for sinus congestion and allergies.
Vitamin C	This natural antioxidant vitamin is believed to have antihistamine properties by helping to reduce histamine levels and stabilizing mast cells. It is widely supplemented for immune support and may indirectly help with allergy symptoms.

4 Decongestants

MEDICATION | 7. Respiratory Meds | Decongestants

Decongestants are a class of medications used to relieve nasal congestion (stuffiness) caused by colds, allergies, hay fever, or sinus infections. They work by narrowing the swollen blood vessels in the nasal passages, which reduces swelling and allows for easier breathing. They are available in oral and topical (nasal spray/drops) forms.

Pseudoephedrine (Sudafed)	This oral decongestant works by constricting blood vessels in the nasal passages and sinuses, which reduces swelling and allows for easier breathing. It is a sympathomimetic amine that acts on adrenergic receptors.
Oxymetazoline (Afrin)	This nasal spray is a topical decongestant that directly stimulates alpha-adrenergic receptors in the nasal lining, causing blood vessels to constrict and rapidly reducing swelling and congestion. It provides quick and long-lasting relief but should not be used for more than a few days to avoid rebound congestion.
Phenylephrine (Neo-Synephrine, Sudafed PE)	This pharmaceutical systemic decongestant works by constricting blood vessels in the nasal passages, helping to reduce swelling and congestion. Its oral effectiveness as a decongestant has been questioned in some studies, but it is widely available over-the-counter.
Fluticasone (Nasal) (Flonase, Avamys)	This pharmaceutical nasal corticosteroid reduces inflammation in the nasal passages, which in turn alleviates swelling and congestion, particularly effective for allergic rhinitis. While primarily an anti-inflammatory, its congestion-relieving effect is significant and makes it widely used.
Xylometazoline (Otrivine)	Similar to oxymetazoline, this nasal spray is a topical alpha-adrenergic agonist that causes vasoconstriction in the nasal passages. It quickly reduces swelling and congestion, offering effective relief, but also carries the risk of rebound congestion with prolonged use.
Budesonide (Nasal) (Rhinocort)	This pharmaceutical nasal corticosteroid works by reducing inflammation in the nasal lining, which helps to relieve nasal congestion, runny nose, and sneezing caused by allergies. It is used for daily management of allergic rhinitis.
Saline Nasal Spray/Rinse	These natural saline solutions help to moisturize nasal passages, thin mucus, and wash away irritants and allergens, providing gentle and safe relief from congestion. They are widely used and can be used frequently without side effects.
Steam Inhalation (Vicks VapoSteam)	This natural method involves inhaling warm, moist air, which helps to loosen and thin mucus in the nasal passages and airways, making it easier to clear congestion. It is a popular home remedy for colds and sinus issues.
Eucalyptus Oil	This natural essential oil contains cineole, which has mucolytic properties that help to thin and break up mucus, and can also act on receptors in the nasal lining to reduce the sensation of stuffiness. It is often used in rubs or for steam inhalation.
Menthol (from Peppermint Oil) (Vicks VapoRub)	This natural compound, found in peppermint oil, creates a cooling sensation that can make breathing feel easier by stimulating cold receptors in the nasal passages. It is commonly found in chest rubs and inhalers.
Capsaicin (from Chili Peppers)	This natural compound can irritate mucous membranes, leading to increased mucus flow and a temporary clearing of nasal passages. Consuming spicy foods or using capsaicin-containing nasal sprays can provide a decongestant effect.
Naphazoline	While often associated with eye redness relief, naphazoline is also used as a topical nasal decongestant. It works by causing vasoconstriction in the small blood vessels of the nasal mucosa, reducing swelling and congestion.
Ephedrine (Vicks VapoInhaler)	Though less common as a standalone oral decongestant today due to side effects, ephedrine directly and indirectly stimulates adrenergic receptors, causing vasoconstriction and bronchodilation. It's still found in some combination products and inhalers for temporary nasal congestion relief.
Propylhexedrine (Benzedrex)	This decongestant is used in nasal inhalers and works by constricting blood vessels in the nasal passages, similar to other sympathomimetics. It provides temporary relief from nasal stuffiness due to colds or allergies.
Levmetamfetamine (Vicks VapoInhaler)	This decongestant, found in some inhalers, acts as a sympathomimetic to constrict nasal blood vessels, reducing swelling and congestion. It provides temporary relief from nasal stuffiness.

5 Antitussives

MEDICATION | 7. Respiratory Meds | Antitussives

Antitussives are medications used to suppress or relieve coughs. They are generally used for dry, irritating, non-productive coughs that don't involve mucus, as suppressing a productive cough can hinder the body's natural clearing mechanism. Antitussives work by affecting the cough reflex, either centrally (in the brain) or peripherally (in the airways).

Dextromethorphan (Robitussin, Delsym)	This non-opioid cough suppressant works by acting on the cough center in the brain, thereby elevating the cough threshold and reducing the urge to cough. It is one of the most common active ingredients in over-the-counter cough medicines.
Honey (Manuka Honey)	A natural remedy, honey coats the throat, soothing irritation and reducing cough frequency, particularly in children. It's believed to have a demulcent effect that calms the cough reflex.
Codeine (Tylenol with Codeine)	This opioid analgesic acts on opioid receptors in the brain to suppress the cough reflex. While effective, its use has become more restricted due to concerns about addiction and respiratory depression.
Guaifenesin (Mucinex)	While primarily an expectorant that thins mucus, guaifenesin is often combined with antitussives in cough and cold formulations, sometimes making it seem like a direct cough suppressant. It helps to make coughs more productive by loosening phlegm, indirectly easing irritation.
Benzonatate (Tessalon Perles)	This pharmaceutical non-narcotic cough suppressant works by numbing the stretch receptors in the lungs and airways, reducing the cough reflex. It is a prescription-only medication for cough relief.

Hydrocodone (often with other agents) (Tussicaps, Hycodan)	This pharmaceutical opioid cough suppressant binds to opioid receptors in the brain, raising the cough threshold to provide relief from severe coughing. It is a potent prescription cough medicine.
Menthol (Vicks VapoRub, Halls cough drops)	This natural compound, often derived from peppermint oil, creates a cooling sensation in the throat and nasal passages, which can soothe irritation and temporarily relieve cough. It is commonly found in lozenges, rubs, and inhalants.
Levodropropizine (Levopront, Levotuss)	This non-opioid antitussive works by blocking certain nerve fibers (C-fibers) in the airways that transmit cough signals to the brain. It is used to suppress non-productive (dry) coughs.
Licorice Root	This natural herb has demulcent properties, meaning it can soothe irritated mucous membranes, and may also have mild anti-inflammatory effects that help to calm a cough. It is traditionally used for sore throats and coughs.
Slippery Elm	This natural herb forms a soothing gel when mixed with water, which can coat the throat and digestive tract to relieve irritation and inflammation, thereby helping to suppress a cough. It is used in lozenges and teas.
Marshmallow Root	This natural herb contains mucilage, which forms a protective, soothing layer over irritated mucous membranes in the throat, reducing the urge to cough. It is commonly used in cough syrups and teas.

6 Expectorants/Mucolytics

Expectorants and mucolytics are types of mucoactive agents that help clear mucus from the airways. Expectorants work by increasing the volume or hydration of respiratory secretions, making mucus thinner and easier to cough up. Mucolytics work by breaking down the chemical bonds within mucus, reducing its viscosity (thickness) and making it less sticky. These medications are primarily used for conditions that involve excessive or thick mucus production, such as colds, bronchitis, COPD, cystic fibrosis, and bronchiectasis.

Guaifenesin (Mucinex, Robitussin Chest Congestion)	This pharmaceutical expectorant works by thinning and loosening mucus in the airways, making coughs more productive and helping to clear phlegm from the lungs. It is the most common active ingredient in over-the-counter cough and chest congestion medicines.
Acetylcysteine (NAC) (Mucomyst, Fluimucil)	This pharmaceutical mucolytic breaks down the disulfide bonds in mucus proteins, making mucus thinner and less viscous, thereby easier to clear from the airways. It is used for various respiratory conditions with thick mucus, and also as an antidote for acetaminophen overdose.
Ambroxol (Mucosolvan, Ambrox)	This pharmaceutical mucolytic and expectorant works by thinning and loosening mucus, and also has anti-inflammatory and antioxidant properties that support respiratory health. It is widely used in many parts of the world for acute and chronic respiratory diseases.
Carbocysteine (Mucodyne, Rhinathiol)	This pharmaceutical mucolytic works by breaking down the chemical bonds within mucus, reducing its viscosity and making it easier to cough up. It is commonly used for respiratory conditions involving excessive or thick mucus.
Dornase Alfa (Pulmozyme)	This pharmaceutical mucolytic is a recombinant human deoxyribonuclease I (DNase I) enzyme that breaks down DNA in the thick, purulent secretions found in the lungs of cystic fibrosis patients, significantly reducing mucus viscosity. It is a highly specialized, prescription-only medication for cystic fibrosis.
Hypertonic Saline (Inhaled)	This pharmaceutical/natural solution, when inhaled as a nebulized mist, draws water into the airways through osmosis, thinning mucus and making it easier to clear through coughing. It is commonly used in cystic fibrosis and for bronchiolitis.
Steam Inhalation (Vicks VapoSteam)	This natural method involves inhaling warm, moist air, which helps to hydrate and loosen mucus in the respiratory tract, making it easier to cough up and clear. It is a common and accessible home remedy.
Eucalyptus Oil (often in rubs or steam inhalants)	This natural essential oil contains cineole, which has mucolytic properties that help to thin and break up mucus in the airways, making it easier to expectorate. It is often used for chest rubs or in diffusers.
Licorice Root (often as tea or lozenges)	This natural herb has demulcent properties, meaning it can soothe irritated mucous membranes, and may also have mild expectorant effects by stimulating mucus production. It is traditionally used to alleviate cough and respiratory discomfort.
N-Acetyl L-Cysteine (NAC)	This natural supplement is the precursor to glutathione, a powerful antioxidant, and also has mucolytic properties, helping to break down mucus. It is used to support respiratory health and reduce mucus viscosity.
Bromelain	This natural enzyme mixture derived from pineapple has mucolytic properties, helping to break down mucus and reduce its thickness. It is often used as a dietary supplement for respiratory congestion.

8 Gastrointestinal Meds

Gastrointestinal (GI) system medications are a diverse class of drugs specifically formulated to treat a wide range of conditions affecting the digestive tract, from the esophagus down to the anus, including associated organs like the liver and pancreas. These medications address common complaints such as heartburn, indigestion, nausea, vomiting, constipation, and diarrhea, as well as more complex diseases like ulcers, inflammatory bowel disease (IBD), and irritable bowel syndrome (IBS).

Their mechanisms of action vary widely, encompassing agents that neutralize stomach acid (antacids), reduce acid production (proton pump inhibitors, H2-receptor antagonists), promote or slow bowel movements (laxatives, antidiarrheals), prevent vomiting (antiemetics), reduce spasms (antispasmodics), or even target specific infections like Helicobacter pylori or inflammatory pathways in IBD. By alleviating symptoms, restoring normal digestive function, and treating underlying pathologies, GI medications significantly improve the quality of life for countless individuals worldwide.

Example Ailments

Heartburn	Irritable Bowel Syndrome	Diarrhea	Constipation	Indigestion	Digestive Cramping

Example Medications

Zofran	Imodium	Mylanta	Senna	Tums	

Subheadings

1. Antacids	2. Anti-ulcer Agents	3. Antiemetics	4. Antidiarrheals
5. Laxatives	6. Antispasmodics (GI)	7. Digestive Enzymes	

1 Antacids

Antacids are a class of medications that neutralize stomach acid to provide quick relief from heartburn, indigestion, and upset stomach. They are often available over-the-counter (OTC) and are frequently the first line of defense for occasional symptoms. While some antacids are single-ingredient, many are combination products.

Calcium Carbonate (Tums)	This antacid works by directly neutralizing stomach acid upon contact, converting it into water and carbon dioxide. It provides rapid relief for heartburn and indigestion.

MEDICATION — 8. Gastrointestinal Meds — Antacids

Magnesium Hydroxide (Milk of Magnesia)	This antacid neutralizes stomach acid and also acts as a laxative in higher doses. It is often combined with aluminum hydroxide to balance its potential to cause diarrhea.
Baking Soda	When dissolved in water, this natural substance, chemically sodium bicarbonate, quickly neutralizes excess stomach acid. It offers a readily available home remedy for occasional heartburn.
Aluminum Hydroxide	This antacid neutralizes stomach acid and can also help with diarrhea. It is often combined with magnesium hydroxide to counteract the constipating effect that aluminum can have.
Gaviscon	This antacid contains alginic acid, which forms a foam layer on top of stomach contents, creating a physical barrier to reflux. It also typically contains calcium carbonate or other acid-neutralizing salts.
Ginger (Fresh Root)	This natural root is believed to help with acid reflux by reducing irritation of the digestive tract and potentially reducing inflammation. It can be consumed as tea or added to meals.
Honey	A natural remedy, honey is believed to soothe the irritated esophageal lining due to its viscous consistency and potential anti-inflammatory properties. It can provide a coating effect that helps with heartburn symptoms.
Aloe Vera	This natural plant extract has calming and anti-inflammatory properties that may help soothe irritated tissues in the esophagus and stomach, potentially reducing heartburn symptoms. It is consumed as a juice or syrup.
Chamomile Tea	This natural herbal tea contains compounds with anti-inflammatory properties that may help calm digestive symptoms like upset stomach and heartburn. It is often consumed to reduce stress, which can be a trigger for acid reflux.
Licorice (Deglycyrrhizinated Licorice - DGL)	This natural herb, particularly the DGL form which avoids blood pressure side effects, is believed to help soothe the stomach lining and esophagus by promoting the production of protective mucus. It is used as a supplement for heartburn and indigestion.
Slippery Elm	This natural herb forms a gel-like substance when mixed with water, which can coat and soothe the lining of the esophagus and stomach, providing relief from irritation and heartburn. It is often taken as a powder or lozenge.
Apple Cider Vinegar	While acidic, some people use this natural remedy counterintuitively, believing it can help balance stomach acid levels and aid digestion, thereby reducing heartburn symptoms in some individuals.

2 Anti-ulcer Agents

MEDICATION — 8. Gastrointestinal Meds — Anti-ulcer Agents

Anti-ulcer agents are medications used to treat and prevent peptic ulcers, which are sores that develop on the lining of the stomach, lower esophagus, or small intestine (duodenum). The most common causes are infection with Helicobacter pylori (H. pylori) bacteria and long-term use of nonsteroidal anti-inflammatory drugs (NSAIDs). Treatment strategies focus on reducing stomach acid, protecting the mucosal lining, and eradicating H. pylori if present.

Omeprazole (Prilosec, Losec)	This pharmaceutical Proton Pump Inhibitor (PPI) potently reduces stomach acid production by irreversibly blocking the proton pump in stomach cells. It is one of the most widely prescribed drugs globally for healing and preventing ulcers, and treating GERD.
Pantoprazole (Protonix)	This pharmaceutical PPI also effectively reduces stomach acid secretion by inhibiting the proton pump. It is extensively used for treating and preventing ulcers, as well as managing conditions caused by excessive stomach acid.
Esomeprazole (Nexium)	This pharmaceutical PPI is the S-enantiomer of omeprazole and works by profoundly reducing stomach acid production. It is widely used for healing erosive esophagitis and treating peptic ulcers.
Lansoprazole (Prevacid)	This pharmaceutical PPI inhibits the proton pump in the stomach lining, significantly decreasing acid secretion. It is commonly prescribed for the treatment and maintenance of peptic ulcers and GERD.
Famotidine (Pepcid, Zantac 360)	This pharmaceutical H2-receptor antagonist reduces stomach acid production by blocking histamine receptors on stomach cells. It is a popular over-the-counter and prescription medication for heartburn, indigestion, and for treating ulcers.
Ranitidine (Zantac)	This pharmaceutical H2-receptor antagonist reduces stomach acid by blocking histamine receptors in the stomach. While historically one of the most used, it has been largely withdrawn from the market in many regions due to contamination concerns.
Bismuth Subsalicylate (Pepto-Bismol, Kaopectate)	This pharmaceutical and over-the-counter agent has both antacid properties and antimicrobial effects, helping to protect the ulcer lining and eradicate H. pylori. It also helps with diarrhea and upset stomach.
Sucralfate (Carafate)	This pharmaceutical medication works by forming a protective barrier over ulcer sites in the stomach and duodenum, shielding them from acid, pepsin, and bile, allowing them to heal. It does not reduce stomach acid itself.
Clarithromycin (Biaxin)	This pharmaceutical antibiotic is a key component of eradication regimens for Helicobacter pylori, the primary bacterial cause of peptic ulcers. It works by inhibiting bacterial protein synthesis.
Amoxicillin (Amoxil)	This pharmaceutical penicillin-class antibiotic is another crucial component in multi-drug regimens to eradicate Helicobacter pylori from the stomach. It works by inhibiting bacterial cell wall synthesis.
Metronidazole (Flagyl)	This pharmaceutical antibiotic and antiprotozoal agent is often included in combination therapies to eradicate Helicobacter pylori, especially in cases of clarithromycin resistance. It disrupts bacterial DNA synthesis.
Misoprostol (Cytotec)	This pharmaceutical synthetic prostaglandin E1 analogue helps prevent ulcers, particularly in patients taking NSAIDs, by reducing stomach acid secretion and increasing protective mucus and bicarbonate production. It is also used to induce labor or abortion.
Deglycyrrhizinated Licorice (DGL)	This natural form of licorice is processed to remove glycyrrhizin, which can cause side effects like high blood pressure, and is believed to promote the healing of ulcers by increasing protective mucus production in the stomach and intestine.
Mastic Gum	This natural resin from the mastic tree is thought to have antibacterial properties against Helicobacter pylori and may also protect the stomach lining, contributing to ulcer healing. It is used as a dietary supplement.
Aloe Vera	This natural plant extract has soothing, anti-inflammatory, and healing properties that may help to calm irritation and support the healing of the stomach lining. It is consumed as a juice or gel.
Curcumin (from Turmeric)	This natural compound is known for its strong anti-inflammatory and antioxidant properties, and some research suggests it may help protect the stomach lining and aid in ulcer healing, potentially also having anti-H. pylori effects.
Ginger (Fresh Ginger, Ginger Root)	This natural root is believed to have anti-inflammatory and anti-ulcer properties, potentially by protecting the stomach lining and inhibiting H. pylori growth. It is often consumed as a tea or added to food.

3 Antiemetics

MEDICATION — 8. Gastrointestinal Meds — Antiemetics

Antiemetics are a diverse group of medications used to prevent or treat nausea and vomiting. They work by targeting various neurotransmitter pathways in the brain (like dopamine, serotonin, histamine, acetylcholine, substance P) or in the gut that are involved in the sensation of nausea and the act of vomiting.

Ondansetron (Zofran)	This pharmaceutical serotonin 5-HT3 receptor antagonist blocks serotonin's action in the brain and gut, effectively preventing and treating severe nausea and vomiting, especially from chemotherapy, radiation, or surgery. It is a cornerstone antiemetic in clinical settings.
Metoclopramide (Reglan, Gimoti)	This pharmaceutical dopamine receptor antagonist and prokinetic agent blocks dopamine receptors in the brain, reducing nausea, and also speeds up stomach emptying. It is used for chemotherapy-induced nausea, diabetic gastroparesis, and post-surgical nausea.
Promethazine (Phenergan)	This pharmaceutical first-generation antihistamine has strong antiemetic, sedative, and anticholinergic properties, blocking histamine and dopamine receptors in the brain. It is used to prevent and treat various forms of nausea and vomiting, including motion sickness.

Dimenhydrinate (Dramamine)	This pharmaceutical first-generation antihistamine primarily works by blocking histamine H1 receptors in the brain, particularly those in the vomiting center, making it effective for preventing and treating motion sickness. It also causes drowsiness.
Ginger (Fresh ginger root)	This natural root contains compounds that have anti-inflammatory and anti-spasmodic effects on the gastrointestinal tract, helping to calm stomach upset and reduce nausea. It is widely used for morning sickness, motion sickness, and post-surgical nausea.
Meclizine (Antivert, Bonine, Dramamine Less Drowsy)	This pharmaceutical first-generation antihistamine blocks histamine H1 receptors, particularly in the inner ear and brain, to prevent and treat dizziness, vertigo, and nausea associated with motion sickness. It is less sedating than some other first-generation antihistamines.
Dexamethasone (Decadron)	This pharmaceutical corticosteroid is used as an antiemetic, particularly in chemotherapy-induced nausea and vomiting (CINV) and postoperative nausea and vomiting (PONV), though its exact mechanism for this effect is not fully understood. It is believed to have anti-inflammatory effects and may influence neurotransmitters involved in emesis.
Prochlorperazine (Compazine, Compro)	This pharmaceutical phenothiazine antipsychotic primarily blocks dopamine receptors in the brain's chemoreceptor trigger zone, making it effective for severe nausea and vomiting. It can also be used for certain psychiatric conditions.
Peppermint Tea	This natural herb has a calming effect on the stomach muscles and may reduce nausea through its aromatic compounds. Peppermint aromatherapy or tea can be used for various forms of nausea.
Lemon/Lemon Essential Oil	The aroma of lemon, particularly through essential oil inhalation, is believed to help alleviate nausea, especially in pregnant women, possibly due to its fresh and uplifting scent.

4 Antidiarrheals

Antidiarrheals are medications that help to stop or reduce the frequency and severity of loose, watery stools. They work through various mechanisms, such as slowing down intestinal movement, absorbing excess water, or targeting the underlying cause of the diarrhea (like a bacterial infection).

Loperamide (Imodium)	This synthetic opioid derivative works by slowing down the movement of the intestines, allowing more water to be absorbed from the stool and making it firmer. It acts on opioid receptors in the gut, reducing the frequency and urgency of bowel movements.
Bismuth Subsalicylate (Pepto-Bismol)	This medication has anti-inflammatory, antibacterial, and antacid properties. It works by protecting the stomach and intestinal lining, absorbing toxins, and reducing inflammation to help resolve diarrhea and upset stomach symptoms.
Oral Rehydration Solutions (ORS) (Gastrolyte, Hydralyte)	These pharmaceutical/natural electrolyte and glucose solutions help to replace fluids and salts lost due to diarrhea, preventing dehydration. They are crucial for managing diarrhea, especially in children, and are widely used globally.
Psyllium Husk (Metamucil, Fybogel)	This natural soluble fiber absorbs water in the gut, forming a bulky gel that can help solidify loose stools, making it effective for both diarrhea and constipation. It is a widely used dietary supplement.
Diphenoxylate/Atropine (Lomotil)	This combination medication works by slowing down intestinal motility through the opioid action of diphenoxylate, while a small amount of atropine is added to discourage abuse by causing unpleasant side effects if taken in high doses. It's used for acute and chronic diarrhea.
Kaopectate (Kaolin and Pectin)	This older pharmaceutical/natural combination of adsorbent agents works by absorbing toxins and excess water in the gut, helping to solidify stools. While the formulation has changed, the concept of adsorbent products remains in use.
Honey (Various brands, e.g., Manuka Honey)	A natural remedy, honey is believed to have antibacterial properties and can help soothe the digestive tract, potentially reducing inflammation and severity of diarrhea. Its demulcent effect can also help reduce irritation.
Probiotics (Culturelle, Align, Florastor)	These are beneficial live microorganisms (good bacteria or yeasts) that can help restore a healthy balance of gut flora, which can be disrupted by diarrhea. They may shorten the duration of diarrhea, especially after antibiotic use.
Zinc Supplements (Zinc Sulfate, Zinc Gluconate)	Zinc is an essential micronutrient that plays a crucial role in immune function and gut health. Zinc supplementation has been shown to reduce the duration and severity of diarrhea, particularly in children in developing countries.
Racecadotril (Hidrasec)	This medication reduces the secretion of water and electrolytes into the intestine without affecting intestinal motility. It works by inhibiting enkephalinase, an enzyme that breaks down natural opioids in the gut, thereby reducing excessive fluid loss in diarrhea.
Diosmectite (Smecta)	This natural clay acts as an intestinal adsorbent, meaning it binds to toxins, bacteria, and viruses in the gut, and helps to strengthen the intestinal mucus barrier. It helps reduce fluid loss and improve stool consistency.
Berberine	This natural compound found in several plants is believed to have antimicrobial properties against various gut pathogens and can help reduce intestinal fluid secretion, making it useful for certain types of diarrhea.
Ginger (Fresh Ginger, Ginger Root)	This natural root is traditionally used to calm the digestive system and may help reduce symptoms of diarrhea due to its anti-inflammatory and antispasmodic properties. It can be consumed as tea or in food.
Charcoal (Activated) (CharcoCaps)	This natural adsorbent works by binding to toxins and chemicals in the digestive tract, preventing their absorption and helping to solidify stools. It is used for acute poisoning and sometimes for diarrhea and gas.

5 Laxatives

Laxatives are a diverse group of medications used to treat constipation, a common condition characterized by infrequent bowel movements or difficulty passing stools. They work through various mechanisms to facilitate bowel movements.

Polyethylene Glycol (PEG) (MiraLAX, Movicol)	This osmotic laxative works by drawing water into the intestines, which softens the stool and increases its bulk, making it easier to pass. It is highly effective and generally well-tolerated for chronic constipation.
Senna (Senokot, Ex-Lax)	This natural stimulant laxative contains compounds called sennosides that irritate the bowel lining, causing the intestinal muscles to contract and push stool through. It's often used for short-term relief of constipation.
Bisacodyl (Dulcolax)	This stimulant laxative directly stimulates the nerves in the intestinal wall, increasing muscle contractions that help move stool through the colon. It is available in oral and suppository forms for various constipation needs.
Psyllium Husk (Metamucil)	This natural bulk-forming laxative is a soluble fiber that absorbs water in the gut, forming a gel-like substance that adds bulk to the stool. This makes the stool softer and easier to pass, promoting regular bowel movements.
Bisacodyl (Dulcolax, Correctol)	This pharmaceutical stimulant laxative directly irritates the lining of the intestines, causing the muscles to contract and push stool through the bowel. It is a popular over-the-counter choice for quick relief of occasional constipation.
Docusate Sodium (Colace)	This stool softener works by allowing water and fats to penetrate the stool, making it softer and easier to pass without stimulating bowel movements. It is often used to prevent straining, especially after surgery or childbirth.
Magnesium Hydroxide (Milk of Magnesia)	This osmotic laxative draws water into the intestines, softening the stool and promoting bowel movements. It also acts as an antacid in lower doses and provides relatively quick relief for occasional constipation.
Lactulose (Enulose, Kristalose)	This synthetic sugar is an osmotic laxative that is not absorbed by the body. Instead, it is broken down by bacteria in the colon, drawing water into the intestines to soften stools and stimulate bowel movements.
Sorbitol	This natural sugar alcohol acts as an osmotic laxative, drawing water into the colon to soften stool and promote bowel movements. It is often found in some foods, sugar-free candies, and as a pharmaceutical preparation.
Glycerin Suppositories	This pharmaceutical/natural emollient laxative draws water into the rectum to stimulate a bowel movement. It works by irritating the rectal lining and providing lubrication, leading to rapid evacuation of stool.
Castor Oil	This natural stimulant laxative works by breaking down in the small intestine to release ricinoleic acid, which stimulates intestinal contractions. It is a potent laxative typically used for bowel preparation or severe constipation due to its strong effects.

Linaclotide (Linzess, Constella)	This pharmaceutical guanylate cyclase-C agonist increases intestinal fluid secretion and accelerates transit, primarily used for chronic idiopathic constipation (CIC) and irritable bowel syndrome with constipation (IBS-C). It is a prescription medication.
Mineral Oil	This natural lubricant laxative coats the stool and the intestinal lining, making stools softer and easier to pass. It is typically used for short-term relief of constipation due to potential absorption issues with long-term use.
Prunes (Dried Plums)	A popular natural remedy, prunes contain both fiber and sorbitol, a sugar alcohol that has a mild laxative effect by drawing water into the bowel. They are effective for promoting regularity.

6 Antispasmodics (GI)

Gastrointestinal (GI) antispasmodics are medications specifically designed to relieve muscle spasms and cramping in the digestive tract. These spasms can cause significant pain and discomfort, often associated with conditions like Irritable Bowel Syndrome (IBS), functional dyspepsia, or other abdominal discomforts.

Dicyclomine (Bentyl)	This pharmaceutical anticholinergic medication relaxes the smooth muscles in the stomach and intestines by blocking acetylcholine receptors, reducing painful spasms and cramps. It is a widely prescribed medication for symptoms of Irritable Bowel Syndrome.
Hyoscyamine (Levsin)	This pharmaceutical anticholinergic agent works by blocking the action of acetylcholine, leading to relaxation of the smooth muscles in the gastrointestinal tract and reducing spasms, pain, and cramping. It is commonly used for various functional bowel disorders.
Hyoscine Butylbromide (Buscopan)	This pharmaceutical anticholinergic medication directly relaxes the smooth muscles of the digestive and urinary tracts, providing relief from stomach cramps, bowel cramps, and discomfort. It is widely available over-the-counter or by prescription in many countries for acute GI spasms.
Mebeverine (Colofac)	This pharmaceutical direct smooth muscle relaxant acts on the muscles of the gut to relieve spasms without affecting normal gut motility. It is widely used in many regions, particularly Europe, for the symptomatic treatment of Irritable Bowel Syndrome.
Peppermint Oil (Colpermin, IBgard)	This natural essential oil directly relaxes the smooth muscles of the gastrointestinal tract, which helps to alleviate abdominal pain, bloating, and gas associated with Irritable Bowel Syndrome. It is a well-established natural remedy, often taken in enteric-coated capsules.
Drotaverine (No-Spa)	This pharmaceutical selective phosphodiesterase-4 inhibitor directly relaxes the smooth muscles in the gastrointestinal, urinary, and biliary tracts. It is a very common antispasmodic in Eastern Europe and parts of Asia for various types of visceral spasms.
Alverine Citrate (Spasmonal)	This pharmaceutical smooth muscle relaxant directly acts on the muscles of the bowel to relieve painful spasms and bloating. It is used for the symptomatic treatment of Irritable Bowel Syndrome and diverticular disease in some regions.
Ginger (Fresh ginger root)	This natural root possesses antispasmodic and anti-inflammatory properties that can help to relax the muscles of the digestive tract and calm stomach upset. It is a popular natural remedy for general GI discomfort.
Chamomile (Often as tea)	This natural herb contains compounds that have mild antispasmodic and anti-inflammatory effects, helping to relax the smooth muscles of the digestive system and reduce cramping. It is often consumed as a calming tea for digestive upset.
Fennel (Often as seeds or tea)	This natural plant and its seeds contain compounds that can help relax the smooth muscles of the digestive tract, alleviating gas, bloating, and mild spasms. It is a common traditional remedy for digestive discomfort.

7 Digestive Enzymes

Digestive enzymes are proteins that help break down large food molecules into smaller ones that the body can absorb. They are naturally produced in the salivary glands, stomach, pancreas, and small intestine. When the body doesn't produce enough of these enzymes, it can lead to maldigestion and malabsorption, resulting in symptoms like bloating, gas, abdominal pain, and nutrient deficiencies.

Pancrelipase (Creon)	This pharmaceutical combination of lipase, amylase, and protease replaces the digestive enzymes normally produced by the pancreas. It is highly prescribed for individuals with exocrine pancreatic insufficiency, a condition where the pancreas does not produce enough enzymes to digest food.
Lactase (Lactaid)	This pharmaceutical/natural enzyme breaks down lactose, the sugar found in milk and dairy products, into simpler sugars that can be absorbed. It is widely used over-the-counter by individuals with lactose intolerance to prevent digestive discomfort.
Alpha-galactosidase (Beano)	This natural enzyme breaks down complex carbohydrates found in beans, vegetables, and grains into simpler sugars before they can cause gas and bloating. It is a popular over-the-counter supplement used to prevent digestive discomfort from certain foods.
Bromelain (Derived from pineapple)	This natural enzyme complex helps digest proteins and also possesses anti-inflammatory properties. It is commonly used as a dietary supplement to aid digestion and reduce inflammation.
Papain (Derived from papaya)	This natural enzyme effectively breaks down proteins into smaller peptides and amino acids. It is often included in digestive enzyme blends and is traditionally used to aid digestion.
Amylase (from fungal/plant sources)	This natural enzyme helps to break down carbohydrates and starches into simpler sugars for easier digestion. It is a common component in broad-spectrum digestive enzyme supplements.
Lipase (from fungal/plant sources)	This natural enzyme helps break down fats into fatty acids and glycerol, facilitating their absorption. It is frequently included in comprehensive digestive enzyme supplements to support fat digestion.
Protease (from fungal/plant sources)	This natural enzyme aids in breaking down proteins into amino acids, which are then absorbed by the body. It is a key component of many natural digestive enzyme blends.

9 Endocrine & Metabolic Meds

Endocrine and Metabolic medications are a vital class of drugs that target disorders of the endocrine system, a network of glands that produce and secrete hormones, and disruptions in the body's metabolic processes, which involve converting food into energy and managing waste. These medications are used to correct imbalances where glands produce too much or too little of a specific hormone, or when the body struggles to properly utilize nutrients.

Common examples include antidiabetics like insulin and metformin to manage blood sugar levels, thyroid hormones for an underactive thyroid, antithyroid agents for an overactive thyroid, corticosteroids to address adrenal gland imbalances or suppress inflammation, and bone resorption inhibitors for conditions like osteoporosis. By either replacing deficient hormones, blocking excessive hormone action, or directly influencing metabolic pathways, these medications help to restore homeostasis and ensure the proper functioning of crucial bodily systems, significantly impacting conditions ranging from diabetes and thyroid disorders to growth abnormalities and bone health.

Subheadings

1. Antidiabetics	**2. Thyroid Hormones**	**3. Antithyroid Agents**	**4. Corticosteroids**
5. Hormone Replacements	**6. Bone Resorption**	**7. Growth Hormones**	

1 Antidiabetics

Antidiabetic agents are medications used to manage diabetes mellitus, a chronic condition characterized by high blood glucose (sugar) levels. These drugs work through various mechanisms to lower blood glucose, increase insulin sensitivity, stimulate insulin production, or reduce glucose absorption. The choice of medication depends on the type of diabetes (Type 1 or Type 2), individual patient factors, and treatment goals.

Metformin (Glucophage)	This pharmaceutical medication reduces glucose production by the liver and improves the body's sensitivity to insulin, helping to lower blood sugar levels. It is typically the first-line and most widely prescribed oral medication for type 2 diabetes.
Insulin Glargine (Lantus)	This pharmaceutical long-acting insulin analog provides a steady, peakless insulin level over 24 hours, mimicking the body's basal insulin secretion. It is widely used to control blood sugar levels, especially overnight and between meals, for both type 1 and type 2 diabetes.
Semaglutide (Ozempic, Rybelsus, Wegovy)	This pharmaceutical GLP-1 receptor agonist enhances insulin release, decreases glucagon secretion, and slows gastric emptying, leading to improved blood sugar control and often significant weight loss. Its injectable form (Ozempic/Wegovy) and oral form (Rybelsus) have seen skyrocketing use in recent years.
Empagliflozin (Jardiance)	This pharmaceutical SGLT2 inhibitor works by blocking the reabsorption of glucose in the kidneys, causing more glucose to be excreted in the urine. It also provides significant cardiovascular and renal benefits, making it a highly used drug.
Dulaglutide (Trulicity)	This pharmaceutical GLP-1 receptor agonist is administered once weekly and helps to improve blood sugar control by increasing insulin release, reducing glucagon, and slowing gastric emptying. It is also approved for cardiovascular risk reduction in type 2 diabetes.
Sitagliptin (Januvia)	This pharmaceutical DPP-4 inhibitor increases the levels of incretin hormones, which stimulate the pancreas to produce more insulin when blood sugar is high and reduce the amount of glucose produced by the liver. It is a common oral medication for type 2 diabetes.
Dapagliflozin (Farxiga)	This pharmaceutical SGLT2 inhibitor works similarly to empagliflozin by increasing glucose excretion through the kidneys, leading to lower blood sugar levels. It also offers significant benefits for heart failure and kidney disease, broadening its use.
Liraglutide (Victoza, Saxenda)	This pharmaceutical GLP-1 receptor agonist mimics natural hormones that help regulate blood sugar, increase insulin release, and reduce appetite. It is an injectable medication used for type 2 diabetes and also approved for weight management.
Insulin Aspart (NovoRapid, Fiasp)	This pharmaceutical rapid-acting insulin analog starts working quickly after injection, helping to control blood sugar spikes that occur after meals. It is a common choice for mealtime insulin for both type 1 and type 2 diabetes.
Glimepiride (Amaryl)	This pharmaceutical sulfonylurea stimulates the pancreas to release more insulin, thereby lowering blood sugar levels. It is an older but still commonly used oral medication, particularly in combination therapies.
Pioglitazone (Actos)	This pharmaceutical thiazolidinedione improves insulin sensitivity in muscle and fat tissues, helping the body use insulin more effectively to lower blood glucose. It is used to treat type 2 diabetes, often in patients with insulin resistance.
Canagliflozin (Invokana)	This pharmaceutical SGLT2 inhibitor reduces blood sugar by causing the kidneys to remove more glucose from the body through urine. It also has demonstrated benefits for cardiovascular and kidney health in type 2 diabetes patients.
Gliclazide (Diamicron)	This pharmaceutical sulfonylurea stimulates the pancreas to produce more insulin, helping to lower blood sugar levels. It is a commonly prescribed oral antidiabetic, particularly outside of North America.
Berberine	This natural compound found in several plants is thought to help lower blood sugar by activating an enzyme called AMPK, similar to how metformin works, and by improving insulin sensitivity. It is a popular natural supplement for metabolic health.
Cinnamon	This natural spice is believed by some to improve insulin sensitivity and reduce blood sugar levels, although scientific evidence is mixed and more research is needed. It is often consumed as a dietary supplement.
Bitter Melon	This natural fruit is traditionally used for its purported blood sugar-lowering effects, possibly by acting like insulin or inhibiting enzymes that convert carbohydrates into glucose. It is consumed as food or a supplement in many cultures.

2 Thyroid Hormones

Thyroid hormones are essential for regulating metabolism, growth, and development in nearly every cell of the body. When the thyroid gland doesn't produce enough of these hormones (a condition called hypothyroidism), replacement therapy is necessary. The primary goal of treatment is to restore normal thyroid hormone levels, thereby alleviating symptoms of hypothyroidism.

Levothyroxine (Synthroid)	This pharmaceutical synthetic form of thyroxine (T4) is the most widely prescribed thyroid hormone, acting as a direct replacement for the naturally produced hormone to restore normal thyroid levels. The body converts T4 into the active T3 hormone as needed.
Liothyronine (Cytomel)	This pharmaceutical synthetic form of triiodothyronine (T3) is the active thyroid hormone, directly affecting metabolism and cellular function. It acts more quickly but has a shorter half-life than levothyroxine, and is often used in specific cases or in combination with levothyroxine.
Desiccated Thyroid Extract (DTE) (Armour Thyroid)	This natural thyroid hormone preparation derived from the dried thyroid glands of pigs contains both T4 and T3, as well as other thyroid hormones (T1, T2) and calcitonin, in a natural ratio. It is used as a replacement therapy for hypothyroidism, offering a combination of hormones.
Liotrix (Thyrolar)	This pharmaceutical combination of synthetic levothyroxine (T4) and liothyronine (T3) provides both thyroid hormones in a fixed ratio, typically 4:1 T4 to T3. It is used to replace missing thyroid hormones, aiming to mimic the body's natural production.

3 Antithyroid Agents

Antithyroid agents are medications used to treat hyperthyroidism, a condition where the thyroid gland produces too much thyroid hormone. The goal of these treatments is to reduce the production or effects of thyroid hormones to bring thyroid function back to a normal range.

Methimazole (Tapazole)	This pharmaceutical thionamide drug prevents the thyroid gland from producing excessive thyroid hormones by blocking the incorporation of iodine into thyroid hormone precursors. It is the most commonly used antithyroid drug globally for treating hyperthyroidism.
Propylthiouracil (PTU)	This pharmaceutical thionamide drug inhibits the production of thyroid hormones by blocking the iodination of tyrosine and the coupling of iodotyrosines. It also uniquely inhibits the peripheral conversion of T4 to the more active T3, and is often preferred in specific situations like thyroid storm or early pregnancy.
Radioactive Iodine (I-131) (Iodotope)	This pharmaceutical treatment involves administering a dose of radioactive iodine, which is selectively absorbed by the overactive thyroid cells, leading to their gradual destruction and reduction in hormone production. It is a common and effective definitive treatment for hyperthyroidism
Potassium Iodide (SSKI, Lugol's Solution) (ThyroSafe, Iosat)	This pharmaceutical/natural iodine compound temporarily inhibits the release of thyroid hormones from the gland and blocks the uptake of iodine by the thyroid. It is typically used for short periods, such as before thyroid surgery or in thyroid storm, due to its rapid but transient effect.
Propranolol (Inderal)	This pharmaceutical beta-blocker primarily helps manage the symptoms of hyperthyroidism, such as rapid heart rate, tremors, and anxiety, by blocking the effects of excess thyroid hormones on the body's cardiovascular system. It can also mildly inhibit the conversion of T4 to T3.
Bugleweed	This natural herb is believed to reduce thyroid hormone levels and is traditionally used to alleviate symptoms of hyperthyroidism, such as rapid heartbeat and anxiety. It may influence thyroid hormone synthesis or release.

Lemon Balm	This natural herb is thought to inhibit the binding of thyroid-stimulating hormone (TSH) to its receptors on the thyroid gland and may also reduce the peripheral conversion of T4 to T3. It is used as a traditional remedy to help manage symptoms of an overactive thyroid.
Lithium (Lithobid)	This pharmaceutical medication, primarily used for bipolar disorder, can inhibit the synthesis and release of thyroid hormones from the thyroid gland. It is occasionally used as an antithyroid agent in patients who cannot tolerate conventional thionamides.
Potassium Perchlorate (Rarely used in clinical practice)	This pharmaceutical agent inhibits the uptake of iodide by the thyroid gland, thus preventing the production of thyroid hormones. Its use is rare due to concerns about side effects, particularly aplastic anemia.

4 Corticosteroids (Systemic)

Systemic corticosteroids are powerful anti-inflammatory and immunosuppressive medications that mimic the effects of hormones produced by the adrenal glands (glucocorticoids). They are used to treat a wide range of conditions due to their potent effects on the immune system and inflammation.

Prednisone (Deltasone, Rayos)	This pharmaceutical synthetic corticosteroid is converted to prednisolone in the liver and is a highly effective anti-inflammatory and immunosuppressant, widely used for short-term and long-term treatment of various inflammatory and autoimmune conditions.
Prednisolone (Orapred, Prelone, Pediapred)	This pharmaceutical synthetic corticosteroid directly reduces inflammation and suppresses the immune system throughout the body. It is frequently prescribed for conditions like asthma, allergies, arthritis, and autoimmune diseases.
Methylprednisolone (Medrol, Solu-Medrol)	This pharmaceutical synthetic corticosteroid offers potent anti-inflammatory and immunosuppressive effects with less mineralocorticoid (salt-retaining) activity than some other corticosteroids. It is commonly used for severe allergic reactions, asthma exacerbations, and inflammatory conditions.
Dexamethasone (Decadron, DexPak)	This pharmaceutical synthetic corticosteroid is one of the most potent and long-acting corticosteroids, providing strong anti-inflammatory and immunosuppressive effects. It is used in a wide array of conditions, including severe allergies, certain cancers, and cerebral edema.
Hydrocortisone (Cortef, Solu-Cortef)	This pharmaceutical synthetic corticosteroid is chemically identical to the natural hormone cortisol and is used for hormone replacement therapy in adrenal insufficiency, as well as for its anti-inflammatory and immunosuppressive effects in various conditions.
Cortisol (natural hormone)	This natural glucocorticoid hormone is produced by the adrenal glands in response to stress and regulates numerous bodily processes, including metabolism, immune response, and inflammation. While not a "medication" in itself, synthetic hydrocortisone mimics its action.
Betamethasone (Celestone)	This pharmaceutical synthetic corticosteroid has strong anti-inflammatory and immunosuppressive properties. It is used for various conditions requiring systemic steroid therapy, including severe allergic disorders, skin conditions, and respiratory diseases.

5 Hormone Replacements

Hormone replacement therapies (HRT) are medications used to supplement or replace natural hormones that are deficient in the body. These deficiencies can arise due to various reasons, including natural aging processes (like menopause or andropause) or medical conditions (like hypothyroidism, hypogonadism, or surgical procedures. The method of action involves providing exogenous hormones that bind to specific receptors in target cells, mimicking the effects of the naturally produced hormones.

Levothyroxine (Synthroid)	This pharmaceutical synthetic form of thyroxine (T4) is the most widely prescribed hormone replacement globally, used daily to treat hypothyroidism by replacing the thyroid hormone that the body is not producing sufficiently.
Estradiol (Estrace, Vivelle-Dot)	This pharmaceutical synthetic or bioidentical form of estrogen is commonly used in hormone replacement therapy (HRT) for menopausal symptoms like hot flashes and vaginal dryness, and to prevent bone loss. It is available in various forms including oral tablets, patches, gels, and vaginal preparations.
Conjugated Estrogens (Premarin)	This pharmaceutical blend of estrogens, primarily estrone, is derived from natural sources (pregnant mare urine) and is widely used in HRT to manage menopausal symptoms and prevent osteoporosis. It was historically one of the most prescribed estrogens.
Progesterone (Micronized) (Prometrium)	This pharmaceutical bioidentical form of progesterone is often prescribed alongside estrogen in HRT for women with an intact uterus to protect against endometrial cancer. It is also used to treat irregular menstrual cycles.
Testosterone (AndroGel, Testim, Depo-Testosterone)	This pharmaceutical synthetic or bioidentical androgen is used as replacement therapy for men with low testosterone (hypogonadism) to improve symptoms such as low libido, fatigue, and muscle loss. It is available in gels, injections, and patches.
Desiccated Thyroid Extract (DTE) (Armour Thyroid, NP Thyroid)	This natural thyroid hormone preparation, derived from the dried thyroid glands of pigs, contains both T4 and T3 (and other thyroid compounds) in a natural ratio. It is used by some individuals as an alternative replacement therapy for hypothyroidism.
Somatropin (Growth Hormone) (Genotropin, Humatrope, Norditropin)	This pharmaceutical recombinant human growth hormone is used to treat growth hormone deficiency in children and adults, promoting growth and metabolism. It is administered via injection.
Black Cohosh (Remifemin)	This natural herb is a popular non-hormonal supplement used by women to alleviate menopausal symptoms, particularly hot flashes and night sweats, though its exact mechanism is not fully understood.
Soy Isoflavones	These natural plant compounds, found in soy products, are phytoestrogens that can mimic weak estrogen effects in the body, and are sometimes used to help manage menopausal symptoms like hot flashes.
DHEA (Dehydroepiandrosterone)	This natural steroid hormone, produced by the adrenal glands, is a precursor to other hormones like testosterone and estrogen. It is available as a supplement and is sometimes used for age-related decline or to improve well-being, though its efficacy as a general hormone replacement is debated.

6 Bone Resorption Inhibitors

Bone resorption inhibitors are a class of medications used to prevent bone loss and treat conditions like osteoporosis, Paget's disease of bone, and hypercalcemia of malignancy. They work by slowing down the activity of osteoclasts, the cells responsible for breaking down bone tissue.

Alendronate (Fosamax)	This pharmaceutical bisphosphonate is the most widely prescribed oral medication for osteoporosis, working by slowing down the bone-resorbing activity of osteoclasts, thereby preserving bone mass and reducing fracture risk. It is typically taken once a week.
Risedronate (Actonel)	This pharmaceutical bisphosphonate inhibits osteoclast activity, reducing bone turnover and increasing bone mineral density. It is commonly used for the treatment and prevention of osteoporosis and Paget's disease of bone, often taken weekly or monthly.
Zoledronic Acid (Reclast, Zometa)	This pharmaceutical bisphosphonate is a highly potent inhibitor of bone resorption, effectively suppressing osteoclast activity. It is administered as an annual intravenous infusion for osteoporosis treatment and also used in cancer to manage bone complications.

Denosumab (Prolia)	This pharmaceutical monoclonal antibody inhibits bone resorption by binding to RANKL, a protein essential for the formation, function, and survival of osteoclasts. It is administered as a subcutaneous injection every six months for osteoporosis.
Raloxifene (Evista)	This pharmaceutical Selective Estrogen Receptor Modulator (SERM) mimics estrogen's beneficial effects on bone density, reducing bone resorption and increasing bone mineral density, without stimulating breast or uterine tissue. It is used for the prevention and treatment of osteoporosis in postmenopausal women.
Calcium (Caltrate, Os-Cal)	This natural mineral is the primary building block of bones, and adequate intake is essential to prevent bone breakdown and support bone health. While not a direct inhibitor of bone resorption, sufficient calcium reduces the body's need to resorb bone to maintain blood calcium levels.
Vitamin D	This natural vitamin is crucial for the absorption of calcium from the gut and plays a key role in bone mineralization. Adequate Vitamin D levels are essential for effective bone resorption inhibition and overall bone health.
Calcitonin (Miacalcin)	This pharmaceutical hormone naturally produced by the thyroid gland directly inhibits osteoclast activity, thereby reducing bone resorption and decreasing blood calcium levels. It is used to treat postmenopausal osteoporosis, Paget's disease, and hypercalcemia.
Vitamin K2	This natural vitamin is important for activating osteocalcin, a protein that helps incorporate calcium into bone matrix, thus supporting bone mineralization and potentially reducing bone loss. It is found in certain fermented foods and supplements.
Strontium Ranelate (Protelos)	This pharmaceutical agent has a dual mechanism, both inhibiting bone resorption and promoting bone formation. It is used for severe osteoporosis, particularly in Europe, but its use is restricted due to cardiovascular concerns.

7 Growth Hormones

Growth hormones are peptide hormones that stimulate growth, cell reproduction, and cell regeneration in humans. The primary growth hormone used therapeutically is synthetic human growth hormone (HGH), known generically as somatropin. It is prescribed for various conditions where there is a deficiency of natural growth hormone or other conditions causing growth failure.

Somatropin (Norditropin, Genotropin, Humatrope)	This pharmaceutical recombinant human growth hormone is a synthetic form of the body's natural growth hormone (HGH). It is the most commonly prescribed growth hormone to treat growth hormone deficiency in children and adults, as well as certain other growth-related disorders.
Growth Hormone-Releasing Peptides/Amino Acids	These natural supplements aim to stimulate the body's own production and release of growth hormone. While individual results vary and efficacy is often debated, certain amino acids and blends are widely marketed to support natural HGH levels.
Melatonin	This natural hormone, primarily known for regulating sleep-wake cycles, can indirectly support growth hormone secretion, as much of the body's natural HGH is released during deep sleep. It is a very common sleep aid supplement.
Somatrogon (Ngenla)	This pharmaceutical long-acting recombinant human growth hormone is a newer option designed for once-weekly administration. It works similarly to somatropin to replace deficient growth hormone, offering convenience for patients.
Somapacitan-beco (Sogroya)	This pharmaceutical long-acting human growth hormone analog is another once-weekly injectable option. It aims to reduce injection frequency while effectively treating growth hormone deficiency in both adults and children.
Tesamorelin (Egrifta)	This pharmaceutical synthetic peptide is a growth hormone-releasing hormone (GHRH) analog that stimulates the pituitary gland to produce and release its own growth hormone. It is specifically approved to reduce excess abdominal fat in HIV patients with lipodystrophy.

10 Anti-Infective Agent Meds

Anti-infective agents are a critical class of medications designed to combat a wide range of harmful microorganisms that invade the human body and cause disease. This broad category encompasses several distinct types, each targeting specific classes of pathogens: antibiotics (or antibacterials) are used to kill or inhibit the growth of bacteria; antivirals specifically combat viral infections; antifungals treat fungal infections; and antiparasitics target parasitic infestations, including protozoa and worms. These drugs work through diverse mechanisms, such as disrupting microbial cell walls, inhibiting protein synthesis, interfering with DNA or RNA replication, or damaging cell membranes, all with the goal of eliminating the pathogen while minimizing harm to the host.

The development and effective use of anti-infective agents have revolutionized healthcare by allowing for the treatment and prevention of countless infectious diseases, though the growing challenge of antimicrobial resistance continues to drive the need for new discoveries and responsible prescribing practices globally.

5. Antituberculosis			

1 Antibiotics/Antibacterials

Antibiotics, also known as antibacterials, are medications used to treat bacterial infections. They work by killing bacteria or inhibiting their growth, thereby allowing the body's immune system to clear the infection. Different classes of antibiotics target different essential bacterial processes. It's crucial to use antibiotics appropriately to prevent the development of antibiotic resistance.

Amoxicillin (Amoxil, Trimox)	This penicillin-class antibiotic works by inhibiting the synthesis of bacterial cell walls, leading to the destruction of the bacteria. It's very commonly prescribed for a wide range of bacterial infections, including ear infections, strep throat, and some respiratory tract infections.
Amoxicillin/Clavulanate Potassium (Augmentin)	This combination medication pairs amoxicillin with clavulanate potassium, which is a beta-lactamase inhibitor. Clavulanate protects amoxicillin from degradation by certain bacterial enzymes, extending the antibiotic's effectiveness against resistant strains.
Azithromycin (Zithromax, Z-Pak)	Belonging to the macrolide class, azithromycin works by inhibiting bacterial protein synthesis, thereby stopping bacterial growth. It's often used for respiratory tract infections, skin infections, and certain sexually transmitted infections, and is known for its convenient dosing schedule.
Cephalexin (Keflex)	This first-generation cephalosporin antibiotic works by interfering with the formation of bacterial cell walls, causing the bacteria to rupture and die. It's effective against a broad range of bacteria, particularly gram-positive strains, and commonly used for skin, bone, and urinary tract infections.
Doxycycline (Vibramycin, Doryx)	This tetracycline antibiotic inhibits bacterial protein synthesis, preventing bacteria from growing and multiplying. It's used for a wide variety of bacterial infections, including respiratory, urinary tract, skin infections, and even some sexually transmitted infections, as well as for malaria prevention.
Sulfamethoxazole/Trimethoprim (Bactrim, Septra)	This combination antibiotic works synergistically by interfering with bacterial folic acid synthesis, which is essential for bacterial DNA and protein production. It's effective against a broad spectrum of bacteria and commonly used for urinary tract infections, respiratory tract infections, and certain skin infections.

MEDICATION

10. Anti-Infective Agent Meds

Antibiotics/Antibacterials

Ciprofloxacin (Cipro)	This fluoroquinolone antibiotic works by inhibiting bacterial DNA gyrase and topoisomerase IV, enzymes crucial for bacterial DNA replication and repair. It is a broad-spectrum antibiotic used for various infections, including urinary tract infections, respiratory infections, and some severe hospital-acquired infections.
Metronidazole (Flagyl)	This antibiotic and antiprotozoal medication works by disrupting the DNA of bacteria and parasites, leading to their death. It is highly effective against anaerobic bacterial infections and certain parasitic infections, such as those causing giardiasis or trichomoniasis.
Garlic	A natural agent, garlic contains compounds like allicin which have demonstrated antibacterial properties, potentially disrupting bacterial cell membranes and inhibiting bacterial growth. It has been traditionally used for its medicinal benefits.
Honey	This natural substance possesses antibacterial properties due to its high sugar content, low pH, and the production of hydrogen peroxide. It can help inhibit bacterial growth and soothe infected areas, especially in wound care.
Clindamycin (Cleocin)	This lincosamide antibiotic inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit. It is primarily used for anaerobic infections and certain serious gram-positive bacterial infections, particularly in penicillin-allergic patients.
Ceftriaxone (Rocephin)	This third-generation cephalosporin antibiotic works by interfering with bacterial cell wall synthesis. It is a broad-spectrum injectable antibiotic often used for serious infections, including meningitis, sepsis, and complicated respiratory or urinary tract infections, due to its potent activity and long half-life.
Vancomycin (Vancocin)	This glycopeptide antibiotic inhibits bacterial cell wall synthesis by blocking peptidoglycan polymerization. It is a crucial antibiotic, primarily used to treat severe infections caused by Gram-positive bacteria, especially methicillin-resistant Staphylococcus aureus (MRSA), usually administered intravenously.
Ginger (Fresh Ginger, Ginger Root)	A natural remedy, ginger contains compounds like gingerols and shogaols that exhibit antimicrobial properties. It has been traditionally used to help fight various bacterial and viral infections and soothe digestive issues.

2 Antivirals

Antivirals

Antivirals are medications specifically designed to treat viral infections by interfering with different stages of the viral life cycle. Unlike antibiotics, which target bacteria, antivirals are virus-specific or target common viral processes. The development of antivirals is challenging because viruses replicate inside host cells, making it difficult to target the virus without harming the host cell.

Oseltamivir (Tamiflu)	This pharmaceutical antiviral works by inhibiting the neuraminidase enzyme on the surface of influenza viruses, preventing them from replicating and spreading in the body. It is widely used for the treatment and prevention of influenza (flu) A and B.
Acyclovir (Zovirax)	This pharmaceutical antiviral is a nucleoside analogue that mimics guanosine and works by interfering with viral DNA replication, effectively stopping the spread of herpesviruses. It is commonly used for infections caused by herpes simplex virus (HSV), varicella-zoster virus (VZV, causing chickenpox and shingles), and Epstein-Barr virus.
Valacyclovir (Valtrex)	A prodrug of acyclovir, valacyclovir is converted to acyclovir in the body and works by the same mechanism to inhibit viral DNA replication. It offers improved bioavailability and less frequent dosing compared to acyclovir, making it a popular choice for herpesvirus infections, including genital herpes and shingles.
Nirmatrelvir/Ritonavir (Paxlovid)	This pharmaceutical combination antiviral is used to treat mild to moderate COVID-19 in high-risk patients. Nirmatrelvir inhibits a key SARS-CoV-2 enzyme required for viral replication, while ritonavir "boosts" nirmatrelvir's levels by inhibiting its breakdown in the body.
Sofosbuvir/Ledipasvir (Harvoni)	This pharmaceutical combination is used to treat chronic hepatitis C virus (HCV) infection. Sofosbuvir inhibits the viral RNA polymerase, while ledipasvir inhibits the NS5A protein, both crucial for HCV replication.
Ginger (Fresh Ginger, Ginger Root)	A natural remedy, ginger contains compounds like gingerols and shogaols that exhibit antiviral and anti-inflammatory properties. It is often used to help alleviate symptoms associated with viral infections, such as colds and flu.
Elderberry (Sambucol)	This natural botanical extract is believed to have antiviral properties, particularly against influenza viruses, by preventing viral entry into cells and inhibiting viral replication. It is commonly used to reduce the duration and severity of cold and flu symptoms.
Garlic (Fresh Garlic, Garlic Supplements)	A natural agent, garlic contains compounds like allicin which have demonstrated antiviral properties by potentially interfering with viral replication and boosting immune responses. It has been traditionally used to help fight various infections.
Baloxavir Marboxil (Xofluza)	This pharmaceutical antiviral works by inhibiting the cap-dependent endonuclease activity of the influenza virus, an enzyme essential for viral gene transcription. It offers a single-dose treatment option for influenza.
Favipiravir (Avigan)	This pharmaceutical antiviral is a prodrug that, once metabolized, inhibits RNA-dependent RNA polymerase (RdRp), an enzyme vital for the replication of many RNA viruses, including influenza and some emerging viral infections. It has been used for influenza and investigated for COVID-19.
Ribavirin (Virazole)	This pharmaceutical antiviral is a nucleoside analog that interferes with viral RNA synthesis and replication. It is used in combination with other antivirals for chronic hepatitis C and for severe respiratory syncytial virus (RSV) infections.

3 Antifungals

Antifungals

Antifungal medications are used to treat fungal infections, which can range from superficial skin conditions (like athlete's foot) to serious systemic infections affecting internal organs. They work by targeting specific components or processes unique to fungal cells, such as their cell wall or cell membrane, thereby minimizing harm to human cells.

Fluconazole (Diflucan)	Fluconazole (Diflucan): This pharmaceutical antifungal works by inhibiting an enzyme crucial for fungal cell membrane synthesis, thereby disrupting the fungal cell and stopping its growth. It is widely used to treat various yeast and fungal infections, including vaginal yeast infections, oral thrush, and some systemic fungal infections.
Clotrimazole (Lotrimin, Canesten)	Clotrimazole (Lotrimin, Canesten): This pharmaceutical antifungal works by damaging the fungal cell membrane, leading to leakage of cellular contents and ultimately the death of the fungus. It is a very common topical treatment for skin infections like athlete's foot, jock itch, ringworm, and vaginal yeast infections.
Terbinafine (Lamisil)	This pharmaceutical antifungal interferes with an early step in fungal cell membrane synthesis, leading to the accumulation of toxic substances within the fungal cell and its death. It is highly effective for fungal nail infections (onychomycosis) and various skin fungal infections.
Miconazole (Monistat, Micatin)	This pharmaceutical antifungal works by altering the permeability of the fungal cell membrane, causing essential cellular components to leak out and the fungus to die. It is a common topical agent for skin and vaginal yeast infections.
Nystatin (Mycostatin, Nystop)	This pharmaceutical antifungal binds to sterols in the fungal cell membrane, creating holes that cause the cell to leak and die. It is primarily used to treat Candida (yeast) infections of the skin, mouth (thrush), and intestinal tract.
Tea Tree Oil	This natural essential oil contains compounds that have demonstrated antifungal properties, possibly by altering the permeability of fungal cell membranes. It is commonly used topically for minor fungal skin infections like athlete's foot.
Apple Cider Vinegar (Bragg's)	This natural remedy is believed to have antifungal properties due to its acetic acid content, which can create an acidic environment unfavorable for fungal growth. It is often used diluted for topical application on fungal skin infections.
Garlic	A natural agent, garlic contains allicin and other compounds that exhibit broad-spectrum antimicrobial activity, including antifungal effects, by potentially disrupting fungal cell processes. It is used both internally and topically.

4 Antiparasitics

Antiparasitic medications are a diverse group of drugs used to treat infections caused by parasites. These parasites include protozoa (single-celled organisms like those causing malaria or giardiasis), helminths (worms like tapeworms, roundworms, and flukes), and ectoparasites (external parasites like lice and scabies). The mechanisms of action vary widely depending on the type of parasite and the drug.

Metronidazole (Flagyl)	While also an antibiotic, metronidazole is a very widely used pharmaceutical antiparasitic that disrupts the DNA of certain protozoan parasites (like Giardia, Trichomonas, and Entamoeba histolytica), leading to their death. It's frequently prescribed for intestinal and other parasitic infections.
Ivermectin (Stromectol)	This pharmaceutical antiparasitic paralyzes and kills parasites by binding to chloride ion channels in nerve and muscle cells of the parasite. It is widely used to treat internal parasitic infections like strongyloidiasis and onchocerciasis, as well as external parasites like scabies and lice.
Albendazole (Albenza)	This pharmaceutical broad-spectrum anthelmintic works by inhibiting microtubule formation in intestinal worms, disrupting their glucose uptake and ultimately leading to their death. It is a key medication for treating various soil-transmitted helminth infections (roundworms, hookworms, whipworms) and some tapeworm infections.
Mebendazole (Vermox, Emverm)	Similar to albendazole, mebendazole is a pharmaceutical anthelmintic that selectively inhibits microtubule synthesis in intestinal worms, impairing their glucose absorption. It is very commonly used for pinworm, roundworm, whipworm, and hookworm infections.
Praziquantel (Biltricide)	This pharmaceutical anthelmintic works by increasing the permeability of the parasite's cell membrane to calcium ions, causing severe muscle contractions, paralysis, and detachment of the parasite from the host. It is the drug of choice for treating tapeworm and fluke infections.
Pyrantel Pamoate (Reese's Pinworm Medicine, Pin-X)	This pharmaceutical anthelmintic acts as a neuromuscular blocking agent, paralyzing intestinal worms so they lose their grip on the intestinal wall and are expelled from the body. It is primarily used for pinworm and roundworm infections.
Nitazoxanide (Alinia)	This pharmaceutical antiparasitic is believed to interfere with the energy metabolism of various protozoa and helminths, leading to their demise. It is effective against Giardia lamblia and Cryptosporidium parvum.
Artemisinin	Derived from the sweet wormwood plant, artemisinin and its derivatives are potent natural antimalarial agents. They work by generating free radicals that damage and kill the malaria parasite within red blood cells.
Berberine	This natural alkaloid, found in plants like goldenseal and barberry, exhibits broad-spectrum antimicrobial activity, including antiparasitic effects. It is thought to interfere with parasitic metabolism and attachment.
Wormwood (Artemisia absinthium)	This natural herb has traditionally been used for its anthelmintic properties, containing compounds that may paralyze or kill intestinal worms. It's often used in herbal formulations for parasitic cleanses.
Oil of Oregano	This natural essential oil contains carvacrol and thymol, compounds with potent antimicrobial properties, including activity against certain parasites. It is used in some natural health circles for parasitic infections.
Quinine	This pharmaceutical antimalarial works by interfering with the malaria parasite's ability to detoxify heme, leading to its accumulation and the parasite's death. It is often used for severe or resistant malaria, particularly where other drugs are not effective.
Praziquantel (Biltricide)	This pharmaceutical anthelmintic works by increasing the permeability of the parasite's cell membrane to calcium ions, causing severe muscle contractions, paralysis, and detachment of the parasite from the host. It is the drug of choice for treating tapeworm and fluke infections.
Chloroquine (Aralen)	This pharmaceutical antimalarial works by concentrating in the parasite's food vacuole and inhibiting the polymerization of heme, which is toxic to the parasite. While once a primary treatment, its use is now limited due to widespread drug resistance in many Plasmodium falciparum strains, but it remains effective for certain types of malaria and non-malarial conditions.
Permethrin (Elimite, Nix)	This antiparasitic is a synthetic pyrethroid that acts as a neurotoxin, disrupting the nervous system of parasites like mites (scabies) and lice, leading to their paralysis and death. It is a very common topical treatment.

5 Antituberculosis Agents

Antituberculosis (anti-TB) agents are specific antibiotics used to treat infections caused by Mycobacterium tuberculosis, the bacterium responsible for tuberculosis (TB). TB treatment typically involves a multi-drug regimen for an extended period (months to years) to effectively kill the slow-growing bacteria and prevent the development of drug resistance. Drugs are categorized as first-line (most effective and commonly used) and second-line (used for drug-resistant TB or when first-line drugs cannot be used).

Isoniazid (INH, Laniazid)	This pharmaceutical bactericidal drug is a cornerstone of TB treatment, working by inhibiting the synthesis of mycolic acids, which are essential components of the mycobacterial cell wall. It is used in combination therapy for active TB and as a standalone for latent TB infection.
Rifampicin (Rifampin) (Rifadin)	This pharmaceutical bactericidal antibiotic inhibits bacterial DNA-dependent RNA polymerase, preventing the bacteria from producing proteins essential for survival. It is a vital part of multi-drug regimens for active TB due to its strong sterilizing activity.
Pyrazinamide (Zinamide)	This pharmaceutical drug is bactericidal against Mycobacterium tuberculosis, particularly effective in the acidic environment within macrophages where the bacteria often reside. It is used in the intensive phase of TB treatment to shorten the overall duration of therapy.
Ethambutol (Myambutol)	This pharmaceutical bacteriostatic drug inhibits cell wall synthesis in Mycobacterium tuberculosis, helping to prevent the development of resistance to other antituberculosis drugs and acting as a critical component in multi-drug regimens.
Streptomycin (Generic)	This pharmaceutical aminoglycoside antibiotic inhibits bacterial protein synthesis, leading to cell death. While an older drug, it is still used as a second-line injectable agent for susceptible mycobacterial infections, particularly in drug-resistant TB.
Bedaquiline (Sirturo)	This pharmaceutical diarylquinoline inhibits mycobacterial ATP synthase, an enzyme essential for the bacteria's energy production. It is a newer drug primarily used in combination with other medicines for multi-drug resistant (MDR) and extensively drug-resistant (XDR) tuberculosis.
Garlic	This natural herb contains compounds like allicin which have demonstrated antibacterial properties against Mycobacterium tuberculosis in various studies. It is often considered a traditional remedy and a dietary supplement to support immune health.
Moxifloxacin (Avelox)	This pharmaceutical fluoroquinolone antibiotic inhibits bacterial DNA gyrase and topoisomerase IV, essential enzymes for DNA replication. It is a potent second-line drug used in regimens for drug-resistant tuberculosis.
Delamanid (Deltyba)	This pharmaceutical nitro-dihydro-imidazooxazole derivative inhibits mycolic acid synthesis, thereby preventing the growth of Mycobacterium tuberculosis. It is a newer medication specifically used for active multidrug-resistant tuberculosis.
Pretomanid (Dovprela)	This pharmaceutical nitroimidazole derivative inhibits cell wall synthesis in Mycobacterium tuberculosis through multiple mechanisms. It is typically used as part of a short, all-oral combination regimen with bedaquiline and linezolid for highly drug-resistant TB.
Turmeric (Curcumin)	This natural spice contains curcumin, which has antibacterial, anti-inflammatory, and antioxidant properties. Research suggests it may have the ability to combat Mycobacterium tuberculosis and support the immune system.
Green Tea	This natural beverage contains epigallocatechin gallate (EGCG), a potent catechin with strong antioxidant and antibacterial qualities, including demonstrated activity against Mycobacterium tuberculosis. Regular consumption may inversely correlate with developing active TB.

11 Immune System & Oncology

MEDICATION

11. Immune System & Oncology

Immune System and Oncology medications represent a rapidly evolving and complex class of drugs that uniquely interact with the body's own defense mechanisms, either to suppress an overactive immune response or to harness it to fight cancer. Immune system medications, such as immunosuppressants, are primarily used to dampen the immune system's activity, which is crucial in treating autoimmune diseases (where the body mistakenly attacks its own tissues, like rheumatoid arthritis or lupus) and preventing the rejection of transplanted organs. Conversely, oncology medications, particularly in the realm of immunotherapy, leverage or boost the immune system's ability to recognize and destroy cancer cells, often by removing "brakes" that cancer uses to hide from the immune system or by genetically engineering immune cells to target tumors more effectively.

Beyond immunotherapy, other oncology medications like chemotherapy directly kill rapidly dividing cells, targeted therapies block specific molecular pathways crucial for cancer growth, and hormone therapies interfere with hormone-dependent cancers. This dual focus on modulating immune responses for therapeutic benefit, whether by suppression or activation, underscores the sophisticated strategies employed to treat debilitating autoimmune conditions and a wide spectrum of cancers globally.

Subheadings

		1. Immunosuppressants	2. Immunostimulants	3. Chemo Agents	4. Biologics/Biotechnology		
		5. Vaccines					

1 Immunosuppressants

Immunosuppressants

Immunosuppressants are a class of drugs that suppress or reduce the strength of the body's immune system. They are crucial in two main scenarios: preventing organ rejection after transplantation and treating autoimmune diseases where the immune system mistakenly attacks the body's own tissues. The mechanisms of action vary widely, targeting different components or pathways of the immune response.

Prednisone (Deltasone)	This pharmaceutical oral corticosteroid is a powerful anti-inflammatory and immunosuppressant, widely used for a broad range of conditions from autoimmune diseases and severe allergies to organ transplant prevention of rejection due to its broad-acting immune suppression.
Methotrexate (Trexall, Otrexup)	This pharmaceutical antimetabolite drug inhibits cell proliferation and has significant anti-inflammatory and immunosuppressive effects. It is a cornerstone treatment for various autoimmune conditions like rheumatoid arthritis, psoriasis, and Crohn's disease, and also used in some cancers.
Cyclosporine (Neoral, Gengraf, Sandimmune)	This pharmaceutical calcineurin inhibitor specifically targets T-cells, crucial immune cells, to prevent organ rejection after transplantation by inhibiting their activation. It is also used in severe autoimmune conditions like psoriasis and rheumatoid arthritis.
Tacrolimus (Prograf, Envarsus XR)	This pharmaceutical calcineurin inhibitor is another potent immunosuppressant that works by inhibiting T-lymphocyte activation. It is widely used to prevent organ rejection in transplant recipients and for severe inflammatory skin conditions.
Mycophenolate Mofetil (CellCept)	This pharmaceutical antiproliferative agent inhibits the proliferation of T and B lymphocytes, thus suppressing the immune system. It is commonly used to prevent organ rejection after transplantation and in some autoimmune diseases like lupus.
Azathioprine (Imuran)	This pharmaceutical antimetabolite drug interferes with DNA synthesis, inhibiting the proliferation of rapidly dividing immune cells. It is used in organ transplantation and for a variety of autoimmune diseases such as rheumatoid arthritis, inflammatory bowel disease, and lupus.
Humira (Adalimumab)	This pharmaceutical TNF inhibitor is a biologic medication that targets and blocks Tumor Necrosis Factor-alpha (TNF-a), a protein that plays a key role in inflammatory processes. It is widely used to treat inflammatory conditions such as rheumatoid arthritis, Crohn's disease, and psoriasis.
Turmeric (Curcumin)	This natural spice contains curcumin, which exhibits potent anti-inflammatory and immunomodulatory properties by influencing various signaling pathways and suppressing pro-inflammatory cytokines. It is widely used as a supplement to help manage inflammatory conditions.
Ginger	This natural root contains bioactive compounds like gingerols that possess anti-inflammatory and immunomodulatory effects, helping to reduce inflammation and modulate immune responses. It is consumed as a food, tea, or supplement for various health benefits.
Reishi Mushroom	This natural fungus is known in traditional medicine for its immunomodulatory properties, containing compounds that can influence immune cell activity. While sometimes described as an immune booster, it can also have balancing effects that may be considered immunosuppressive in certain contexts, particularly by moderating immune responses.
Ashwagandha	This natural herb, commonly used in Ayurvedic medicine, is an adaptogen that can modulate the immune system, often balancing immune responses and reducing inflammation, which can be seen as an immunosuppressive effect in hyperactive immune states.
Sirolimus (Rapamune)	This pharmaceutical mTOR inhibitor prevents the proliferation of T-cells and smooth muscle cells, helping to prevent organ rejection after transplantation and used in some rare conditions like Lymphangioleiomyomatosis (LAM).
Everolimus (Zortress, Afinitor)	This pharmaceutical mTOR inhibitor also suppresses the immune system by inhibiting T-cell activation and proliferation, primarily used to prevent organ rejection and for certain types of cancer and non-cancerous tumors.
Anti-thymocyte Globulin (ATG) (Thymoglobulin, Atgam)	This pharmaceutical antibody preparation derived from horses or rabbits targets and depletes T-lymphocytes, leading to profound immunosuppression. It is primarily used for induction therapy in organ transplantation and to treat severe aplastic anemia.

2 Immunostimulants

Immunostimulants

Immunostimulants are substances that stimulate the immune system, either specifically (e.g., vaccines targeting a particular pathogen) or non-specifically (e.g., enhancing the activity of immune cells). They are used in various contexts, including treating immunodeficiencies, certain cancers, and chronic infections, and as adjuvants in vaccines.

Vaccines (Fluarix, Gardasil)	These pharmaceutical preparations contain weakened or inactivated pathogens, or parts of them, that stimulate the immune system to produce antibodies and memory cells without causing disease. They are the most widespread and effective specific immunostimulants for preventing infectious diseases.
Echinacea	This natural herb is a very popular supplement believed to stimulate the immune system, particularly by enhancing the activity of immune cells like macrophages and natural killer cells. It is commonly used to prevent or reduce the severity of common colds and flu.
Colony-Stimulating Factors (CSFs) (Neupogen, Neulasta)	These pharmaceutical glycoproteins stimulate the production and maturation of specific white blood cells (like neutrophils and macrophages) in the bone marrow. They are widely used to boost white blood cell counts in cancer patients undergoing chemotherapy or after bone marrow transplantation.
Interferons (Avonex, Rebif, Pegasys)	These pharmaceutical proteins, naturally produced by immune cells, have antiviral and immunomodulatory effects, activating immune responses against viral infections and certain cancers. They are used to treat conditions like multiple sclerosis, hepatitis C, and some leukemias.
Vitamin C	This natural vitamin is a powerful antioxidant that plays a crucial role in various immune functions, supporting the activity of immune cells and protecting them from damage. It is a widely used dietary supplement for general immune support.
Vitamin D	This natural vitamin is essential for immune system regulation, influencing the function of various immune cells. Adequate levels are linked to a healthier immune response and reduced susceptibility to infections.
Zinc	This natural mineral is vital for immune cell development and function, playing a role in immune signaling and antioxidant defense. It is commonly taken as a supplement to support immune health and may reduce the duration of common colds.

Beta-Glucans (From mushrooms like Reishi, Shiitake, or Oats)	These natural polysaccharides are potent immunomodulators that activate various immune cells, including macrophages and natural killer cells, enhancing the body's defense mechanisms. They are popular in immune support supplements.
Astragalus	This natural herb is traditionally used in Chinese medicine to enhance immune function by potentially increasing white blood cell production and activity. It is often used as an adaptogen and for general immune system support.
Imiquimod (Aldara)	This pharmaceutical topical immune response modifier activates immune cells through Toll-like Receptor 7 (TLR7), leading to the production of interferons and other cytokines. It is used to treat certain skin conditions, including external genital and perianal warts, and some superficial skin cancers.
Sipuleucel-T (Provenge)	This pharmaceutical autologous cellular immunotherapy is a type of cancer vaccine where a patient's own immune cells are collected, activated with a specific prostate cancer antigen, and then reinfused. It stimulates the patient's immune system to target and attack prostate cancer cells.

3 Antineoplastics (Chemotherapy Agents)

Antineoplastics are medications used to treat cancer. They work by targeting and disrupting the growth and division of cancer cells, often by interfering with DNA, RNA, or protein synthesis, or by directly inducing cell death. While highly effective, they often affect healthy rapidly dividing cells, leading to various side effects.

Keytruda (Pembrolizumab)	This pharmaceutical monoclonal antibody is an immune checkpoint inhibitor that blocks the PD-1 protein on immune cells, unleashing the immune system to recognize and attack cancer cells. It is a leading blockbuster drug approved for a wide range of cancers.
Revlimid (Lenalidomide)	This pharmaceutical immunomodulatory drug affects tumor cell proliferation, angiogenesis (new blood vessel formation), and the immune system. It is a top-selling drug primarily used for multiple myeloma, myelodysplastic syndromes, and mantle cell lymphoma.
Opdivo (Nivolumab)	This pharmaceutical monoclonal antibody is an immune checkpoint inhibitor that also targets the PD-1 protein, helping the body's immune system fight various types of cancer. It has transformed treatment for melanoma, lung cancer, and other advanced malignancies.
Imbruvica (Ibrutinib)	This pharmaceutical Bruton's tyrosine kinase (BTK) inhibitor blocks a protein essential for the survival and proliferation of certain cancer cells, particularly in blood cancers. It is a first-line treatment for chronic lymphocytic leukemia (CLL) and other lymphomas.
Darzalex (Daratumumab)	This pharmaceutical monoclonal antibody targets CD38, a protein found on the surface of multiple myeloma cells, leading to their destruction through various immune mechanisms. It is a highly effective treatment for multiple myeloma.
Ibrance (Palbociclib)	This pharmaceutical cyclin-dependent kinase (CDK) 4/6 inhibitor blocks enzymes that promote cancer cell division and growth. It is primarily used in combination with hormone therapy for hormone receptor-positive, HER2-negative breast cancer.
Taxanes (Paclitaxel - Taxol; Docetaxel - Taxotere)	These pharmaceutical chemotherapy agents work by interfering with the microtubule structures essential for cell division, causing cancer cells to stop dividing and eventually die. They are widely used in breast, ovarian, lung, and other cancers.
Platinum-based drugs (Cisplatin - Platinol; Carboplatin - Paraplatin)	These pharmaceutical chemotherapy agents create cross-links in cancer cell DNA, damaging it and preventing the cells from replicating, leading to their death. They are used in a broad spectrum of cancers, including testicular, ovarian, lung, and colorectal cancer.
Antimetabolites (Fluorouracil - 5-FU, Adrucil)	These pharmaceutical chemotherapy agents mimic essential building blocks of DNA and RNA, tricking cancer cells into incorporating them and disrupting their ability to divide and grow. They are used in various cancers, including colorectal, breast, and leukemia.
Vinca Alkaloids (Vincristine - Oncovin; Vinblastine - Velban)	These pharmaceutical chemotherapy agents interfere with microtubule formation, which is crucial for cell division, thereby preventing cancer cells from dividing and causing them to die. They are used in leukemias, lymphomas, and certain solid tumors.
Curcumin (from Turmeric)	This natural compound found in turmeric has demonstrated anti-inflammatory, antioxidant, and potential anticancer properties by modulating various cellular pathways involved in cancer growth, proliferation, and metastasis. It is widely researched as a complementary agent.
Green Tea Extract (EGCG)	This natural extract contains epigallocatechin-3-gallate (EGCG), a catechin with antioxidant and potential anti-tumor effects, influencing various cellular processes relevant to cancer development. It is widely consumed and supplemented for its health benefits.
Resveratrol	This natural compound found in grapes, red wine, and berries, is an antioxidant with anti-inflammatory properties and has shown preclinical evidence of inhibiting cancer cell growth and inducing apoptosis (programmed cell death). It is available as a dietary supplement.
Artemisinin	This natural compound derived from the sweet wormwood plant has shown promise in preclinical studies for its selective toxicity towards cancer cells, particularly when combined with iron, leading to oxidative stress and cell death. Research is ongoing for its potential in cancer treatment.

4 Biologics/Biotechnology Products

Biologics are a class of medications derived from living organisms or their components, such as proteins, sugars, nucleic acids, cells, or tissues. Unlike traditional "small molecule" drugs that are chemically synthesized, biologics are often much larger and more complex molecules. They typically target specific molecular pathways or immune cells, leading to highly targeted therapeutic effects. This specificity often results in fewer widespread side effects compared to traditional broad-acting drugs.

Humira (Adalimumab)	This pharmaceutical monoclonal antibody targets and blocks Tumor Necrosis Factor-alpha (TNF-a), a key inflammatory protein. It is the world's best-selling biologic, widely used for a broad spectrum of autoimmune diseases including rheumatoid arthritis, Crohn's disease, ulcerative colitis, and psoriasis.
Keytruda (Pembrolizumab)	This pharmaceutical monoclonal antibody is an immune checkpoint inhibitor that blocks the PD-1 protein on immune cells, unleashing the immune system to recognize and attack cancer cells. It has become a leading cancer therapy for numerous types of malignancies.
Enbrel (Etanercept)	This pharmaceutical fusion protein acts as a TNF-a inhibitor, binding to TNF-a to reduce inflammation. It is widely prescribed for autoimmune conditions such as rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis.
Stelara (Ustekinumab)	This pharmaceutical monoclonal antibody targets interleukin-12 (IL-12) and interleukin-23 (IL-23), two cytokines involved in inflammatory and immune responses. It is used to treat plaque psoriasis, psoriatic arthritis, Crohn's disease, and ulcerative colitis.
Remicade (Infliximab)	This pharmaceutical chimeric monoclonal antibody also targets TNF-a, neutralizing its inflammatory effects. It is administered intravenously for conditions like Crohn's disease, ulcerative colitis, rheumatoid arthritis, and ankylosing spondylitis.
Dupixent (Dupilumab)	This pharmaceutical monoclonal antibody blocks the signaling of IL-4 and IL-13, two key cytokines involved in type 2 inflammation. It is used to treat atopic dermatitis (eczema), asthma, and chronic rhinosinusitis with nasal polyps.
Insulin (various brands, e.g., Lantus, Humalog, Novolog)	This pharmaceutical/natural protein hormone, produced naturally by the pancreas, regulates blood glucose levels. Pharmaceutical insulin, often produced via biotechnology, is essential for treating diabetes mellitus by allowing cells to absorb glucose for energy.
Rituxan (Rituximab)	This pharmaceutical monoclonal antibody targets the CD20 protein on the surface of B-cells, leading to their destruction. It is used in the treatment of certain lymphomas, leukemias, and autoimmune diseases like rheumatoid arthritis and granulomatosis with polyangiitis.

Curcumin (from Turmeric)	This natural compound is a polyphenol with potent anti-inflammatory and immunomodulatory properties, affecting various cellular signaling pathways. It is widely researched and used as a supplement to influence biological processes related to inflammation and immunity.
Reishi Mushroom (Ganoderma lucidum)	This natural fungus is known in traditional medicine for its immunomodulatory effects, containing bioactive compounds like polysaccharides and triterpenes that can influence various immune cell activities. It is consumed as a supplement for immune support.

5 Vaccines

Vaccines are biological preparations that provide active acquired immunity to a particular infectious disease. They work by introducing a weakened, inactivated, or partial form of a pathogen (or its genetic material) to the immune system. This allows the body to recognize the pathogen's antigens (substances that trigger an immune response) and develop antibodies and memory cells without causing the full-blown illness. If the vaccinated individual is later exposed to the actual pathogen, their immune system can quickly recognize and neutralize it, preventing or mitigating the disease.

Tuberculosis Vaccine (BCG)	This vaccine contains a live, weakened strain of Mycobacterium bovis and is primarily used to prevent severe forms of tuberculosis, especially in infants and young children in high-burden countries. It helps the immune system recognize and fight the bacterium.
Diphtheria, Tetanus, and Pertussis (DTaP/Tdap) Vaccine	This combination vaccine protects against three serious bacterial diseases. The diphtheria and tetanus components are toxoids (inactivated toxins) that train the immune system to neutralize the toxins, while the pertussis component (whooping cough) contains inactivated bacterial parts to prevent infection. It is a cornerstone of childhood immunization and adult boosters.
Polio Vaccine (IPV/OPV)	The inactivated polio vaccine (IPV) contains killed poliovirus to trigger an immune response without causing disease. The oral polio vaccine (OPV) uses weakened live poliovirus to induce immunity in the gut and is crucial for eradicating polio. Both protect against poliomyelitis, a debilitating and potentially fatal disease.
Hepatitis B (HepB) Vaccine	This vaccine contains a purified protein from the surface of the Hepatitis B virus, stimulating the immune system to produce antibodies that protect against infection. It is routinely given to infants to prevent chronic hepatitis B, which can lead to liver cancer and cirrhosis.
Measles, Mumps, and Rubella (MMR) Vaccine	This live-attenuated combination vaccine contains weakened forms of the measles, mumps, and rubella viruses. It stimulates a strong immune response, providing long-lasting protection against these highly contagious viral diseases.
Haemophilus influenzae type b (Hib) Vaccine	This conjugate vaccine contains a purified polysaccharide from the outer capsule of the Hib bacterium linked to a carrier protein. It helps the immune system of infants and young children recognize and fight off Hib, which can cause severe infections like meningitis and pneumonia.
Pneumococcal Conjugate Vaccine (PCV)	This vaccine contains polysaccharides from the outer capsules of several common Streptococcus pneumoniae strains, conjugated to a protein to enhance the immune response. It protects against various pneumococcal diseases, including pneumonia, meningitis, and ear infections, especially in children and older adults.
Rotavirus Vaccine (Rotarix, RotaTeq)	This live-attenuated oral vaccine contains weakened rotavirus strains that replicate in the gut, stimulating an immune response to protect against severe diarrhea and dehydration caused by rotavirus infection in infants.
Influenza (Flu) Vaccine (Fluzone, Afluria, Fluarix)	This vaccine is updated annually and typically contains inactivated or recombinant components of circulating influenza virus strains. It helps the immune system recognize and fight off the flu virus, reducing the risk of severe illness, hospitalization, and death.
Elderberry (Sambucol)	This natural botanical extract is believed to possess antiviral properties that may help to reduce the duration and severity of cold and flu symptoms. It is thought to support immune function.
Vitamin C	While not a vaccine, Vitamin C is a powerful antioxidant that plays a crucial role in immune system function, supporting various cellular functions of both the innate and adaptive immune system. It is commonly taken to boost overall immunity.
Zinc	This essential mineral is vital for immune cell development and function. Adequate zinc levels are important for maintaining a healthy immune response and may help reduce the duration of common colds.

Vaccination Schedules

These are a typical vaccine schedule for a first-world country.

Vaccination Schedule for Persons Birth to 15 Months

Vaccine	Birth	1 mo	2 mos	4 mos	6 mos	9 mos	12 mos	15 mos
Hepatitis B1 (HepB)	1st dose	2nd dose			3rd dose			
Rotavirus2 (RV) RV1 (2-dose series); RV5 (3-dose series)			1st dose	2nd dose	3rd dose			
Diphtheria, tetanus, & acellular pertussis3 (DTaP: <7 yrs)			1st dose	2nd dose	3rd dose			4th dose
Haemophilus influenzae type b4 (Hib)			1st dose	2nd dose	3rd dose		3rd or 4th dose	
Pneumococcal conjugate5 (PCV13)			1st dose	2nd dose	3rd dose		4th dose	
Inactivated poliovirus6 (IPV:<18 yrs)			1st dose	2nd dose	3rd dose			
Influenza7 (IIV)					Annual vaccination (IIV) 1 or 2 doses			
Measles, mumps, rubella8 (MMR)							1st dose	
Varicella9 (VAR)							1st dose	
Hepatitis A10 (HepA)							2 dose series	
Meningococcal11 MenACWY-D ≥9 mos; MenACWY-CRM ≥2 mos)								
Tetanus, diphtheria, & acellular pertussis13 (Tdap: ≥7 yrs)								
Human papillomavirus14 (HPV)								
Meningococcal B12								
Pneumococcal polysaccharide5 (PPSV23)								

Legend				
Meaning	Range of recommended ages for all children	Range of recommended ages for catch-up immunization	Range of recommended ages for certain high-risk groups	No Recommendation

Vaccination Schedule for Persons 18 Months to 18 Years

Vaccine	18 mos	19-23 mos	2-3 yrs	4-6 yrs	7-10 yrs	11-12 yrs	13-15 yrs	16 yrs	17-18 yrs
Hepatitis B1 (HepB)	3rd dose								
Rotavirus2 (RV) RV1 (2-dose series); RV5 (3-dose series)									
Diphtheria, tetanus, & acellular pertussis3 (DTaP: <7 yrs)									
Haemophilus influenzae type b4 (Hib)									
Pneumococcal conjugate5 (PCV13)									
Inactivated poliovirus6 (IPV:<18 yrs)	3rd dose			4th dose					
Influenza7 (IIV)	Annual vaccination (IIV) 1 or 2 doses				Annual vaccination (IIV) 1 dose only				
Measles, mumps, rubella8 (MMR)				2nd dose					

Vaccine									
Varicella9 (VAR)				2nd dose					
Hepatitis A10 (HepA)	2 dose series								
Hepatitis A10 (HepA)									
Meningococcal11 MenACWY-D ≥9 mos; MenACWY-CRM ≥2 mos)						1st dose		2nd dose	
Tetanus, diphtheria, & acellular pertussis13						Tdap			
Human papillomavirus14 (HPV)									
Meningococcal B12									
Pneumococcal polysaccharide5 (PPSV23)									

Legend				
Meaning	Range of recommended ages for all children	Range of recommended ages for catch-up immunization	Range of recommended ages for certain high-risk groups	No Recommendation

Vaccination Schedule for Adults

Vaccine	19-21 years	22-26 years	27-49 years	50-64 years	≥65 years
Influenza	1 dose annually				
Tdap or Td	1 dose Tdap, then Td booster every 10 yrs				
MMR	1 or 2 doses depending on indication (if born in 1957 or later)				
VAR	2 doses				
RZV (preferred)				2 doses RZV (preferred)	
or ZVL					or 1 dose ZVL
HPV-Female	2 or 3 doses depending on age at series initiation				
HPV-Male	2 or 3 doses depending on age at series initiation				
PCV13	1 dose (includes yellow section)				
PPSV23	1 or 2 doses depending on indication				1 dose
HepA	2 or 3 doses depending on vaccine				
HepB	3 doses				
MenACWY	1 or 2 doses depending on indication, then booster every 5 yrs if risk remains				
MenB	2 or 3 doses depending on vaccine				
Hib	1 or 3 doses depending on indication				

Legend			
Meaning	Recommended for adults who meet the age requirement, lack documentation of vaccination, or lack evidence of past infection	Recommended for adults with other indications	No recommendation

12 Musculoskeletal Meds

Musculoskeletal system medications are a diverse group of drugs primarily focused on treating conditions that affect the bones, muscles, joints, ligaments, and tendons, which collectively enable movement and support the body. These medications aim to alleviate symptoms like pain, inflammation, stiffness, and to manage underlying pathologies that can lead to impaired mobility and reduced quality of life.

Common examples include non-steroidal anti-inflammatory drugs (NSAIDs) for pain and inflammation in conditions like arthritis, muscle relaxants for spasms, disease-modifying antirheumatic drugs (DMARDs) and biologics to slow the progression of autoimmune joint diseases such as rheumatoid arthritis, and agents like bisphosphonates to strengthen bones and prevent fractures in osteoporosis. Some medications may also include topical pain relievers, corticosteroid injections directly into joints, or specific treatments for conditions like gout or fibromyalgia, all contributing to improving function and reducing discomfort for individuals worldwide.

Subheadings

1. Anti-inflammatory Drugs	2. Disease-Modifying Antirheumatic Drugs	3. Anti-gout Agents	4. Skeletal Muscle Relaxants

1 Anti-inflammatory Drugs (Non-steroidal)

To reduce inflammation (NSAIDs).

Ibuprofen (Advil, Motrin IB)	This pharmaceutical NSAID is widely used to reduce pain, inflammation, and fever in musculoskeletal conditions by inhibiting prostaglandin production. It is a common first-line treatment for muscle aches, sprains, strains, and various forms of arthritis.
Diclofenac (Voltaren, Cataflam)	This pharmaceutical NSAID is a potent anti-inflammatory that works by inhibiting prostaglandin synthesis, effectively reducing pain and swelling in joints and muscles. It's available in oral, topical (gel, patch), and injectable forms, making it highly versatile for musculoskeletal pain.
Naproxen (Aleve, Naprosyn)	This pharmaceutical NSAID reduces pain and inflammation in musculoskeletal conditions by inhibiting prostaglandin production. Its longer duration of action makes it a preferred choice for chronic conditions like osteoarthritis and back pain, allowing for less frequent dosing.
Celecoxib (Celebrex)	This pharmaceutical NSAID is a selective COX-2 inhibitor, specifically targeting the enzyme involved in inflammation and pain, while aiming to reduce gastrointestinal side effects. It's often prescribed for long-term management of chronic musculoskeletal conditions like osteoarthritis and rheumatoid arthritis.
Meloxicam (Mobic)	This pharmaceutical NSAID preferentially inhibits COX-2, leading to effective anti-inflammatory and pain-relieving effects with a potentially better gastrointestinal safety profile than non-selective NSAIDs. Its once-daily dosing makes it convenient for managing chronic musculoskeletal pain, such as from arthritis.
Curcumin (from Turmeric)	This natural compound found in turmeric possesses strong anti-inflammatory properties by modulating various inflammatory pathways. It is widely used as a supplement to help reduce pain and inflammation associated with joint and muscle conditions like arthritis.

MEDICATION | 12. Musculoskeletal Meds | Anti-inflammatory

Topical Ibuprofen (Nurofen Gel, Advil Gel)	This pharmaceutical NSAID applied directly to the skin provides localized pain and inflammation relief for musculoskeletal injuries like sprains, strains, and localized arthritis. It works by inhibiting prostaglandins at the site of application with potentially fewer systemic side effects than oral NSAIDs.
Ginger	A natural remedy, ginger contains bioactive compounds that exhibit anti-inflammatory effects by inhibiting prostaglandin and leukotriene synthesis. It is commonly used to alleviate musculoskeletal pain and reduce inflammation, particularly in conditions like osteoarthritis and muscle soreness.
Topical Ketoprofen (Ketopron, Fastum Gel)	This pharmaceutical NSAID, applied topically, reduces local pain and inflammation by inhibiting prostaglandin synthesis directly at the affected muscle or joint. It is often used for sprains, strains, and tendonitis.
White Willow Bark	This natural botanical contains salicin, which is converted in the body to salicylic acid, acting as a natural anti-inflammatory and analgesic. It has been traditionally used for musculoskeletal pain, particularly back pain and joint discomfort.

2 Disease-Modifying Antirheumatic Drugs

MEDICATION | 12. Musculoskeletal Meds | Disease-Modifying Antirheumatic Drugs (DMARDs)

Disease-Modifying Antirheumatic Drugs (DMARDs) are a class of medications that slow down the progression of rheumatic diseases, such as rheumatoid arthritis, by targeting specific immune pathways rather than just treating symptoms. They help to prevent joint damage and preserve function.

Methotrexate (Trexall)	This pharmaceutical conventional synthetic DMARD is the most commonly prescribed and often considered the first-line treatment for rheumatoid arthritis and psoriatic arthritis. It works by suppressing parts of the immune system and reducing inflammation.
Adalimumab (Humira)	This pharmaceutical biologic DMARD is a monoclonal antibody that blocks Tumor Necrosis Factor-alpha (TNF-a), a key inflammatory protein. It is widely used for rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, and other autoimmune conditions.
Hydroxychloroquine (Plaquenil)	This pharmaceutical conventional synthetic DMARD is an antimalarial drug that also has immunomodulatory and anti-inflammatory effects. It is commonly used for milder rheumatoid arthritis and systemic lupus erythematosus.
Etanercept (Enbrel)	This pharmaceutical biologic DMARD is a fusion protein that also acts as a TNF-a inhibitor, reducing inflammation and preventing joint damage. It is widely prescribed for rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis.
Infliximab (Remicade)	This pharmaceutical chimeric monoclonal antibody targets TNF-a, neutralizing its inflammatory effects. It is administered intravenously for conditions like rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis, as well as inflammatory bowel diseases.
Sulfasalazine (Azulfidine)	This pharmaceutical conventional synthetic DMARD is an anti-inflammatory and immunomodulatory drug. It is used to treat rheumatoid arthritis, psoriatic arthritis, and inflammatory bowel diseases.
Leflunomide (Arava)	This pharmaceutical conventional synthetic DMARD works by inhibiting the development of certain immune cells, thereby suppressing the immune system and reducing inflammation. It is used to treat moderate to severe rheumatoid arthritis.
Rituximab (Rituxan)	This pharmaceutical biologic DMARD is a monoclonal antibody that targets the CD20 protein on the surface of B-cells, leading to their depletion. It is used for rheumatoid arthritis, especially when other DMARDs have been ineffective, and in certain lymphomas.
Tocilizumab (Actemra)	This pharmaceutical biologic DMARD is a monoclonal antibody that blocks the interleukin-6 (IL-6) receptor, reducing inflammation. It is used for rheumatoid arthritis, systemic juvenile idiopathic arthritis, and giant cell arteritis.
Abatacept (Orencia)	This pharmaceutical biologic DMARD works by selectively modulating a co-stimulatory signal required for T-cell activation, thereby dampening the immune response. It is used for rheumatoid arthritis and psoriatic arthritis.
Tofacitinib (Xeljanz)	This pharmaceutical targeted synthetic DMARD is a Janus kinase (JAK) inhibitor that blocks specific enzymes involved in immune signaling. It is an oral medication used for rheumatoid arthritis, psoriatic arthritis, and ulcerative colitis.
Baricitinib (Olumiant)	This pharmaceutical targeted synthetic DMARD is another JAK inhibitor that blocks immune signaling pathways, reducing inflammation. It is used for moderate to severe rheumatoid arthritis and severe atopic dermatitis.
Upadacitinib (Rinvoq)	This pharmaceutical targeted synthetic DMARD is also a JAK inhibitor, highly selective for JAK1, and is used for rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, and atopic dermatitis.
Curcumin (from Turmeric)	This natural compound is known for its potent anti-inflammatory and immunomodulatory properties by influencing various cellular pathways involved in inflammation. It is widely used as a supplement to help manage arthritis symptoms.
Boswellia Serrata	This natural herb, also known as Indian frankincense, contains boswellic acids that have anti-inflammatory effects by inhibiting enzymes involved in inflammation. It is used as a natural supplement for arthritis and inflammatory conditions.
Ginger (Fresh ginger root)	This natural root contains compounds with anti-inflammatory properties that can help reduce pain and inflammation associated with various forms of arthritis. It is consumed as a food, tea, or supplement.

3 Anti-gout Agents

MEDICATION | 12. Musculoskeletal Meds | Anti-gout Agents

Anti-gout agents are medications and natural substances that target the mechanisms behind gout, a painful form of arthritis caused by the accumulation of uric acid crystals in the joints. They either reduce uric acid levels in the body or manage the inflammation during acute gout attacks.

Allopurinol (Zyloprim)	This pharmaceutical xanthine oxidase inhibitor reduces the production of uric acid in the body, which is crucial for preventing recurrent gout attacks and managing chronic gout. It is the most commonly prescribed long-term medication for gout.
Colchicine (Colcrys)	This pharmaceutical anti-inflammatory agent works by disrupting microtubule formation, which prevents the activation, degranulation, and migration of neutrophils, thereby reducing the inflammatory response to uric acid crystals during an acute gout attack. It is also used at lower doses for gout flare prophylaxis.
Nonsteroidal Anti-inflammatory Drugs (NSAIDs) (Ibuprofen;	These pharmaceutical medications reduce pain and inflammation by inhibiting enzymes involved in the production of inflammatory prostaglandins. They are frequently used to rapidly relieve pain and swelling during acute gout attacks.
Febuxostat (Uloric)	This pharmaceutical non-purine selective xanthine oxidase inhibitor also reduces uric acid production in the body, serving as an alternative to allopurinol for chronic gout management, particularly when allopurinol is not tolerated or effective.
Corticosteroids (Prednisone - Deltasone)	These pharmaceutical powerful anti-inflammatory and immunosuppressive agents quickly reduce the intense pain and inflammation of acute gout attacks. They can be taken orally or injected directly into the affected joint.
Tart Cherry Juice/Cherries	This natural fruit and its juice are rich in anthocyanins and other antioxidants, which are believed to lower serum urate levels and reduce inflammation, thereby potentially reducing the frequency and severity of gout attacks. It is a widely used traditional remedy.
Probenecid (Probalan)	This pharmaceutical uricosuric agent helps the kidneys remove more uric acid from the body by inhibiting its reabsorption in the renal tubules, leading to lower blood uric acid levels. It is used in patients who underexcrete uric acid.
Celery Seed	This natural supplement contains compounds like luteolin and 3-n-butylphthalide, which are believed to have anti-inflammatory and uric acid-lowering properties by inhibiting xanthine oxidase and reducing oxidative stress. It is a traditional remedy for gout.
Ginger (Fresh ginger root)	This natural root possesses anti-inflammatory properties that may help reduce the pain and swelling associated with gout flares. It is also thought to potentially inhibit xanthine oxidase and lower uric acid levels.
Curcumin (from Turmeric)	This natural compound is known for its potent anti-inflammatory and antioxidant effects. Research suggests it may help in gout by inhibiting xanthine oxidase, reducing uric acid production, and alleviating inflammation.
Lesinurad (Zurampic)	This pharmaceutical uricosuric agent selectively inhibits URAT1, a transporter responsible for reabsorbing uric acid in the kidneys, thus increasing its excretion. It was typically used in combination with a xanthine oxidase inhibitor for uncontrolled gout.

Pegloticase (Krystexxa)	This pharmaceutical recombinant uricase enzyme converts uric acid into allantoin, a more soluble and easily excreted substance, rapidly lowering uric acid levels. It is an intravenous medication reserved for severe, chronic refractory gout where other treatments have failed.

4 Skeletal Muscle Relaxants

To alleviate muscle pain and stiffness.

Cyclobenzaprine (Flexeril)	This pharmaceutical centrally acting muscle relaxant works primarily in the brainstem to reduce muscle spasms associated with acute, painful musculoskeletal conditions. It is one of the most commonly prescribed muscle relaxants for short-term use.
Tizanidine (Zanaflex)	This pharmaceutical centrally acting alpha-2 adrenergic agonist reduces muscle spasticity by inhibiting the release of excitatory amino acids in the spinal cord. It is effective for spasticity caused by neurological conditions like multiple sclerosis or spinal cord injury, as well as for acute muscle spasms.
Methocarbamol (Robaxin)	The exact mechanism of this pharmaceutical muscle relaxant is not fully understood, but it is believed to work by calming overactive nerves in the brain and spinal cord, which helps to relax muscles and alleviate pain and stiffness associated with muscle spasms. It's considered to have a relatively mild sedative effect.
Carisoprodol (Soma)	This pharmaceutical central nervous system depressant works by interrupting neuronal communication within the reticular formation and spinal cord, leading to sedation and alteration in pain perception, thereby providing muscle relaxation. Due to its potential for abuse and dependence, its use is more restricted in some regions.
Baclofen (Lioresal)	This pharmaceutical medication is a gamma-aminobutyric acid (GABA)-B receptor agonist that works at the spinal cord level to reduce severe muscle spasticity. It is thought to decrease the release of excitatory neurotransmitters and stimulate inhibitory signals, effectively relaxing muscles in conditions like multiple sclerosis and spinal cord injury.
Diazepam (Valium)	This pharmaceutical benzodiazepine enhances the effects of gamma-aminobutyric acid (GABA), an inhibitory neurotransmitter, in the brain and spinal cord. By increasing GABA activity, it helps to calm the central nervous system, leading to muscle relaxation and reduced spasms, though it also has significant sedative effects.
Magnesium	This natural mineral plays a crucial role in muscle contraction and relaxation by influencing calcium levels and nerve impulse transmission. Magnesium deficiency can contribute to muscle cramps and spasms, and supplementation is commonly used to support muscle function.
Valerian Root	This natural herb contains compounds that are believed to enhance GABA activity in the brain, similar to benzodiazepines, leading to calming and muscle-relaxing effects. It is traditionally used to relieve anxiety, promote sleep, and reduce muscle tension.
Chamomile	This natural herb contains flavonoids and other compounds that have mild sedative and muscle-relaxing properties. It is often consumed as a tea to help calm the nervous system and ease muscle tension and spasms.

13 Urogenital Meds

Urogenital system medications are a specialized category of drugs used to treat a range of conditions affecting both the urinary tract (kidneys, bladder, ureters, urethra) and the reproductive organs. Given the anatomical proximity and shared pathways, especially in males, issues in one system can often impact the other. These medications address diverse problems such as urinary tract infections (UTIs) with antibiotics, overactive bladder and incontinence with anticholinergics or beta-3 agonists that relax bladder muscles, and benign prostatic hyperplasia (BPH) with alpha-blockers or 5-alpha-reductase inhibitors to improve urinary flow.

Additionally, this category includes medications for erectile dysfunction, hormonal therapies related to reproductive health (like contraception or fertility treatments), and agents to manage specific urological pains or kidney stone formation. By targeting various physiological processes in these intertwined systems, urogenital medications aim to restore normal function, alleviate discomfort, and improve the overall quality of life for individuals experiencing these specific health challenges.

Subheadings

1. Urinary Antispasmodics	**2. Prostatic Hyperplasia**	**3. Erectile Dysfunction**	**4. Contraceptives**
5. Urinary Tract Anti-infectives			

1 Urinary Antispasmodics

Urinary antispasmodics are medications and substances used to alleviate spasms of the bladder muscles, which can cause symptoms like urinary urgency, frequency, and incontinence associated with an overactive bladder (OAB) or other bladder irritations. They work by relaxing the bladder muscle, allowing it to hold more urine and reducing the sudden urge to urinate.

Oxybutynin (Ditropan, Ditropan XL)	This pharmaceutical anticholinergic medication works by blocking muscarinic receptors in the bladder muscle, leading to its relaxation and a decrease in bladder spasms, urgency, and frequency. It is one of the oldest and most widely prescribed medications for overactive bladder.
Solifenacin (VESIcare)	This pharmaceutical anticholinergic medication specifically targets muscarinic receptors in the bladder, relaxing the detrusor muscle and increasing bladder capacity to reduce symptoms of overactive bladder. It is a commonly prescribed option for OAB.
Tolterodine (Detrol, Detrol LA)	This pharmaceutical anticholinergic medication also works by blocking muscarinic receptors in the bladder, which helps to relax the bladder muscle and reduce symptoms like urinary urgency, frequency, and urge incontinence. It is widely used for overactive bladder.
Mirabegron (Myrbetriq)	This pharmaceutical beta-3 adrenergic agonist works by activating beta-3 receptors in the bladder, causing the bladder muscle to relax during the filling phase. This increases the bladder's capacity and reduces symptoms of overactive bladder, without the typical anticholinergic side effects.
Trospium (Sanctura, Sanctura XR)	This pharmaceutical anticholinergic medication reduces bladder muscle spasms by blocking muscarinic receptors. Its charged molecular structure means it has less central nervous system penetration, potentially leading to fewer cognitive side effects.
Flavoxate (Urispas)	This pharmaceutical antispasmodic directly acts on the smooth muscles of the urinary tract, helping to relieve spasms, pain, and discomfort associated with bladder irritation or inflammation. It is used for symptomatic relief of bladder conditions.
Pumpkin Seed Extract	This natural extract contains compounds that are believed to strengthen bladder muscles and pelvic floor function, helping to improve bladder control and reduce urinary frequency. It is a popular natural supplement for bladder health.
Gosha-jinki-gan (GJG)	This natural traditional Japanese herbal formula comprises a blend of ten herbs. It is used to improve bladder function and reduce symptoms of overactive bladder and frequent urination, particularly nocturia, through its various active compounds.
Corn Silk (Herbal Terra Corn Silk)	This natural part of the corn plant has traditional uses as a diuretic and anti-inflammatory agent. It is believed to help soothe the urinary tract and may reduce bladder irritation and spasms.

Duloxetine (Cymbalta, Yentreve)	While primarily an antidepressant, this pharmaceutical serotonin-norepinephrine reuptake inhibitor (SNRI) increases the activity of the external urethral sphincter, thereby improving continence. It is specifically approved for the treatment of moderate to severe stress urinary incontinence in some regions.

2 Drugs for Benign Prostatic Hyperplasia (BPH)

Drugs for Benign Prostatic Hyperplasia (BPH) aim to alleviate urinary symptoms caused by an enlarged prostate, such as frequent urination, weak stream, and incomplete bladder emptying. They work by relaxing prostate muscles, shrinking the prostate, or improving overall urinary flow.

Tamsulosin (Flomax)	This pharmaceutical alpha-blocker relaxes the smooth muscles in the prostate and bladder neck, which reduces the obstruction of urine flow and improves urinary symptoms. It is the most commonly prescribed alpha-blocker for BPH.
Finasteride (Proscar)	This pharmaceutical 5-alpha reductase inhibitor blocks the conversion of testosterone to dihydrotestosterone (DHT), a hormone responsible for prostate growth. This leads to a reduction in prostate size over time and can prevent disease progression.
Dutasteride (Avodart)	This pharmaceutical 5-alpha reductase inhibitor is similar to finasteride but blocks both types of the 5-alpha reductase enzyme, leading to a more complete reduction in DHT and a greater potential to shrink the prostate. It is often used for larger prostates or in combination with alpha-blockers.
Tadalafil (Cialis)	This pharmaceutical phosphodiesterase-5 (PDE5) inhibitor, primarily known for erectile dysfunction, also relaxes smooth muscles in the bladder and prostate, helping to improve lower urinary tract symptoms associated with BPH. It is approved for daily use in men with BPH, with or without erectile dysfunction.
Alfuzosin (Uroxatral)	This pharmaceutical alpha-blocker relaxes the muscles in the prostate and bladder neck, making it easier for urine to flow. It is another commonly used alpha-blocker for BPH symptoms, often taken once daily with food.
Silodosin (Rapaflo)	This pharmaceutical alpha-blocker specifically targets the alpha1A-adrenoreceptors in the prostate, bladder, and urethra, relaxing these muscles to improve urine flow and reduce BPH symptoms. It is known for its high selectivity but can cause a reduction in semen volume.
Saw Palmetto (Prostate SR)	This natural extract from the berries of the saw palmetto tree is one of the most common herbal supplements used for BPH. It is believed to work by inhibiting DHT and reducing inflammation, though scientific evidence on its efficacy has been mixed.
Beta-Sitosterol	This natural plant sterol, found in various plants, is thought to improve urinary flow and reduce residual urine volume in men with BPH. It is commonly included in prostate health supplements and is believed to reduce inflammation.
Pygeum Africanum	This natural extract from the bark of the African plum tree has been traditionally used to treat BPH symptoms. It is believed to have anti-inflammatory properties and to affect bladder contractility, helping to relieve urinary issues.
Rye Pollen Extract (Cernilton)	This natural extract from rye grass pollen contains various substances that are believed to help relax the muscles of the urethra and improve bladder emptying. It is used to alleviate symptoms like urinary frequency and urgency.

3 Erectile Dysfunction Agents

Erectile dysfunction (ED) is the inability to achieve or maintain an erection firm enough for satisfactory sexual intercourse. Drugs for ED primarily work by increasing blood flow to the penis, facilitating an erection when sexually stimulated.

Sildenafil (Viagra, Revatio)	This pharmaceutical phosphodiesterase type 5 (PDE5) inhibitor increases blood flow to the penis by relaxing smooth muscles and allowing blood vessels to widen during sexual stimulation. It is the original and most widely recognized oral medication for ED.
Tadalafil (Cialis)	This pharmaceutical PDE5 inhibitor also increases blood flow to the penis but has a longer duration of action, lasting up to 36 hours, earning it the nickname "the weekend pill." It can be taken as needed or in a low daily dose.
Vardenafil (Levitra, Staxyn)	This pharmaceutical PDE5 inhibitor works similarly to sildenafil and tadalafil by increasing blood flow to the penis during sexual arousal. It has a quicker onset of action than sildenafil for some individuals.
L-Arginine	This natural amino acid is a precursor to nitric oxide, a molecule that helps relax blood vessels and increase blood flow to the penis, which is essential for an erection. It is commonly taken as a dietary supplement.
Panax Ginseng (Often as Korean Red Ginseng)	This natural herb is believed to enhance nitric oxide synthesis and may affect central nervous system activity, potentially improving erectile function and libido. It is a widely used traditional remedy.
Avanafil (Stendra)	This pharmaceutical newer PDE5 inhibitor works by selectively blocking PDE5 to increase blood flow to the penis. It is known for its rapid onset of action and potentially fewer side effects compared to older PDE5 inhibitors.
Yohimbe (Derived from bark)	This natural supplement acts as an alpha-2 adrenergic receptor antagonist, which may increase norepinephrine release and blood flow to the penis. However, its use is associated with potential side effects and safety concerns.
Horny Goat Weed	This natural herb contains icariin, which is thought to inhibit PDE5, similar to pharmaceutical ED drugs, thereby increasing blood flow to the penis. While popular, human studies on its efficacy are limited.

4 Contraceptives

Contraceptives are methods used to prevent pregnancy, working through various mechanisms such as blocking sperm from reaching an egg, preventing ovulation, or altering the uterine environment. They can be hormonal, non-hormonal, or behavioral.

Male Condom (Durex, Trojan)	This natural barrier method is a thin sheath worn over the penis that physically prevents sperm from entering the vagina. It is widely accessible, inexpensive, and also provides protection against sexually transmitted infections (STIs).
Combined Oral Contraceptive Pill (Yasmin, Levlen)	This pharmaceutical hormonal method contains both estrogen and progestin, working primarily by preventing ovulation, thickening cervical mucus to block sperm, and thinning the uterine lining. It is one of the most popular and effective forms of reversible birth control.
Progestin-Only Pill (Microlut, Noriday)	This pharmaceutical hormonal method contains only progestin, primarily working by thickening cervical mucus to block sperm and sometimes by suppressing ovulation. It is an option for women who cannot use estrogen, such as those breastfeeding.
Intrauterine Device (IUD) - Hormonal (Mirena, Kyleena)	This pharmaceutical long-acting reversible contraceptive (LARC) is a small, T-shaped device inserted into the uterus that releases progestin, which thickens cervical mucus, thins the uterine lining, and may suppress ovulation. It can provide contraception for several years.
Intrauterine Device (IUD) - Copper (Paragard, Copper T)	This natural/non-hormonal LARC is a small, T-shaped device inserted into the uterus that releases copper ions, which create an inflammatory reaction toxic to sperm and eggs, preventing fertilization. It does not contain hormones and can be effective for up to 10 years or more.
Contraceptive Implant (Nexplanon, Implanon)	This pharmaceutical LARC is a small, flexible rod inserted under the skin of the upper arm that continuously releases progestin, primarily preventing ovulation and thickening cervical mucus. It can provide highly effective contraception for 3 to 5 years.
Contraceptive Injection (Depo-Provera)	This pharmaceutical hormonal method involves an injection of progestin every 3 months, which primarily prevents ovulation and thickens cervical mucus. It offers highly effective, convenient, and reversible contraception.
Natural Family Planning	Various methods like Calendar, Basal Body Temperature, Cervical Mucus. These natural methods involve tracking a woman's menstrual cycle and physiological signs to identify fertile and infertile periods, avoiding unprotected intercourse during fertile times. Their effectiveness relies heavily on consistent and accurate tracking.

Withdrawal Method (Coitus Interruptus)	This natural method involves the male partner withdrawing the penis from the vagina before ejaculation to prevent sperm from entering the female reproductive tract. While widely practiced, its effectiveness is lower due to pre-ejaculate and imperfect timing.
Vaginal Ring (NuvaRing, EluRyng)	This pharmaceutical flexible ring is inserted into the vagina and releases both estrogen and progestin, working similarly to the combined oral contraceptive pill to prevent ovulation. It is typically left in for three weeks, followed by a ring-free week.
Contraceptive Patch (Xulane, Evra)	This pharmaceutical hormonal patch is applied to the skin and releases estrogen and progestin, which are absorbed through the skin to prevent ovulation. A new patch is applied weekly for three weeks, followed by a patch-free week.
Female Condom (FC2, Protectiv)	This natural barrier method is a pouch inserted into the vagina before intercourse, lining the vaginal walls and physically preventing sperm from reaching the cervix. It offers protection against STIs and pregnancy.
Lactational Amenorrhea Method (LAM)	This natural method relies on exclusive or near-exclusive breastfeeding to suppress ovulation. It can be a highly effective temporary contraceptive method for up to 6 months postpartum if specific criteria (amenorrhea, full breastfeeding, infant under 6 months) are met.
Diaphragm/Cervical Cap with Spermicide	These natural barrier methods are domes or cups placed over the cervix before intercourse, blocking sperm. They are used in conjunction with spermicide, which inactivates or kills sperm. They are often used with spermicide.
Spermicide (Contraceptrol, Gynol II)	This chemical agent is inserted into the vagina before intercourse to inactivate or kill sperm, acting as a barrier. It is typically used in combination with other barrier methods like diaphragms or condoms to increase their effectiveness.

5 Urinary Tract Anti-infectives

Urinary Tract Anti-infectives are substances used to treat or prevent infections in the urinary tract, most commonly caused by bacteria. They work by killing or inhibiting the growth of these microbes, often by targeting bacterial processes or by creating an unfavorable environment for them in the urinary system.

Nitrofurantoin (Macrobid, Macrodantin)	This pharmaceutical antibiotic works by interfering with various bacterial enzyme systems, particularly in the urinary tract, which prevents bacterial growth and kills common UTI-causing bacteria. It is a first-line treatment for uncomplicated urinary tract infections.
Sulfamethoxazole/Trimethoprim (Bactrim, Septra)	This pharmaceutical combination antibiotic works synergistically by blocking two sequential steps in bacterial folic acid synthesis, which is vital for bacterial DNA and protein production. It is a very common and effective treatment for urinary tract infections.
Cranberry (extract/juice)	This natural remedy contains proanthocyanidins (PACs) that prevent certain bacteria, particularly E. coli, from adhering to the lining of the urinary tract walls. It is widely used for the prevention of recurrent UTIs.
Cephalexin (Keflex)	This pharmaceutical first-generation cephalosporin antibiotic works by inhibiting the synthesis of bacterial cell walls, leading to bacterial death. It is often used for urinary tract infections, especially in situations where other antibiotics might be less suitable.
Fosfomycin (Monurol)	This pharmaceutical antibiotic inhibits an enzyme crucial for bacterial cell wall synthesis, leading to the destruction of the bacteria. It is known for its single-dose treatment regimen for uncomplicated urinary tract infections.
Ciprofloxacin (Cipro)	This pharmaceutical fluoroquinolone antibiotic works by inhibiting bacterial DNA gyrase, an enzyme essential for bacterial DNA replication and repair. While effective for UTIs, its use for uncomplicated cases is now often reserved due to concerns about resistance and potential side effects.
D-Mannose (AZO D-Mannose)	This natural sugar is thought to work by binding to E. coli bacteria in the urinary tract, preventing them from adhering to the bladder walls and allowing them to be flushed out with urine. It is commonly used as a supplement for UTI prevention.
Amoxicillin/Clavulanate Potassium (Augmentin)	This pharmaceutical combination antibiotic includes amoxicillin, which inhibits bacterial cell wall synthesis, and clavulanate, which protects amoxicillin from bacterial enzymes. It's used for UTIs when other first-line agents are not appropriate.
Uva Ursi (Bearberry Leaf)	This natural herb contains arbutin, which is metabolized into hydroquinone, a compound with antiseptic properties in the urinary tract. It is traditionally used for mild urinary tract infections.

14 Dermatological Meds

Dermatological condition medications encompass a broad range of drugs specifically designed to treat ailments affecting the skin, hair, and nails. These conditions can vary widely, from common issues like acne, eczema, and psoriasis to infections (bacterial, fungal, viral, parasitic) and more complex autoimmune or inflammatory skin disorders. Medications in this field are often applied topically as creams, ointments, lotions, or gels to target the affected area directly, minimizing systemic side effects.

However, for more severe, widespread, or resistant conditions, systemic medications taken orally or by injection are prescribed, including powerful anti-inflammatory agents like corticosteroids, immune-modulating drugs (e.g., biologics), and various anti-infectives. The goal of these treatments is to alleviate symptoms such as itching, redness, inflammation, and pain, as well as to control disease progression, clear infections, promote healing, and ultimately improve the appearance and overall health of the integumentary system.

Subheadings

1 Topical Anti-infectives

Topical anti-infectives are substances applied to the skin, wounds, or mucous membranes to kill or inhibit the growth of microorganisms (bacteria, fungi, viruses) and prevent or treat local infections. They are commonly used for cuts, scrapes, burns, skin infections, and acne.

Povidone-iodine (Betadine)	This pharmaceutical antiseptic releases iodine, which rapidly kills a broad spectrum of bacteria, viruses, fungi, and spores by oxidizing cellular components. It is extensively used for skin disinfection before surgery, wound care, and as a general antiseptic.
Mupirocin (Bactroban)	This pharmaceutical antibiotic ointment works by inhibiting bacterial protein synthesis, effectively stopping the growth of certain bacteria, especially Staphylococcus aureus (including MRSA) and Streptococcus pyogenes. It is commonly prescribed for impetigo and to eliminate nasal MRSA colonization.
Triple Antibiotic Ointment (Neosporin) (Bacitracin/Neomycin)	This pharmaceutical combination ointment contains three different antibiotics that work together to prevent and treat minor skin infections. Bacitracin primarily targets Gram-positive bacteria, while neomycin and polymyxin B cover a range of Gram-negative bacteria.
Clotrimazole (Lotrimin, Canesten)	This pharmaceutical antifungal cream works by damaging the fungal cell membrane, leading to leakage of cellular contents and ultimately the death of the fungus. It is a very common topical treatment for skin fungal infections like athlete's foot, jock itch, and ringworm.

Chlorhexidine (Hibiclens, Savlon)	This pharmaceutical antiseptic is a broad-spectrum antimicrobial that binds to the skin and disrupts bacterial cell membranes, leading to their inactivation. It is widely used for surgical hand scrubs, skin preparation before procedures, and as an oral rinse for gum disease.
Hydrogen Peroxide (Rexall, Peroxide)	This pharmaceutical antiseptic works by releasing oxygen bubbles that help to clean wounds and kill certain bacteria by oxidizing their cellular components. It's a common household antiseptic for minor cuts and scrapes.
Silver Sulfadiazine (Silvadene)	This pharmaceutical topical antimicrobial combines silver ions with sulfadiazine, a sulfonamide antibiotic. The silver ions have broad-spectrum antimicrobial activity, making it highly effective in preventing and treating wound infections, particularly in burn patients.
Tea Tree Oil	This natural essential oil contains compounds like terpinen-4-ol that exhibit broad-spectrum antimicrobial properties, including antibacterial and antifungal effects, by damaging microbial cell membranes. It is frequently used topically for minor skin infections, acne, and fungal conditions.
Honey (Manuka Honey)	This natural substance possesses antibacterial properties due to its high sugar content, low pH, and the production of hydrogen peroxide and other compounds. It has been traditionally used and is increasingly recognized for its efficacy in wound healing and preventing infection.
Acyclovir (Zovirax topical)	This pharmaceutical antiviral cream or ointment works by interfering with viral DNA replication, thereby stopping the spread of herpes simplex virus infections. It is used topically to treat cold sores and genital herpes lesions, helping them heal faster.
Aloe Vera	While known for its soothing properties, the gel from the aloe vera plant also contains compounds with mild antibacterial and antifungal properties. It is often used to soothe and potentially help heal minor skin irritations and infections.

MEDICATION — 14. Dermatological Meds — Topical Anti-infectives

2 Topical Corticosteroids

Topical corticosteroids are anti-inflammatory medications applied to the skin to reduce redness, swelling, itching, and irritation caused by various dermatological conditions like eczema, psoriasis, and dermatitis. They work by mimicking the effects of natural cortisol, a hormone produced by the body, to suppress immune responses and inflammation in the skin.

Hydrocortisone (Cortizone-10, Cortaid, Dermacort)	This pharmaceutical mild-potency corticosteroid works by reducing inflammation, itching, and redness in a wide range of skin conditions like eczema, dermatitis, and insect bites. It's widely available over-the-counter and in prescription strengths.
Triamcinolone Acetonide (Kenalog, Aristocort)	This pharmaceutical moderate-potency corticosteroid effectively reduces inflammation, itching, and redness by suppressing the immune response in the skin. It is commonly prescribed for various skin conditions, including eczema, psoriasis, and allergic reactions.
Mometasone Furoate (Elocon, Nasonex - nasal spray)	This pharmaceutical potent corticosteroid reduces inflammation, itching, and redness by acting on inflammatory pathways in skin cells. It's frequently prescribed for more severe skin conditions such as moderate to severe eczema and psoriasis.
Betamethasone Valerate (Betnovate, Valisone)	This pharmaceutical potent corticosteroid works by decreasing inflammation, swelling, and itching in the skin. It is used to treat a variety of inflammatory skin conditions, including eczema, psoriasis, and dermatitis.
Clobetasol Propionate (Clobex, Temovate)	This pharmaceutical super-potent corticosteroid is one of the strongest topical steroids available, working rapidly to suppress inflammation and itching. It is typically prescribed for very severe inflammatory skin conditions like severe psoriasis and resistant eczema for short periods.
Curcumin (from Turmeric)	This natural compound found in turmeric possesses potent anti-inflammatory properties by modulating various cellular pathways involved in inflammation. It is often used topically in formulations to help reduce redness and swelling in skin conditions.
Aloe Vera	The gel from the aloe vera plant contains compounds with anti-inflammatory, soothing, and healing properties. It is widely used to calm irritated skin, reduce redness, and promote healing in conditions like sunburns and minor skin inflammations.
Witch Hazel	This natural astringent and anti-inflammatory extract from the witch hazel plant contains tannins that can reduce swelling, itching, and redness. It is commonly used topically for minor skin irritations, insect bites, and hemorrhoids due to its soothing and vasoconstrictive effects.
Apple Cider Vinegar (Bragg's, Heinz)	When diluted, this natural substance is believed to have mild anti-inflammatory and antimicrobial properties due to its acetic acid content. It is sometimes used topically for skin conditions like acne or mild rashes, though its direct anti-inflammatory action is less potent than corticosteroids.

MEDICATION — 14. Dermatological Meds — Topical Corticosteroids

3 Antipsoriatics

Antipsoriatics are a class of treatments used to manage psoriasis, a chronic autoimmune skin condition characterized by red, itchy, scaly patches. These agents work by slowing down the rapid growth of skin cells, reducing inflammation, and modulating the immune system.

Topical Corticosteroids (Hydrocortisone, Triamcinolone)	These pharmaceutical medications reduce inflammation, itching, and redness by suppressing the immune response in the skin. They are a first-line and most frequently used treatment for mild to moderate psoriasis.
Calcipotriene (Dovonex, Sorilux)	This pharmaceutical synthetic vitamin D analog works by slowing down the rapid growth and proliferation of skin cells, helping to normalize skin cell turnover in psoriasis. It is a very common topical treatment for plaque psoriasis.
Combination Calcipotriene/Betamethasone (Taclonex)	This pharmaceutical combination product pairs a vitamin D analog with a potent corticosteroid, providing both cell growth regulation and strong anti-inflammatory effects. It is highly effective for plaque psoriasis due to its dual action.
Salicylic Acid (Dermarest Psoriasis)	This pharmaceutical keratolytic agent helps to soften, lift, and remove scales from psoriasis plaques. By descaling the skin, it can also improve the penetration and effectiveness of other topical treatments.
Coal Tar (Fototar, Psoriasin)	This pharmaceutical topical treatment has anti-inflammatory, antipruritic (anti-itch), and antiproliferative (slows cell growth) effects. It is an older, but still used, treatment for various forms of psoriasis, particularly on the scalp.
Tazarotene (Tazorac)	This pharmaceutical topical retinoid is a vitamin A derivative that helps to normalize skin cell growth and reduce inflammation in psoriatic plaques. It is used to treat mild to moderate plaque psoriasis.
Methotrexate (Trexall, Otrexup)	This pharmaceutical systemic medication is an immunosuppressant that works by inhibiting cell growth and inflammation. It is a widely used oral systemic therapy for moderate to severe psoriasis that has not responded to topical treatments.
Adalimumab (Humira)	This pharmaceutical biologic is a TNF-alpha inhibitor that blocks a specific protein (TNF-alpha) involved in the inflammatory process of psoriasis. It is a highly effective injectable treatment for moderate to severe plaque psoriasis and psoriatic arthritis.
Ustekinumab (Stelara)	This pharmaceutical biologic targets specific interleukins (IL-12 and IL-23), key proteins involved in the inflammatory pathway of psoriasis. It is an injectable medication used for moderate to severe plaque psoriasis and psoriatic arthritis.
Etanercept (Enbrel)	This pharmaceutical biologic is a TNF-alpha blocker that acts as a "decoy receptor" for TNF-alpha, preventing it from activating inflammatory responses. It is an injectable treatment used for moderate to severe plaque psoriasis and psoriatic arthritis.
Secukinumab (Cosentyx)	This pharmaceutical biologic specifically targets and neutralizes interleukin-17A (IL-17A), a cytokine that plays a central role in the inflammatory process of psoriasis. It is an injectable treatment for moderate to severe plaque psoriasis, psoriatic arthritis, and ankylosing spondylitis.
Acitretin (Soriatane)	This pharmaceutical oral retinoid (vitamin A derivative) works by slowing down the excessive growth of skin cells. It is used for severe forms of psoriasis, particularly erythrodermic and pustular psoriasis.
Curcumin (from Turmeric)	This natural compound found in turmeric has potent anti-inflammatory and antioxidant properties, which may help to reduce the inflammation and scaling associated with psoriasis. It is often used as a dietary supplement.

MEDICATION — 14. Dermatological Meds — Antipsoriatics

Aloe Vera	The gel from the aloe vera plant has soothing, moisturizing, and anti-inflammatory properties that can help reduce redness and scaling in mild psoriasis. It is used topically to calm irritated skin.
Oatmeal (Colloidal Oatmeal) (Aveeno)	Used in baths or topical products, colloidal oatmeal is a natural emollient that can soothe irritated, itchy, and dry skin characteristic of psoriasis. It forms a protective barrier and reduces inflammation.

4 Emollients/Moisturizers

Emollients, often synonymous with moisturizers, are essential for skin health, especially for dry, irritated, or compromised skin conditions. They work by creating a protective barrier on the skin's surface, trapping moisture, and filling in gaps between skin cells, leading to smoother, softer, and more hydrated skin.

Petroleum Jelly (Vaseline)	This pharmaceutical/natural occlusive agent creates a highly effective protective barrier on the skin, preventing water loss and promoting healing. It is incredibly versatile and widely used for dry skin, cracked lips, minor cuts, and as a barrier for various skin irritations.
Glycerin	This pharmaceutical/natural humectant attracts and binds water from the air and deeper layers of the skin, drawing it to the skin's surface to enhance hydration. It is a common ingredient in many moisturizers and lotions due to its excellent hydrating properties.
Mineral Oil (Baby Oil)	This pharmaceutical/natural occlusive agent forms a thin, protective layer on the skin to prevent moisture loss. It is a highly refined petroleum product, commonly used in baby oils and lotions for its emollient properties and low allergenic potential.
Ceramides	These pharmaceutical/natural lipids are naturally occurring in the skin and are crucial components of the skin barrier, helping to retain moisture and protect against irritants. Many pharmaceutical moisturizers incorporate synthetic ceramides to restore and strengthen the skin's natural barrier.
Lanolin (Lansinoh, Lano)	This natural waxy substance derived from sheep's wool is a powerful occlusive and emollient, forming a protective barrier on the skin to prevent moisture loss and soften rough areas. It is commonly used for dry, chapped skin, and cracked nipples in breastfeeding mothers.
Urea (Eucerin UreaRepair, Urelia)	This pharmaceutical humectant and keratolytic agent helps the skin retain moisture at lower concentrations, and at higher concentrations, it can break down rough, scaly skin. It is frequently used for very dry, rough, scaly conditions like eczema, psoriasis, and keratosis pilaris.
Shea Butter	This natural fat extracted from the shea tree nut is a rich emollient and moisturizer, providing deep hydration and anti-inflammatory benefits due to its fatty acid and vitamin content. It is widely used in creams, lotions, and balms.
Hyaluronic Acid	This pharmaceutical/natural powerful humectant can hold up to 1,000 times its weight in water, drawing moisture into the skin to plump it and reduce the appearance of fine lines. It is a popular ingredient in serums and moisturizers for intense hydration.
Cocoa Butter	This natural fat derived from cocoa beans is a rich emollient that deeply moisturizes and helps to improve skin elasticity, often used to prevent stretch marks and nourish dry skin.
Jojoba Oil	This natural liquid wax, structurally similar to the skin's natural sebum, is a lightweight emollient that provides hydration without clogging pores. It is suitable for all skin types and is often found in moisturizers and cleansers.
Colloidal Oatmeal (Gold Bond)	This natural finely ground oat flour forms a protective, soothing barrier on the skin, reducing itching and inflammation. It is widely used for sensitive, dry, and eczema-prone skin due to its anti-inflammatory properties.
Coconut Oil	This natural edible oil is a rich emollient that provides intense moisturization and has some antimicrobial properties due to its fatty acid content. It is often used for body moisturization and as a natural remedy for dry skin.

5 Acne Treatments

Acne treatments aim to reduce blemishes, inflammation, and scarring by addressing factors like excess oil production, clogged pores, bacteria, and inflammation. They work through various mechanisms, including regulating skin cell turnover, killing bacteria, or reducing hormonal influences.

Benzoyl Peroxide (Proactiv, PanOxyl)	This pharmaceutical topical agent is highly effective due to its antibacterial action against Cutibacterium acnes (formerly Propionibacterium acnes) and its ability to gently exfoliate skin cells, preventing clogged pores. It is widely available over-the-counter and often combined with other treatments.
Topical Retinoids (Adapalene, Tretinoin)	These pharmaceutical vitamin A derivatives work by normalizing skin cell turnover, preventing pores from becoming clogged, and reducing inflammation. Adapalene 0.1% is available over-the-counter, while other retinoids require a prescription.
Salicylic Acid (Clearasil)	This pharmaceutical beta-hydroxy acid (BHA) is a chemical exfoliant that penetrates oil to unclog pores and reduce inflammation. It is commonly found in over-the-counter cleansers, toners, and spot treatments.
Topical Antibiotics (Clindamycin, Erythromycin)	These pharmaceutical medications work by reducing the amount of acne-causing bacteria on the skin and in follicles, as well as providing anti-inflammatory effects. They are typically used in combination with benzoyl peroxide to prevent antibiotic resistance.
Oral Antibiotics (Doxycycline, Minocycline)	These pharmaceutical systemic medications reduce bacterial colonization and inflammation throughout the body, including in the skin's affected follicles. They are prescribed for moderate to severe acne, often for limited durations due to concerns about antibiotic resistance.
Tea Tree Oil	This natural essential oil possesses antibacterial, anti-inflammatory, and antioxidant properties, which help to kill acne-causing bacteria and reduce redness and swelling of pimples. It is a popular natural remedy for mild to moderate acne.
Azelaic Acid (Finacea, Azelex)	This pharmaceutical topical dicarboxylic acid has antibacterial, anti-inflammatory, and mild exfoliating properties, helping to unclog pores and reduce redness. It is effective for both inflammatory acne and the post-inflammatory hyperpigmentation (dark spots) left by acne.
Isotretinoin (Accutane, Roaccutane)	This pharmaceutical powerful oral retinoid dramatically reduces sebum production, normalizes skin cell shedding, and has anti-inflammatory effects, leading to long-term remission for severe, recalcitrant acne. It requires strict medical supervision due to potential side effects.
Witch Hazel	This natural astringent and anti-inflammatory extract from the witch hazel plant can help reduce excess oil, tighten pores, and calm inflamed skin. It is commonly used in toners for oily and acne-prone skin.
Aloe Vera	This natural plant gel has soothing, anti-inflammatory, and antibacterial properties that can help calm irritated skin and reduce the appearance of acne. It is often used as a spot treatment or general skin soother.
Sulfur	This pharmaceutical/natural topical agent has mild antibacterial and keratolytic (exfoliating) properties, helping to dry out blemishes and reduce excess oil. It is often found in spot treatments and masks.

15 Ophthalmic & Otic Meds

MEDICATION 15. Ophthalmic & Otic Meds

Ophthalmic and Otic Condition Medications are distinct but often grouped categories of drugs specifically formulated to treat ailments of the eyes and ears, respectively. Ophthalmic medications are designed for topical application to the eye, typically as drops, gels, or ointments, and are used to address a wide range of conditions such as infections (bacterial, viral, fungal), inflammation (e.g., conjunctivitis, iritis), glaucoma (by reducing intraocular pressure), dry eye syndrome, and allergies. They must be sterile and precisely formulated to avoid irritation and damage to the delicate eye tissues.

Otic medications, conversely, are prepared for application into the ear canal, usually as ear drops. These are primarily used to treat ear infections (e.g., otitis externa or media), reduce inflammation and pain, or aid in earwax removal. Both ophthalmic and otic preparations require careful administration to ensure effectiveness and prevent contamination, and they play a crucial role in maintaining sensory health and comfort.

Subheadings

1 Ophthalmic Agents

Ophthalmic agents are medications and substances used to treat conditions affecting the eyes, such as dryness, infections, glaucoma, and inflammation. They work through various mechanisms to alleviate symptoms, protect eye structures, or improve visual function.

Artificial Tears / Lubricating Eye Drops (Refresh, Systane, TheraTears)	These pharmaceutical drops mimic natural tears to lubricate the surface of the eye, reduce dryness, irritation, and discomfort. They are the most widely used ophthalmic agents for dry eye syndrome, which is a very common condition.
Latanoprost (Xalatan)	This pharmaceutical prostaglandin analog eye drop works by increasing the outflow of fluid from the eye, thereby lowering intraocular pressure. It is a highly effective and very commonly prescribed medication for treating open-angle glaucoma and ocular hypertension.
Timolol (Timoptic)	This pharmaceutical beta-blocker eye drop reduces the production of fluid inside the eye, thereby lowering intraocular pressure. It is a widely used and effective treatment for open-angle glaucoma and ocular hypertension.
Olopatadine (Patanol, Pataday)	This pharmaceutical antihistamine and mast cell stabilizer eye drop blocks histamine receptors and prevents the release of inflammatory substances from mast cells, effectively relieving itchy, red, and watery eyes caused by allergic conjunctivitis. It is a very common over-the-counter and prescription allergy eye drop.
Moxifloxacin (Vigamox, Moxeza)	This pharmaceutical fluoroquinolone antibiotic eye drop works by inhibiting bacterial DNA replication, effectively killing a broad range of bacteria that cause eye infections. It is a commonly prescribed antibiotic for bacterial conjunctivitis and other ocular infections.
Prednisolone Acetate (Pred Forte, Omnipred)	This pharmaceutical corticosteroid eye drop reduces inflammation, swelling, and redness in the eye by suppressing the immune response. It is commonly used for various inflammatory eye conditions, including post-surgical inflammation and severe allergic conjunctivitis.
Cyclosporine Ophthalmic (Restasis, Cequa)	This pharmaceutical immunomodulator eye drop works by decreasing inflammation on the surface of the eye, which can increase the eye's natural tear production. It is used to treat chronic dry eye disease caused by inflammation.
Brimonidine (Alphagan P, Lumify	This pharmaceutical alpha-adrenergic agonist eye drop primarily reduces fluid production in the eye and also increases outflow, thereby lowering intraocular pressure. It is used for open-angle glaucoma and ocular hypertension, and lower concentrations are used for redness relief.
Dorzolamide (Trusopt)	This pharmaceutical carbonic anhydrase inhibitor eye drop works by reducing the production of fluid inside the eye, thereby lowering intraocular pressure. It is often used alone or in combination with other medications for glaucoma.
Hot/Warm Compresses	A natural method, applying a warm compress helps to soothe irritated eyes, promote blood flow, and can help to loosen blockages in oil glands, often used for dry eyes, styes, or blepharitis.
Cold Compresses	A natural method, applying a cold compress helps to constrict blood vessels, reducing swelling, redness, and itching in the eyes. It's often used for allergic reactions, puffy eyes, or minor eye injuries.
Rose Water	This natural floral water has soothing and mild anti-inflammatory properties, often used to calm irritated or tired eyes. It can be applied as a gentle eyewash or compress.
Chamomile Tea Bags (cooled)	This natural herbal remedy, when cooled and placed over the eyes, can provide soothing and mild anti-inflammatory effects due to compounds like flavonoids. It is often used to reduce puffiness and calm irritated eyes.

2 Otic Agents

Otic agents are medications and substances used to treat conditions affecting the ear, such as infections, inflammation, and earwax buildup. They are typically applied topically as ear drops to alleviate pain, reduce microbial growth, or aid in cerumen removal.

Ciprofloxacin/Dexamethasone (Ciprodex)	This pharmaceutical combination ear drop contains an antibiotic (ciprofloxacin) to kill bacteria and a corticosteroid (dexamethasone) to reduce inflammation and swelling. It is very commonly prescribed for middle ear infections (otitis media) with tubes and outer ear infections (otitis externa or "swimmer's ear").
Ofloxacin (Floxin Otic)	This pharmaceutical fluoroquinolone antibiotic ear drop works by inhibiting bacterial DNA replication, effectively killing a broad range of bacteria. It is widely used to treat various ear infections, including otitis externa and chronic suppurative otitis media.
Hydrocortisone/Neomycin/Polymyxin B (Cortisporin Otic)	This pharmaceutical combination ear drop contains a corticosteroid for inflammation and three antibiotics to target a wide spectrum of bacteria. It is a common treatment for otitis externa, especially when inflammation is significant.
Acetic Acid (Vosol, Domeboro Otic)	This pharmaceutical and naturally occurring substance creates an acidic environment in the ear canal, which inhibits the growth of bacteria and fungi responsible for ear infections. It is often used for mild cases of swimmer's ear and to prevent recurrence.
Docusate Sodium (Earwax Removal) (Debrox, Cerumenex)	While not an anti-infective, this pharmaceutical ear drop is a very common over-the-counter agent that softens and loosens earwax. It works by reducing the surface tension of the earwax, making it easier to wash out.
Olive Oil	A natural emollient, warmed olive oil is commonly used to soften earwax, making it easier for the body to expel or for professional removal. It is a gentle home remedy for earwax blockage.
Hydrogen Peroxide (Earwax Removal)	This pharmaceutical and naturally occurring substance works by releasing oxygen bubbles that help to break down and loosen earwax. It is a common over-the-counter option for earwax removal.
Ciprofloxacin (Cipro ear drops)	Similar to its use in combination, ciprofloxacin alone as an ear drop is a pharmaceutical antibiotic that kills bacteria causing ear infections by inhibiting DNA replication. It is used for various bacterial ear infections.
Garlic Oil	This natural remedy contains allicin, a compound with antibacterial and antifungal properties. It is traditionally used by some for ear infections, often by infusing garlic in oil and applying a few drops.
Rubbing Alcohol	This common household item, sometimes used diluted with white vinegar, acts as a drying agent in the ear canal. It helps to evaporate water, which can prevent the growth of bacteria and fungi in cases of swimmer's ear.

MEDICATION

16. Hematological Meds

16 Hematological Meds

Hematological system medications are a specialized category of drugs that specifically target disorders of the blood and blood-forming organs, such as the bone marrow, spleen, and lymph nodes. This vital group of medications addresses a wide range of conditions, including various forms of anemia (by stimulating red blood cell production or supplementing essential nutrients like iron and vitamins), bleeding disorders (by promoting clotting with factors or antifibrinolytics), and clotting disorders (by preventing or dissolving harmful blood clots with anticoagulants, antiplatelet agents, and thrombolytics).

Additionally, some hematological medications are used in the context of blood cancers (leukemias, lymphomas, myelomas), often in conjunction with broader oncology treatments, and may include agents to stimulate white blood cell or platelet production, or targeted therapies for specific blood cell abnormalities. By directly influencing blood cell production, function, and the complex coagulation cascade, these medications are crucial for maintaining blood health, preventing life-threatening complications, and managing chronic hematological diseases worldwide.

Subheadings

1. Hematopoietic Agents	2. Hemostatics

1 Hematopoietic Agents

Hematopoietic agents are substances that stimulate the production, maturation, and differentiation of blood cells, including red blood cells, white blood cells, and platelets. They are crucial for treating various conditions such as anemia, neutropenia (low white blood cell count), and thrombocytopenia (low platelet count), often caused by chronic diseases, chemotherapy, or bone marrow disorders.

Epoetin Alfa (Epogen, Procrit)	This pharmaceutical erythropoiesis-stimulating agent (ESA) is a recombinant form of human erythropoietin, a hormone that stimulates the bone marrow to produce red blood cells. It is widely used to treat anemia associated with chronic kidney disease, chemotherapy, and certain HIV treatments.
Filgrastim (Neupogen, Zarxio)	A recombinant form of human granulocyte colony-stimulating factor (G-CSF). It stimulates the bone marrow to produce neutrophils, a type of white blood cell, to reduce the risk of infection in patients undergoing chemotherapy.
Pegfilgrastim (Neulasta)	A pegylated form of filgrastim, providing a longer-acting effect. It stimulates the bone marrow to produce neutrophils, reducing the frequency of injections needed to prevent febrile neutropenia in chemotherapy patients.
Ferrous sulfate (Feosol, Slow FE)	A common iron supplement. It provides elemental iron necessary for the body to produce healthy red blood cells, treating and preventing iron deficiency anemia.
Eltrombopag (Promacta, Revolade)	A thrombopoietin receptor agonist. It stimulates the bone marrow to produce more platelets, used to increase platelet counts in conditions like chronic immune thrombocytopenia (ITP) and aplastic anemia.
Romiplostim (Nplate)	A thrombopoietin (TPO) mimetic. It binds to and activates the TPO receptor, stimulating platelet production in patients with chronic immune thrombocytopenia (ITP).
Folic Acid	A B vitamin. It is essential for the production of red blood cells and for cell division and growth, used to treat or prevent folate deficiency anemia and to prevent neural tube defects during pregnancy.
Cyanocobalamin (Nascobal)	A manufactured version of vitamin B12. It is vital for red blood cell formation and nervous system function, used to treat and prevent vitamin B12 deficiency anemia.

2 Hemostatics

Hemostatics are substances that promote hemostasis, the process of stopping bleeding. They achieve this by enhancing blood coagulation or by forming a physical barrier to restrict blood flow.

Tranexamic acid (Cyklokapron, Lysteda)	An antifibrinolytic agent that prevents the breakdown of blood clots. It is commonly used to reduce blood loss in various surgical procedures, heavy menstrual bleeding, and other bleeding disorders.
Aminocaproic acid (Amicar)	Another antifibrinolytic agent that inhibits the dissolution of blood clots. It is primarily used to control bleeding in conditions like hemophilia or to prevent excessive bleeding after surgery.
Desmopressin (DDAVP, Stimate)	A synthetic analog of vasopressin that promotes the release of von Willebrand factor and factor VIII from endothelial cells. It is used to improve hemostasis in patients with mild hemophilia A and von Willebrand disease.
Oxidized cellulose (Surgicel)	A topical hemostatic agent that works by providing a physical matrix for clot formation and initiating the coagulation cascade. It is widely used in surgery to control capillary, venous, and small arterial hemorrhages.
Thrombin, topical (Recothrom, Thrombin-JMI)	An enzyme that converts fibrinogen to fibrin, leading to the formation of a stable blood clot. It is applied directly to bleeding surfaces during surgery to achieve local hemostasis.
Fibrin sealant (Tisseel, Evicel)	A biological adhesive composed of human fibrinogen and thrombin. When mixed, they mimic the final stages of the coagulation cascade, forming a fibrin clot that seals tissues and stops bleeding.
Recombinant Factor VIIa (NovoSeven RT)	A recombinant form of human coagulation Factor VIIa. It bypasses deficiencies in the intrinsic coagulation pathway to promote clot formation, primarily used to treat bleeding in hemophilia A or B patients with inhibitors.
Platelet-Rich Plasma (PRP)	A concentration of platelets derived from the patient's own blood. While not a "drug" in the traditional sense, it's a natural biological product used topically in some surgical fields to enhance clotting and promote tissue healing due to its high concentration of growth factors and clotting proteins.

17. Miscellaneous Meds

17 Miscellaneous Meds

These are medications which don't come under one of the categories above, such as antidotes, supplements and diagnostic agents.

Subheadings

1. Antidotes	2. Supplements	3. Diagnostic Agents	4. Smoking Cessation
5. Weight Management			

1 Antidotes

To counteract the effects of poisons or drug overdoses.

N-Acetylcysteine (NAC) (Acetadote, Mucomyst)	This pharmaceutical antidote is the specific treatment for acetaminophen (paracetamol) overdose. It works by replenishing glutathione stores in the liver, which are essential for detoxifying the toxic metabolite of acetaminophen, thereby preventing severe liver damage.
Naloxone (Narcan)	This pharmaceutical opioid receptor antagonist rapidly reverses the effects of opioid overdose by blocking opioid receptors in the brain, restoring breathing and consciousness. It is widely used in emergency situations involving opioid toxicity.
Activated Charcoal (Actidose-Aqua, SuperChar)	This pharmaceutical non-specific adsorbent binds to many drugs and toxins in the gastrointestinal tract, preventing their absorption into the bloodstream. It is often one of the first interventions in many acute poisonings, administered orally or via nasogastric tube.
Activated Charcoal (Natural Source)	While widely used in a pharmaceutical context, activated charcoal is derived from natural sources (e.g., wood, coconut shells) and its mechanism is physical adsorption. It acts as an emergency adsorbent for ingested poisons.
Atropine	This pharmaceutical anticholinergic agent blocks the effects of acetylcholine at muscarinic receptors. It is a primary antidote for organophosphate and carbamate pesticide poisoning, which cause an excess of acetylcholine, by counteracting symptoms like bradycardia and bronchorrhea.
Flumazenil (Romazicon)	This pharmaceutical benzodiazepine receptor antagonist rapidly reverses the sedative and respiratory depressant effects of benzodiazepine overdose. It works by competitively binding to the benzodiazepine site on the GABA-A receptor.
Phytonadione (Vitamin K) (Mephyton)	This pharmaceutical vitamin is essential for the synthesis of several blood clotting factors. It is the specific antidote for warfarin overdose or toxicity, reversing its anticoagulant effects by promoting the production of active clotting factors.
Protamine Sulfate	This pharmaceutical antagonist rapidly reverses the anticoagulant effects of heparin by forming a stable ion pair with heparin, thereby neutralizing its activity. It is used in cases of heparin overdose or bleeding.
Calcium Salts (e.g., Calcium Gluconate, Calcium Chloride)	These pharmaceutical agents are used as antidotes for hydrofluoric acid burns (to neutralize fluoride ions) and for overdose of calcium channel blockers (to restore calcium influx and cardiac function). They help counteract cardiotoxic effects.
Fomepizole (Antizol)	This pharmaceutical alcohol dehydrogenase inhibitor prevents the metabolism of methanol and ethylene glycol into their toxic metabolites. It is the preferred antidote for poisoning with these toxic alcohols.
Antivenoms / Antitoxins (CroFab - for snakebites, Botulism Antitoxin)	These pharmaceutical (and often naturally sourced, e.g., from animal plasma) preparations contain antibodies that specifically neutralize venoms from snakebites, spider bites, or toxins from bacterial infections like botulism or tetanus. They bind to and inactivate the specific toxins.
Pyridoxine (Vitamin B6)	This pharmaceutical vitamin is the specific antidote for isoniazid overdose or poisoning, as isoniazid interferes with pyridoxine's role in GABA synthesis. It helps prevent and treat seizures caused by isoniazid toxicity.
Glucagon (Glucagen)	This pharmaceutical hormone is used as an antidote for beta-blocker overdose, especially when unresponsive to atropine. It works by increasing intracellular cAMP, bypassing the blocked beta-receptors to improve heart rate and contractility.
Milk Thistle (Silymarin)	This natural herb is often used as supportive therapy for liver protection, particularly in cases of mushroom poisoning (e.g., Amanita phalloides). Silymarin is thought to protect liver cells and aid in regeneration.
Strong Tea (Tannins)	In some traditional or very initial poisoning scenarios, strong tea (rich in tannins) might be suggested as a natural agent to help precipitate or bind certain heavy metals or alkaloids, potentially reducing their absorption, though pharmaceutical interventions are always preferred.

2 Nutritional Supplements

These are nutritional supplements that are commonly used.

Multivitamins	These pharmaceutical/dietary supplements contain a combination of various vitamins and minerals designed to fill potential nutritional gaps in the diet. They are the most consumed type of supplement globally, aiming to support overall health and well-being.
Vitamin D	This pharmaceutical/dietary supplement is crucial for bone health, calcium absorption, immune function, and mood regulation. Many people globally have insufficient levels due to limited sun exposure, making it one of the most frequently recommended and consumed supplements.
Omega-3 Fatty Acids (Fish Oil/Algae Oil)	These natural/dietary supplements, rich in EPA and DHA, are known for their anti-inflammatory properties and benefits for heart health, brain function, and eye health. They are widely consumed due to perceived cardiovascular and cognitive advantages.
Vitamin C	This pharmaceutical/dietary supplement is a powerful antioxidant essential for immune function, collagen production, and skin health. It is frequently taken, especially during cold and flu season, for its immune-boosting properties.
Magnesium	This pharmaceutical/dietary mineral is involved in over 300 biochemical reactions in the body, supporting muscle and nerve function, blood sugar control, blood pressure regulation, and bone health. It's commonly supplemented for muscle cramps, sleep, and overall well-being.
Calcium (Caltrate, Ostelin Calcium & D3)	This pharmaceutical/dietary mineral is vital for strong bones and teeth, muscle function, and nerve transmission. It's particularly recommended for women, older adults, and those with dietary restrictions to prevent osteoporosis.
Probiotics (Culturelle, Inner Health)	These natural/dietary supplements contain live beneficial bacteria that help maintain a healthy balance of gut flora. They are widely used to support digestive health, improve gut motility, and boost the immune system.
Vitamin B Complex (including B12, Folate)	These pharmaceutical/dietary supplements contain a range of B vitamins that are essential for energy metabolism, nerve function, and red blood cell formation. B12 and folate are particularly noted for their importance in certain diets (e.g., vegan) or for specific health needs (e.g., pregnancy).
Iron	This pharmaceutical/dietary mineral is crucial for oxygen transport in the blood and preventing anemia. It is often supplemented, particularly in individuals with iron deficiency anemia, pregnant women, and vegetarians/vegans.
Protein Powders (e.g., Whey, Casein, Plant-based)	These natural/dietary supplements provide concentrated protein, essential for muscle repair, growth, and overall satiety. They are highly popular among athletes, fitness enthusiasts, and those looking to increase protein intake.
Turmeric/Curcumin	This natural supplement, derived from the turmeric plant, contains curcuminoids which are known for their potent anti-inflammatory and antioxidant properties. It's widely used for joint health, digestive support, and overall wellness.
Creatine	This natural compound, found in muscle cells, helps muscles produce energy during heavy lifting or high-intensity exercise. It's a very popular dietary supplement among athletes for improving strength, power, and muscle mass.
Ashwagandha	This natural adaptogenic herb is used to help the body adapt to stress, reduce anxiety, and improve sleep and cognitive function. It has gained significant popularity for its stress-modulating properties.
Glucosamine/Chondroitin	These natural compounds are components of cartilage and are used as dietary supplements to support joint health, reduce joint pain, and potentially slow the progression of osteoarthritis.
Zinc	This pharmaceutical/dietary mineral is essential for immune function, wound healing, and cell growth. It's commonly supplemented, especially during cold and flu season, for its immune-modulating effects.

See the NATURAL REMEDIES section for more information on these.

3 Diagnostic Agents

Used to aid in medical diagnosis (e.g., contrast media).

MEDICATION | 17. Miscellaneous Meds | Diagnostic Agents

Iodinated Contrast Media (Omnipaque, Isovue)	These pharmaceutical agents contain iodine which absorbs X-rays, making blood vessels, organs, and other tissues more visible during CT scans, X-rays, and angiography. They are extremely common for enhancing imaging in radiology departments worldwide.
Gadolinium-based Contrast Agents (Dotarem, Gadavist)	These pharmaceutical agents alter the magnetic properties of water molecules, enhancing the visibility of tissues and lesions in MRI scans. They are widely used for detailed imaging of various body parts, including the brain, spine, and joints.
Technetium-99m (Tc-99m) (Sestamibi for Myoview)	This pharmaceutical radioisotope is the most widely used in nuclear medicine. It is tagged to various molecules to target specific organs or tissues, emitting gamma rays that are detected by a gamma camera to create images that assess organ function or detect disease (e.g., bone scans, cardiac stress tests, thyroid scans).
Fluorescein Sodium (Fluorescein)	This pharmaceutical dye is used in ophthalmology to visualize corneal abrasions, foreign bodies, and blood flow in the retina during angiography. It fluoresces under blue light, highlighting areas of damage or vascular leakage in the eye.
Barium Sulfate (Readi-Cat, E-Z-Paque)	This pharmaceutical contrast agent is a dense, insoluble substance that coats the lining of the gastrointestinal tract, making it visible on X-ray images. It is commonly used for upper GI series and barium enemas to diagnose conditions of the esophagus, stomach, and intestines.
Fludeoxyglucose F 18 (FDG-PET)	This pharmaceutical radioactive glucose analog is absorbed by metabolically active cells, particularly cancer cells, which consume more glucose than normal cells. It is a key diagnostic agent in PET scans for detecting and monitoring various cancers, as well as for assessing brain and heart activity.
Indocyanine Green (ICG) (ICG-Pulsion, Cardio-Green)	This pharmaceutical dye binds to plasma proteins and is used for various diagnostic purposes, including assessing liver function, cardiac output, and visualizing blood flow during angiography (e.g., ophthalmic and surgical applications).
Diagnostic Dyes for Endoscopy/Surgery (Methylene Blue, Indigotindisulfonic acid)	These pharmaceutical dyes are used to stain or mark specific tissues during endoscopic procedures or surgery. They help visualize abnormal cells, delineate tissue planes, or confirm anatomical structures.
Urine Dipsticks / Reagent Strips (for urinalysis) (Chemstrip, Multistix)	While technically a device with impregnated chemical agents, these pharmaceutical diagnostic tools contain various reagents that change color in the presence of specific substances (e.g., glucose, protein, blood, nitrites) in urine. They are very commonly used for rapid screening of kidney function, urinary tract infections, and diabetes.
Litmus Paper	This simple natural indicator paper changes color to indicate the acidity or alkalinity (pH) of a substance. While basic, it's a fundamental "diagnostic" tool in many settings, including for assessing bodily fluids in some contexts.
Breath Tests (Pylori-Check, Helikit)	These pharmaceutical tests involve ingesting a substance (e.g., urea labeled with a carbon isotope) which, if broken down by bacteria like H. pylori, releases labeled carbon dioxide detected in the breath. This non-invasive method diagnoses bacterial infections in the stomach.

MEDICATION | 17. Miscellaneous Meds | Smoking Cessation Aids

4 Smoking Cessation Aids

To help people quit smoking.

Nicotine Patches (Nicoderm CQ, Nicorette Patch)	These pharmaceutical patches deliver a steady, controlled dose of nicotine through the skin, reducing withdrawal symptoms and cravings over a 24-hour period. They are a common and convenient form of nicotine replacement therapy (NRT).
Nicotine Gum (Nicotinell Gum)	This pharmaceutical gum releases nicotine when chewed, providing quick relief from cravings and withdrawal symptoms by allowing the user to control their nicotine intake as needed. It's a popular over-the-counter NRT.
Varenicline (Chantix, Champix)	This pharmaceutical prescription medication is a partial agonist at nicotine receptors in the brain, meaning it reduces the pleasure from smoking while also alleviating withdrawal symptoms. It is considered one of the most effective prescription medications for smoking cessation.
Nicotine Lozenges (Nicorette Lozenge, Nicotinell Lozenge)	These pharmaceutical lozenges dissolve in the mouth, releasing nicotine that is absorbed through the oral lining, providing a discreet and convenient way to manage cravings. They offer a quick onset of action for sudden urges.
Bupropion (Zyban, Wellbutrin SR)	This pharmaceutical prescription antidepressant works by affecting neurotransmitters in the brain, reducing nicotine cravings and withdrawal symptoms. It can also help to alleviate depressive symptoms that might arise during quitting.
Nicotine Inhalers (Nicotrol Inhaler, Nicorette Inhalator)	These pharmaceutical devices deliver nicotine vapor into the mouth and throat, mimicking the hand-to-mouth action of smoking while providing nicotine relief. They can help address both the physical and behavioral aspects of addiction.
Nicotine Nasal Sprays (Nicotrol NS)	This pharmaceutical spray delivers a rapid dose of nicotine through the nasal passages, providing fast relief from strong cravings. It offers the quickest nicotine delivery among NRTs, closely mimicking the speed of nicotine from a cigarette.
Cytisine (Tabex, Desmoxan)	This pharmaceutical plant-derived alkaloid acts similarly to varenicline as a partial agonist at nicotine receptors, reducing cravings and withdrawal symptoms. It is a widely used and effective smoking cessation aid, particularly in Eastern Europe.
Black Pepper Essential Oil	Inhaling the vapor from black pepper essential oil is a natural aromatherapy approach that some studies suggest can help reduce the severity and frequency of cigarette cravings. It is thought to provide a sensation similar to smoking.

MEDICATION | 17. Miscellaneous Meds | Weight Management

5 Weight Management

To assist in weight loss.

Semaglutide (Wegovy)	This is a glucagon-like peptide-1 (GLP-1) receptor agonist that helps regulate appetite by signaling to the brain, slowing gastric emptying, and increasing feelings of fullness. It is administered as a weekly injection to promote significant weight loss.
Liraglutide (Saxenda)	Another GLP-1 receptor agonist, this daily injectable medication works by affecting gut hormones that signal to the brain, reducing hunger and increasing satiety. It helps patients feel full more quickly and decrease overall food intake.
Phentermine (Adipex-P)	A stimulant that acts as an appetite suppressant, it helps reduce hunger and can provide an initial boost to weight loss. It is often prescribed for short-term use due to its stimulant properties.
Phentermine/Topiramate (Qsymia)	This combination medication pairs phentermine with topiramate, an anticonvulsant that can decrease appetite and cravings. It offers enhanced efficacy for weight loss by acting on multiple pathways.
Naltrexone/Bupropion (Contrave)	This combination drug works on areas of the brain involved in the pleasure-reward system, helping to reduce cravings and appetite. It combines an opioid antagonist with an antidepressant to aid in weight management.
Orlistat (Xenical, Alli)	This medication works by blocking the absorption of dietary fat in the intestines. It inhibits the enzyme lipase, preventing the breakdown and subsequent absorption of about one-third of the fat consumed.
Green Tea Extract	A natural supplement containing caffeine and catechins, which are believed to boost metabolism and promote fat burning. While widely used, its direct impact on significant weight loss is often modest.
Garcinia Cambogia	Derived from a tropical fruit, this supplement contains hydroxycitric acid (HCA), which is thought to inhibit an enzyme involved in fat production and increase serotonin levels to suppress appetite. Scientific evidence for substantial weight loss is mixed.
Glucomannan	A type of dietary fiber derived from the konjac plant. It absorbs water and expands in the stomach, promoting feelings of fullness and potentially reducing overall food intake.

Dietary Modifications	This broad category encompasses changes to eating habits, such as calorie restriction, portion control, increasing fruit and vegetable intake, reducing processed foods, or adopting specific eating patterns like low-carb or Mediterranean diets. The goal is to create a sustainable calorie deficit while ensuring adequate nutrition.
Exercise	Physical activity in many forms, such as walking, running, strength training, or cycling, burns calories and builds muscle mass, both of which are crucial for creating a calorie deficit and improving metabolism. It also contributes to overall health and well-being.

18 Medication List

This is the list of medications referred to above. They are sorted by medication name (not the brand name) in alphabetical order into evenly split groupings to make finding the one you're after easier. If you're looking for Pandadol/Paracetamol, you would look for Paracetamol below.

If you're looking for a list of which medications you should stockpile, head to the below sections:
- GEAR > Gear Descriptions > Medication
- GEAR > Household Gear > Home Clinic > Medications

BLACK BOX WARNING: For some of the medications below, under the Warnings & Precautions section, you may see a 'BLACK BOX WARNING'. A Black Box Warning, officially known as a Boxed Warning, is the strongest warning that some governments require for prescription drugs and medical devices. Its purpose is to prominently alert healthcare professionals and patients to serious or even life-threatening risks associated with the medication.

As mentioned at the start of this document, none of this information is meant as medical advice. Talk to your own trusted doctor to determine the best course of action for your health.

A - C

Any medications starting with A through to C.

Activated Charcoal

Purpose/Indication	Activated charcoal is primarily used in emergency situations to treat certain types of poisoning or drug overdose. It helps prevent or reduce the systemic absorption of toxins from the gastrointestinal tract. It can also be used for alleviating gas and bloating, though this is a less critical application in a survival scenario.
Method of Action	Activated charcoal works by a process called adsorption. Its highly porous surface binds to ingested toxins and chemicals within the gastrointestinal tract, preventing them from being absorbed into the bloodstream. It's most effective when administered quickly after ingestion of the toxic substance.
Medication Name & Brand Names	♦ Medication Name: Activated Charcoal ♦ Brand Names: Actidose-Aqua, CharcoalAid, Insta-Char, Liqui-Char, Superchar
Pharmaceutical Forms & Appearance	Activated charcoal typically comes as a fine black powder or granules, often suspended in water as a liquid, or available in capsules or tablets. The liquid suspensions are usually thick and black.
Dosage & Administration	For poisoning or overdose, doses are generally high, often 50g for adults and 1g/kg (up to 50g) for children, mixed with water. It should be administered as soon as possible after ingestion of the toxin (ideally within one hour). For gas/bloating, smaller doses (e.g., 250mg tablets) are used, often a few times a day. It is taken orally.
Supplied As	Activated charcoal is supplied as oral capsules, oral tablets, oral granules for reconstitution, and oral suspensions.
Contraindications	Activated charcoal is contraindicated in individuals with unprotected airways (if not intubated or unable to protect their airway), decreased levels of consciousness, or uncontrolled vomiting due to aspiration risk. It should not be used after ingestion of caustic substances (acids/alkalis), hydrocarbons (e.g., gasoline, kerosene), metals (e.g., iron, lithium, lead), or alcohols (e.g., ethanol, methanol). Also contraindicated in intestinal obstruction or recent GI surgery.
Storage & Expiry	Activated charcoal should be stored in a cool, dry place, sealed in its original container, to prevent it from adsorbing moisture or other substances from the air, which would reduce its effectiveness. While specific expiry dates vary by product, its adsorptive capacity can diminish over time, especially if exposed to air.
Side Effects	♦ Common side effects include black stools and constipation. ♦ Less common but more serious side effects can include intestinal blockage (with prolonged or repeated use), vomiting, and aspiration (if inhaled into the lungs, leading to chemical pneumonitis).
Warnings & Precautions	♦ Always consult a medical professional or poison control center before administering activated charcoal for poisoning. ♦ Do not administer to unconscious or seizing individuals unless their airway is protected (e.g., via intubation). ♦ It can bind to and reduce the absorption of other medications, vitamins, and minerals. ♦ The benefits must outweigh the risks, especially the risk of aspiration.
Missed Dose Instructions	For poisoning/overdose, activated charcoal is typically a single or short-course emergency treatment, not a regularly scheduled medication. If a dose is vomited, consult a medical professional immediately. For non-emergency use (e.g., gas), if a dose is missed, take it as soon as remembered unless it's almost time for the next dose; do not double the dose.
Overdose Instructions	If an overdose of activated charcoal itself occurs, it is generally not life-threatening but can worsen side effects like constipation or lead to intestinal blockage. Seek medical advice. In cases of accidental poisoning by other substances where activated charcoal was given, if the patient's condition worsens, immediately seek emergency medical help.
Medicine Interactions	Activated charcoal can significantly reduce the absorption and effectiveness of many orally administered medications, including but not limited to: ♦ Oral contraceptives ♦ Antidepressants ♦ Painkillers (e.g., acetaminophen, ibuprofen) ♦ Heart medications (e.g., propranolol, digoxin) ♦ Antibiotics (e.g., moxifloxacin, sulfamethoxazole/trimethoprim) ♦ Vitamins and minerals ♦ Laxatives (e.g., those containing sorbitol, as sorbitol reduces charcoal's binding capacity). It is generally recommended to separate the administration of activated charcoal from other oral medications by at least 2 hours.

Acyclovir (Zovirax)

Purpose/Indication	Acyclovir is an antiviral medication used to treat infections caused by herpes viruses, including cold sores (herpes labialis), genital herpes, chickenpox, and shingles (herpes zoster). It can help relieve pain, discomfort, and promote the healing of sores. It is not a cure for herpes and does not prevent transmission.

Method of Action	Acyclovir works by selectively inhibiting viral DNA synthesis. When a herpes virus infects a cell, its enzyme, thymidine kinase, converts acyclovir into a monophosphate form. Cellular enzymes then further convert it to a triphosphate, which competes with natural nucleotides and becomes incorporated into the viral DNA, ultimately stopping viral DNA replication and preventing the virus from multiplying.
Medication Name & Brand Names	The generic name is Acyclovir (or Aciclovir in some regions). Common brand names include Zovirax and Sitavig.
Pharmaceutical Forms & Appearance	Acyclovir is available in several forms: oral tablets and capsules, oral suspension (liquid), topical cream or ointment, and intravenous (IV) injection. Oral tablets and capsules are typically white or off-white. The oral suspension is often a white or off-white liquid. Topical creams are white, and ointments are translucent.
Dosage & Administration	Dosage and administration vary significantly based on the specific viral infection, its severity, and the patient's age and kidney function. Oral forms are typically taken multiple times a day, often for 5 to 10 days, but can be used for longer in suppressive therapy. Topical forms are applied directly to affected areas several times daily. IV administration is reserved for severe infections. It's crucial to start treatment as early as possible after symptom onset.
Supplied As	Acyclovir is supplied as oral tablets (various strengths), capsules, oral suspension, topical cream or ointment, and as a sterile powder for intravenous infusion.
Contraindications	Acyclovir is contraindicated in individuals with known hypersensitivity to acyclovir or valacyclovir. Caution is advised in patients with kidney problems, dehydration, or neurological conditions, as dose adjustments or close monitoring may be necessary.
Storage & Expiry	Oral tablets and capsules should be stored at room temperature, protected from moisture and light, and remain stable until their expiry date (usually two years). Acyclovir oral suspension should typically be stored refrigerated, and any unused portion discarded after a specific period (e.g., 28 days after reconstitution). Topical forms are stored at room temperature. Always check the specific product packaging for precise storage and expiry information.
Side Effects	Common side effects include headache, nausea, vomiting, diarrhea, and dizziness. Topical application may cause mild burning or stinging. More serious, but less common, side effects include kidney problems (especially with high doses or in dehydrated patients), confusion, hallucinations, seizures, and severe allergic reactions (e.g., rash, hives, swelling, difficulty breathing).
Warnings & Precautions	Patients with kidney impairment, the elderly, and those receiving high doses should ensure adequate hydration to prevent kidney problems. Acyclovir can cause neurological side effects; caution is advised when driving or operating machinery until effects are known. This medication only treats herpes viruses; it does not prevent the spread of genital herpes, and safe sex practices are still necessary. Resistance to acyclovir can develop, particularly in immunocompromised patients, if treatment is not effective.
Missed Dose Instructions	If an oral dose of Acyclovir is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose to make up for a missed one. For topical applications, apply when remembered and continue the regular frequency.
Overdose Instructions	In case of an Acyclovir overdose, contact a healthcare professional, emergency services, or a poison control center immediately. While typically not life-threatening, an overdose can cause severe gastrointestinal symptoms, headaches, confusion, and in rare cases, kidney dysfunction. Supportive care and hydration are usually recommended.
Medicine Interactions	Acyclovir can interact with other medications, potentially increasing their levels or increasing the risk of kidney toxicity. Notable interactions include with probenecid and cimetidine, which can increase acyclovir levels. Concurrent use with other nephrotoxic drugs (e.g., aminoglycosides, cyclosporine, tacrolimus) may increase the risk of kidney injury. It's important to inform your doctor about all medications, supplements, and herbal products you are taking.

Adalimumab (Humira)

Purpose/Indication	Adalimumab is a biologic medication used to treat various chronic inflammatory and autoimmune conditions. These include rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, Crohn's disease, ulcerative colitis, plaque psoriasis, hidradenitis suppurativa, and certain types of uveitis. It works by reducing inflammation in the body.
Method of Action	Adalimumab is a monoclonal antibody that specifically binds to and neutralizes tumor necrosis factor-alpha (TNF-a), a protein that plays a key role in inflammatory and immune responses. By blocking TNF-a, adalimumab reduces the inflammation and tissue damage associated with various autoimmune diseases.
Medication Name & Brand Names	The generic name is Adalimumab. The original brand name is Humira. There are also several biosimilar versions available globally, such as Amgevita, Hyrimoz, Idacio, Imraldi, and Yuflyma.
Pharmaceutical Forms & Appearance	Adalimumab is supplied as a clear to slightly opalescent, colorless to pale yellow solution. It is available in prefilled syringes or autoinjector pens for subcutaneous (SC) injection. Some formulations may also be available in single-dose vials.
Dosage & Administration	Adalimumab is administered by subcutaneous injection. The dosage and frequency vary significantly depending on the condition being treated, as well as the patient's age and weight. For many conditions, it is given as an initial loading dose followed by maintenance doses every other week. Patients or caregivers are often trained to self-administer the injections at home.
Supplied As	Adalimumab is typically supplied in single-use prefilled syringes or autoinjector pens. These devices contain the ready-to-use solution for subcutaneous injection. Some original formulations may also be available in single-dose vials.
Contraindications	Adalimumab is contraindicated in patients with a history of hypersensitivity to adalimumab or any of its components. It should not be initiated in patients with active, serious infections, including active tuberculosis. Caution is advised in patients with chronic or recurrent infections, moderate to severe heart failure, or certain demyelinating neurological disorders.
Storage & Expiry	Adalimumab should be stored refrigerated at 2°C to 8°C (36°F to 46°F) in its original carton to protect from light. It must not be frozen. If removed from refrigeration, it can typically be stored at room temperature (up to 25°C or 77°F) for a limited period, usually up to 14 days, but must be discarded if not used within that timeframe. Always refer to the specific product packaging for exact storage conditions and expiration dates.
Side Effects	Common side effects include injection site reactions (redness, pain, swelling), headaches, and upper respiratory tract infections. More serious but less common side effects can include serious infections (e.g., tuberculosis, fungal infections, bacterial sepsis), reactivation of hepatitis B virus, new or worsening heart failure, certain cancers (e.g., lymphoma), and rare neurological reactions. Patients should be monitored for signs of infection.

Warnings & Precautions	Patients must be screened for latent tuberculosis and hepatitis B infection before starting treatment. Live vaccines should not be administered during adalimumab therapy or shortly after discontinuation. Patients should be closely monitored for signs of infection throughout treatment, and any serious infections require discontinuation. Use with caution in patients with a history of malignancy, heart failure, or demyelinating disorders. Hypersensitivity reactions can occur, and patients should be advised on symptoms requiring immediate medical attention.
Missed Dose Instructions	If a dose of Adalimumab is missed, it should be injected as soon as remembered. Subsequent doses should then be administered according to the newly established schedule, maintaining the recommended interval. Do not take a double dose to make up for a missed one. Patients should contact their healthcare provider for specific guidance if a dose is missed.
Overdose Instructions	There is limited clinical experience with adalimumab overdose. In cases of overdose, patients should be monitored for any signs or symptoms of adverse reactions and provided with appropriate symptomatic treatment. Contact a healthcare professional or poison control center immediately for advice.
Medicine Interactions	Concurrent use of Adalimumab with other TNF blockers (e.g., etanercept, infliximab) or other biologic DMARDs (e.g., abatacept, anakinra) is not recommended due to an increased risk of serious infections. Live vaccines should be avoided. While often used with methotrexate, it can increase adalimumab levels. Caution is advised when used with other immunosuppressants. Patients should inform their healthcare provider of all concomitant medications, including over-the-counter drugs and supplements.

Albendazole (Zentel)

Purpose/Indication	Albendazole is an anti-parasitic medication used to treat various worm infections in humans. Its primary uses include treating neurocysticercosis (caused by pork tapeworms), cystic hydatid disease (caused by dog tapeworms), and a range of intestinal worm infections like roundworm, hookworm, whipworm, pinworm, and strongyloidiasis.
Method of Action	Albendazole works by interfering with the worm's metabolism. Specifically, it inhibits tubulin polymerization, which leads to the loss of cytoplasmic microtubules in the parasitic worms. This disruption prevents the worms from absorbing glucose, depleting their energy stores, and ultimately leading to their death.
Medication Name & Brand Names	♦ Medication Name: Albendazole ♦ Brand Name: Albenza (US), Zentel (International)
Pharmaceutical Forms & Appearance	Albendazole is typically available as oral tablets, which may be chewable. The tablets are usually white or off-white.
Dosage & Administration	Dosage varies widely depending on the type of worm infection. For many intestinal infections, a single dose of 400 mg is common. For systemic infections like neurocysticercosis or hydatid disease, higher doses (e.g., 400 mg twice daily) are given for longer durations (days to months), often in cycles with breaks. It should generally be taken with food, especially a fatty meal, to enhance absorption.
Supplied As	Albendazole is supplied as oral tablets, commonly 200 mg or 400 mg strengths.
Contraindications	Albendazole is generally contraindicated in individuals with known hypersensitivity to albendazole or similar drugs (e.g., mebendazole). It is usually avoided during pregnancy, especially in the first trimester, due to potential risk to the fetus. Caution is advised in patients with liver disease or pre-existing bone marrow suppression.
Storage & Expiry	Albendazole tablets should be stored at room temperature (typically below 30°C or 86°F), protected from moisture. Keep them in their original packaging, out of direct light. Always check the specific expiry date printed on the packaging.
Side Effects	Common side effects include headache, nausea, vomiting, abdominal pain, and dizziness. For longer courses of treatment, more serious side effects can occur, such as elevated liver enzymes, temporary hair loss, and suppression of bone marrow (leading to low white blood cell or platelet counts).
Warnings & Precautions	♦ For prolonged treatment, liver function tests and blood counts (e.g., complete blood count) should be monitored. ♦ In neurocysticercosis, treatment can cause increased intracranial pressure or seizures due to the inflammatory response to dying parasites, requiring co-administration of corticosteroids and anticonvulsants. ♦ Women of childbearing age should use effective contraception during and for a period after treatment. ♦ Patients should be advised about potential dizziness affecting the ability to drive or operate machinery.
Missed Dose Instructions	If a dose is missed, take it as soon as remembered with food. However, if it is almost time for the next dose, skip the missed dose and continue the regular dosing schedule. Do not double the dose to catch up. For multi-day or cyclical treatments, adherence is important for efficacy.
Overdose Instructions	In case of an overdose, immediately seek medical attention or contact a poison control center. Symptoms of overdose are generally an exaggeration of known side effects. Supportive care and monitoring for adverse reactions would be the primary approach.
Medicine Interactions	Albendazole's levels can be increased by drugs like dexamethasone and praziquantel, or by grapefruit. Its levels can be decreased by phenytoin and fosphenytoin. Concomitant use with myelosuppressive agents may lead to additive bone marrow suppression. Always inform healthcare providers about all other medications being taken.

Alendronate (Fosamax)

Purpose/Indication	Alendronate is a bisphosphonate medication primarily used to prevent and treat osteoporosis, a condition characterized by weak, brittle bones that are prone to fractures. It is effective in postmenopausal women, men, and individuals with glucocorticoid-induced osteoporosis. It is also used to treat Paget's disease of bone.
Method of Action	Alendronate works by inhibiting osteoclast activity, which are the cells responsible for breaking down bone tissue. By slowing down bone resorption, alendronate allows the bone-forming cells (osteoblasts) to build new bone more effectively, leading to increased bone density and reduced risk of fractures.
Medication Name & Brand Names	♦ Medication Name: Alendronate ♦ Brand Names: Fosamax, Binosto, Fosavance
Pharmaceutical Forms & Appearance	Alendronate is typically available as oral tablets (various strengths), effervescent tablets that dissolve in water, and oral solution (liquid). Tablets are usually white or off-white. The effervescent tablets will fizz when dissolved.

Dosage & Administration	Alendronate is usually taken once daily or once weekly, depending on the indication and specific product. It must be taken first thing in the morning with a full glass of plain water (not mineral water or other beverages), at least 30 minutes before any food, drink, or other medications. Patients must remain upright (sitting or standing) for at least 30 minutes after taking the dose and until after their first food of the day to prevent esophageal irritation.
Supplied As	Alendronate is supplied as oral tablets (e.g., 5 mg, 10 mg, 35 mg, 40 mg, 70 mg), effervescent tablets (70 mg), and oral solution (70 mg/75 mL).
Contraindications	Alendronate is contraindicated in patients with known hypersensitivity to any component, abnormalities of the esophagus that delay esophageal emptying (e.g., stricture, achalasia), inability to stand or sit upright for at least 30 minutes, or hypocalcemia (low blood calcium). It is not recommended for patients with severe renal impairment (creatinine clearance less than 35 mL/min).
Storage & Expiry	Alendronate tablets and solutions should be stored at room temperature, typically between 15°C to 30°C (59°F to 86°F), protected from moisture. Keep in the original container. Effervescent tablets should be protected from moisture. Always check the specific expiry date on the packaging and do not use if expired.
Side Effects	Common side effects include abdominal pain, dyspepsia (indigestion), nausea, constipation, diarrhea, flatulence, and musculoskeletal pain (bone, joint, and/or muscle). Serious but less common side effects include esophageal irritation/ulcers, osteonecrosis of the jaw (ONJ), atypical femur fractures, and severe bone, joint, or muscle pain.
Warnings & Precautions	♦ Ensure adequate calcium and vitamin D intake. Correct hypocalcemia before starting treatment. ♦ Patients must strictly follow administration instructions to minimize esophageal irritation. ♦ Rare cases of osteonecrosis of the jaw (ONJ) have been reported, often associated with dental procedures or poor oral hygiene; dental evaluation is recommended before starting. ♦ Atypical femur fractures have been reported; patients with new or worsening thigh or groin pain should be evaluated. ♦ Discontinue if severe musculoskeletal pain develops. ♦ Use with caution in patients with active upper GI problems or kidney impairment.
Missed Dose Instructions	If a daily dose is missed, skip it and take the next dose as scheduled the following morning; do not take two doses on the same day. If a weekly dose is missed, take it on the morning after remembered; then return to the usual weekly schedule. Do not take two doses on the same day.
Overdose Instructions	Symptoms of overdose may include hypocalcemia, hypophosphatemia, and upper gastrointestinal adverse reactions like upset stomach, heartburn, esophagitis, gastritis, or ulcer. In case of overdose, milk or antacids should be given orally to bind alendronate and minimize absorption. Vomiting should not be induced due to the risk of esophageal irritation. The patient should remain fully upright. Seek immediate medical attention.
Medicine Interactions	♦ Food, beverages (other than plain water), calcium supplements, antacids, iron supplements, and multivitamins with minerals significantly reduce the absorption of alendronate. These should be taken at least 30 minutes, and ideally 2 hours, after alendronate. ♦ NSAIDs (e.g., aspirin, ibuprofen) may increase the risk of upper gastrointestinal side effects when taken with alendronate. ♦ Some specific drugs like ranitidine or certain polyvalent cations can affect absorption.

Amlodipine (Norvasc)

Purpose/Indication	Amlodipine is a calcium channel blocker primarily used to treat high blood pressure (hypertension) and certain types of chest pain (angina pectoris), including chronic stable angina and vasospastic (Prinzmetal's) angina. It helps relax blood vessels, allowing blood to flow more easily and reducing the workload on the heart.
Method of Action	Amlodipine works by blocking the influx of calcium ions into vascular smooth muscle and myocardial (heart muscle) cells. This action causes relaxation of vascular smooth muscle, leading to vasodilation (widening of blood vessels), which lowers blood pressure and increases blood flow to the heart muscle, relieving angina.
Medication Name & Brand Names	♦ Medication Name: Amlodipine ♦ Brand Name: Norvasc
Pharmaceutical Forms & Appearance	Amlodipine is typically available as oral tablets in various strengths (e.g., 2.5 mg, 5 mg, 10 mg). The tablets are usually white and may be scored or debossed with the strength or manufacturer's code.
Dosage & Administration	Amlodipine is usually taken once daily, with or without food. The starting dose for hypertension is often 2.5 mg or 5 mg, which can be titrated up to a maximum of 10 mg daily depending on the patient's response and tolerability. It's important to take it consistently at about the same time each day.
Supplied As	Amlodipine is supplied as oral tablets in various strengths.
Contraindications	Amlodipine is contraindicated in individuals with known hypersensitivity to amlodipine or other dihydropyridine calcium channel blockers. It should be used with caution, or doses may need adjustment, in patients with severe aortic stenosis, obstructive coronary artery disease, or liver impairment.
Storage & Expiry	Amlodipine tablets should be stored at room temperature (typically 15°C to 30°C or 59°F to 86°F), protected from light and moisture. Keep them in their original container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include peripheral edema (swelling, especially in ankles and feet), headache, fatigue, nausea, abdominal pain, and flushing. Less common but more serious side effects can include dizziness, palpitations, excessive lowering of blood pressure (hypotension), and rarely, worsening of angina or myocardial infarction (heart attack) upon initiation or dose increase.
Warnings & Precautions	♦ Caution should be exercised in patients with severe heart failure, as it may worsen their condition in some cases. ♦ Patients with liver impairment may require lower doses and careful monitoring. ♦ Excessive lowering of blood pressure can occur, especially during initial therapy or dose titration. ♦ Peripheral edema is a common side effect and should be monitored, but it is often dose-dependent.
Missed Dose Instructions	If a dose of Amlodipine is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose (e.g., within 10-12 hours of the next dose), skip the missed dose and continue with the regular dosing schedule. Do not take a double dose to make up for a missed one.
Overdose Instructions	Overdose can lead to excessive peripheral vasodilation with marked and prolonged systemic hypotension (very low blood pressure) and possibly reflex tachycardia (rapid heart rate). Severe, prolonged hypotension may result in shock and death. Treatment involves supportive cardiovascular care, including monitoring of cardiac and respiratory function, elevation of extremities, and management of fluid volume and blood pressure with vasopressors if necessary. Calcium gluconate may also be administered intravenously. Seek immediate medical attention.

Medicine Interactions	♦ Concurrent use with strong CYP3A4 inhibitors (e.g., ketoconazole, itraconazole, clarithromycin, ritonavir) can significantly increase amlodipine exposure, potentially leading to increased side effects. ♦ Strong CYP3A4 inducers (e.g., rifampicin, St. John's Wort) may reduce amlodipine's effectiveness. ♦ Amlodipine may increase blood levels of simvastatin and tacrolimus. ♦ Grapefruit juice should be consumed in moderation as it may increase amlodipine levels.

Amoxicillin (Amoxil)

Purpose/Indication	Amoxicillin is a common antibiotic prescribed to treat a variety of bacterial infections, including those affecting the ears, nose, throat, lungs, skin, and urinary tract. It is also used in combination with other medications to treat H. pylori infections and associated stomach ulcers. This medication is not effective against viral infections like the common cold or flu.
Method of Action	Amoxicillin acts by inhibiting the synthesis of bacterial cell walls, which is essential for the bacteria's survival and structural integrity. This leads to the weakening and eventual death of the bacterial cells. It is a penicillin-class antibiotic, but its effectiveness can be reduced by certain bacterial enzymes known as beta-lactamases.
Medication Name & Brand Names	The generic name is Amoxicillin. It is widely available under various brand names, including Amoxil, Trimox, Sumox, and Moxatag (an extended-release form).
Pharmaceutical Forms & Appearance	Amoxicillin is available in several oral forms: capsules, tablets (which may be scored or chewable), and as a powder for oral suspension that is reconstituted with water to form a liquid, often pink and flavored, commonly used for children. Dispersible tablets are also an option. In healthcare settings, it may be provided as a powder for injection.
Dosage & Administration	The dosage and duration of Amoxicillin therapy depend on the specific infection, its severity, and patient factors like age, weight, and kidney function. It is typically taken two or three times a day and can be administered with or without food. Completing the full course of treatment, even if symptoms improve, is crucial to effectively eradicate the infection and prevent antibiotic resistance.
Supplied As	Amoxicillin is commonly supplied as capsules, tablets (including chewable and extended-release), and as a dry powder that is reconstituted to form an oral suspension. It can also be found as a powder for injection in medical environments.
Contraindications	Amoxicillin is contraindicated in individuals with a history of severe allergic reactions (e.g., anaphylaxis or severe skin reactions) to amoxicillin or other beta-lactam antibiotics (penicillins or cephalosporins). It should generally be avoided in patients with infectious mononucleosis due to an increased risk of a generalized skin rash.
Storage & Expiry	Capsules and tablets typically have a shelf life of around two years when stored at room temperature in their original, moisture-protected packaging. Once the powder for oral suspension is mixed with water, it usually must be refrigerated and used within 7 to 14 days, after which any remaining portion should be discarded. Always check the specific packaging for storage instructions and expiry dates.
Side Effects	Common side effects include mild gastrointestinal disturbances such as diarrhea, nausea, and vomiting. A skin rash may also occur, which could indicate an allergic reaction, especially if severe. More serious but less frequent side effects can include severe allergic reactions (e.g., hives, swelling, breathing difficulties, requiring immediate medical attention), severe skin conditions, or Clostridioides difficile-associated diarrhea. Rarely, liver issues or drug-induced enterocolitis syndrome can occur.
Warnings & Precautions	Patients should inform their healthcare provider of any allergy history, particularly to penicillins or cephalosporins, as severe allergic reactions can be life-threatening. Amoxicillin should only be used for bacterial infections to prevent antibiotic resistance, and the full course of treatment is vital. Persistent or severe diarrhea should be reported due to the risk of Clostridioides difficile-associated diarrhea. Caution is advised for patients with kidney impairment, potentially requiring dosage adjustments. Amoxicillin can interfere with some urine glucose tests, leading to false-positive results. Use during breastfeeding should be discussed with a healthcare professional, as it can pass into breast milk. Older adults may also require dosage adjustments due to reduced kidney function.
Missed Dose Instructions	If a dose of Amoxicillin is missed, it should be taken as soon as remembered. However, if it is almost time for the next scheduled dose, the missed dose should be skipped, and the regular dosing schedule resumed. Double doses should not be taken to compensate for a missed one, as this can increase the risk of side effects. If multiple doses are missed, consult a healthcare professional for guidance.
Overdose Instructions	In the event of an Amoxicillin overdose, immediate contact with a healthcare professional, emergency services, or a poison control center is recommended. While an overdose is rarely life-threatening, it can lead to significant gastrointestinal symptoms like severe stomach upset and diarrhea, and in rare instances, kidney problems. Increased fluid intake may be advised to help with symptoms.
Medicine Interactions	Amoxicillin can interact with several other medications. It may enhance the effects of blood thinners like warfarin, increasing bleeding risk. Concurrent use with allopurinol can raise the risk of skin rash. Probenecid can increase amoxicillin levels in the body, potentially increasing side effects. Amoxicillin may reduce the effectiveness of some oral contraceptives, necessitating alternative birth control methods. It can also increase levels of methotrexate and may reduce the efficacy of certain live bacterial vaccines. Always inform your healthcare professional about all medications, supplements, and herbal products being taken to prevent potential interactions.

Amoxicillin/Clavulanate (Augmentin)

Purpose/Indication	Amoxicillin/Clavulanate is a combination antibiotic used to treat a wide range of bacterial infections. It's effective against infections of the ear (otitis media), sinus (sinusitis), respiratory tract (pneumonia, bronchitis), skin and soft tissue, and urinary tract, particularly those caused by bacteria that produce beta-lactamase enzymes.
Method of Action	This medication combines amoxicillin, a penicillin-class antibiotic, with clavulanate (clavulanic acid), a beta-lactamase inhibitor. Amoxicillin works by inhibiting bacterial cell wall synthesis, leading to bacterial death. Clavulanate protects amoxicillin from degradation by beta-lactamase enzymes produced by some bacteria, thus extending amoxicillin's spectrum of activity against resistant strains.
Medication Name & Brand Names	♦ Medication Name: Amoxicillin/Clavulanate ♦ Brand Name: Augmentin (most common globally), Co-amoxiclav, Clavamox, Curam, Amoxiclav
Pharmaceutical Forms & Appearance	It is commonly available as oral tablets (various strengths), chewable tablets, and a powder for oral suspension (liquid that needs to be reconstituted with water). Tablets are typically white or off-white, and the reconstituted suspension is usually an off-white to yellowish liquid, often with a fruit flavor.
Dosage & Administration	Dosage varies based on the infection's severity, patient's age/weight, and renal function. It's typically taken two or three times a day, usually at the start of a meal or with a snack to minimize gastrointestinal upset and optimize absorption. The full prescribed course should be completed, even if symptoms improve.

Supplied As	Amoxicillin/Clavulanate is supplied as oral tablets (e.g., 250mg/125mg, 500mg/125mg, 875mg/125mg, 1000mg/62.5mg extended-release) and as a powder for oral suspension (various concentrations, e.g., 200mg/28.5mg/5mL, 400mg/57mg/5mL, 600mg/42.9mg/5mL).
Contraindications	It is contraindicated in patients with a history of severe hypersensitivity (e.g., anaphylaxis, severe skin reactions) to amoxicillin, clavulanate, or other penicillin antibiotics. It should also not be used in individuals with a history of cholestatic jaundice or liver dysfunction associated with previous amoxicillin/clavulanate therapy.
Storage & Expiry	Tablets should be stored at room temperature, protected from moisture. The reconstituted oral suspension must be stored in a refrigerator (2°C to 8°C or 36°F to 46°F) and typically remains stable for 7 to 10 days; discard any unused portion after this time. Check the specific product label for exact storage and expiry information. Do not freeze the suspension.
Side Effects	Common side effects include diarrhea, nausea, vomiting, abdominal pain, and skin rash. More serious, but less common, side effects can include severe allergic reactions (anaphylaxis), liver dysfunction (jaundice), Clostridioides difficile-associated diarrhea (CDAD), and skin reactions (e.g., Stevens-Johnson syndrome).
Warnings & Precautions	♦ Prior to initiation, inquire about previous hypersensitivity reactions to penicillins or cephalosporins. ♦ Monitor liver function tests, especially during prolonged therapy, and discontinue if liver dysfunction occurs. ♦ Clostridioides difficile-associated diarrhea (CDAD) has been reported and can occur even months after therapy; evaluate patients presenting with diarrhea. ♦ A high percentage of patients with mononucleosis treated with amoxicillin/clavulanate develop a rash. ♦ Not effective against viral infections.
Missed Dose Instructions	If a dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose to make up for a missed one. It's crucial to complete the entire course of antibiotics.
Overdose Instructions	Overdose is generally not life-threatening but can lead to gastrointestinal symptoms such as nausea, vomiting, abdominal pain, and diarrhea. In rare cases, neurological symptoms like seizures may occur, especially in patients with impaired renal function. Treatment is supportive, focusing on managing symptoms and maintaining hydration. Hemodialysis can remove both amoxicillin and clavulanate from the circulation. Seek medical attention for significant overdose.
Medicine Interactions	♦ Probenecid increases amoxicillin levels. ♦ Allopurinol may increase the incidence of skin rash. ♦ Warfarin and other anticoagulants: May increase the risk of bleeding; increased monitoring of INR/prothrombin time may be required. ♦ Oral contraceptives: May reduce the effectiveness of oral contraceptives; advise patients to use an alternative or additional method of contraception. ♦ Methotrexate: May increase methotrexate toxicity by reducing its renal excretion.

Ampicillin (Principen)

Purpose/Indication	Ampicillin is an aminopenicillin antibiotic used to treat a variety of bacterial infections. It is effective against susceptible Gram-positive bacteria (e.g., certain Streptococcus species, Listeria monocytogenes) and some Gram-negative bacteria (e.g., Haemophilus influenzae, Escherichia coli, Salmonella species, Shigella species). Indications include respiratory tract infections, urinary tract infections, gastrointestinal infections, meningitis, and specific infections like listeriosis.
Method of Action	Ampicillin is a beta-lactam antibiotic that acts by inhibiting bacterial cell wall synthesis. It binds to penicillin-binding proteins (PBPs) located on the inner surface of the bacterial cell membrane, which are essential for the cross-linking of peptidoglycan strands, a crucial step in the formation of the bacterial cell wall. By inhibiting this process, ampicillin weakens the cell wall, leading to osmotic lysis and ultimately bacterial cell death (bactericidal action).
Medication Name & Brand Names	♦ Medication Name: Ampicillin (often as Ampicillin Trihydrate or Ampicillin Sodium) ♦ Brand Names: Principen (oral capsules - regional), Omnipen (oral/injection - regional), Amcill (regional), Ampicillin (generic) ♦ Combination Products: Unasyn (ampicillin/sulbactam)
Pharmaceutical Forms & Appearance	Ampicillin is available as oral capsules, oral suspensions (for reconstitution), and powder for injection (for intravenous or intramuscular administration). Oral capsules are typically opaque, with various colors and imprints. Oral suspensions are granular powders that become opaque white or off-white when reconstituted. The powder for injection is white or off-white.
Dosage & Administration	Dosage varies widely depending on the type and severity of infection, patient age, weight, and renal function. For oral infections, typical adult doses are 250 mg to 500 mg every 6 hours. For intravenous/intramuscular severe infections, typical adult doses range from 1 gram to 2 grams every 4-6 hours. It is best taken on an empty stomach (at least 30 minutes before or 2 hours after meals) to optimize absorption. Dose adjustments are necessary for patients with renal impairment.
Supplied As	Ampicillin is supplied as: oral capsules (e.g., 250 mg, 500 mg), powder for oral suspension (e.g., 125 mg/5 mL, 250 mg/5 mL after reconstitution), and powder for injection (e.g., 250 mg, 500 mg, 1 gram, 2 grams per vial).
Contraindications	Ampicillin is strictly contraindicated in patients with known severe hypersensitivity (e.g., anaphylaxis, Stevens-Johnson syndrome) to ampicillin, any penicillin, or any other beta-lactam antibiotic (due to potential cross-reactivity). It is also contraindicated in patients with infectious mononucleosis, as a characteristic non-allergic rash can develop.
Storage & Expiry	Ampicillin oral capsules and powder for injection should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F). The powder for oral suspension should be stored dry, and once reconstituted, the suspension typically requires refrigeration (2°C to 8°C or 36°F to 46°F) and has a limited shelf life (e.g., 14 days). Reconstituted IV solutions also have limited stability and should be used promptly. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal disturbances (diarrhea, nausea, vomiting), rash (maculopapular, non-allergic, particularly in mononucleosis), and candidiasis (oral or vaginal thrush). More serious but less common side effects include hypersensitivity reactions (e.g., anaphylaxis, angioedema, urticaria), Clostridioides difficile-associated diarrhea (CDAD), severe skin reactions (e.g., Stevens-Johnson Syndrome), hematologic abnormalities (e.g., anemia, leukopenia, thrombocytopenia), and liver enzyme elevations.
Warnings & Precautions	♦ Hypersensitivity Reactions: Serious and occasionally fatal hypersensitivity (anaphylactic) reactions have been reported, especially in individuals with a history of penicillin or multiple allergen sensitivities. Careful inquiry about previous allergic reactions is essential before starting therapy. Discontinue immediately if an allergic reaction occurs. ♦ Infectious Mononucleosis: Patients with infectious mononucleosis who receive ampicillin often develop a non-allergic, erythematous maculopapular rash. Avoid use in this condition. ♦ Clostridioides difficile-associated Diarrhea (CDAD): Can occur with nearly all antibacterial agents, including ampicillin, ranging from mild diarrhea to fatal colitis. Evaluate patients who present with diarrhea after antibiotic use. ♦ Renal Impairment: Dose adjustments are necessary for patients with impaired renal function due to potential accumulation of ampicillin and increased risk of toxicity. ♦ Hepatic Impairment: Use with caution in patients with hepatic dysfunction. ♦ Superinfection: Prolonged use can lead to overgrowth of non-susceptible organisms, including fungi and other bacteria. ♦ Seizures: High doses, especially in patients with renal impairment, can lead to CNS toxicity and seizures. ♦ Electrolyte Imbalance: High IV doses can lead to sodium overload. ♦ Drug Resistance: Use responsibly to prevent the development of antibiotic resistance.

Missed Dose Instructions	If a dose of Ampicillin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Completing the full prescribed course of antibiotics is crucial for effective bacterial eradication and preventing the development of drug resistance and relapse of infection.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily gastrointestinal upset (nausea, vomiting, diarrhea), and potential for severe allergic reactions or neurological toxicity (e.g., seizures), especially with high doses or in patients with renal impairment. There is no specific antidote for ampicillin. Treatment is supportive and and symptomatic. Hemodialysis can remove ampicillin from the blood and may be beneficial in severe overdose or acute renal failure. Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Oral Contraceptives: May reduce the effectiveness of oral contraceptives, increasing the risk of unintended pregnancy. Advise alternative birth control methods during therapy. ♦ Allopurinol: Concomitant use with ampicillin significantly increases the incidence of skin rash, particularly in hyperuricemic patients. ♦ Probenecid: Decreases the renal tubular secretion of ampicillin, leading to increased and prolonged blood levels of ampicillin. This interaction is sometimes used therapeutically to enhance ampicillin's effect. ♦ Tetracyclines: Bacteriostatic antibiotics like tetracyclines may antagonize the bactericidal effect of penicillin-type antibiotics like ampicillin. Avoid concomitant use when the bactericidal effect of ampicillin is crucial. ♦ Aminoglycosides (e.g., gentamicin, amikacin): Can inactivate aminoglycosides in vitro when mixed together, especially in high concentrations or in patients with severe renal impairment. Administer separately. ♦ Warfarin: May potentiate the anticoagulant effect, increasing bleeding risk by altering gut flora. Monitor INR closely. ♦ Methotrexate: Ampicillin may reduce methotrexate clearance, potentially increasing its toxicity. Monitor methotrexate levels.

Apixaban (Eliquis)

Purpose/Indication	Apixaban is an oral anticoagulant used to prevent and treat blood clots. It is primarily indicated to reduce the risk of stroke and systemic embolism in patients with nonvalvular atrial fibrillation. It also treats deep vein thrombosis (DVT) and pulmonary embolism (PE), and prevents recurrent DVT and PE after initial therapy, as well as preventing DVT/PE in patients undergoing hip or knee replacement surgery.
Method of Action	Apixaban is a highly selective, direct Factor Xa (FXa) inhibitor. Factor Xa is a key component in the coagulation cascade, responsible for converting prothrombin to thrombin, which then leads to fibrin formation and clot development. By inhibiting both free and clot-bound FXa, apixaban prevents thrombin generation and thus inhibits blood clot formation.
Medication Name & Brand Names	♦ Medication Name: Apixaban ♦ Brand Name: Eliquis
Pharmaceutical Forms & Appearance	Apixaban is available as oral tablets in various strengths (e.5 mg and 2.5 mg are common). The tablets are typically round, biconvex, and film-coated, with different colors and debossed markings depending on the strength (e.g., 2.5 mg may be yellow, 5 mg may be pink).
Dosage & Administration	Apixaban is usually taken twice daily, with or without food. The dosage varies depending on the indication (e.g., 5 mg twice daily for most atrial fibrillation patients, 2.5 mg twice daily for prophylaxis post-surgery, or initial higher doses for DVT/PE treatment). Consistency in timing is important. Tablets can be crushed and mixed with water, apple juice, or applesauce for those who cannot swallow them whole.
Supplied As	Apixaban is supplied as oral tablets in blister packs, in various strengths (e.g., 2.5 mg, 5 mg).
Contraindications	Apixaban is contraindicated in patients with active pathological bleeding (e.g., active ulcer disease, intracranial hemorrhage) and in those with a history of severe hypersensitivity reaction to apixaban. It should be used with extreme caution or avoided in patients with hepatic disease associated with coagulopathy and clinically relevant bleeding risk, or severe renal impairment.
Storage & Expiry	Apixaban tablets should be stored at room temperature (typically below 30°C or 86°F), protected from moisture and light, in their original packaging. Always check the specific expiry date printed on the packaging and do not use if expired.
Side Effects	The most significant side effect is bleeding, which can range from minor (e.g., bruising, nosebleeds, gum bleeding) to serious or even fatal (e.g., gastrointestinal bleeding, intracranial hemorrhage). Other common side effects include nausea. Allergic reactions, though rare, can also occur.
Warnings & Precautions	♦ Increased Risk of Thrombotic Events after Premature Discontinuation: Premature discontinuation significantly increases the risk of stroke or blood clots. Do not stop taking without consulting a doctor. ♦ Bleeding Risk: Apixaban increases the risk of bleeding. Patients should be advised of signs of bleeding and to report them immediately. Concomitant use with other drugs affecting hemostasis (e.g., NSAIDs, antiplatelet agents, other anticoagulants) further increases this risk. ♦ Spinal/Epidural Hematoma: Risk of severe, potentially permanent paralysis if used with spinal anesthesia or spinal puncture. ♦ Not recommended for patients with prosthetic heart valves. ♦ Caution with liver or kidney disease.
Missed Dose Instructions	If a dose of Apixaban is missed, it should be taken as soon as remembered. However, if it is almost time for the next scheduled dose (e.g., less than 6 hours until the next dose for twice-daily dosing), the missed dose should be skipped, and the regular dosing schedule resumed. Do not take a double dose to make up for a missed one. Consistent adherence is crucial for efficacy.
Overdose Instructions	Overdose with apixaban significantly increases the risk of bleeding. Symptoms are primarily exaggerated bleeding events. There is a specific reversal agent (andexanet alfa) available in some regions for life-threatening or uncontrolled bleeding. Activated charcoal may be considered if ingested within a few hours of a significant overdose to reduce absorption. Hemodialysis does not substantially remove apixaban. Immediate medical attention is crucial for suspected overdose.
Medicine Interactions	♦ Increased Bleeding Risk: Concomitant use with other anticoagulants (e.g., warfarin, heparin), antiplatelet agents (e.g., aspirin, clopidogrel), NSAIDs (e.g., ibuprofen, naproxen), SSRIs/SNRIs, and thrombolytic agents significantly increases the risk of bleeding. Avoid concurrent use where possible, or use with extreme caution. ♦ CYP3A4 and P-gp Inhibitors/Inducers: Strong dual inhibitors of CYP3A4 and P-glycoprotein (e.g., ketoconazole, itraconazole, ritonavir, clarithromycin) can increase apixaban levels and bleeding risk. Strong dual inducers (e.g., rifampicin, carbamazepine, phenytoin, St. John's Wort) can decrease apixaban levels, reducing effectiveness. Dose adjustments or avoidance may be necessary. ♦ Grapefruit juice may increase apixaban levels.

Aspirin (Bayer Aspirin)

Purpose/Indication	Aspirin is a non-steroidal anti-inflammatory drug (NSAID) with multiple uses. It is primarily used to relieve mild to moderate pain (e.g., headache, muscle aches, toothache), reduce fever, and alleviate inflammation (e.g., in arthritis). In low doses, it's widely used to prevent blood clots, thereby reducing the risk of heart attacks and strokes in individuals at high risk.

Method of Action	Aspirin's analgesic, anti-inflammatory, and antipyretic (fever-reducing) effects stem from its irreversible inhibition of cyclooxygenase (COX-1 and COX-2) enzymes. This prevents the synthesis of prostaglandins, which are mediators of pain, inflammation, and fever. Its antiplatelet effect, crucial for cardiovascular prevention, comes from its irreversible inhibition of COX-1 in platelets, which reduces thromboxane A2 production, thereby preventing platelet aggregation and clot formation.
Medication Name & Brand Names	♦ Medication Name: Aspirin (Acetylsalicylic Acid - ASA) ♦ Brand Names: Bayer, Disprin, Ecotrin, Bufferin, Anacin, Excedrin, Empirin (often combined with other drugs)
Pharmaceutical Forms & Appearance	Aspirin is available in various oral forms: regular tablets, chewable tablets, enteric-coated tablets (to reduce stomach irritation), extended-release tablets, and effervescent tablets (dissolve in water). It can also be found in suppository form. Tablets are typically white.
Dosage & Administration	Dosage varies greatly depending on the indication. For pain and fever, doses typically range from 325 mg to 650 mg every 4-6 hours. For cardiovascular prevention, low doses (e.g., 75 mg to 325 mg daily) are commonly used. Enteric-coated tablets should be swallowed whole. It's generally recommended to take aspirin with food or milk to minimize gastrointestinal upset.
Supplied As	Aspirin is supplied as oral tablets (various strengths: e.g., 81 mg, 325 mg, 500 mg), chewable tablets, enteric-coated tablets, extended-release tablets, and effervescent tablets.
Contraindications	Aspirin is contraindicated in individuals with known hypersensitivity (allergy) to aspirin or other NSAIDs, or a history of asthma, urticaria, or other allergic-type reactions after taking NSAIDs. It should not be used in children and teenagers for viral infections (e.g., flu, chickenpox) due to the risk of Reye's syndrome. It is also contraindicated in patients with active peptic ulcer disease, bleeding disorders, or severe liver or kidney impairment.
Storage & Expiry	Aspirin tablets should be stored at room temperature (typically 15°C to 30°C or 59°F to 86°F), protected from moisture. Do not use if the tablets smell strongly of vinegar, as this indicates degradation. Keep in the original container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., heartburn, nausea, stomach pain), and increased risk of bleeding (e.g., bruising, nosebleeds). More serious but less common side effects include gastrointestinal ulcers or bleeding, allergic reactions (rash, difficulty breathing), tinnitus (ringing in ears) at high doses, and kidney dysfunction.
Warnings & Precautions	♦ Bleeding Risk: Aspirin can increase the risk of serious bleeding, including gastrointestinal bleeding and hemorrhagic stroke. Use with caution in patients with bleeding disorders, a history of ulcers, or those undergoing surgery. ♦ Reye's Syndrome: Do not give to children or teenagers with viral illnesses due to the rare but serious risk of Reye's syndrome, which can cause severe liver and brain swelling. ♦ Kidney/Liver Impairment: Use with caution in patients with pre-existing kidney or liver disease. ♦ Asthma: Can exacerbate asthma in some susceptible individuals (aspirin-exacerbated respiratory disease). ♦ Discontinue several days prior to surgery to minimize bleeding risk.
Missed Dose Instructions	For pain/fever relief (as-needed dosing), take a dose when pain/fever is present. For regular low-dose cardiovascular prevention, if a daily dose is missed, take it as soon as remembered unless it's almost time for the next dose; in that case, skip the missed dose. Do not take a double dose. Consistency is important for antiplatelet effect, but missing one dose is usually not critical.
Overdose Instructions	Aspirin overdose (salicylate toxicity) can be very serious and requires immediate medical attention. Symptoms can include tinnitus, dizziness, nausea, vomiting, confusion, rapid breathing, fever, sweating, and in severe cases, seizures, coma, and metabolic acidosis. Treatment involves supportive care, gastric decontamination (e.g., activated charcoal if early), urinary alkalinization to promote excretion, and possibly hemodialysis for severe cases.
Medicine Interactions	♦ Anticoagulants/Antiplatelets: Increased risk of bleeding when taken with warfarin, heparin, clopidogrel, or other NSAIDs. ♦ Corticosteroids: Increased risk of gastrointestinal ulcers and bleeding. ♦ Methotrexate: Aspirin can increase methotrexate levels, leading to increased toxicity. ♦ Diuretics and ACE Inhibitors: Aspirin can reduce the effectiveness of these blood pressure medications. ♦ Alcohol: Increased risk of gastrointestinal bleeding. ♦ Other NSAIDs: Avoid concurrent use with other NSAIDs (e.g., ibuprofen, naproxen) as it can increase side effects without significant additional benefit.

Atazanavir (Reyataz)

Purpose/Indication	Atazanavir is an antiretroviral medication used to treat human immunodeficiency virus (HIV-1) infection in adults and pediatric patients. It belongs to the class of drugs known as protease inhibitors. It is always used in combination with other antiretroviral agents to manage HIV infection, helping to reduce the viral load and increase CD4 cell counts.
Method of Action	Atazanavir works by selectively inhibiting HIV-1 protease, an enzyme essential for the proteolytic cleavage of viral Gag and Gag-Pol polyproteins into mature functional proteins. This inhibition prevents the assembly of new, infectious HIV particles, thereby reducing viral replication and progression of the disease.
Medication Name & Brand Names	♦ Medication Name: Atazanavir ♦ Brand Name: Reyataz
Pharmaceutical Forms & Appearance	Atazanavir is available as oral capsules and as an oral powder (for pediatric use). Capsules are typically opaque, hard gelatin capsules of various colors (e.g., blue and white) with specific imprints indicating the dosage strength. The oral powder is typically a granular powder.
Dosage & Administration	Atazanavir is typically taken once daily, with food, to enhance absorption. The dosage varies based on whether it is boosted with ritonavir or cobicistat, and patient factors like renal or hepatic impairment. It is crucial to take it consistently with a meal to ensure adequate absorption and efficacy.
Supplied As	Atazanavir is supplied as oral capsules (e.g., 150 mg, 200 mg, 300 mg) and as an oral powder (e.g., 50 mg packets) for reconstitution.
Contraindications	Atazanavir is contraindicated in patients with a known hypersensitivity to atazanavir or any of its components. It is also contraindicated in patients with severe hepatic impairment, and in combination with certain medications due to significant drug-drug interactions that can lead to serious and/or life-threatening adverse events (e.g., strong CYP3A4 inducers, specific direct-acting antivirals, certain acid-reducing agents).
Storage & Expiry	Atazanavir capsules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), in a tightly closed container, protected from moisture and light. The oral powder should also be stored at room temperature. Always check the specific expiry date on the packaging and do not use if expired.

Side Effects	Common side effects include nausea, vomiting, diarrhea, headache, abdominal pain, and rash. A notable side effect is hyperbilirubinemia (increased bilirubin levels), which can cause jaundice (yellowing of skin/eyes), usually benign but can be cosmetically undesirable. Other serious side effects can include kidney stones, PR interval prolongation (heart rhythm issue), and severe skin reactions.
Warnings & Precautions	♦ Cardiac Conduction Abnormalities: Use with caution in patients with pre-existing conduction system disease or those taking drugs that prolong the PR interval. ♦ Hyperbilirubinemia: Patients commonly experience reversible increases in indirect bilirubin, which may cause jaundice or scleral icterus (yellowing of eyes). ♦ Nephrolithiasis/Cholelithiasis: Kidney stones and gallstones have been reported. ♦ Hepatotoxicity: Liver problems, including severe hepatic dysfunction, have occurred. ♦ Diabetes Mellitus/Hyperglycemia: New onset or worsening of diabetes has been reported in patients taking protease inhibitors. ♦ Fat Redistribution: Redistribution/accumulation of body fat can occur. ♦ Immune Reconstitution Inflammatory Syndrome (IRIS): Can occur in HIV-infected patients starting antiretroviral therapy.
Missed Dose Instructions	If a dose of atazanavir is missed and it is within 12 hours of the regularly scheduled time, take it with food as soon as remembered. If it is more than 12 hours past the usual time, skip the missed dose and resume the normal dosing schedule the next day. Do not take a double dose to make up for a missed one. Adherence to the dosing schedule is critical for effective HIV management.
Overdose Instructions	There is limited experience with atazanavir overdose. Symptoms would likely be an exaggeration of known side effects, particularly gastrointestinal issues and potential worsening of hyperbilirubinemia. Treatment should be supportive, involving general supportive measures, monitoring of vital signs, and observation for any adverse reactions. Hemodialysis is unlikely to be effective in removing atazanavir. Contact a healthcare professional or poison control center immediately.
Medicine Interactions	♦ Acid-Reducing Agents: Antacids, H2-receptor antagonists (e.g., famotidine), and proton pump inhibitors (e.g., omeprazole) significantly reduce atazanavir absorption; co-administration is generally not recommended or requires specific timing/dosing adjustments. ♦ CYP3A4 Substrates/Inhibitors/Inducers: Atazanavir is metabolized by and is an inhibitor of CYP3A4. Co-administration with drugs highly dependent on CYP3A4 for clearance can lead to increased levels of those drugs (e.g., statins, sildenafil, certain calcium channel blockers). Strong CYP3A4 inducers (e.g., rifampin, St. John's Wort, carbamazepine, phenytoin) can significantly decrease atazanavir levels, leading to loss of virologic response and resistance; co-administration is generally contraindicated. ♦ Ritonavir/Cobicistat: Atazanavir is typically boosted with low-dose ritonavir or cobicistat to improve its pharmacokinetic profile. ♦ Oral Contraceptives: Atazanavir may alter hormone levels; alternative contraception may be needed.

Atenolol (Tenormin)

Purpose/Indication	Atenolol is a beta-blocker medication used to treat high blood pressure (hypertension), angina pectoris (chest pain), and to manage certain cardiac arrhythmias (irregular heartbeats). It also helps to prevent future heart attacks in patients who have already had one. By slowing the heart rate and relaxing blood vessels, it reduces the heart's workload.
Method of Action	Atenolol selectively blocks beta-1 adrenergic receptors, primarily located in the heart. This blockade leads to a decrease in heart rate, force of myocardial contraction, and cardiac output. It also reduces the release of renin from the kidneys, contributing to its blood pressure-lowering effects. Its selective action means it has less impact on beta-2 receptors in the lungs, making it generally safer for patients with respiratory conditions compared to non-selective beta-blockers.
Medication Name & Brand Names	♦ Medication Name: Atenolol ♦ Brand Name: Tenormin
Pharmaceutical Forms & Appearance	Atenolol is most commonly available as oral tablets in various strengths (e.g., 25 mg, 50 mg, 100 mg). The tablets are typically white, round, or oval, and may be scored or debossed with the strength or manufacturer's identifying marks.
Dosage & Administration	Atenolol is usually taken once daily, with or without food. The starting dose for hypertension is often 25 mg or 50 mg, which can be adjusted based on the patient's response and tolerability, up to a maximum of 100 mg daily. It's important to take it consistently at about the same time each day. It should not be stopped abruptly.
Supplied As	Atenolol is supplied as oral tablets in various strengths (e.g., 25 mg, 50 mg, 100 mg).
Contraindications	Atenolol is contraindicated in patients with severe bradycardia (very slow heart rate), second- or third-degree atrioventricular (AV) block, cardiogenic shock, overt cardiac failure, or sick sinus syndrome (unless a pacemaker is in place). It is also contraindicated in individuals with known hypersensitivity to atenolol or any component of the formulation.
Storage & Expiry	Atenolol tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep them in their original container. Always check the specific expiry date on the packaging and do not use if expired.
Side Effects	Common side effects include bradycardia (slow heart rate), cold extremities, fatigue, dizziness, lightheadedness, nausea, and depression. Less common but more serious side effects can include worsening of heart failure, bronchospasm (in susceptible individuals), hypotension, and very rarely, skin reactions or hallucinations.
Warnings & Precautions	♦ Abrupt Cessation: Do not discontinue atenolol abruptly, especially in patients with coronary artery disease, as it can worsen angina or precipitate a myocardial infarction. Doses should be gradually tapered over 1-2 weeks. ♦ Heart Failure: Use with caution in patients with heart failure, as it can worsen symptoms in some cases. ♦ Bronchospastic Disease: While beta-1 selective, it should be used with caution in patients with asthma or COPD; higher doses or non-selectivity can worsen respiratory issues. ♦ Diabetes: May mask symptoms of hypoglycemia (e.g., rapid heart rate). ♦ Thyrotoxicosis: May mask clinical signs of hyperthyroidism. ♦ Renal Impairment: Dose adjustment is necessary in patients with kidney dysfunction.
Missed Dose Instructions	If a dose of Atenolol is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. Consistency in daily dosing is important for maintaining stable blood pressure and heart rate control.
Overdose Instructions	Overdose can lead to severe bradycardia, hypotension, acute cardiac failure, and bronchospasm. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered if ingestion was recent. Atropine can be used for bradycardia, glucagon for myocardial depression, and vasopressors for hypotension. Pacemaker insertion may be required for refractory bradycardia. Seek immediate medical attention.
Medicine Interactions	♦ Calcium Channel Blockers (non-dihydropyridine): Concurrent use with verapamil or diltiazem can cause additive effects leading to severe bradycardia, AV block, and heart failure; generally avoided. ♦ Antihypertensive Agents: May have an additive hypotensive effect with other blood pressure-lowering drugs. ♦ Digoxin: Can increase digoxin levels and cause additive bradycardia. ♦ NSAIDs: May blunt the antihypertensive effect of beta-blockers. ♦ Insulin/Oral Hypoglycemics: May mask symptoms of hypoglycemia. ♦ Clonidine: If discontinuing clonidine and a beta-blocker concurrently, taper the beta-blocker first to avoid rebound hypertension.

Atorvastatin (Lipitor)

Purpose/Indication	Atorvastatin is a statin medication used to lower high cholesterol levels and reduce the risk of cardiovascular events such as heart attacks and strokes. It is indicated for treating primary hypercholesterolemia, mixed dyslipidemia, homozygous familial hypercholesterolemia, and for primary prevention of cardiovascular disease in patients with multiple risk factors.
Method of Action	Atorvastatin works by competitively inhibiting HMG-CoA reductase, an enzyme essential for cholesterol synthesis in the liver. By blocking this enzyme, it reduces the production of cholesterol. This leads to a decrease in low-density lipoprotein cholesterol (LDL-C, "bad" cholesterol) and triglycerides, while increasing high-density lipoprotein cholesterol (HDL-C, "good" cholesterol) in the blood.
Medication Name & Brand Names	♦ Medication Name: Atorvastatin ♦ Brand Name: Lipitor
Pharmaceutical Forms & Appearance	Atorvastatin is available as oral tablets in various strengths (e.g., 10 mg, 20 mg, 40 mg, 80 mg). The tablets are typically white to off-white, oval-shaped, and may be debossed with the strength or manufacturer's identifying marks.
Dosage & Administration	Atorvastatin is usually taken once daily, with or without food, at any time of day. However, consistency in timing is often recommended to establish a routine. The starting dose is typically 10 mg or 20 mg daily, which can be adjusted based on the patient's cholesterol levels and treatment goals, up to a maximum of 80 mg daily.
Supplied As	Atorvastatin is supplied as oral tablets in various strengths (e.g., 10 mg, 20 mg, 40 mg, 80 mg).
Contraindications	Atorvastatin is contraindicated in individuals with active liver disease or unexplained persistent elevations of serum transaminases (liver enzymes). It is also contraindicated during pregnancy and breastfeeding, and in patients with known hypersensitivity to atorvastatin or any component of the formulation.
Storage & Expiry	Atorvastatin tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light, in their original container. Always check the specific expiry date on the packaging and do not use if expired.
Side Effects	Common side effects include nasopharyngitis, arthralgia (joint pain), diarrhea, pain in extremity, and urinary tract infection. More serious but less common side effects can include myopathy (muscle pain or weakness) and rhabdomyolysis (severe muscle breakdown), liver dysfunction, and elevated blood glucose levels.
Warnings & Precautions	♦ Muscle Effects: Patients should be advised to report any unexplained muscle pain, tenderness, or weakness, especially if accompanied by fever or malaise. Creatine kinase (CK) levels should be checked if muscle symptoms occur. The risk of myopathy/rhabdomyolysis is increased with higher doses and concurrent use of certain interacting drugs. ♦ Liver Dysfunction: Liver function tests should be performed before initiation and periodically during treatment. If persistent elevations in liver enzymes occur, the drug should be discontinued. ♦ Diabetes Risk: Statins may increase HbA1c and fasting serum glucose levels. ♦ Pregnancy/Lactation: Contraindicated due to potential fetal harm.
Missed Dose Instructions	If a dose of Atorvastatin is missed, take it as soon as remembered if it is still within the same day. If a full day has passed or it's almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule the next day. Do not take a double dose to make up for a missed one.
Overdose Instructions	There is no specific treatment for atorvastatin overdose. In the event of an overdose, treatment should be symptomatic and supportive, focusing on managing any adverse effects that arise. Liver function tests and CK levels should be monitored. Because atorvastatin is highly protein-bound, hemodialysis is unlikely to significantly enhance its clearance. Seek immediate medical attention.
Medicine Interactions	♦ Strong CYP3A4 Inhibitors: Co-administration with strong CYP3A4 inhibitors (e.g., cyclosporine, telithromycin, clarithromycin, itraconazole, ritonavir-boosted HIV protease inhibitors) can significantly increase atorvastatin levels, increasing the risk of myopathy/rhabdomyolysis. Avoid or use lower atorvastatin doses. ♦ Gemfibrozil/Fibrates: Increased risk of muscle problems when used with fibrates like gemfibrozil. ♦ Niacin: High doses of niacin (≥1 g/day) can increase the risk of muscle problems. ♦ Colchicine: Increased risk of myopathy. ♦ Grapefruit Juice: Consumption of large quantities of grapefruit juice (e.g., >1.2 liters/day) can significantly increase atorvastatin levels.

Atovaquone/Proguanil (Malarone)

Purpose/Indication	Atovaquone/Proguanil is a combination antimalarial medication used for both the prevention and treatment of malaria, especially against Plasmodium falciparum, including chloroquine-resistant strains. For prevention (prophylaxis), it's typically taken before, during, and after travel to malaria-endemic areas. For treatment, it's used for acute, uncomplicated malaria.
Method of Action	This combination works synergistically by targeting two different pathways in the malaria parasite. Atovaquone inhibits the parasite's mitochondrial electron transport, disrupting pyrimidine biosynthesis. Proguanil, through its active metabolite cycloguanil, inhibits dihydrofolate reductase, thereby disrupting deoxythymidylate synthesis. These combined actions interfere with nucleic acid replication, leading to the death of the malaria parasite.
Medication Name & Brand Names	♦ Medication Name: Atovaquone/Proguanil ♦ Brand Name: Malarone (most common globally)
Pharmaceutical Forms & Appearance	Atovaquone/Proguanil is available as oral tablets, in adult and pediatric strengths. The tablets are typically pink, film-coated, and round or biconvex, with specific engravings.
Dosage & Administration	Dosage depends on whether it's for prophylaxis or treatment, and for treatment, it also depends on the patient's weight. For prophylaxis, adults usually take one adult tablet daily, starting 1-2 days before entering a malaria-risk area, continuing daily throughout the stay, and for 7 days after leaving. For treatment, a higher dose is given daily for 3 consecutive days. It must always be taken with food or a milky drink to ensure proper absorption. If vomiting occurs within 1 hour of dosing, a repeat dose should be taken.
Supplied As	Atovaquone/Proguanil is supplied as oral tablets: adult strength (250 mg atovaquone/100 mg proguanil HCl) and pediatric strength (62.5 mg atovaquone/25 mg proguanil HCl).
Contraindications	Atovaquone/Proguanil is contraindicated in individuals with known hypersensitivity to atovaquone, proguanil hydrochloride, or any component of the formulation. It is also contraindicated for malaria prophylaxis in patients with severe renal impairment (creatinine clearance less than 30 mL/min) due to accumulation of proguanil.
Storage & Expiry	Tablets should be stored at room temperature (typically below 30°C or 86°F), protected from moisture and light, in their original packaging. Always check the specific expiry date printed on the pack.

MEDICATION | Medication | A - C | Atovaquone/Proguanil (Malarone)

Side Effects	Common side effects include abdominal pain, nausea, vomiting, diarrhea, headache, and dizziness. These are often mitigated by taking the medication with food. Less common but more serious side effects can include severe allergic reactions, liver problems (hepatitis, jaundice), and blood disorders like anemia.
Warnings & Precautions	♦ Vomiting/Diarrhea: If patients vomit or have severe diarrhea, absorption of atovaquone may be reduced, potentially leading to treatment failure. Monitor closely and consider antiemetics. ♦ Renal Impairment: Not recommended for prophylaxis in severe renal impairment; use with caution for treatment. ♦ Relapse: This medication does not provide radical cure for all Plasmodium species (e.g., P. vivax, P. ovale), so a relapse may occur. ♦ It does not guarantee complete protection from malaria; mosquito bite prevention measures remain essential.
Missed Dose Instructions	If a dose of Atovaquone/Proguanil is missed, take it as soon as remembered with food. However, if it's almost time for the next dose, skip the missed dose and continue with the regular schedule. Do not take two doses to make up for a missed one. Completing the full course as prescribed is critical for effectiveness.
Overdose Instructions	There is limited information on specific overdose symptoms for atovaquone/proguanil. Overdose would likely lead to an exaggeration of common side effects, primarily gastrointestinal upset. In cases of significant overdose, general supportive care and monitoring for adverse reactions are recommended. Activated charcoal may be considered if ingestion was recent. Hemodialysis is not effective for atovaquone. Seek immediate medical attention.
Medicine Interactions	♦ Rifampin/Rifabutin: Concurrent use significantly decreases atovaquone levels, leading to reduced efficacy. Co-administration is generally contraindicated. ♦ Metoclopramide: May decrease atovaquone levels. ♦ Tetracycline: Concurrent use may decrease atovaquone levels. ♦ Warfarin and other anticoagulants: May enhance the anticoagulant effect of warfarin, increasing bleeding risk; INR monitoring is recommended. ♦ Efavirenz/Indinavir: May reduce atovaquone levels. ♦ Food/Fat: Taking with food, especially fatty meals, enhances atovaquone absorption; taking it without food significantly reduces its effectiveness.

Azathioprine (Imuran)

MEDICATION | Medication | A - C | Azathioprine (Imuran)

Purpose/Indication	Azathioprine is an immunosuppressant medication used to prevent organ rejection after transplantation and to treat severe autoimmune diseases. It is indicated for conditions such as rheumatoid arthritis, Crohn's disease, ulcerative colitis, systemic lupus erythematosus, and certain types of vasculitis, where other treatments have failed or are not tolerated.
Method of Action	Azathioprine is a prodrug that is converted in the body to 6-mercaptopurine (6-MP), and then further metabolized to active thiopurine nucleotides. These metabolites interfere with purine synthesis, which is essential for DNA and RNA production. This inhibits the proliferation of rapidly dividing cells, particularly T and B lymphocytes, thereby suppressing the immune system's activity and reducing inflammation.
Medication Name & Brand Names	♦ Medication Name: Azathioprine ♦ Brand Names: Imuran, Azasan
Pharmaceutical Forms & Appearance	Azathioprine is typically available as oral tablets in various strengths (e.g., 25 mg, 50 mg, 75 mg, 100 mg). The tablets are usually yellow, round, and scored or debossed with identifying marks. It can also be available as a powder for injection for intravenous administration, but oral forms are more common for chronic use.
Dosage & Administration	Dosage varies widely based on the patient's condition, weight, and response, and is often individualized. It is typically taken once daily, with or after food, to minimize gastrointestinal upset. Regular blood tests are required to monitor blood counts and liver function to ensure safe and effective dosing. It is crucial to take this medication exactly as prescribed and not to stop it abruptly without medical guidance.
Supplied As	Azathioprine is supplied as oral tablets (e.g., 25 mg, 50 mg, 75 mg, 100 mg).
Contraindications	Azathioprine is contraindicated in patients with known hypersensitivity to azathioprine or any of its components. It is also contraindicated in patients with severe infections, severe bone marrow suppression, or a history of pancreatitis directly related to prior azathioprine therapy. Pregnancy and breastfeeding are generally considered contraindications due to potential harm to the fetus/infant.
Storage & Expiry	Azathioprine tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture, in a tightly closed container. Always check the specific expiry date on the packaging. Keep out of reach of children.
Side Effects	Common side effects include nausea, vomiting, abdominal pain, diarrhea, and loss of appetite. More serious but less common side effects include bone marrow suppression (leading to low white blood cell count, anemia, or thrombocytopenia), increased risk of infections, liver dysfunction, pancreatitis, and an increased risk of certain cancers (especially lymphoma and skin cancer with long-term use).
Warnings & Precautions	♦ Bone Marrow Suppression: Azathioprine can cause severe and dose-related bone marrow suppression. Regular complete blood counts (CBC) are essential for monitoring. The risk is significantly increased in patients with low or absent thiopurine methyltransferase (TPMT) enzyme activity, which should be tested before or early in treatment. ♦ Increased Risk of Infection: Immunosuppression increases susceptibility to bacterial, viral, fungal, and opportunistic infections. ♦ Hepatotoxicity: Liver function should be monitored regularly. ♦ Malignancy Risk: Long-term use is associated with an increased risk of certain lymphomas, skin cancers, and other malignancies. ♦ Pancreatitis: Can cause pancreatitis. ♦ Avoid live vaccines.
Missed Dose Instructions	If a dose of Azathioprine is missed, take it as soon as remembered if it is on the same day. If a full day has passed or it's almost time for the next scheduled dose, skip the missed dose and take the next dose as scheduled. Do not take a double dose to make up for a missed one. Consistent daily dosing is important for maintaining stable immunosuppression. Contact a healthcare provider for specific guidance, especially for transplant patients.
Overdose Instructions	Symptoms of overdose are primarily an exaggeration of known side effects, particularly severe bone marrow suppression (leading to severe leukopenia, thrombocytopenia, anemia), infection, liver dysfunction, and nausea/vomiting. There is no specific antidote. Treatment is supportive, focusing on managing hematologic toxicities (e.g., blood transfusions, granulocyte colony-stimulating factors) and preventing/treating infections. Liver function should be monitored. Seek immediate medical attention.
Medicine Interactions	♦ Allopurinol/Febuxostat: These drugs (used for gout) significantly inhibit the metabolism of azathioprine, leading to dangerously high levels and severe bone marrow suppression. The dose of azathioprine must be drastically reduced (typically by 75%) if co-administered; co-administration is generally discouraged unless strictly necessary with very careful monitoring. ♦ Warfarin: Azathioprine may reduce the anticoagulant effect of warfarin. INR monitoring is recommended. ♦ Aminosalicylates (e.g., mesalamine, olsalazine, sulfasalazine): Can inhibit TPMT, increasing the risk of bone marrow suppression; requires careful monitoring. ♦ Live Vaccines: Avoid concurrent use due to compromised immune response. ♦ Other Myelosuppressive Agents: Increased risk of bone marrow suppression when used with other drugs that suppress bone marrow.

MEDICATION

List

A - C - A - C - A - C - A

Azithromycin (Zithromax)

Purpose/Indication	Azithromycin is a macrolide antibiotic used to treat various bacterial infections. It's commonly prescribed for respiratory tract infections (e.g., bronchitis, pneumonia, sinusitis), ear infections (otitis media), skin and soft tissue infections, and certain sexually transmitted infections (e.g., chlamydia). Its long half-life allows for shorter treatment courses.
Method of Action	Azithromycin works by inhibiting bacterial protein synthesis. It binds to the 50S ribosomal subunit of susceptible bacteria, thereby interfering with the translocation of peptides and inhibiting the assembly of new proteins. This bacteriostatic action ultimately prevents the growth and reproduction of bacteria.
Medication Name & Brand Names	♦ Medication Name: Azithromycin ♦ Brand Names: Zithromax, Zmax
Pharmaceutical Forms & Appearance	Azithromycin is available as oral tablets, oral capsules, extended-release oral suspension, and powder for oral suspension (liquid that needs to be reconstituted). Tablets are typically white or off-white, often oval-shaped. The reconstituted liquid is usually a white to off-white suspension.
Dosage & Administration	Dosage and duration vary depending on the infection. For many infections, a single daily dose for 3-5 days is common (e.g., 500 mg on day 1, then 250 mg on days 2-5). For certain STIs, a single 1 gram dose is often prescribed. It can be taken with or without food, but taking it with food may help reduce gastrointestinal upset. Always complete the full course.
Supplied As	Azithromycin is supplied as oral tablets (e.g., 250 mg, 500 mg, 600 mg), oral capsules (250 mg), powder for oral suspension (various concentrations), and extended-release oral suspension (2 g).
Contraindications	Azithromycin is contraindicated in patients with a history of allergic reactions to azithromycin, erythromycin, any macrolide or ketolide antibiotic. It is also contraindicated in patients with a history of cholestatic jaundice or hepatic dysfunction associated with prior azithromycin use.
Storage & Expiry	Tablets and capsules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. The reconstituted oral suspension must be stored at or below 30°C (86°F) and typically remains stable for 10 days; discard any unused portion after this time. Always check the specific product label for exact storage and expiry information.
Side Effects	Common side effects include diarrhea, nausea, vomiting, abdominal pain, and headache. Less common but more serious side effects can include severe allergic reactions (e.g., Stevens-Johnson syndrome, anaphylaxis), liver problems, QT prolongation (a heart rhythm abnormality that can lead to serious arrhythmias), and Clostridioides difficile-associated diarrhea (CDAD).
Warnings & Precautions	♦ Hypersensitivity Reactions: Serious allergic reactions, including angioedema and anaphylaxis, have been reported. ♦ QT Prolongation: Can prolong the QT interval on an electrocardiogram, increasing the risk of potentially fatal arrhythmias, especially in patients with pre-existing heart conditions, electrolyte disturbances, or those taking other QT-prolonging drugs. ♦ Liver Dysfunction: Use with caution in patients with impaired liver function; severe liver problems have been reported. ♦ Clostridioides difficile-Associated Diarrhea (CDAD): Can occur during or after antibiotic therapy. ♦ Myasthenia Gravis: May exacerbate symptoms of myasthenia gravis. ♦ Not effective against viral infections.
Missed Dose Instructions	If a dose of Azithromycin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose to make up for a missed one. It is crucial to complete the entire course of antibiotics to prevent the development of antibiotic resistance.
Overdose Instructions	Symptoms of overdose are generally an exaggeration of known side effects, primarily severe gastrointestinal symptoms such as nausea, vomiting, diarrhea, and abdominal discomfort. Reversible hearing loss has also been reported with very high doses. Treatment is supportive and symptomatic; activated charcoal may be considered if ingestion was recent. Seek immediate medical attention.
Medicine Interactions	♦ Antacids containing aluminum or magnesium: Can significantly reduce azithromycin absorption; administer azithromycin at least 2 hours before or after these antacids. ♦ Warfarin: May enhance the anticoagulant effect of warfarin, increasing bleeding risk; INR monitoring is recommended. ♦ Digoxin: May increase digoxin levels. ♦ Ergot derivatives (e.g., ergotamine): Concurrent use may lead to acute ergot toxicity (vasospasm with ischemia). ♦ QT-prolonging drugs: Use with caution with other medications that prolong the QT interval (e.g., antiarrhythmics, antipsychotics, certain antidepressants) due to increased risk of arrhythmias. ♦ Cyclosporine: May increase cyclosporine levels; monitoring is recommended.

Azithromycin (Zithromax)

Baloxavir Marboxil (Xofluza)

Purpose/Indication	Baloxavir marboxil is an antiviral medication used to treat acute, uncomplicated influenza (flu) caused by influenza A or B viruses. It is indicated for individuals 12 years of age and older who have been symptomatic for no more than 48 hours. It can also be used for post-exposure prophylaxis of influenza in people aged 12 years and older.
Method of Action	Baloxavir marboxil is a prodrug that is converted to its active form, baloxavir acid. Baloxavir acid acts as a selective inhibitor of influenza cap-dependent endonuclease, an enzyme that is part of the viral polymerase complex. By inhibiting this enzyme, baloxavir interferes with the initiation of messenger RNA (mRNA) synthesis, thereby preventing the replication of the influenza virus.
Medication Name & Brand Names	♦ Medication Name: Baloxavir Marboxil ♦ Brand Name: Xofluza
Pharmaceutical Forms & Appearance	Baloxavir marboxil is available as oral tablets in various strengths (e.g., 20 mg, 40 mg). The tablets are typically light yellow to yellow, oval-shaped, and film-coated, with specific imprints indicating the dosage strength.
Dosage & Administration	Baloxavir marboxil is a single-dose oral treatment. For treatment, the dose is based on the patient's body weight (e.g., 40 mg for 40 kg to <80 kg, 80 mg for ≥80 kg). For post-exposure prophylaxis, the same weight-based single dose applies. It can be taken with or without food, but should be avoided with dairy products, calcium-fortified beverages, or polyvalent cation-containing laxatives, antacids, or oral supplements.
Supplied As	Baloxavir marboxil is supplied as oral film-coated tablets in blister packs (e.g., 20 mg, 40 mg).
Contraindications	Baloxavir marboxil is contraindicated in individuals with known hypersensitivity to baloxavir marboxil or any component of the formulation. It is generally not recommended for use in severe influenza complications requiring hospitalization, or in immunocompromised patients, as its efficacy in these populations has not been established.
Storage & Expiry	Baloxavir marboxil tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light, in their original packaging. Always check the specific expiry date printed on the packaging.

Baloxavir Marboxil (Xofluza)

MEDICATION

Medication

Side Effects	Common side effects include diarrhea, bronchitis, nausea, headache, and nasopharyngitis. Less common but serious side effects can include hypersensitivity reactions (e.g., anaphylaxis, urticaria), although these are rare. Postmarketing reports have included allergic reactions and serious skin reactions.
Warnings & Precautions	♦ Bacterial Co-infections: Baloxavir marboxil is not effective against bacterial infections. Patients should be monitored for bacterial co-infections and treated appropriately if suspected. ♦ Efficacy in Specific Populations: Efficacy has not been established in patients with complicated or severe influenza, or in hospitalized patients, or in immunocompromised patients. ♦ Antiviral Resistance: Resistance to baloxavir can emerge, especially in certain patient populations (e.g., children). ♦ Drug Interactions: Avoid co-administration with polyvalent cation-containing products (see interactions).
Missed Dose Instructions	Baloxavir marboxil is a single-dose treatment. Therefore, there are no "missed dose" instructions in the traditional sense. It should be taken as soon as possible after symptom onset (within 48 hours for treatment) or after exposure for prophylaxis. If the dose is vomited within 30 minutes, a repeat dose may be considered.
Overdose Instructions	There is limited experience with overdose of baloxavir marboxil. In case of overdose, general supportive care and monitoring for any adverse reactions would be recommended. Hemodialysis is unlikely to remove baloxavir acid effectively due to its high protein binding. Contact a healthcare professional or poison control center immediately.
Medicine Interactions	♦ Polyvalent Cation-Containing Products: Co-administration with dairy products, calcium-fortified beverages, or polyvalent cation-containing laxatives, antacids, or oral supplements (e.g., containing iron, zinc, selenium, calcium, magnesium) significantly reduces the plasma concentration of baloxavir, leading to reduced efficacy. These should be avoided for 2 hours before and 6 hours after taking baloxavir marboxil. ♦ No clinically significant interactions with other commonly used medications have been identified.

Bedaquiline (Sirturo)

Purpose/Indication	Bedaquiline is an antitubercular medication specifically used as part of combination therapy to treat pulmonary tuberculosis (TB) caused by Mycobacterium tuberculosis that is resistant to other medicines, particularly multi-drug-resistant TB (MDR-TB). It is crucial that it is used in conjunction with at least three other anti-TB drugs to which the patient's isolate is likely susceptible.
Method of Action	Bedaquiline works by inhibiting mycobacterial ATP synthase, an enzyme essential for the replication of Mycobacterium tuberculosis. By blocking this enzyme, it disrupts the energy generation process of the bacteria, leading to their death and inhibiting their growth. This novel mechanism of action makes it effective against strains resistant to conventional anti-TB drugs.
Medication Name & Brand Names	♦ Medication Name: Bedaquiline ♦ Brand Name: Sirturo
Pharmaceutical Forms & Appearance	Bedaquiline is available as oral tablets, typically in strengths of 20 mg and 100 mg. The tablets are usually white and may be functionally scored (20 mg tablets).
Dosage & Administration	Bedaquiline is administered orally with food. The treatment duration is typically 24 weeks. For the first 2 weeks, it is taken daily (e.g., 400 mg once daily for adults). From Week 3 to Week 24, it is taken three times per week (e.g., 200 mg three times per week for adults), with at least 48 hours between doses. Pediatric dosing is weight-based.
Supplied As	Bedaquiline is supplied as oral tablets, commonly in 20 mg and 100 mg strengths.
Contraindications	Bedaquiline is contraindicated in patients with known hypersensitivity to bedaquiline or any of its components. It is also contraindicated in patients with severe hepatic impairment, a QTc interval of greater than 500 ms (confirmed by repeat ECG), or clinically significant ventricular arrhythmia.
Storage & Expiry	Bedaquiline tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep them in their original container. Always check the specific expiry date printed on the packaging.
Side Effects	Common side effects include nausea, headache, arthralgia (joint pain), and elevated liver enzymes. Serious and important side effects include QT prolongation (a heart rhythm abnormality), hepatotoxicity (liver injury), and a higher rate of mortality compared to placebo in clinical trials (though causes were varied and not directly linked to bedaquiline in all cases).
Warnings & Precautions	♦ QT Prolongation: Bedaquiline can prolong the QT interval; ECGs and electrolyte levels (potassium, magnesium, calcium) must be monitored at baseline and regularly during treatment. Discontinue if significant QT prolongation or ventricular arrhythmia occurs. ♦ Hepatotoxicity: Liver function tests should be monitored monthly. Discontinue if significant liver enzyme elevations occur. ♦ Increased Mortality: An imbalance in deaths was observed in clinical trials; the cause is not fully understood. ♦ Administer as part of combination therapy for MDR-TB only. ♦ Avoid in patients with severe renal impairment.
Missed Dose Instructions	If a dose is missed during the first 2 weeks of daily dosing, do not make up the missed dose; continue with the next scheduled daily dose. From Week 3 onwards (three times a week dosing), if a dose is missed, take it as soon as possible and then resume the three times a week schedule. Ensure at least 24 hours between taking the missed dose and the next scheduled dose, and do not exceed the recommended weekly dose.
Overdose Instructions	Limited information is available on specific overdose symptoms. Overdose would likely lead to an exaggeration of known side effects, particularly QT prolongation and hepatotoxicity. Treatment should be supportive, involving immediate medical attention, monitoring of vital signs, ECG, and liver function. Activated charcoal may be considered if ingestion was recent. Hemodialysis is not effective for removal.
Medicine Interactions	♦ Strong CYP3A4 Inducers: Co-administration with strong CYP3A4 inducers (e.g., rifampicin, phenytoin, carbamazepine, St. John's Wort) significantly reduces bedaquiline exposure, potentially leading to treatment failure. Co-administration is generally contraindicated. ♦ Strong CYP3A4 Inhibitors: Concurrent use with strong CYP3A4 inhibitors (e.g., ketoconazole, itraconazole, clarithromycin, ritonavir-boosted HIV protease inhibitors) can increase bedaquiline exposure, increasing the risk of adverse effects including QT prolongation. Co-administration should be done with caution and increased ECG monitoring. ♦ QT-Prolonging Drugs: Avoid or use with extreme caution with other drugs that prolong the QT interval (e.g., fluoroquinolones, macrolides, clofazimine), as this can lead to additive QT prolongation and increased risk of arrhythmias.

Benzyl Benzoate (Benylate)

Purpose/Indication	Benzyl benzoate is an antiparasitic agent used topically to treat scabies and pediculosis (lice infestations). It works by acting as a miticide (kills mites) and pediculicide (kills lice), effectively eliminating the parasites that cause these highly contagious skin conditions.
Method of Action	The exact mechanism of action of benzyl benzoate is not fully understood, but it is believed to act as a neurotoxin to the parasites. It likely exerts a toxic effect on the nervous system of the mites and lice, causing paralysis and death. It also acts as a solvent for the cement substance that attaches the nits (lice eggs) to hair shafts, aiding in their removal.

Medication Name & Brand Names	♦ Medication Name: Benzyl Benzoate ♦ Brand Names: Scabanca, Ascabiol (historical/regional), Benzemul (historical/regional)
Pharmaceutical Forms & Appearance	Benzyl benzoate is primarily available as a topical lotion or emulsion, typically containing 25% w/v benzyl benzoate. It appears as a white or off-white, slightly viscous liquid with a characteristic aromatic odor.
Dosage & Administration	For scabies, it's typically applied as a 25% emulsion. Adults usually apply it over the entire body (from the neck down) after a warm bath, left on for 24 hours, and then washed off. A second application after 2-3 days may be necessary. For children, it may be diluted. For lice, it's applied to affected hair and scalp. Always follow specific product instructions.
Supplied As	Benzyl benzoate is supplied as a topical emulsion or lotion, commonly in 25% strength, in bottles.
Contraindications	Benzyl benzoate is contraindicated in individuals with known hypersensitivity to benzyl benzoate or any component of the formulation. It should not be applied to inflamed, broken, or weeping skin, or to large areas of the body, especially in very young children, due to potential for systemic absorption and irritation.
Storage & Expiry	Benzyl benzoate emulsion/lotion should be stored at room temperature (typically below 30°C or 86°F), protected from light. Keep the container tightly closed. Always check the specific expiry date on the packaging. Do not use if expired.
Side Effects	Common side effects are usually localized and include skin irritation, itching (which may persist for a few weeks after treatment, even if parasites are gone), burning sensation, redness, or dryness. More serious but less common side effects can include severe skin reactions, neurological symptoms (e.g., tremors, convulsions) if absorbed systemically, especially in children or after extensive application.
Warnings & Precautions	♦ External Use Only: For topical use on skin only. Avoid contact with eyes, mouth, nose, and other mucous membranes. If contact occurs, rinse thoroughly with water. ♦ Skin Irritation: May cause skin irritation. Avoid application to broken or severely inflamed skin. ♦ Children: Use with extreme caution and consider dilution in infants and young children due to increased risk of systemic absorption and neurotoxicity. Always consult a healthcare professional for pediatric use. ♦ Resistance: Excessive or improper use may contribute to resistance in parasites.
Missed Dose Instructions	For scabies, benzyl benzoate is typically a single or two-application treatment. If an application is missed or not performed correctly, consult a healthcare professional for guidance on re-application to ensure effective eradication of the infestation. It is not a daily, ongoing medication.
Overdose Instructions	Overdose from topical application is rare but can occur with excessive use, particularly in children or on compromised skin. Symptoms of systemic absorption may include CNS excitation (e.g., restlessness, tremors, convulsions), especially in young children. Treatment is symptomatic and supportive. Gastric lavage may be considered if accidental oral ingestion occurs, but vomiting should not be induced due to aspiration risk. Seek immediate medical attention.
Medicine Interactions	No significant systemic drug interactions are commonly reported with topical application of benzyl benzoate due to limited systemic absorption. However, avoid co-application with other topical preparations that may increase skin irritation or alter skin permeability.

Bismuth Subsalicylate (Pepto-Bismol)

Purpose/Indication	Bismuth subsalicylate is an antidiarrheal and anti-inflammatory medication commonly used to treat temporary discomforts of the stomach and gastrointestinal tract. Its main indications include diarrhea (including traveler's diarrhea), upset stomach, indigestion, nausea, and heartburn. It can also be used as part of combination therapy to eradicate Helicobacter pylori in peptic ulcer disease.
Method of Action	Bismuth subsalicylate has multiple mechanisms of action. The salicylate component provides anti-inflammatory effects and may inhibit prostaglandin synthesis, contributing to its antidiarrheal action. The bismuth component has direct antimicrobial activity against common gastrointestinal pathogens (e.g., E. coli, H. pylori) and forms a protective coating over irritated stomach and intestinal lining, adsorbing toxins and providing a soothing effect.
Medication Name & Brand Names	♦ Medication Name: Bismuth Subsalicylate ♦ Brand Names: Pepto-Bismol, Kaopectate (some formulations), Diotame
Pharmaceutical Forms & Appearance	Bismuth subsalicylate is widely available as oral liquid suspensions (syrup) and chewable tablets. The liquid suspension is distinctively pink, opaque, and relatively viscous. Tablets are typically pink or white and chewable.
Dosage & Administration	Dosage varies by product and indication, but for adults, it's typically taken every 30 minutes to 1 hour as needed, with a maximum number of doses per 24 hours. The liquid should be shaken well before use. Chewable tablets should be chewed thoroughly before swallowing. It can be taken with or without food.
Supplied As	Bismuth subsalicylate is supplied as oral liquid suspensions (e.g., 262 mg/15 mL, 525 mg/15 mL) and chewable tablets (e.g., 262 mg).
Contraindications	Bismuth subsalicylate is contraindicated in individuals with known hypersensitivity to salicylates (including aspirin) or any component of the formulation. It should not be used in children and teenagers recovering from chickenpox or flu-like symptoms due to the risk of Reye's syndrome. It is also contraindicated in patients with active stomach ulcers, bleeding problems, or black/bloody stools.
Storage & Expiry	Bismuth subsalicylate liquid and tablets should be stored at room temperature (typically between 20°C to 25°C or 68°F to 77°F), protected from light and freezing. Keep bottles tightly closed. Always check the specific expiry date on the packaging and do not use if expired.
Side Effects	Common side effects include darkening of the tongue and black stools (due to reaction of bismuth with sulfur in the mouth/intestine), which are harmless and temporary. Less common but more serious side effects can occur with high doses or prolonged use, especially due to the salicylate component, and include tinnitus (ringing in ears), hearing loss, and rarely, salicylate toxicity.
Warnings & Precautions	♦ Reye's Syndrome: Avoid in children and teenagers with viral infections (e.g., flu, chickenpox) due to the risk of Reye's syndrome, a rare but serious condition affecting the brain and liver. ♦ Salicylate Toxicity: Symptoms like ringing in the ears or hearing loss indicate potential salicylate toxicity; discontinue use and seek medical advice. ♦ Bleeding Risk: Use with caution in patients taking anticoagulants or with bleeding disorders, as the salicylate component can have antiplatelet effects. ♦ Constipation: May cause or worsen constipation. ♦ Gout: Use with caution in patients with gout, as salicylates can interfere with uric acid excretion.

Missed Dose Instructions	Bismuth subsalicylate is typically taken on an as-needed basis for symptom relief. If a dose is missed, take it when symptoms return, adhering to the recommended dosage intervals and maximum daily dose. It is not a regularly scheduled medication where missed doses have cumulative effects.
Overdose Instructions	Overdose is typically due to the salicylate component, leading to salicylate toxicity. Symptoms can include tinnitus, hearing loss, dizziness, confusion, nausea, vomiting, rapid breathing, and in severe cases, metabolic acidosis. Treatment involves supportive care, gastric decontamination (e.g., activated charcoal if early), urinary alkalinization to promote excretion, and possibly hemodialysis for severe cases. Seek immediate medical attention.
Medicine Interactions	♦ Anticoagulants: May increase the risk of bleeding when taken with warfarin or other anticoagulants. ♦ Oral Hypoglycemics: May enhance the effects of certain oral diabetes medications. ♦ Tetracycline Antibiotics: Bismuth can interfere with the absorption of tetracycline antibiotics; administer these medications at least 2 hours apart. ♦ Probenecid and Sulfinpyrazone: Salicylates can reduce the uricosuric (uric acid lowering) effect of these gout medications. ♦ Other Salicylates/NSAIDs: Avoid concurrent use with other salicylate-containing products or NSAIDs (e.g., aspirin, ibuprofen) to prevent additive side effects and increased risk of salicylate toxicity.

Budesonide (Pulmicort)

Purpose/Indication	Budesonide is a corticosteroid medication used to treat various inflammatory conditions. Depending on its formulation, it is indicated for the maintenance treatment of asthma (inhaled), chronic obstructive pulmonary disease (COPD) (inhaled), Crohn's disease and ulcerative colitis (oral and rectal), allergic rhinitis (nasal spray), and eosinophilic esophagitis (oral suspension). It works by reducing inflammation.
Method of Action	Budesonide is a potent glucocorticoid with strong anti-inflammatory activity. It works by binding to intracellular glucocorticoid receptors, which then modulate gene expression to decrease the synthesis and release of inflammatory mediators (e.g., prostaglandins, leukotrienes) and cytokines. It also reduces the activity of immune cells involved in inflammation, thereby suppressing the inflammatory response. The specific formulation determines its targeted action (e.g., topical in the airways, locally in the gut).
Medication Name & Brand Names	♦ Medication Name: Budesonide ♦ Brand Names: Pulmicort (inhaled), Entocort EC (oral for GI), Uceris/Cortiment (oral for UC), Rhinocort (nasal), Jorveza (oral for EoE)
Pharmaceutical Forms & Appearance	Budesonide comes in various forms: metered-dose inhalers (MDIs), dry powder inhalers (DPIs), nebulizer suspensions (for inhalation), oral capsules/tablets (often extended-release or targeted release), rectal foam/enema, and nasal sprays. The appearance varies by form (e.g., white powder for inhalers, capsules/tablets).
Dosage & Administration	Dosage and administration methods are highly specific to the form and condition being treated. Inhaled forms are typically used once or twice daily for asthma/COPD. Oral capsules for Crohn's are taken once daily in the morning. Rectal forms are used for ulcerative colitis. Nasal spray is usually once daily per nostril. It is critical to use the correct formulation for the intended purpose and follow specific instructions.
Supplied As	Budesonide is supplied in various forms, including: inhalers (e.g., Pulmicort Flexhaler, Pulmicort Respules for nebulization), oral capsules (e.g., Entocort EC 3 mg, Uceris 9 mg), rectal foam/enema, and nasal sprays (e.g., Rhinocort Aqua).
Contraindications	Budesonide is generally contraindicated in individuals with known hypersensitivity to budesonide or any component of the formulation. Inhaled forms are contraindicated for the rapid relief of acute bronchospasm. Oral forms for Crohn's/UC are contraindicated in patients with intestinal obstruction. Systemic fungal infections are also a general contraindication for steroid use.
Storage & Expiry	Storage conditions vary by formulation. Inhalers and nebulizer suspensions should typically be stored at room temperature (15°C to 30°C or 59°F to 86°F), protected from light and moisture, and not frozen. Oral capsules should also be stored at room temperature. Always refer to the specific product packaging for precise storage instructions and expiry dates.
Side Effects	Common side effects depend on the route of administration. Inhaled: oral candidiasis (thrush), dysphonia (hoarseness), cough. Oral: dyspepsia, nausea, headache, dizziness, abdominal pain. As a corticosteroid, systemic side effects can occur with higher doses or prolonged use, including adrenal suppression, increased risk of infection, bone density loss, and psychiatric effects.
Warnings & Precautions	♦ Adrenal Suppression: Prolonged use, especially at high doses or switching from systemic corticosteroids, can lead to adrenal insufficiency. Patients may need supplemental systemic corticosteroids during periods of stress. ♦ Infections: May mask signs of infection and increase susceptibility to new infections. Monitor for fungal infections (thrush) with inhaled forms. ♦ Osteoporosis: Long-term use can affect bone mineral density. ♦ Ocular Effects: May cause cataracts or glaucoma; regular eye exams are recommended for long-term users. ♦ Growth Suppression: Can cause growth suppression in children. ♦ Liver Impairment: Use with caution in patients with liver disease as systemic exposure may increase.
Missed Dose Instructions	If a dose of Budesonide (for maintenance therapy) is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Regular, consistent use is important for disease control.
Overdose Instructions	Acute overdose with budesonide is unlikely to cause serious problems due to its low systemic bioavailability and short half-life, especially with inhaled forms. However, chronic overuse, particularly with systemic absorption, can lead to signs and symptoms of hypercorticism (e.g., Cushingoid features, adrenal suppression). Treatment is symptomatic and supportive. Gradual withdrawal may be necessary after chronic excessive use. Seek medical advice if symptoms of overdose occur.
Medicine Interactions	♦ Strong CYP3A4 Inhibitors: Concomitant use with strong CYP3A4 inhibitors (e.g., ketoconazole, itraconazole, ritonavir, cobicistat, clarithromycin, grapefruit juice) can significantly increase systemic exposure to budesonide, potentially leading to increased systemic corticosteroid side effects. Co-administration should be avoided or used with caution and close monitoring. ♦ CYP3A4 Inducers: Strong inducers (e.g., rifampin, carbamazepine, phenytoin) may decrease budesonide levels. ♦ No specific interactions are typically associated with topical or locally acting formulations unless significant systemic absorption occurs.

Calcitonin Salmon (Miacalcic)

Purpose/Indication	Calcitonin salmon is a synthetic hormone preparation used primarily to treat postmenopausal osteoporosis, especially in women who cannot take other osteoporosis medications. It is also indicated for the treatment of Paget's disease of bone, and for the emergency treatment of hypercalcemia (high blood calcium levels). It works by regulating calcium and bone metabolism.

Method of Action	Calcitonin salmon is a polypeptide hormone that directly inhibits bone resorption by binding to receptors on osteoclasts, the cells responsible for breaking down bone tissue. This action reduces the release of calcium and phosphate from bone, thereby decreasing bone turnover. In hypercalcemia, it also increases renal excretion of calcium and phosphate. It also has an analgesic effect, possibly due to a direct effect on the central nervous system.
Medication Name & Brand Names	♦ Medication Name: Calcitonin Salmon ♦ Brand Names: Miacalcin (nasal spray, injection), Fortical (nasal spray)
Pharmaceutical Forms & Appearance	Calcitonin salmon is available as a nasal spray and as an injectable solution (for subcutaneous or intramuscular use). The nasal spray solution is typically clear and colorless. The injectable solution is also clear and colorless.
Dosage & Administration	Dosage and administration vary significantly by indication and form. For osteoporosis, the nasal spray is commonly used (e.g., 200 international units (IU) daily, alternating nostrils). For Paget's disease, injections are typically given subcutaneously or intramuscularly (e.g., 100 IU daily or every other day). For hypercalcemia, higher doses are used via injection.
Supplied As	Calcitonin salmon is supplied as: nasal spray (e.g., a bottle delivering 200 IU per actuation), and injectable solution in multi-dose vials (e.g., 200 IU/mL).
Contraindications	Calcitonin salmon is contraindicated in individuals with known hypersensitivity to calcitonin salmon or any component of the formulation. Products containing fish protein should be avoided in patients with known allergies to salmon.
Storage & Expiry	Nasal spray formulations should be stored refrigerated (2°C to 8°C or 36°F to 46°F) prior to opening. Once opened, they can usually be stored at room temperature (below 25°C or 77°F) for a limited period (e.g., 30 days) and then discarded. Injectable vials should also be refrigerated. Do not freeze. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nasal irritation (with nasal spray), rhinitis, epistaxis (nosebleed), flushing of the face and hands, nausea, and vomiting. Less common but more serious side effects can include hypersensitivity reactions (including anaphylaxis), and a very small potential increased risk of malignancy with long-term use (though data is conflicting and minimal).
Warnings & Precautions	♦ Hypersensitivity Reactions: Serious allergic reactions, including anaphylaxis, can occur. Patients should be warned of potential reactions, especially those with a history of fish allergy. ♦ Malignancy Risk: Long-term use of calcitonin salmon has been associated with a small, increased risk of cancer in some studies; the clinical significance of this is under evaluation. ♦ Hypocalcemia: Although rare, temporary hypocalcemia can occur, especially with high doses; monitor serum calcium. ♦ Nasal Irritation: Nasal spray can cause local irritation; inspect nasal passages regularly. ♦ Renal Impairment: Use with caution in patients with severe renal impairment.
Missed Dose Instructions	For regular maintenance therapy (e.g., osteoporosis nasal spray), if a dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For hypercalcemia, it's typically administered in a hospital setting under close medical supervision.
Overdose Instructions	Overdose with calcitonin salmon can lead to symptoms of hypocalcemia (e.g., paresthesia, muscle spasms, tetany, seizures) and exaggerated typical side effects like nausea and vomiting. Treatment involves immediate discontinuation of the drug and supportive measures. Calcium supplementation may be required to correct hypocalcemia. Seek immediate medical attention.
Medicine Interactions	♦ Lithium: Concurrent use may lead to a decrease in plasma lithium concentrations, requiring monitoring and possible dose adjustment of lithium. ♦ No other significant drug interactions are widely reported, as calcitonin salmon is a peptide and is metabolized differently than most small molecule drugs. However, always inform healthcare providers of all medications being taken.

Candesartan (Atacand)

Purpose/Indication	Candesartan is an angiotensin II receptor blocker (ARB) primarily used to treat high blood pressure (hypertension) and heart failure. It helps to relax blood vessels, allowing blood to flow more easily and reducing the workload on the heart. It is also used to reduce the risk of cardiovascular morbidity and mortality in patients with left ventricular systolic dysfunction or heart failure.
Method of Action	Candesartan works by selectively blocking the binding of angiotensin II to the AT1 receptor, which is found in many tissues, including vascular smooth muscle and the adrenal glands. Angiotensin II is a powerful vasoconstrictor and a stimulator of aldosterone secretion. By blocking its effects, candesartan causes vasodilation, reduces sodium and water retention, and ultimately lowers blood pressure.
Medication Name & Brand Names	♦ Medication Name: Candesartan Cilexetil ♦ Brand Name: Atacand
Pharmaceutical Forms & Appearance	Candesartan is available as oral tablets in various strengths (e.g., 4 mg, 8 mg, 16 mg, 32 mg). The tablets are typically white, round, or biconvex, and may be scored or debossed with the strength or manufacturer's identifying marks.
Dosage & Administration	Candesartan is usually taken once daily, with or without food. The typical starting dose for hypertension is 8 mg or 16 mg once daily, which can be adjusted based on response. For heart failure, dosing is typically initiated at a lower dose and gradually titrated up. It's important to take it consistently at about the same time each day.
Supplied As	Candesartan is supplied as oral tablets in various strengths (e.g., 4 mg, 8 mg, 16 mg, 32 mg).
Contraindications	Candesartan is contraindicated in patients with known hypersensitivity to candesartan or any component of the formulation. It is contraindicated in pregnancy due to the risk of fetal harm. It should not be co-administered with aliskiren in patients with diabetes or renal impairment (GFR <60 mL/min/1.73m²) due to increased risk of hypotension, hyperkalemia, and renal failure.
Storage & Expiry	Candesartan tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light, in a tightly closed container. Always check the specific expiry date on the packaging and do not use if expired.
Side Effects	Common side effects include headache, dizziness, upper respiratory tract infection, pharyngitis, and back pain. Less common but more serious side effects can include hypotension (low blood pressure), hyperkalemia (high potassium levels), renal impairment (kidney problems), and angioedema (swelling of face, lips, tongue, throat).

Warnings & Precautions	♦ Fetal Toxicity: Can cause injury or death to the developing fetus; discontinue as soon as pregnancy is detected. ♦ Hypotension: May cause symptomatic hypotension, especially in volume-depleted patients; correct volume depletion before starting. ♦ Renal Impairment: May cause or worsen renal impairment; monitor renal function, especially in patients with pre-existing kidney disease or severe heart failure. ♦ Hyperkalemia: Can cause hyperkalemia; monitor potassium levels, especially in patients with renal impairment, diabetes, or those taking potassium-sparing diuretics or potassium supplements. ♦ Angioedema: Rare but serious swelling of the face, lips, or throat can occur; seek immediate medical attention if symptoms develop.
Missed Dose Instructions	If a dose of Candesartan is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose to make up for a missed one. Regular, consistent use is important for blood pressure and heart failure control.
Overdose Instructions	Overdose is most likely to result in hypotension (low blood pressure) and possibly tachycardia (rapid heart rate) or bradycardia (slow heart rate). Treatment is supportive. If ingestion was recent, gastric lavage and/or administration of activated charcoal may be considered. Intravenous fluids and vasopressors may be needed to manage hypotension. Hemodialysis is not effective for removing candesartan. Seek immediate medical attention.
Medicine Interactions	♦ Potassium-Sparing Diuretics/Potassium Supplements: Increased risk of hyperkalemia. ♦ NSAIDs (Non-Steroidal Anti-Inflammatory Drugs): May blunt the antihypertensive effect and increase the risk of renal impairment, especially in elderly or volume-depleted patients. ♦ Lithium: May increase serum lithium concentrations and lithium toxicity; monitor lithium levels. ♦ Dual Blockade of RAAS: Co-administration with ACE inhibitors or aliskiren increases the risk of hypotension, hyperkalemia, and renal impairment and is generally not recommended, especially with aliskiren in diabetic or renally impaired patients.

Capreomycin (Capastat)

Purpose/Indication	Capreomycin is an injectable polypeptide antibiotic used as a second-line agent for the treatment of active tuberculosis (TB), particularly multi-drug-resistant TB (MDR-TB), caused by susceptible strains of Mycobacterium tuberculosis. It is always used in combination with other effective anti-tuberculosis agents to prevent the development of resistance.
Method of Action	Capreomycin inhibits bacterial protein synthesis by binding to the 70S ribosome, specifically interacting with both the 30S and 50S ribosomal subunits. This binding disrupts the normal function of the ribosome, preventing it from effectively synthesizing proteins. It interferes with the elongation phase of protein synthesis, causing misreading of the mRNA template and obstructing the translocation of tRNA and mRNA.
Medication Name & Brand Names	♦ Medication Name: Capreomycin Sulfate ♦ Brand Name: Capastat Sulfate (less commonly marketed now, often referred to generically)
Pharmaceutical Forms & Appearance	Capreomycin is available as a sterile powder for injection, typically reconstituted with sterile water for injection or 0.9% sodium chloride for intramuscular (IM) or intravenous (IV) administration. The reconstituted solution is almost colorless to pale straw-colored.
Dosage & Administration	Capreomycin is administered by deep intramuscular injection or intravenous infusion. The usual adult dose is 1 gram daily for 60 to 120 days, followed by 1 gram two to three times per week. Dosage adjustments are often necessary for patients with renal impairment. It is crucial to monitor renal function and auditory/vestibular function throughout treatment.
Supplied As	Capreomycin is supplied as a powder for injection in vials (e.g., 1 gram equivalent of capreomycin activity per vial).
Contraindications	Capreomycin is contraindicated in patients with known hypersensitivity to capreomycin. It should be used with extreme caution or contraindicated in patients with pre-existing auditory impairment, severe renal insufficiency, or neuromuscular disorders (e.g., myasthenia gravis, Parkinson's disease) due to the risk of exacerbating these conditions.
Storage & Expiry	Unopened vials of capreomycin powder for injection should be stored at controlled room temperature (typically 15°C to 30°C or 59°F to 86°F), protected from moisture. Once reconstituted, the solution should be refrigerated (2°C to 8°C or 36°F to 46°F) and typically used within 24 hours. Always check the specific product label for precise storage and expiry.
Side Effects	Common side effects include nephrotoxicity (kidney damage), ototoxicity (hearing loss and vestibular dysfunction like dizziness or vertigo), pain and sterile abscesses at the injection site, and abnormalities in electrolyte levels (e.g., hypokalemia, hypomagnesemia). Other side effects can include rash, fever, and eosinophilia.
Warnings & Precautions	♦ Ototoxicity and Nephrotoxicity: These are major concerns. Audiometric and vestibular function tests and renal function (creatinine, BUN, urine output) should be monitored at baseline and regularly during therapy. The risk is increased in elderly patients, those with pre-existing kidney or hearing impairment, or when co-administered with other ototoxic or nephrotoxic drugs. ♦ Neuromuscular Blockade: Can cause partial neuromuscular blockade and respiratory paralysis, especially with rapid IV infusion or in patients with neuromuscular disease. ♦ Electrolyte Abnormalities: Monitor serum potassium, magnesium, and calcium regularly. ♦ Pregnancy: Potential for fetal harm; typically avoided during pregnancy unless benefits outweigh risks.
Missed Dose Instructions	Since Capreomycin is typically administered in a clinical setting by a healthcare professional, missed doses are generally rare. If a dose is missed, the healthcare provider managing the patient's TB treatment should be contacted immediately for instructions. Consistency in dosing is crucial for effective TB therapy and preventing resistance.
Overdose Instructions	Overdose is typically an exaggeration of known side effects, primarily severe nephrotoxicity (kidney failure, oliguria) and ototoxicity (profound hearing loss, severe vertigo). Neuromuscular blockade leading to respiratory depression may also occur. Treatment is supportive and symptomatic. Gastric decontamination is not relevant for injectable forms. Hemodialysis is not effective for removal. Close monitoring of renal function, electrolytes, hearing, and respiratory status is essential. Seek immediate medical attention.
Medicine Interactions	♦ Nephrotoxic/Ototoxic Drugs: Co-administration with other drugs known to cause kidney damage or hearing damage (e.g., aminoglycosides like amikacin, gentamicin, tobramycin; polymyxins; colistin; loop diuretics like furosemide; amphotericin B) significantly increases the risk of these toxicities and should generally be avoided or used with extreme caution and close monitoring. ♦ Neuromuscular Blockers: May enhance the effects of neuromuscular blocking agents (e.g., succinylcholine, rocuronium), leading to prolonged muscle paralysis and respiratory depression. ♦ Live Bacterial Vaccines: May reduce the effectiveness of live bacterial vaccines (e.g., typhoid vaccine).

Carbamazepine (Tegretol)

Purpose/Indication	Carbamazepine is an anticonvulsant medication used to treat various types of seizures (e.g., partial seizures, generalized tonic-clonic seizures), but it is not effective for absence seizures. It is also indicated for the pain associated with trigeminal neuralgia (a severe facial nerve pain), and as a mood stabilizer in bipolar disorder.
Method of Action	Carbamazepine works primarily by stabilizing hyperexcited nerve membranes and inhibiting repetitive neuronal firing. It achieves this by prolonging the inactive state of voltage-gated sodium channels, thereby reducing the spread of abnormal electrical activity in the brain that causes seizures. For trigeminal neuralgia, it reduces synaptic transmission in the trigeminal nucleus. Its mechanism in bipolar disorder is less clear but involves effects on various neurotransmitter systems.
Medication Name & Brand Names	♦ Medication Name: Carbamazepine ♦ Brand Names: Tegretol, Carbatrol, Equetro
Pharmaceutical Forms & Appearance	Carbamazepine is available as immediate-release tablets, chewable tablets, extended-release tablets/capsules, and an oral suspension. Immediate-release tablets are usually white or off-white and may be scored. Extended-release forms are designed for once or twice daily dosing. The suspension is typically an off-white to yellowish liquid.
Dosage & Administration	Dosage varies significantly based on the indication, patient response, and tolerability. It is typically started at a low dose and gradually increased to achieve therapeutic effects while minimizing side effects. Dosing frequency depends on the formulation (e.g., 2-4 times daily for immediate-release, 1-2 times daily for extended-release). It is generally taken with food to reduce GI upset and improve absorption. Blood levels are often monitored.
Supplied As	Carbamazepine is supplied as oral tablets (e.g., 100 mg, 200 mg), chewable tablets, extended-release tablets (e.g., 100 mg, 200 mg, 300 mg, 400 mg) and capsules, and oral suspension (e.g., 100 mg/5 mL).
Contraindications	Carbamazepine is contraindicated in patients with a history of bone marrow depression or known hypersensitivity to carbamazepine or any tricyclic antidepressant. It should not be used in patients with severe cardiac disease, or within 14 days of taking a monoamine oxidase inhibitor (MAOI). Concomitant use with nefazodone is also contraindicated.
Storage & Expiry	Carbamazepine tablets and oral suspension should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in a tightly closed container. Always check the specific expiry date on the packaging. Shake oral suspension well before each use.
Side Effects	Common side effects often experienced initially include dizziness, drowsiness, ataxia (impaired coordination), nausea, vomiting, and blurred vision. More serious but less common side effects include serious dermatologic reactions (e.g., Stevens-Johnson syndrome, toxic epidermal necrolysis, especially in individuals with HLA-B*1502 allele), aplastic anemia, agranulocytosis (severe reduction in white blood cells), liver dysfunction, hyponatremia (low sodium), and cardiac conduction abnormalities.
Warnings & Precautions	♦ Serious Dermatologic Reactions: Patients, especially of Asian ancestry (screening for HLA-B*1502 allele is recommended before initiation), are at higher risk. Discontinue at the first sign of rash unless clearly not drug-related. ♦ Aplastic Anemia/Agranulocytosis: Can cause life-threatening blood dyscrasias. Complete blood counts (CBC) should be performed at baseline and regularly during treatment. ♦ Hyponatremia: Can cause clinically significant low sodium levels, especially in elderly patients. ♦ Liver Dysfunction: Monitor liver function tests. ♦ Suicidal Ideation: Antiepileptic drugs carry an increased risk of suicidal thoughts or behavior; monitor patients for changes in mood or behavior. ♦ Cardiac Effects: Use with caution in patients with cardiac conduction disturbances. ♦ Drug Interactions: Numerous significant drug interactions (see below).
Missed Dose Instructions	If a dose of Carbamazepine is missed, take it as soon as remembered unless it's almost time for the next scheduled dose. In that case, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. Consistent dosing is important for seizure control and preventing breakthrough seizures. For extended-release forms, if a dose is missed, take it as soon as remembered and then resume the next dose at the regularly scheduled time (do not take more than one dose every 12 hours for twice-daily dosing).
Overdose Instructions	Overdose can cause severe central nervous system depression (drowsiness, coma), respiratory depression, seizures, cardiovascular effects (tachycardia, hypotension, cardiac arrest), and hyponatremia. Treatment involves immediate medical attention, gastric lavage, administration of activated charcoal (repeated doses may be needed), and supportive care. Hemodialysis is generally not effective. Monitor vital signs, ECG, and blood drug levels.
Medicine Interactions	♦ Strong CYP3A4 Inhibitors: Increase carbamazepine levels, leading to toxicity (e.g., macrolide antibiotics like erythromycin/clarithromycin, azoles like ketoconazole/itraconazole, ritonavir, diltiazem, verapamil, grapefruit juice). ♦ CYP3A4 Inducers: Carbamazepine is a strong inducer of many liver enzymes (including CYP3A4, CYP2C9, CYP2C19, UGT), significantly reducing levels of many other drugs, such as: oral contraceptives (leading to contraceptive failure), warfarin, many other antiepileptics (e.g., phenytoin, valproate, lamotrigine), some antidepressants, antipsychotics, corticosteroids, and others. ♦ Lithium: Concurrent use may increase neurotoxicity. ♦ MAOIs: Concomitant use is contraindicated. ♦ Nefazodone: Concomitant use is contraindicated due to increased carbamazepine levels and potential for serious adverse events.

Carvedilol (Coreg)

Purpose/Indication	Carvedilol is a beta-blocker with alpha-blocking activity primarily used to treat heart failure (to improve survival and reduce hospitalizations), high blood pressure (hypertension), and left ventricular dysfunction following a heart attack. It helps to relax blood vessels and slow the heart rate, reducing the heart's workload and improving its pumping efficiency.
Method of Action	Carvedilol acts as a non-selective beta-adrenergic blocker (blocking beta-1 and beta-2 receptors) and a selective alpha-1 adrenergic blocker. Beta-blockade reduces heart rate, myocardial contractility, and oxygen demand. Alpha-1 blockade causes vasodilation, leading to a decrease in peripheral vascular resistance. The combined effect results in a reduction in blood pressure and improved cardiac function in heart failure. It also has antioxidant properties.
Medication Name & Brand Names	♦ Medication Name: Carvedilol ♦ Brand Name: Coreg (immediate-release), Coreg CR (extended-release)
Pharmaceutical Forms & Appearance	Carvedilol is available as immediate-release oral tablets and extended-release capsules. Immediate-release tablets are typically white, oval, and scored, with various strengths (e.g., 3.125 mg, 6.25 mg, 12.5 mg, 25 mg). Extended-release capsules contain beads and are designed for once-daily dosing.
Dosage & Administration	Dosage varies significantly by indication and formulation. For heart failure, it's initiated at a very low dose (e.g., 3.125 mg twice daily for immediate-release) and slowly titrated up over weeks to months. For hypertension, it's typically started at 6.25 mg twice daily. Immediate-release tablets should be taken with food to slow absorption and reduce orthostatic hypotension. Extended-release capsules should be taken once daily with food. Do not stop abruptly.
Supplied As	Carvedilol is supplied as immediate-release oral tablets (e.g., 3.125 mg, 6.25 mg, 12.5 mg, 25 mg) and extended-release oral capsules (e.g., 10 mg, 20 mg, 40 mg, 80 mg).

Contraindications	Carvedilol is contraindicated in patients with decompensated heart failure requiring intravenous inotropic therapy, bronchial asthma or related bronchospastic conditions (including COPD, if severe), second- or third-degree AV block (unless a permanent pacemaker is in place), sick sinus syndrome (unless a permanent pacemaker is in place), cardiogenic shock, severe bradycardia, and severe hepatic impairment.
Storage & Expiry	Carvedilol tablets and capsules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light, in a tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include dizziness, fatigue, hypotension (low blood pressure), bradycardia (slow heart rate), and worsening of heart failure symptoms (especially at initiation or dose increase). Less common but serious side effects include exacerbation of bronchospasm, severe allergic reactions, liver dysfunction, and masking of hypoglycemia symptoms.
Warnings & Precautions	♦ Abrupt Cessation: Do not discontinue carvedilol abruptly, especially in patients with coronary artery disease, as it can worsen angina or precipitate a myocardial infarction. Doses should be gradually tapered over 1-2 weeks. ♦ Heart Failure: Worsening of heart failure or fluid retention can occur during initial titration; diuretics may need adjustment. ♦ Bronchospastic Disease: Use with caution in patients with mild-to-moderate bronchospastic disease; generally contraindicated in severe cases. ♦ Diabetes: May mask symptoms of hypoglycemia and potentially worsen glycemic control. ♦ Peripheral Vascular Disease: May precipitate or aggravate symptoms of arterial insufficiency. ♦ Liver Impairment: Use with caution and lower doses in patients with liver dysfunction.
Missed Dose Instructions	If a dose of Carvedilol is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. Consistent daily dosing is important for heart failure management and blood pressure control.
Overdose Instructions	Overdose can lead to severe hypotension (very low blood pressure), bradycardia (slow heart rate), cardiac insufficiency, cardiogenic shock, and bronchospasm. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered if ingestion was recent. Atropine can be used for bradycardia, glucagon for myocardial depression, and vasopressors for hypotension. Bronchodilators for bronchospasm. Seek immediate medical attention.
Medicine Interactions	♦ CYP2D6 and CYP2C9 Inhibitors/Inducers: Carvedilol is metabolized by these enzymes. Potent inhibitors (e.g., quinidine, fluoxetine, paroxetine, propafenone, cimetidine) can increase carvedilol levels. Inducers (e.g., rifampicin) can decrease levels. ♦ Rifampin: Significantly decreases carvedilol levels. ♦ Insulin/Oral Hypoglycemics: May enhance the blood-glucose-lowering effect and mask symptoms of hypoglycemia. ♦ Clonidine: If discontinuing clonidine and carvedilol concurrently, taper the beta-blocker first to avoid rebound hypertension. ♦ Digitalis Glycosides: Both can slow AV conduction; additive bradycardia may occur. ♦ Calcium Channel Blockers (non-dihydropyridine): Concurrent use with verapamil or diltiazem can cause additive effects leading to severe bradycardia, AV block, and heart failure; close monitoring is required.

Cefdinir (Omnicef)

Purpose/Indication	Cefdinir is a third-generation cephalosporin antibiotic used to treat a variety of bacterial infections. It is commonly prescribed for respiratory tract infections (e.g., bronchitis, pneumonia, sinusitis, tonsillitis/pharyngitis), acute otitis media (ear infection), and uncomplicated skin and skin structure infections. It is effective against a broad spectrum of gram-positive and gram-negative bacteria.
Method of Action	Cefdinir is a bactericidal antibiotic that works by inhibiting bacterial cell wall synthesis. It binds to penicillin-binding proteins (PBPs) located inside the bacterial cell wall, which are essential for the final stages of cell wall synthesis. This interference weakens the cell wall, leading to bacterial lysis and death.
Medication Name & Brand Names	♦ Medication Name: Cefdinir ♦ Brand Name: Omnicef
Pharmaceutical Forms & Appearance	Cefdinir is available as oral capsules and as a powder for oral suspension (liquid that needs to be reconstituted with water). Capsules are typically opaque, hard gelatin capsules with various colors (e.g., light orange to pink) and imprints indicating the dosage strength. The reconstituted suspension is usually an off-white to yellowish liquid, often with a strawberry flavor.
Dosage & Administration	Dosage varies based on the infection, patient's age (adults vs. children), and renal function. For adults, it is typically taken 300 mg every 12 hours or 600 mg once daily for 5-10 days. For children, it is weight-based. It can be taken with or without food. The full prescribed course should be completed, even if symptoms improve, to prevent resistance.
Supplied As	Cefdinir is supplied as oral capsules (e.g., 300 mg) and as a powder for oral suspension (e.g., 125 mg/5 mL, 250 mg/5 mL).
Contraindications	Cefdinir is contraindicated in patients with known hypersensitivity (severe allergic reaction) to cefdinir, other cephalosporin antibiotics, or any component of the formulation. Caution is advised in patients with a history of penicillin allergy due to the potential for cross-reactivity.
Storage & Expiry	Cefdinir capsules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. The reconstituted oral suspension must be stored at controlled room temperature (20°C to 25°C or 68°F to 77°F) or refrigerated (2°C to 8°C or 36°F to 46°F) and typically remains stable for 10 days; discard any unused portion after this time. Check the specific product label for exact storage and expiry information.
Side Effects	Common side effects include diarrhea, nausea, vomiting, abdominal pain, and rash. Less common but more serious side effects can include severe allergic reactions (e.g., anaphylaxis, Stevens-Johnson syndrome), Clostridioides difficile-associated diarrhea (CDAD), kidney dysfunction, and transient elevations in liver enzymes.
Warnings & Precautions	♦ Hypersensitivity Reactions: Serious and sometimes fatal hypersensitivity reactions have been reported; inquire about prior allergies to cephalosporins or penicillins. ♦ Clostridioides difficile-Associated Diarrhea (CDAD): Can occur during or after antibiotic therapy; evaluate patients presenting with diarrhea. ♦ Renal Impairment: Dose adjustment is necessary in patients with significant kidney impairment. ♦ Fecal Discoloration: Can cause red-orange discoloration of stool in infants due to non-absorbed drug complexing with iron in formulas/foods. ♦ Not effective against viral infections.
Missed Dose Instructions	If a dose of Cefdinir is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose to make up for a missed one. It's crucial to complete the entire course of antibiotics to prevent the development of antibiotic resistance and ensure complete eradication of the infection.
Overdose Instructions	Overdose is generally not life-threatening but can lead to symptoms such as nausea, vomiting, epigastric distress, diarrhea, and possibly convulsions (especially in patients with renal impairment). Treatment is supportive and symptomatic. Hemodialysis is effective in removing cefdinir from the body. Seek medical attention for significant overdose.

Medicine Interactions	♦ Antacids containing aluminum or magnesium: Can reduce the absorption of cefdinir; administer cefdinir at least 2 hours before or after these antacids. ♦ Iron Supplements (including fortified foods/infant formula): Can significantly reduce cefdinir absorption and may cause reddish-brown discoloration of stools. Administer cefdinir at least 2 hours before or after iron supplements. ♦ Probenecid: Decreases the renal excretion of cefdinir, resulting in increased and prolonged plasma levels of cefdinir.

Celecoxib (Celebrex)

Purpose/Indication	Celecoxib is a non-steroidal anti-inflammatory drug (NSAID) primarily used to relieve pain and inflammation. It is indicated for conditions such as osteoarthritis, rheumatoid arthritis, ankylosing spondylitis, acute pain, and primary dysmenorrhea (menstrual pain). As a COX-2 selective inhibitor, it aims to reduce gastrointestinal side effects compared to non-selective NSAIDs.
Method of Action	Celecoxib works by selectively inhibiting cyclooxygenase-2 (COX-2) enzyme. COX-2 is primarily responsible for producing prostaglandins, which are mediators of pain and inflammation, especially at sites of injury or inflammation. By selectively blocking COX-2, celecoxib reduces pain, inflammation, and fever, while theoretically having less impact on COX-1, which is involved in protecting the stomach lining and platelet function.
Medication Name & Brand Names	♦ Medication Name: Celecoxib ♦ Brand Name: Celebrex
Pharmaceutical Forms & Appearance	Celecoxib is available as oral capsules in various strengths (e.g., 50 mg, 100 mg, 200 mg, 400 mg). The capsules are typically opaque, hard gelatin capsules with distinct colors and imprints for different strengths.
Dosage & Administration	Dosage varies by indication and patient response. For osteoarthritis, a common dose is 200 mg once daily or 100 mg twice daily. For rheumatoid arthritis, it's often 100 mg or 200 mg twice daily. It can be taken with or without food, but taking it with food may help reduce gastrointestinal upset.
Supplied As	Celecoxib is supplied as oral capsules in various strengths (e.g., 50 mg, 100 mg, 200 mg, 400 mg).
Contraindications	Celecoxib is contraindicated in patients with a known hypersensitivity (e.g., allergic reactions, asthma, urticaria) to celecoxib, sulfonamides, or aspirin and other NSAIDs. It is also contraindicated in patients with a history of asthma, urticaria, or allergic-type reactions after taking NSAIDs. It should not be used for pain after coronary artery bypass graft (CABG) surgery.
Storage & Expiry	Celecoxib capsules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in a tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include abdominal pain, diarrhea, dyspepsia (indigestion), flatulence, peripheral edema (swelling), and headache. More serious but less common side effects can include cardiovascular thrombotic events (e.g., heart attack, stroke), gastrointestinal bleeding or ulceration, kidney problems, serious skin reactions, and elevated liver enzymes.
Warnings & Precautions	♦ Cardiovascular Risk: NSAIDs, including celecoxib, can increase the risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may increase with duration of use. Contraindicated for pain after CABG surgery. ♦ Gastrointestinal Risk: Can cause serious gastrointestinal adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. Risk is higher in elderly patients or those with a history of GI bleeding. ♦ Renal Effects: Can cause new onset or worsening of renal impairment, especially in dehydrated patients or those with pre-existing kidney disease or heart failure. ♦ Hypertension: Can cause new onset hypertension or worsen pre-existing hypertension. ♦ Skin Reactions: Serious skin reactions (e.g., Stevens-Johnson syndrome, toxic epidermal necrolysis) can occur. Discontinue at first appearance of rash. ♦ Sulfonamide Allergy: Contraindicated in patients with known sulfonamide allergy.
Missed Dose Instructions	If a dose of Celecoxib is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. Consistent dosing helps manage pain and inflammation effectively.
Overdose Instructions	Symptoms of acute celecoxib overdose are generally limited to lethargy, drowsiness, nausea, vomiting, and epigastric pain, which are usually reversible with supportive care. Gastrointestinal bleeding, hypertension, acute renal failure, respiratory depression, and coma may occur with more severe overdose. Treatment is symptomatic and supportive. Gastric decontamination with activated charcoal may be considered if ingestion was recent. Hemodialysis is unlikely to be effective due to high protein binding. Seek immediate medical attention for significant overdose.
Medicine Interactions	♦ Warfarin and other anticoagulants: Increased risk of bleeding; monitor INR closely. ♦ ACE Inhibitors/ARBs/Diuretics: NSAIDs can reduce the antihypertensive effect and increase the risk of renal impairment. ♦ Lithium: May increase lithium plasma concentrations and toxicity; monitor lithium levels. ♦ Methotrexate: May increase methotrexate toxicity. ♦ Fluconazole: Increases celecoxib plasma concentrations due to CYP2C9 inhibition; reduce celecoxib dose when co-administered. ♦ Dextromethorphan: Celecoxib can increase dextromethorphan levels. ♦ Cyclosporine/Tacrolimus: Increased risk of nephrotoxicity.

Cephalexin (Keflex)

Purpose/Indication	Cephalexin is a first-generation cephalosporin antibiotic used to treat a wide range of bacterial infections. It is commonly prescribed for infections of the respiratory tract, ear (otitis media), skin and soft tissue, bones and joints, and urinary tract. It is particularly effective against gram-positive bacteria like Staphylococcus aureus and Streptococcus pyogenes.
Method of Action	Cephalexin is a bactericidal antibiotic that works by inhibiting bacterial cell wall synthesis. It binds to penicillin-binding proteins (PBPs), which are enzymes located in the bacterial cell membrane that are crucial for the cross-linking of peptidoglycan, a major component of the bacterial cell wall. This inhibition leads to a defective cell wall, increased osmotic pressure, and ultimately, lysis and death of the bacterial cell.
Medication Name & Brand Names	♦ Medication Name: Cephalexin ♦ Brand Names: Keflex, Zartan (regional), Ceporex (regional)
Pharmaceutical Forms & Appearance	Cephalexin is available as oral capsules, oral tablets, and as a powder for oral suspension (liquid that needs to be reconstituted with water). Capsules are typically opaque with various colors (e.g., green and white, or pink) and imprints indicating the dosage strength. Tablets are usually white and may be scored. The reconstituted suspension is often a pink or off-white liquid, usually with a fruit flavor.
Dosage & Administration	Dosage varies based on the infection's severity, patient's age (adults vs. children), and renal function. For adults, typical doses range from 250 mg to 500 mg every 6 hours or 500 mg every 12 hours. For children, it is weight-based. It can be taken with or without food. The full prescribed course should always be completed, even if symptoms improve, to prevent the development of antibiotic resistance and ensure complete eradication of the infection.

Supplied As	Cephalexin is supplied as oral capsules (e.g., 250 mg, 500 mg), oral tablets (e.g., 250 mg, 500 mg), and powder for oral suspension (e.g., 125 mg/5 mL, 250 mg/5 mL).
Contraindications	Cephalexin is contraindicated in patients with known hypersensitivity (severe allergic reaction) to cephalexin, other cephalosporin antibiotics, or any component of the formulation. Caution is advised in patients with a history of penicillin allergy due to the potential for cross-reactivity.
Storage & Expiry	Cephalexin capsules and tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. The reconstituted oral suspension must be stored in a refrigerator (2°C to 8°C or 36°F to 46°F) and typically remains stable for 14 days; discard any unused portion after this time. Check the specific product label for exact storage and expiry information.
Side Effects	Common side effects include diarrhea, nausea, vomiting, abdominal pain, dyspepsia, and rash. Less common but more serious side effects can include severe allergic reactions (e.g., anaphylaxis, Stevens-Johnson syndrome), Clostridioides difficile-associated diarrhea (CDAD), and kidney problems.
Warnings & Precautions	♦ Hypersensitivity Reactions: Serious and sometimes fatal hypersensitivity reactions have been reported; inquire about prior allergies to cephalosporins or penicillins before initiation. ♦ Clostridioides difficile-Associated Diarrhea (CDAD): Can occur during or after antibiotic therapy; evaluate patients presenting with severe diarrhea. ♦ Renal Impairment: Dose adjustment is necessary in patients with significant kidney impairment. ♦ Positive Coombs' Test: Can result in a positive direct Coombs' test, which may interfere with blood typing procedures. ♦ Not effective against viral infections.
Missed Dose Instructions	If a dose of Cephalexin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose to make up for a missed one. It's crucial to complete the entire course of antibiotics to prevent the development of antibiotic resistance and ensure complete eradication of the infection.
Overdose Instructions	Overdose is generally not life-threatening but can lead to symptoms such as nausea, vomiting, epigastric distress, diarrhea, and possibly hematuria (blood in urine) or convulsions (especially in patients with renal impairment). Treatment is supportive and symptomatic. Hemodialysis may be useful in removing cephalexin from the body. Seek medical attention for significant overdose.
Medicine Interactions	♦ Metformin: Cephalexin may increase the plasma concentration of metformin; monitor for metformin-related adverse effects. ♦ Probenecid: Decreases the renal excretion of cephalexin, resulting in increased and prolonged plasma levels of cephalexin. ♦ Oral Contraceptives: While less common than with penicillins, some antibiotics can theoretically reduce the effectiveness of oral contraceptives; advise patients to use an alternative or additional method of contraception if concerned. ♦ Cholestyramine: May reduce the absorption of cephalexin; separate administration by at least 2 hours.

Cetirizine (Zyrtec)

Purpose/Indication	Cetirizine is a second-generation antihistamine used to relieve symptoms of seasonal and perennial allergic rhinitis (hay fever) such as sneezing, runny nose, itchy or watery eyes, and itchy throat. It is also effective in treating chronic idiopathic urticaria (hives) to reduce itching and the number and size of hives.
Method of Action	Cetirizine works by selectively blocking histamine H1 receptors. Histamine is a natural substance released by the body during an allergic reaction, causing symptoms like itching, sneezing, and watery eyes. By blocking these receptors, cetirizine prevents histamine from binding and exerting its effects, thereby alleviating allergic symptoms. As a second-generation antihistamine, it generally causes less drowsiness than older antihistamines because it penetrates the blood-brain barrier poorly.
Medication Name & Brand Names	♦ Medication Name: Cetirizine Hydrochloride ♦ Brand Names: Zyrtec, Reactine (Canada), Cetrine (UK), Allergex (South Africa)
Pharmaceutical Forms & Appearance	Cetirizine is widely available as oral tablets, chewable tablets, oral syrup/solution, and oral dissolving tablets. Tablets are typically white and small, often scored. The syrup is usually clear or slightly yellowish.
Dosage & Administration	For adults and children 6 years and older, the typical dose is 5 mg or 10 mg once daily, with or without food. For children 2-5 years, a lower dose is used. Dosing may be adjusted for patients with kidney or liver impairment. It is often recommended to take it in the evening if drowsiness is a concern, though it is generally non-drowsy.
Supplied As	Cetirizine is supplied as oral tablets (e.g., 5 mg, 10 mg), chewable tablets, oral syrup/solution (e.g., 1 mg/mL, 5 mg/5 mL), and oral dissolving tablets.
Contraindications	Cetirizine is contraindicated in individuals with known hypersensitivity to cetirizine, hydroxyzine, or any piperazine derivatives. It should not be used in patients with severe kidney disease (creatinine clearance less than 10 mL/min).
Storage & Expiry	Cetirizine tablets, chewable tablets, and oral solutions should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in a tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include drowsiness (though less than first-generation antihistamines), fatigue, dry mouth, and headache. Less common side effects can include dizziness, nausea, and pharyngitis. In some individuals, paradoxical excitation or agitation may occur, particularly in children.
Warnings & Precautions	♦ Drowsiness/Sedation: While generally considered non-drowsy, some individuals may experience drowsiness, especially at higher doses or when combined with alcohol or other sedatives. Caution should be exercised when driving or operating machinery. ♦ Renal/Hepatic Impairment: Dose adjustment is necessary in patients with kidney or liver dysfunction. ♦ Elderly: Elderly patients may be more susceptible to side effects, particularly drowsiness. ♦ Urinary Retention: Use with caution in patients with conditions that predispose to urinary retention (e.g., prostatic hypertrophy, spinal cord lesion).
Missed Dose Instructions	If a dose of Cetirizine is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular daily schedule. Do not take a double dose.
Overdose Instructions	Overdose symptoms can include drowsiness, sedation, tachycardia (rapid heart rate), urinary retention, and rarely, tremors. In children, agitation or restlessness may be prominent. Treatment is symptomatic and supportive. There is no specific antidote. Gastric lavage and activated charcoal may be considered if ingestion was recent. Hemodialysis is not effective. Seek medical attention for significant overdose.

MEDICATION

Medication

A - C

Medicine Interactions	♦ Central Nervous System (CNS) Depressants: Concurrent use with alcohol, sedatives, hypnotics, tranquilizers, or other CNS depressants can enhance CNS depressant effects (e.g., increased drowsiness, impaired alertness). ♦ Theophylline: Concomitant administration of theophylline (at 400 mg daily) resulted in a small decrease in cetirizine clearance, but the clinical significance is minimal. ♦ No other significant drug interactions are commonly reported with cetirizine due to its minimal metabolism by CYP enzymes.

Chloroquine (Aralen)

Purpose/Indication	Chloroquine is an antimalarial and amebicide medication primarily used for the prophylaxis and treatment of malaria, especially in areas where Plasmodium falciparum is still sensitive to it. It is also indicated for the treatment of extraintestinal amebiasis and has been used in some autoimmune conditions like rheumatoid arthritis and systemic lupus erythematosus due to its immunomodulatory effects, though hydroxychloroquine is more commonly used for these.
Method of Action	In malaria, chloroquine accumulates in the parasite's food vacuole and inhibits the detoxification of heme, a toxic byproduct of hemoglobin digestion, into hemozoin. This leads to the accumulation of toxic heme within the parasite, causing oxidative damage and parasitic death. It also has anti-inflammatory and immunomodulatory properties, though its exact mechanism in autoimmune diseases is not fully understood.
Medication Name & Brand Names	♦ Medication Name: Chloroquine Phosphate ♦ Brand Names: Aralen (historical, now often generic), Resochin (regional)
Pharmaceutical Forms & Appearance	Chloroquine is primarily available as oral tablets, usually in strengths of 250 mg or 500 mg (referring to the phosphate salt). Tablets are typically white or yellow, often scored. It can also be available as an injectable solution for severe cases of malaria, though less common.
Dosage & Administration	Dosage varies significantly based on indication (prophylaxis vs. treatment), patient weight, and local resistance patterns. For malaria prophylaxis, it's typically taken once weekly, starting 1-2 weeks before travel and continuing for 4 weeks after leaving. For treatment, a higher initial loading dose is followed by smaller daily doses. It can be taken with food to reduce gastrointestinal upset.
Supplied As	Chloroquine is supplied as oral tablets (e.g., 250 mg, 500 mg chloroquine phosphate, equivalent to different amounts of chloroquine base).
Contraindications	Chloroquine is contraindicated in patients with known hypersensitivity to chloroquine or 4-aminoquinoline compounds. It is also contraindicated in individuals with pre-existing retinal or visual field changes, or long-term use in patients with psoriasis, as it may exacerbate symptoms. Severe liver or kidney impairment may also be a contraindication.
Storage & Expiry	Chloroquine tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in a tightly closed container and out of reach of children. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, vomiting, abdominal cramps, headache, dizziness, and blurring of vision. More serious side effects, especially with long-term use or high doses, can include retinopathy (irreversible eye damage leading to visual loss), ototoxicity (hearing impairment), cardiomyopathy (heart muscle disease), seizures, and blood disorders.
Warnings & Precautions	♦ Retinopathy: Irreversible retinal damage can occur, especially with high cumulative doses. Regular ophthalmologic examinations, including visual field testing and fundoscopy, are essential for long-term therapy. Discontinue if any visual disturbance occurs. ♦ Cardiac Effects: Can cause QT prolongation and arrhythmias; use with caution in patients with heart disease or those taking other QT-prolonging drugs. ♦ Neurological Effects: May cause seizures, particularly in patients with epilepsy. ♦ Hematologic Effects: Rare cases of bone marrow depression have been reported. ♦ Psoriasis: May exacerbate psoriasis. ♦ Children: Children are particularly sensitive to chloroquine overdose; keep out of reach. ♦ Liver/Kidney Impairment: Use with caution and adjust dose in patients with hepatic or renal dysfunction.
Missed Dose Instructions	For malaria prophylaxis, if a weekly dose of Chloroquine is missed, take it as soon as remembered if it's within a few days. If it's almost time for the next dose, take the missed dose and the next dose as scheduled (for a brief overlap). However, if significant time has passed, consult a healthcare professional for guidance. For treatment, strict adherence to the dosing schedule is crucial, and missed doses should be taken as soon as possible.
Overdose Instructions	Chloroquine overdose is extremely dangerous and can be rapidly fatal, especially in children. Symptoms include headache, drowsiness, visual disturbances, cardiovascular collapse, seizures, severe hypokalemia, and cardiac arrest. Treatment requires immediate and aggressive medical intervention, including respiratory and cardiac support, gastric lavage, activated charcoal (multiple doses), and treatment for arrhythmias and hypokalemia. Diazepam may be used for seizures and to help with cardiac stability. Seek immediate emergency medical attention.
Medicine Interactions	♦ Antacids/Kaolin: May reduce the absorption of chloroquine; separate administration by at least 4 hours. ♦ Mefloquine: Concurrent use may increase the risk of seizures and abnormal heart rhythms. ♦ Amiodarone/Other QT-prolonging drugs: Increased risk of serious ventricular arrhythmias. ♦ Cyclosporine: May increase cyclosporine levels. ♦ Praziquantel: May decrease praziquantel levels. ♦ Vaccines: May reduce the antibody response to rabies vaccine. ♦ Oral Contraceptives: Potential for reduced effectiveness, though clinical significance is debated.

Ciclopirox (Loprox)

Purpose/Indication	Ciclopirox is a broad-spectrum antifungal agent used topically to treat various fungal and yeast infections of the skin, nails, and scalp. It is indicated for conditions such as tinea pedis (athlete's foot), tinea cruris (jock itch), tinea corporis (ringworm), cutaneous candidiasis, and tinea versicolor. It is also available as a lacquer for onychomycosis (fungal nail infections) and as a shampoo for seborrheic dermatitis of the scalp.
Method of Action	Ciclopirox exerts its fungicidal activity by interfering with the synthesis of fungal cell membrane and inhibiting key metabolic processes within the fungal cell. It chelates polyvalent metal ions, such as ferric iron, which are essential cofactors for various enzymes involved in fungal metabolism. This leads to the disruption of fungal cell integrity and metabolic pathways, ultimately resulting in the death of the fungal organism.
Medication Name & Brand Names	♦ Medication Name: Ciclopirox Olamine (topical cream, gel, solution, powder) or Ciclopirox (nail lacquer, shampoo) ♦ Brand Names: Loprox (cream, gel, suspension), Penlac (nail lacquer), Ciclodan (nail lacquer), Stieprox (shampoo)
Pharmaceutical Forms & Appearance	Ciclopirox is available in various topical forms: creams, gels, solutions, powders, nail lacquers, and shampoos. Creams are typically white and opaque. Solutions and gels are often clear to translucent. Nail lacquers are clear, varnish-like solutions. Shampoos are clear or pearlescent liquids.

Dosage & Administration	Dosage and administration vary significantly by form and indication. For skin infections, creams, gels, or solutions are typically applied twice daily to the affected area and surrounding skin for 2-4 weeks. Nail lacquers are applied daily to affected nails. Shampoos are used 2-3 times per week. Always follow the specific product instructions and complete the full course of treatment, even if symptoms improve.
Supplied As	Ciclopirox is supplied as: creams (e.g., 0.77%), gels (e.g., 0.77%), solutions (e.g., 0.77%), topical powders (1%), nail lacquers (e.g., 8%), and shampoos (e.g., 1%).
Contraindications	Ciclopirox is contraindicated in individuals with known hypersensitivity (allergy) to ciclopirox or any component of the formulation. It is for external use only and should not be applied to the eyes or orally.
Storage & Expiry	Ciclopirox topical formulations should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and freezing. Nail lacquers should be kept tightly capped to prevent evaporation. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally localized and include mild skin irritation, itching, redness, burning, or stinging at the application site. For nail lacquer, periungual erythema and irritation are possible. Systemic side effects are rare due to minimal absorption.
Warnings & Precautions	♦ External Use Only: For topical application only. Avoid contact with eyes and mucous membranes. ♦ Irritation/Sensitization: If irritation or sensitization develops, discontinue use and institute appropriate therapy. ♦ Not for Ophthalmic, Oral, or Intravaginal Use: Not intended for internal use or use in the eyes. ♦ Nail Lacquer Specific: For onychomycosis, treatment often requires several months to a year, and regular debridement of the nail may be necessary. Not all fungal nail infections respond. ♦ Flammability: Nail lacquer is flammable; avoid use near heat or open flame.
Missed Dose Instructions	If a dose of topical Ciclopirox is missed, apply it as soon as remembered. However, if it is almost time for the next scheduled application, skip the missed dose and continue with the regular schedule. Do not apply a double amount. Consistency is important for effective treatment of fungal infections.
Overdose Instructions	Overdose with topical ciclopirox is highly unlikely to cause systemic toxicity due to minimal absorption through the skin. Accidental oral ingestion may cause gastrointestinal upset (nausea, vomiting), but serious systemic effects are not anticipated. Treatment for accidental ingestion is supportive. Seek medical advice if a large amount is ingested or if severe irritation occurs.
Medicine Interactions	No significant systemic drug interactions are commonly reported with topical application of ciclopirox due to its negligible systemic absorption. However, avoid co-application with other topical preparations on the same area unless directed by a healthcare professional, as this could alter absorption or cause irritation.

Ciprofloxacin (Cipro)

Purpose/Indication	Ciprofloxacin is a fluoroquinolone antibiotic used to treat a broad range of bacterial infections. It is commonly prescribed for urinary tract infections (UTIs), respiratory tract infections (e.g., pneumonia, bronchitis), skin and soft tissue infections, bone and joint infections, infectious diarrhea, and certain sexually transmitted infections. It is also used to treat or prevent anthrax and plague.
Method of Action	Ciprofloxacin is a bactericidal antibiotic that inhibits bacterial DNA gyrase and topoisomerase IV, enzymes essential for bacterial DNA replication, transcription, repair, and recombination. By interfering with these vital processes, ciprofloxacin prevents the bacteria from multiplying and ultimately leads to their death.
Medication Name & Brand Names	♦ Medication Name: Ciprofloxacin Hydrochloride ♦ Brand Names: Cipro, Cipro XR (extended-release), Ciloxan (ophthalmic), Cipro HC (otic)
Pharmaceutical Forms & Appearance	Ciprofloxacin is available as oral tablets (immediate and extended-release), oral suspension, and solutions for intravenous (IV) injection. Ophthalmic solutions/ointments and otic solutions are also available for eye and ear infections, respectively. Oral tablets are typically white to yellowish-white, often oval, and may be scored. The oral suspension is usually a micro-pellet formulation that is white to slightly yellow.
Dosage & Administration	Dosage and duration vary widely based on the infection, its severity, and patient factors (e.g., renal function). Oral doses typically range from 250 mg to 750 mg once or twice daily. Extended-release forms are once daily. IV doses are also common. It can be taken with or without food, but avoid taking it with dairy products, calcium-fortified juices, or antacids, as these can interfere with absorption. Always complete the full course.
Supplied As	Ciprofloxacin is supplied as: oral tablets (e.g., 250 mg, 500 mg, 750 mg), extended-release tablets (e.g., 500 mg, 1000 mg), powder for oral suspension (e.g., 250 mg/5 mL, 500 mg/5 mL), intravenous solution (e.g., 200 mg, 400 mg vials), ophthalmic solution/ointment, and otic solution.
Contraindications	Ciprofloxacin is contraindicated in patients with known hypersensitivity to ciprofloxacin, other fluoroquinolones, or any component of the formulation. Concurrent administration with tizanidine is contraindicated. It is generally not recommended for use in children under 18 years for most indications due to risk of musculoskeletal adverse events, except when benefits outweigh risks (e.g., anthrax, complicated UTIs).
Storage & Expiry	Ciprofloxacin tablets and IV solutions should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light. The reconstituted oral suspension should be stored at room temperature or refrigerated and typically used within 14 days; discard any unused portion. Always check the specific product label for precise storage and expiry information.
Side Effects	Common side effects include nausea, diarrhea, abdominal pain, vomiting, and headache. More serious and important side effects (especially from oral/IV forms) include tendonitis and tendon rupture, peripheral neuropathy, central nervous system effects (e.g., dizziness, confusion, seizures), QT prolongation (heart rhythm abnormality), and Clostridioides difficile-associated diarrhea (CDAD).
Warnings & Precautions	♦ Serious Adverse Reactions: Can cause disabling and potentially irreversible serious adverse reactions that may occur together, including tendinitis and tendon rupture, peripheral neuropathy, and central nervous system effects. Discontinue immediately if these occur. ♦ QT Prolongation: Can prolong the QT interval, increasing the risk of potentially fatal arrhythmias. Use with caution in patients with pre-existing heart conditions, electrolyte disturbances, or those taking other QT-prolonging drugs. ♦ Hypersensitivity Reactions: Serious and sometimes fatal hypersensitivity reactions, including anaphylaxis, can occur. ♦ Clostridioides difficile-Associated Diarrhea (CDAD): Can occur during or after antibiotic therapy. ♦ Photosensitivity: Can cause moderate to severe photosensitivity reactions. ♦ Glucose Dysregulation: Can cause hypo- or hyperglycemia. ♦ Aortic Aneurysm/Dissection: Increased risk in elderly patients or those with risk factors. ♦ Resistance: Risk of bacterial resistance development; use only for proven or strongly suspected bacterial infections.

Missed Dose Instructions	If a dose of Ciprofloxacin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. It's crucial to complete the entire course of antibiotics to ensure eradication of the infection and prevent resistance.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, including acute renal failure. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered if ingestion was recent. Hemodialysis and peritoneal dialysis are generally not effective in removing significant amounts of ciprofloxacin. Maintain adequate hydration. Seek immediate medical attention.
Medicine Interactions	♦ Multivalent Cation-Containing Products: Antacids (aluminum, magnesium, calcium), iron/zinc/calcium supplements, dairy products, and calcium-fortified juices can significantly reduce ciprofloxacin absorption. Administer ciprofloxacin at least 2 hours before or 6 hours after these products. ♦ Tizanidine: Co-administration is contraindicated due to increased tizanidine levels, leading to severe hypotension and somnolence. ♦ Theophylline: Ciprofloxacin can increase theophylline levels, leading to toxicity; monitor theophylline levels. ♦ Warfarin: May enhance the anticoagulant effect of warfarin, increasing bleeding risk; monitor INR. ♦ Cyclosporine: May increase cyclosporine levels, leading to nephrotoxicity. ♦ Methotrexate: May increase methotrexate levels, increasing toxicity. ♦ NSAIDs: Concomitant use may increase the risk of CNS stimulation and convulsions. ♦ QT-prolonging drugs: Increased risk of QT prolongation and arrhythmias.

Clarithromycin (Biaxin)

Purpose/Indication	Clarithromycin is a macrolide antibiotic used to treat various bacterial infections. It is commonly prescribed for respiratory tract infections (e.g., bronchitis, pneumonia, sinusitis, pharyngitis/tonsillitis), skin and soft tissue infections, and disseminated mycobacterial infections (e.g., MAC). It is also a key component of combination therapies for eradicating Helicobacter pylori in peptic ulcer disease.
Method of Action	Clarithromycin works by inhibiting bacterial protein synthesis. It binds to the 50S ribosomal subunit of susceptible bacteria, thereby interfering with the translocation of peptides and inhibiting the assembly of new proteins. This bacteriostatic action prevents the growth and multiplication of bacteria.
Medication Name & Brand Names	♦ Medication Name: Clarithromycin ♦ Brand Names: Biaxin, Klaricid (regional)
Pharmaceutical Forms & Appearance	Clarithromycin is available as immediate-release oral tablets, extended-release oral tablets, and as a powder for oral suspension (liquid that needs to be reconstituted). Immediate-release tablets are typically yellow, film-coated, and oval-shaped. Extended-release tablets are generally larger and also often yellow. The reconstituted suspension is usually a white to off-white liquid.
Dosage & Administration	Dosage and duration vary depending on the infection. For adults, immediate-release tablets are typically 250 mg or 500 mg twice daily. Extended-release tablets are usually 500 mg or 1000 mg once daily with food. For children, it is weight-based and typically given as a suspension. Always complete the full prescribed course, even if symptoms improve, to prevent resistance.
Supplied As	Clarithromycin is supplied as: immediate-release oral tablets (e.g., 250 mg, 500 mg), extended-release oral tablets (e.g., 500 mg, 1000 mg), and powder for oral suspension (e.g., 125 mg/5 mL, 250 mg/5 mL).
Contraindications	Clarithromycin is contraindicated in patients with a history of allergic reactions to clarithromycin, erythromycin, any macrolide or ketolide antibiotic. It is also contraindicated in patients with a history of cholestatic jaundice or hepatic dysfunction associated with prior clarithromycin use. Concurrent use with certain medications (e.g., cisapride, pimozide, ergotamine, colchicine in patients with renal/hepatic impairment, and some statins) is contraindicated due to risk of serious interactions.
Storage & Expiry	Clarithromycin tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. The reconstituted oral suspension should be stored at room temperature (15°C to 30°C or 59°F to 86°F) and typically remains stable for 14 days; do not refrigerate as it may thicken. Always check the specific product label for precise storage and expiry information.
Side Effects	Common side effects include nausea, vomiting, diarrhea, abdominal pain, altered taste (dysgeusia), and headache. More serious but less common side effects can include severe allergic reactions, liver problems (including cholestatic hepatitis), QT prolongation (a heart rhythm abnormality), and Clostridioides difficile-associated diarrhea (CDAD).
