Warnings & Precautions	♦ QT Prolongation: Can prolong the QT interval, increasing the risk of potentially fatal arrhythmias (Torsades de Pointes). Use with caution in patients with pre-existing heart conditions, electrolyte disturbances, or those taking other QT-prolonging drugs. ♦ Hepatotoxicity: Liver dysfunction, ranging from mild elevations in liver enzymes to severe hepatic failure, has been reported. ♦ Clostridioides difficile-Associated Diarrhea (CDAD): Can occur during or after antibiotic therapy. ♦ Renal Impairment: Dose adjustment is necessary in patients with severe kidney impairment. ♦ Myasthenia Gravis: May exacerbate symptoms of myasthenia gravis. ♦ Not effective against viral infections. ♦ Drug Interactions: Numerous significant drug interactions due to strong CYP3A4 inhibition (see interactions).
Missed Dose Instructions	If a dose of Clarithromycin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. It's crucial to complete the entire course of antibiotics to ensure eradication of the infection and prevent resistance.
Overdose Instructions	Symptoms of overdose are generally an exaggeration of known side effects, primarily severe gastrointestinal symptoms such as nausea, vomiting, diarrhea, and abdominal discomfort. Allergic reactions and QT prolongation are also possible. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered if ingestion was recent. Hemodialysis and peritoneal dialysis are not effective in removing significant amounts of clarithromycin. Seek immediate medical attention.
Medicine Interactions	♦ Strong CYP3A4 Substrates: Clarithromycin is a strong CYP3A4 inhibitor and can significantly increase levels of drugs metabolized by this enzyme, leading to increased toxicity. Examples include: statins (simvastatin, lovastatin - contraindicated due to rhabdomyolysis risk), colchicine (contraindicated in renal/hepatic impairment), warfarin, oral midazolam, sildenafil, cyclosporine, tacrolimus, carbamazepine, cisapride, pimozide (both contraindicated due to QT prolongation). ♦ QT-prolonging drugs: Increased risk of QT prolongation and arrhythmias with other QT-prolonging agents (e.g., antiarrhythmics, antipsychotics). ♦ Oral Contraceptives: May reduce effectiveness, requiring alternative contraception. ♦ Digoxin: May increase digoxin levels. ♦ Rifampin/Phenytoin/Carbamazepine/St. John's Wort: These strong inducers can decrease clarithromycin levels, potentially leading to treatment failure.

Clindamycin (Cleocin)

MEDICATION - Medication List - A - C - Clindamycin (Cleocin)

Purpose/Indication	Clindamycin is a lincosamide antibiotic used to treat serious bacterial infections, particularly those caused by anaerobic bacteria (e.g., intra-abdominal infections, pelvic infections) and certain susceptible aerobic gram-positive bacteria (e.g., strep and staph infections). It is often used for skin and soft tissue infections, osteomyelitis, septicemia, and in some cases, for acne (topical) or bacterial vaginosis (topical/oral).
Method of Action	Clindamycin inhibits bacterial protein synthesis by binding to the 50S ribosomal subunit of susceptible bacteria. This binding prevents the elongation of peptide chains by interfering with the peptidyl transferase reaction. This action is primarily bacteriostatic (inhibits growth) but can be bactericidal against highly susceptible organisms or at high concentrations.
Medication Name & Brand Names	♦ Medication Name: Clindamycin Hydrochloride (oral), Clindamycin Phosphate (topical, injectable), Clindamycin Palmitate HCl (oral solution) ♦ Brand Names: Cleocin (oral, injectable, topical), Clinda-Derm (topical), Dalacin C (regional)
Pharmaceutical Forms & Appearance	Clindamycin is available in various forms: oral capsules, oral solution, topical solution/gel/foam/lotion, vaginal cream/suppositories, and injectable solutions. Oral capsules are typically opaque, hard gelatin capsules with various colors and imprints. The oral solution is a clear or slightly viscous liquid. Topical preparations vary in appearance depending on the base. Injectable solutions are clear, colorless to slightly yellow.
Dosage & Administration	Dosage and route of administration vary significantly based on the infection, its severity, and patient factors. Oral doses typically range from 150 mg to 450 mg every 6-8 hours. Injectable doses are higher. Topical preparations are applied once or twice daily. Oral forms can be taken with or without food. Complete the full prescribed course.
Supplied As	Clindamycin is supplied as: oral capsules (e.g., 75 mg, 150 mg, 300 mg), granules for oral solution (e.g., 75 mg/5 mL), injectable solution (e.g., 150 mg/mL), topical solution/gel/foam/lotion (e.g., 1%), and vaginal cream/suppositories.
Contraindications	Clindamycin is contraindicated in patients with a history of hypersensitivity to clindamycin or lincomycin. It is also contraindicated in patients with a history of pseudomembranous colitis associated with antibiotic use.
Storage & Expiry	Clindamycin capsules and topical preparations should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. The reconstituted oral solution should be stored at room temperature and used within a specific period (check product label, typically 2 weeks). Injectable solutions are stored at room temperature. Always check the specific expiry date on the packaging.
Side Effects	The most significant and common side effect is Clostridioides difficile-associated diarrhea (CDAD), which can range from mild diarrhea to severe, life-threatening pseudomembranous colitis. Other common side effects include nausea, vomiting, abdominal pain, and rash. Topical forms may cause local irritation, dryness, or peeling.
Warnings & Precautions	♦ Clostridioides difficile-Associated Diarrhea (CDAD): This is the most serious and frequent adverse effect. It can occur during or even several weeks after discontinuation of clindamycin. Patients presenting with diarrhea should be evaluated for CDAD. ♦ Severe Allergic Reactions: Anaphylaxis and severe skin reactions (e.g., Stevens-Johnson syndrome, DRESS syndrome) have been reported. ♦ Gastrointestinal Effects: Use with caution in patients with a history of gastrointestinal disease, especially colitis. ♦ Liver/Kidney Impairment: Use with caution in patients with severe hepatic or renal impairment; dose adjustment may be necessary. ♦ Not indicated for the treatment of meningitis due to poor penetration into the CSF.
Missed Dose Instructions	If a dose of Clindamycin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Completing the full course of antibiotics is essential for effective treatment and to prevent the development of resistance.
Overdose Instructions	Overdose with clindamycin is rare and typically results in an exaggeration of known side effects, mainly gastrointestinal disturbances (nausea, vomiting, diarrhea, abdominal pain). Severe cases may present with signs of pseudomembranous colitis. Treatment is symptomatic and supportive. Gastric decontamination (e.g., activated charcoal) may be considered if a significant oral overdose was recent. Hemodialysis and peritoneal dialysis are not effective. Seek medical attention if severe symptoms occur.
Medicine Interactions	♦ Neuromuscular Blocking Agents: Clindamycin has neuromuscular blocking properties and can enhance the action of other neuromuscular blocking agents (e.g., succinylcholine, rocuronium), leading to prolonged muscle paralysis and respiratory depression. Use with caution. ♦ Erythromycin: In vitro studies suggest antagonism between clindamycin and erythromycin (another macrolide); co-administration is generally not recommended. ♦ Kaolin-pectin antidiarrheals: May delay or decrease the absorption of oral clindamycin; separate administration by at least 2 hours. ♦ Oral Typhoid Vaccine: Clindamycin can inhibit the growth of the live bacteria in the typhoid vaccine; avoid concomitant use.

Clopidogrel (Plavix)

Purpose/Indication	Clopidogrel is an antiplatelet medication used to prevent serious cardiovascular events such as heart attacks and strokes in patients at high risk. It is indicated for individuals with a recent myocardial infarction (heart attack), recent stroke, established peripheral arterial disease, or those with acute coronary syndrome (ACS), often in combination with aspirin. It works by reducing the formation of blood clots.
Method of Action	Clopidogrel is a prodrug that is metabolized by the liver (primarily by CYP2C19) into an active thiol metabolite. This active metabolite irreversibly blocks the P2Y12 adenosine diphosphate (ADP) receptor on the surface of platelets. By blocking this receptor, it prevents ADP from binding and activating platelets, thereby inhibiting platelet aggregation and the formation of blood clots. Because the binding is irreversible, the antiplatelet effect lasts for the lifetime of the platelet (7-10 days).
Medication Name & Brand Names	♦ Medication Name: Clopidogrel Bisulfate ♦ Brand Names: Plavix, Apo-Clopidogrel (Canada), GenRx Clopidogrel (Australia)
Pharmaceutical Forms & Appearance	Clopidogrel is available as oral tablets, typically in strengths of 75 mg and 300 mg. Tablets are usually pink, round, biconvex, and film-coated, often with specific imprints indicating the dosage strength.
Dosage & Administration	Dosage varies by indication. For acute coronary syndrome, a loading dose of 300 mg or 600 mg is often given, followed by a maintenance dose of 75 mg once daily. For other indications (e.g., recent MI/stroke/PAD), the usual dose is 75 mg once daily. It can be taken with or without food. Consistent daily administration is important.
Supplied As	Clopidogrel is supplied as oral film-coated tablets (e.g., 75 mg, 300 mg).
Contraindications	Clopidogrel is contraindicated in patients with active pathological bleeding (e.g., peptic ulcer, intracranial hemorrhage) and in individuals with known hypersensitivity to clopidogrel or any component of the formulation.
Storage & Expiry	Clopidogrel tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in their original container. Always check the specific expiry date on the packaging.

MEDICATION

Medication

A C - A C - A C

Side Effects	The most significant and common side effect is bleeding, which can range from minor (e.g., bruising, nosebleeds) to major (e.g., gastrointestinal bleeding, intracranial hemorrhage). Other common side effects include dyspepsia, abdominal pain, diarrhea, and rash. Less common but serious side effects include thrombotic thrombocytopenic purpura (TTP), severe allergic reactions, and liver dysfunction.
Warnings & Precautions	♦ Bleeding Risk: Clopidogrel increases the risk of bleeding. Use with caution in patients at increased risk of bleeding (e.g., recent surgery, trauma, active ulcers, concomitant use of other anticoagulants/antiplatelets). Discontinue 5-7 days prior to elective surgery if antiplatelet effect is not desired. ♦ Genetic Polymorphism (CYP2C19): Patients who are "poor metabolizers" of CYP2C19 may have diminished antiplatelet response and an increased risk of cardiovascular events. Genetic testing may be considered. ♦ Thrombotic Thrombocytopenic Purpura (TTP): Rare but potentially fatal TTP has been reported, sometimes after short-term use. Prompt treatment is required. ♦ Hypersensitivity: Angioedema or other allergic reactions may occur. ♦ Cross-reactivity: Patients with a history of hypersensitivity to another thienopyridine (e.g., prasugrel, ticlopidine) may be at increased risk of reaction to clopidogrel.
Missed Dose Instructions	If a dose of Clopidogrel is missed and it's less than 12 hours since the usual time, take it as soon as remembered, then continue with the next dose at the regularly scheduled time. If it's more than 12 hours, skip the missed dose and simply take the next dose at the regularly scheduled time. Do not take a double dose. Consistent daily dosing is essential for maintaining antiplatelet protection.
Overdose Instructions	Overdose can lead to prolonged bleeding time and subsequent bleeding complications. Symptoms may include gastrointestinal bleeding, nosebleeds, bruising, or more severe hemorrhages. There is no specific antidote to reverse the antiplatelet effects of clopidogrel immediately. Platelet transfusions may be considered in cases of severe bleeding requiring rapid reversal. Treatment is supportive and symptomatic. Seek immediate medical attention.
Medicine Interactions	♦ CYP2C19 Inhibitors: Strong and moderate inhibitors of CYP2C19 (e.g., omeprazole, esomeprazole, fluoxetine, fluvoxamine, ticlopidine, voriconazole) can reduce the active metabolite formation of clopidogrel, potentially decreasing its antiplatelet effect. Avoid concurrent use, particularly with PPIs like omeprazole/esomeprazole. ♦ Other Antiplatelet Agents/Anticoagulants/NSAIDs: Concurrent use with aspirin, other NSAIDs, warfarin, heparin, or other anticoagulants significantly increases the risk of bleeding. Use with caution and monitor closely. ♦ Opioids: Reduced absorption of clopidogrel has been observed with opioid co-administration, potentially decreasing its antiplatelet effect. ♦ Repaglinide: Clopidogrel can increase repaglinide levels, increasing the risk of hypoglycemia.

Clopidogrel (Plavix)

Clotrimazole (Canesten)

Purpose/Indication	Clotrimazole is an antifungal medication used to treat various fungal and yeast infections of the skin, mouth, and vagina. It is commonly indicated for conditions such as athlete's foot (tinea pedis), jock itch (tinea cruris), ringworm (tinea corporis), oral thrush (oropharyngeal candidiasis), and vaginal yeast infections (vulvovaginal candidiasis).
Method of Action	Clotrimazole is an azole antifungal that works by inhibiting the biosynthesis of ergosterol, a vital component of the fungal cell membrane. By disrupting ergosterol synthesis, it compromises the integrity and permeability of the fungal cell membrane, leading to leakage of essential intracellular components and ultimately, the death of the fungal organism.
Medication Name & Brand Names	♦ Medication Name: Clotrimazole ♦ Brand Names: Lotrimin AF, Canesten, Mycelex, Desenex (some formulations), Gyne-Lotrimin (vaginal)
Pharmaceutical Forms & Appearance	Clotrimazole is available in various topical forms: creams, lotions, solutions, powders, sprays, vaginal tablets, and vaginal creams. For oral use, it's available as lozenges (troches). Creams, lotions, and vaginal creams are typically white and smooth. Vaginal tablets are usually white. Lozenges are white.
Dosage & Administration	Dosage and administration vary significantly by form and indication. For skin infections, creams/lotions are typically applied twice daily to the affected area for 2-4 weeks. Vaginal tablets/creams are inserted once daily at bedtime for 1-7 days depending on strength. Oral lozenges are usually dissolved slowly in the mouth 5 times daily. Always follow specific product instructions and complete the full course.
Supplied As	Clotrimazole is supplied as: topical creams, lotions, solutions, powders, and sprays (e.g., 1%); vaginal creams (e.g., 1%, 2%); vaginal tablets (e.g., 100 mg, 200 mg, 500 mg); and oral lozenges (e.g., 10 mg).
Contraindications	Clotrimazole is contraindicated in individuals with known hypersensitivity (allergy) to clotrimazole or any component of the formulation. Topical forms are for external use only and should not be used in the eyes. Oral lozenges are contraindicated in patients with severe liver impairment.
Storage & Expiry	Clotrimazole topical and vaginal formulations should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from heat and moisture. Oral lozenges should also be stored at room temperature. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally localized to the application site and include mild skin irritation, itching, redness, burning, or stinging. Vaginal forms can cause burning, itching, or irritation. Oral lozenges may cause nausea, vomiting, or abnormal liver function tests (rarely). Systemic side effects are rare due to minimal absorption.
Warnings & Precautions	♦ External Use Only: For topical application on skin, in the mouth, or vaginally. Avoid contact with eyes. ♦ Irritation/Sensitization: If irritation or sensitization develops (e.g., worsening redness, swelling, burning), discontinue use and consult a healthcare professional. ♦ Vaginal Use: If symptoms do not improve within a few days or worsen, or if recurrence is frequent, consult a healthcare professional as other conditions may be present. Avoid sexual intercourse during treatment of vaginal infections. ♦ Oral Use: Prolonged use of oral lozenges may lead to liver enzyme elevations; monitor liver function in such cases.
Missed Dose Instructions	If a dose of topical or oral Clotrimazole (for an ongoing course) is missed, apply/take it as soon as remembered. However, if it is almost time for the next scheduled application/dose, skip the missed dose and continue with the regular schedule. Do not apply/take a double amount. Consistency is important for effective treatment of fungal infections.
Overdose Instructions	Overdose with topical or vaginal clotrimazole is highly unlikely to cause systemic toxicity due to negligible absorption. Accidental oral ingestion of topical forms may cause gastrointestinal upset (nausea, vomiting, abdominal pain). Overdose with oral lozenges is also rare but could potentially lead to increased liver enzyme levels. Treatment is symptomatic and supportive. Seek medical advice if a large amount is ingested or if severe irritation occurs.
Medicine Interactions	♦ Topical/Vaginal Forms: No significant systemic drug interactions are commonly reported due to minimal systemic absorption. However, vaginal creams may weaken latex condoms or diaphragms. ♦ Oral Lozenges: Although systemic absorption is low, some potential for interaction with drugs metabolized by CYP450 enzymes (e.g., tacrolimus, cyclosporine) exists, similar to other azole antifungals, but is generally not clinically significant with this formulation. However, always inform healthcare providers of all medications being used.

Clotrimazole (Canesten)

MEDICATION
MEDICATION
Medication List

Cycloserine (Seromycin)

Purpose/Indication	Cycloserine is an antibiotic primarily used as a second-line agent for the treatment of active tuberculosis (TB), especially in cases of multi-drug-resistant TB (MDR-TB) or extensively drug-resistant TB (XDR-TB) caused by susceptible strains of Mycobacterium tuberculosis. It is always used in combination with other anti-tuberculosis drugs to prevent resistance and enhance efficacy. It also has a limited role in treating certain urinary tract infections caused by susceptible organisms when first-line agents are ineffective.
Method of Action	Cycloserine acts as an antimetabolite, interfering with bacterial cell wall synthesis. It is a structural analogue of D-alanine, an essential component of peptidoglycan synthesis in the bacterial cell wall. Cycloserine competitively inhibits two key enzymes: D-alanine racemase (which converts L-alanine to D-alanine) and D-alanine:D-alanine ligase (which joins two D-alanine molecules). This disruption prevents the formation of a stable bacterial cell wall, leading to bacterial lysis and death.
Medication Name & Brand Names	♦ Medication Name: Cycloserine ♦ Brand Name: Seromycin (often referred to generically now)
Pharmaceutical Forms & Appearance	Cycloserine is available as oral capsules, typically in a strength of 250 mg. The capsules are usually hard gelatin capsules, often with a white or off-white body and cap, and may have imprints.
Dosage & Administration	Dosage is individualized based on patient factors, including renal function and plasma cycloserine concentrations, which should be monitored to minimize toxicity. For adults, the typical initial dose for TB is 250 mg twice daily, increasing to 250-500 mg every 12 hours, with a maximum daily dose of 1 gram. It is usually taken by mouth, with or without food.
Supplied As	Cycloserine is supplied as oral capsules (e.g., 250 mg).
Contraindications	Cycloserine is contraindicated in patients with known hypersensitivity to cycloserine. It is also contraindicated in individuals with epilepsy or a history of convulsions, active depression, severe anxiety, or psychosis, as the drug can exacerbate these neurological and psychiatric conditions. Severe renal insufficiency and alcohol abuse are also contraindications.
Storage & Expiry	Cycloserine capsules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in a tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	The most common and significant side effects of cycloserine are neurological and psychiatric, including headache, dizziness, drowsiness, confusion, irritability, anxiety, depression, tremors, psychosis, and seizures. Other side effects can include peripheral neuropathy and, rarely, liver dysfunction.
Warnings & Precautions	♦ Neuropsychiatric Effects: Can cause severe central nervous system toxicity, including psychosis, depression, and seizures. Close monitoring for changes in mental status is essential, especially in patients with pre-existing psychiatric conditions. Pyridoxine (Vitamin B6) should be co-administered to reduce the risk of neurological toxicity, especially peripheral neuropathy. ♦ Renal Impairment: Dose adjustment is necessary in patients with kidney impairment to prevent drug accumulation and toxicity; careful monitoring of serum levels is crucial. ♦ Alcohol: Alcohol consumption should be avoided as it increases the risk of convulsions and CNS toxicity. ♦ Liver Dysfunction: Monitor liver function, although hepatotoxicity is rare. ♦ Drug Monitoring: Therapeutic drug monitoring (plasma cycloserine levels) is highly recommended to guide dosing and minimize toxicity.
Missed Dose Instructions	Given the critical nature of TB treatment and the potential for resistance, if a dose of Cycloserine is missed, the healthcare provider managing the patient's TB therapy should be contacted immediately for specific instructions. Do not take a double dose. Adherence to the prescribed regimen is paramount.
Overdose Instructions	Overdose is most likely to lead to severe neuropsychiatric toxicity, including profound drowsiness, dizziness, confusion, severe psychosis, tremors, and seizures. Coma and respiratory depression can occur in severe cases. There is no specific antidote. Treatment is supportive. Gastric lavage and repeated doses of activated charcoal may be considered if oral ingestion was recent. Hemodialysis can effectively remove cycloserine from the body. Pyridoxine administration is crucial. Seek immediate medical attention.
Medicine Interactions	♦ Alcohol: Concurrent alcohol consumption significantly increases the risk of seizures and CNS toxicity. ♦ Isoniazid (INH): Co-administration with isoniazid can increase the risk of CNS side effects (dizziness, drowsiness), especially if isoniazid dosage is too high or if cycloserine levels are elevated. Pyridoxine is particularly important in this combination. ♦ Ethionamide: Concurrent use may increase the risk of CNS adverse effects. ♦ No other significant drug interactions are commonly reported, but given its CNS effects, caution is advised with other CNS depressants or drugs affecting neurological function.

Cyclosporine (Sandimmune)

Purpose/Indication	Cyclosporine is a potent immunosuppressant medication primarily used to prevent organ rejection after transplantation (kidney, liver, heart, lung, etc.) by suppressing the body's immune response to the transplanted organ. It is also indicated for certain severe autoimmune diseases, such as severe active rheumatoid arthritis, severe psoriasis, and nephrotic syndrome, when other treatments are ineffective or not tolerated.
Method of Action	Cyclosporine works by selectively inhibiting T-lymphocyte activation. It forms a complex with cyclophilin, an intracellular protein, which then inhibits the calcium-dependent phosphatase calcineurin. Calcineurin is crucial for the dephosphorylation of the nuclear factor of activated T-cells (NFAT), preventing its translocation into the nucleus. This ultimately blocks the transcription of early T-cell activation genes, particularly those encoding interleukin-2 (IL-2), a cytokine essential for T-cell proliferation and differentiation, thereby suppressing the immune response.
Medication Name & Brand Names	♦ Medication Name: Cyclosporine (modified or non-modified) ♦ Brand Names: Sandimmune (non-modified), Neoral (modified), Gengraf (modified), Restasis (ophthalmic)
Pharmaceutical Forms & Appearance	Cyclosporine is available as oral capsules (soft gelatin), oral solution, and solution for intravenous (IV) injection. Oral capsules are typically soft gelatin capsules, with various colors and sizes depending on the strength and formulation (modified vs. non-modified). The oral solution is usually an oily, clear liquid. The injectable solution is a clear, yellowish liquid.
Dosage & Administration	Dosage is highly individualized based on the patient's weight, the type of transplant or autoimmune condition, and most importantly, therapeutic drug monitoring of blood levels. It is typically taken twice daily, exactly 12 hours apart, and consistently with or without food. Different formulations (modified vs. non-modified) are not bioequivalent and should not be interchanged without careful dose adjustment and monitoring by a healthcare professional.

MEDICATION | List | A - C | Cyclosporine (Sandimmune)

Supplied As	Cyclosporine is supplied as: oral soft gelatin capsules (e.g., 25 mg, 50 mg, 100 mg - both modified and non-modified), oral solution (e.g., 100 mg/mL), and concentrated solution for intravenous infusion (e.g., 50 mg/mL).
Contraindications	Cyclosporine is contraindicated in patients with known hypersensitivity to cyclosporine or any component of the formulation. For non-transplant indications, it is also contraindicated in patients with uncontrolled hypertension, uncontrolled infections, or malignancy. Concomitant use with specific drugs like bosentan (for pulmonary hypertension) or pitavastatin/lovastatin (for cholesterol) is also contraindicated.
Storage & Expiry	Cyclosporine capsules and oral solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. The oral solution should not be refrigerated as it may gel. Keep in its original packaging. Always check the specific expiry date. The IV concentrate must be stored properly and protected from light.
Side Effects	Common side effects include nephrotoxicity (kidney damage), hypertension (high blood pressure), hirsutism (excessive hair growth), gingival hyperplasia (gum overgrowth), tremor, headache, and gastrointestinal upset. More serious side effects can include increased risk of infections (bacterial, viral, fungal, opportunistic), malignancy (especially lymphoma, skin cancer), neurotoxicity (seizures, encephalopathy), hyperkalemia (high potassium), and hyperlipidemia (high cholesterol).
Warnings & Precautions	♦ Nephrotoxicity: Dose-dependent and can be acute or chronic. Renal function (creatinine, BUN) must be monitored closely. ♦ Hypertension: Common and often requires antihypertensive therapy. ♦ Increased Risk of Infection & Malignancy: Immunosuppression significantly increases the risk of opportunistic infections and various cancers, particularly skin cancers and lymphomas. ♦ Neurotoxicity: Tremor, headache, paresthesia are common; seizures and encephalopathy can occur. ♦ Drug Monitoring: Therapeutic drug monitoring (blood cyclosporine levels) is essential to ensure optimal immunosuppression and minimize toxicity. ♦ Bioequivalence: Non-modified and modified formulations are NOT interchangeable without careful supervision due to different bioavailability. ♦ Hyperkalemia/Hyperlipidemia: Monitor potassium and lipid levels. ♦ Hepatotoxicity: Liver function should be monitored.
Missed Dose Instructions	If a dose of Cyclosporine is missed, take it as soon as remembered if it is still within a few hours of the scheduled time. If it is almost time for the next scheduled dose (e.g., more than 6 hours after the usual time), skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. Missing doses can increase the risk of organ rejection or worsening of autoimmune disease. Contact your transplant team or healthcare provider for specific advice.
Overdose Instructions	Overdose can lead to an exaggeration of known dose-dependent side effects, primarily severe nephrotoxicity, hypertension, tremor, and neurotoxicity. There is no specific antidote. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered if oral ingestion was recent and substantial. Hemodialysis is not effective for removing cyclosporine due to its high protein binding and large volume of distribution. Monitor blood cyclosporine levels, renal function, blood pressure, and neurological status closely. Seek immediate medical attention.
Medicine Interactions	Cyclosporine is a substrate, inhibitor, and inducer of CYP3A4 and a substrate and inhibitor of P-glycoprotein, leading to numerous significant interactions: ♦ CYP3A4 Inhibitors (e.g., azole antifungals like ketoconazole/itraconazole, macrolide antibiotics like erythromycin/clarithromycin, diltiazem, verapamil, amiodarone, grapefruit juice): Significantly increase cyclosporine levels, increasing toxicity risk. Dose reduction of cyclosporine is often required. ♦ CYP3A4 Inducers (e.g., rifampin, carbamazepine, phenytoin, phenobarbital, St. John's Wort): Significantly decrease cyclosporine levels, increasing rejection risk. Avoid co-administration or increase cyclosporine dose with close monitoring. ♦ Nephrotoxic Agents (e.g., aminoglycosides, NSAIDs, amphotericin B, trimethoprim/sulfamethoxazole): Increased risk of nephrotoxicity. Avoid or use with extreme caution and close monitoring. ♦ Potassium-Sparing Diuretics/Potassium Supplements/ACE Inhibitors/ARBs: Increased risk of hyperkalemia. ♦ Statins (lovastatin, simvastatin, pitavastatin): Increased risk of myopathy/rhabdomyolysis; pitavastatin/lovastatin contraindicated with cyclosporine. ♦ Digoxin/Colchicine: Increased levels of these drugs.

D - G

Any medications starting with D through to G.

Daptomycin (Cubicin)

MEDICATION | D - G | Daptomycin (Cubicin)

Purpose/Indication	Daptomycin is a lipopeptide antibiotic used to treat serious infections caused by susceptible Gram-positive bacteria. It is indicated for complicated skin and skin structure infections (cSSSI), Staphylococcus aureus bloodstream infections (bacteremia), including those associated with right-sided infective endocarditis. It is active against methicillin-resistant S. aureus (MRSA) and vancomycin-resistant enterococci (VRE).
Method of Action	Daptomycin works by a unique calcium-dependent mechanism. It inserts into the bacterial cell membrane, leading to rapid depolarization of the membrane potential. This disruption inhibits essential bacterial processes such as protein, DNA, and RNA synthesis, ultimately resulting in rapid, concentration-dependent bacterial cell death. Unlike some other antibiotics, it does not penetrate the outer membrane of Gram-negative bacteria.
Medication Name & Brand Names	♦ Medication Name: Daptomycin ♦ Brand Name: Cubicin, Cubicin RF (for rapid reconstitution)
Pharmaceutical Forms & Appearance	Daptomycin is available as a sterile lyophilized powder for intravenous (IV) infusion. The powder is typically white to pale yellow. When reconstituted with sterile water for injection or saline, it forms a clear to pale yellow solution.
Dosage & Administration	Dosage and duration depend on the infection type and severity. For cSSSI, it is typically 4 mg/kg once every 24 hours. For S. aureus bacteremia and endocarditis, a higher dose of 6 mg/kg once every 24 hours is used. It is administered as an intravenous infusion over 30 minutes. Dose adjustment is required for patients with significant renal impairment.
Supplied As	Daptomycin is supplied as a sterile lyophilized powder for intravenous infusion in single-dose vials (e.g., 250 mg, 500 mg).
Contraindications	Daptomycin is contraindicated in patients with known hypersensitivity to daptomycin or any component of the formulation. It is generally not indicated for the treatment of pneumonia, as it is inactivated by pulmonary surfactant.
Storage & Expiry	Unopened vials of daptomycin powder should be stored under refrigeration (2°C to 8°C or 36°F to 46°F). Once reconstituted, the solution should be used promptly. If not used immediately, the reconstituted solution and diluted infusion solution can be stored for a limited time (e.g., up to 12 hours at room temperature or 48 hours refrigerated, depending on the diluent), as specified by the manufacturer. Always check the specific product label for precise storage and expiry information.

Side Effects	Common side effects include headache, nausea, constipation, diarrhea, rash, and injection site reactions. More serious but less common side effects can include muscle pain or weakness (myopathy), often associated with elevated creatine phosphokinase (CPK) levels, eosinophilic pneumonia (a rare lung condition), peripheral neuropathy, and severe allergic reactions.
Warnings & Precautions	♦ Myopathy/CPK Elevation: Can cause muscle pain and weakness, often associated with elevated CPK levels. CPK levels should be monitored at baseline and regularly (e.g., weekly) during treatment. Discontinue if significant CPK elevation or muscle symptoms occur. ♦ Eosinophilic Pneumonia: A rare but potentially serious lung adverse event. Monitor for new or worsening fever, cough, or dyspnea. ♦ Peripheral Neuropathy: Monitor for symptoms of neuropathy. ♦ Hypersensitivity Reactions: Serious and sometimes fatal hypersensitivity reactions, including anaphylaxis and DRESS syndrome, have been reported. ♦ Renal Impairment: Dose adjustment is required in patients with creatinine clearance <30 mL/min, and monitoring for CPK elevation should be more frequent. ♦ Not for Pneumonia: Not effective for the treatment of pneumonia as pulmonary surfactant inhibits its activity. ♦ Monitoring: Regular monitoring of CPK, renal function, and signs of muscle toxicity is essential.
Missed Dose Instructions	Daptomycin is an IV antibiotic administered by a healthcare professional, typically daily. If a scheduled dose is missed in a clinical setting, the healthcare team will be responsible for ensuring it is administered as soon as feasible to maintain consistent drug levels and effective treatment.
Overdose Instructions	Limited information is available on daptomycin overdose. Symptoms would likely be an exaggeration of known side effects, particularly myopathy with elevated CPK and potential for renal toxicity. Treatment is supportive and symptomatic. Daptomycin is slowly cleared by hemodialysis and peritoneal dialysis. Close monitoring of CPK, renal function, and signs of muscle toxicity is essential. Seek immediate medical attention.
Medicine Interactions	♦ Statins (HMG-CoA Reductase Inhibitors): Concomitant use with statins can increase the risk of myopathy and CPK elevations. Consider temporarily suspending statin therapy during daptomycin treatment, or monitor CPK levels more frequently if co-administration is necessary. ♦ Other Myopathy-Associated Drugs: Use with caution with other medications associated with myopathy (e.g., fibrates). ♦ Warfarin: No clinically significant interaction with warfarin requiring dose adjustment; however, monitor for bleeding if used concurrently with other anticoagulants.

Dexamethasone (Decadron)

Purpose/Indication	Dexamethasone is a potent synthetic corticosteroid used for its strong anti-inflammatory and immunosuppressive effects. It is indicated for a wide range of conditions, including allergic disorders, dermatologic diseases, endocrine disorders, gastrointestinal diseases, hematologic disorders, neoplastic diseases (as part of chemotherapy regimens), nervous system conditions (e.g., cerebral edema), ophthalmic diseases, renal diseases, and respiratory diseases. It is also used in the diagnosis of Cushing's syndrome.
Method of Action	Dexamethasone acts by binding to intracellular glucocorticoid receptors, forming a complex that translocates to the nucleus and modulates gene expression. This leads to the inhibition of pro-inflammatory mediators (e.g., prostaglandins, leukotrienes, cytokines) and suppression of various immune cell functions. It also has catabolic and antianabolic effects, influences fat and carbohydrate metabolism, and can stabilize lysosomal membranes.
Medication Name & Brand Names	♦ Medication Name: Dexamethasone ♦ Brand Names: Decadron (historical, now often generic), Dexamethasone Intensol (oral solution), Ozurdex (ophthalmic implant), Dexycu (ophthalmic solution)
Pharmaceutical Forms & Appearance	Dexamethasone is available in numerous forms: oral tablets, oral solution, intravenous (IV) injection, intramuscular (IM) injection, ophthalmic solution/ointment, otic solution, and even ophthalmic implants. Oral tablets are typically white, small, and may be scored. The oral solution is a clear liquid. Injectable solutions are clear and colorless.
Dosage & Administration	Dosage is highly variable and individualized based on the specific condition being treated, severity, and patient response. It can be given once daily or in divided doses. Oral forms can be taken with food or milk to reduce gastrointestinal upset. IV administration is used for rapid effect or severe conditions. Long-term therapy requires careful titration and often a gradual taper to avoid withdrawal symptoms.
Supplied As	Dexamethasone is supplied as: oral tablets (e.g., 0.5 mg, 0.75 mg, 1 mg, 1.5 mg, 2 mg, 4 mg, 6 mg), oral solution (e.g., 0.5 mg/5 mL, 1 mg/mL concentrate), injectable solution (e.g., 4 mg/mL, 10 mg/mL, 20 mg/mL), ophthalmic solutions/ointments, otic solutions, and ophthalmic implants.
Contraindications	Dexamethasone is contraindicated in patients with systemic fungal infections and in individuals with known hypersensitivity to dexamethasone or any component of the formulation. Live or live attenuated vaccines are generally contraindicated during treatment with immunosuppressive doses of corticosteroids.
Storage & Expiry	Dexamethasone tablets and solutions should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging. Some injectable forms may require protection from freezing.
Side Effects	Common side effects with short-term use include increased appetite, weight gain, fluid retention, mood changes (e.g., irritability, insomnia), and indigestion. Long-term or high-dose use can lead to more serious effects such as adrenal suppression, osteoporosis, increased risk of infections, hyperglycemia/diabetes, hypertension, cataracts, glaucoma, Cushingoid features (e.g., moon face, buffalo hump), muscle weakness, and impaired wound healing.
Warnings & Precautions	♦ Adrenal Suppression: Prolonged use suppresses the hypothalamic-pituitary-adrenal (HPA) axis. Abrupt withdrawal can lead to life-threatening adrenal insufficiency. Doses should be tapered gradually. ♦ Increased Susceptibility to Infection: Immunosuppression increases the risk of new infections and exacerbation of latent infections (e.g., tuberculosis, herpes, fungal infections). Masking of infection symptoms is possible. ♦ Ocular Effects: Can cause cataracts and glaucoma; regular eye exams are recommended for long-term users. ♦ Metabolic Effects: Can cause hyperglycemia (and diabetes), hypertension, and dyslipidemia. ♦ Bone Effects: Long-term use can lead to osteoporosis and fractures. ♦ Psychiatric Disturbances: Mood swings, depression, euphoria, or psychotic manifestations can occur. ♦ Peptic Ulcer/GI Bleeding: Increased risk, especially with concomitant NSAIDs. ♦ Growth Suppression: Can cause growth retardation in children.
Missed Dose Instructions	For a short course of Dexamethasone or when used for an acute condition, take the missed dose as soon as remembered. However, if it is almost time for the next dose, skip the missed dose and continue with the regular schedule. Do not double dose. For long-term, chronic conditions, consistent dosing is important, and consultation with a healthcare professional regarding missed doses is advised due to the risk of HPA axis suppression.
Overdose Instructions	Acute overdose with corticosteroids is generally not life-threatening. Chronic overdose, however, leads to signs and symptoms of hypercorticism, resembling Cushing's syndrome (e.g., weight gain, fluid retention, hypertension, hyperglycemia, muscle weakness). Treatment is symptomatic and supportive. Gradual tapering of the drug, rather than abrupt cessation, is typically recommended after chronic overdose to avoid adrenal crisis. Seek medical attention for significant or chronic overdose.

Medicine Interactions	♦ CYP3A4 Inducers: Drugs that induce CYP3A4 (e.g., phenobarbital, phenytoin, rifampin, carbamazepine, ephedrine) can increase dexamethasone metabolism, leading to decreased corticosteroid effect. ♦ CYP3A4 Inhibitors: Drugs that inhibit CYP3A4 (e.g., ketoconazole, macrolide antibiotics, ritonavir) may increase dexamethasone levels. ♦ NSAIDs: Concomitant use increases the risk of gastrointestinal ulceration and bleeding. ♦ Anticoagulants: May alter the effects of oral anticoagulants; monitor INR. ♦ Diabetes Medications: Dexamethasone can increase blood glucose, requiring adjustment of antidiabetic therapy. ♦ Diuretics (potassium-depleting): Increased risk of hypokalemia. ♦ Live Vaccines: Contraindicated during immunosuppressive doses of corticosteroids due to risk of severe infection.

Dextromethorphan (Robitussin DM)

Purpose/Indication	Dextromethorphan (DXM) is a cough suppressant (antitussive) indicated for the temporary relief of cough caused by minor throat and bronchial irritation, such as that occurring with the common cold or inhaled irritants. It is a common ingredient in many over-the-counter (OTC) cough and cold preparations and is generally used to reduce the frequency and intensity of coughing.
Method of Action	Dextromethorphan acts centrally on the cough center in the medulla oblongata of the brain, elevating the cough threshold. While its exact mechanism is not fully understood, it is believed to act as a non-competitive antagonist of N-methyl-D-aspartate (NMDA) receptors, similar to dissociative anesthetics, and also as a sigma-1 receptor agonist. It also weakly inhibits serotonin and norepinephrine reuptake. These actions suppress the urge to cough without causing significant respiratory depression at therapeutic doses.
Medication Name & Brand Names	♦ Medication Name: Dextromethorphan Hydrobromide ♦ Brand Names: Robitussin DM (combination), Delsym (extended-release), Mucinex DM (combination), DayQuil/NyQuil (combination), Vicks NyQuil/DayQuil (combination), Dimetapp Cold & Cough (combination), DXM (generic)
Pharmaceutical Forms & Appearance	Dextromethorphan is widely available in various oral forms, including syrups, lozenges, chewable tablets, capsules, and extended-release suspensions or capsules. Syrups are typically clear or colored liquids, lozenges are solid and flavored, and tablets/capsules vary in color and shape depending on the brand and combination.
Dosage & Administration	Dosage varies by formulation and patient age, typically for short-term use. For adults and children 12 years and older, common doses are 10-30 mg every 4-8 hours as needed, with a maximum daily dose often around 120 mg. Extended-release formulations (e.g., 60 mg) are taken every 12 hours. Doses for children under 12 should follow product labeling or pediatrician's advice. It can be taken with or without food. Do not exceed recommended doses.
Supplied As	Dextromethorphan is supplied in various strengths and forms, often as part of multi-symptom cold medications: oral syrup/solution (e.g., 5 mg/5 mL, 10 mg/5 mL, 15 mg/5 mL, 30 mg/10 mL), extended-release oral suspension (e.g., 30 mg/5 mL), lozenges, capsules, and chewable tablets.
Contraindications	Dextromethorphan is strictly contraindicated in patients taking monoamine oxidase inhibitors (MAOIs) or within 14 days of stopping an MAOI, due to the significant risk of serotonin syndrome. It is also contraindicated in patients with known hypersensitivity to dextromethorphan or any component of the formulation. Its use for chronic productive cough (e.g., associated with asthma, emphysema) is generally not recommended as suppressing these coughs can be harmful.
Storage & Expiry	Dextromethorphan preparations should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and excessive moisture. Keep tightly closed and out of reach of children. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and include dizziness, drowsiness, nausea, vomiting, and stomach discomfort. Less common but more serious side effects, especially with high doses or drug interactions, include serotonin syndrome (agitation, confusion, rapid heart rate, fever), hallucinations, excitement, and respiratory depression.
Warnings & Precautions	♦ MAOI Interaction: STRICTLY CONTRAINDICATED with MAOIs (or within 14 days of stopping/starting an MAOI) due to the risk of serotonin syndrome. ♦ Serotonin Syndrome: Potentially life-threatening condition that can occur with concomitant use of other serotonergic drugs (e.g., SSRIs, SNRIs, TCAs, triptans, tramadol, linezolid, methylene blue). Symptoms include mental status changes, autonomic instability, neuromuscular aberrations, and GI symptoms. Seek immediate medical attention if suspected. ♦ Abuse Potential: While not an opioid, DXM can cause dissociative effects at supra-therapeutic doses, leading to a potential for abuse (often referred to as "robo-tripping"). Monitor for signs of abuse, especially in adolescents. ♦ Respiratory Depression: While generally safe at recommended doses, high doses or co-administration with other CNS depressants (e.g., alcohol, benzodiazepines) can lead to respiratory depression. ♦ Persistent/Chronic Cough: Do not use for cough that is persistent or chronic (e.g., occurs with smoking, asthma, emphysema) or accompanied by excessive phlegm, unless directed by a doctor. ♦ Hepatic Impairment: Metabolized by CYP2D6; use with caution in patients with hepatic impairment. ♦ Driving/Operating Machinery: May cause drowsiness or dizziness; advise caution when performing tasks requiring mental alertness. ♦ Underlying Conditions: Consult a doctor if cough lasts more than 7 days, recurs, or is accompanied by fever, rash, or persistent headache.
Missed Dose Instructions	Dextromethorphan is an as-needed medication. If a dose is missed, take it when you remember if you still need cough relief, ensuring you do not exceed the maximum daily dose and adhere to the recommended dosing interval (e.g., 4-8 hours). Do not take a double dose to make up for a missed one.
Overdose Instructions	Overdose symptoms are typically related to excessive CNS depression and serotonergic effects. They can include severe dizziness, drowsiness, nausea, vomiting, hallucinations, agitation, confusion, ataxia, nystagmus (involuntary eye movements), serotonin syndrome (e.g., hyperthermia, tachycardia, muscle rigidity), respiratory depression, and rarely, seizures or coma. There is no specific antidote. Treatment is supportive and symptomatic, focusing on maintaining an open airway, ventilation, and cardiovascular support. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Seek immediate emergency medical help.
Medicine Interactions	♦ MAOIs (Monoamine Oxidase Inhibitors, e.g., phenelzine, tranylcypromine, selegiline, linezolid, methylene blue): STRICTLY CONTRAINDICATED. Concomitant use can lead to severe, potentially fatal serotonin syndrome. ♦ Other Serotonergic Drugs (e.g., SSRIs - fluoxetine, paroxetine, sertraline; SNRIs - venlafaxine, duloxetine; TCAs; triptans; tramadol; St. John's Wort; buspirone): Increased risk of serotonin syndrome. Use with caution; monitor for symptoms. ♦ CYP2D6 Inhibitors (e.g., quinidine, fluoxetine, paroxetine, amiodarone, cimetidine, bupropion): Can significantly inhibit the metabolism of dextromethorphan, leading to increased and prolonged plasma levels and an increased risk of adverse effects, including serotonin syndrome and dissociative effects. Avoid or use with extreme caution and reduced dextromethorphan dose. ♦ CNS Depressants (e.g., alcohol, benzodiazepines, opioids, sedatives, hypnotics): Additive CNS depressant effects, increasing drowsiness, dizziness, and respiratory depression. Avoid concomitant use or use with extreme caution. ♦ Grapefruit Juice: May inhibit CYP3A4 and potentially CYP2D6, increasing dextromethorphan levels. Advise caution.

Diazepam (Valium)

Purpose/Indication	Diazepam is a benzodiazepine medication with anxiolytic (anti-anxiety), sedative, hypnotic, anticonvulsant, and muscle relaxant properties. It is indicated for the management of anxiety disorders, short-term relief of anxiety symptoms, acute alcohol withdrawal syndrome (to alleviate symptoms like agitation, tremor, and delirium tremens), as an adjunct in convulsive disorders, and for the relief of skeletal muscle spasm. It can also be used as premedication for medical procedures.

Method of Action	Diazepam enhances the effect of gamma-aminobutyric acid (GABA), the main inhibitory neurotransmitter in the central nervous system (CNS). It binds to specific benzodiazepine receptors on the GABA-A receptor complex, leading to an increased frequency of chloride channel opening. This influx of chloride ions hyperpolarizes the neuron, making it less excitable and resulting in the observed CNS depressant effects, including reduced anxiety, sedation, and anticonvulsant action.
Medication Name & Brand Names	♦ Medication Name: Diazepam ♦ Brand Names: Valium, Diazepam Intensol (oral solution), Diastat (rectal gel), Dizac (injectable)
Pharmaceutical Forms & Appearance	Diazepam is available as oral tablets, oral solution, rectal gel, and solutions for intravenous (IV) or intramuscular (IM) injection. Oral tablets are typically small, scored, and may be colored (e.g., yellow, blue, white) with various strengths. The oral solution is usually clear. Rectal gel is a clear or translucent gel. Injectable solutions are clear and colorless to slightly yellow.
Dosage & Administration	Dosage varies widely depending on the indication, patient's age, and response. For anxiety, it typically ranges from 2 mg to 10 mg, 2-4 times daily. For acute alcohol withdrawal, higher initial doses are used. For status epilepticus, IV administration is common. Rectal gel is used for acute repetitive seizures. Doses should be individualized and initiated at the lowest effective dose. Duration of treatment for anxiety should be short-term due to dependence risk.
Supplied As	Diazepam is supplied as: oral tablets (e.g., 2 mg, 5 mg, 10 mg), oral solution (e.g., 1 mg/mL, 5 mg/5 mL), rectal gel (e.g., 2.5 mg, 5 mg, 10 mg, 15 mg, 20 mg syringes), and injectable solution (e.g., 5 mg/mL).
Contraindications	Diazepam is contraindicated in patients with known hypersensitivity to diazepam or any component of the formulation, acute narrow-angle glaucoma, severe respiratory insufficiency, severe hepatic insufficiency, sleep apnea syndrome, and myasthenia gravis (due to muscle relaxant properties). It should not be used in children younger than 6 months.
Storage & Expiry	Diazepam oral tablets, solution, and rectal gel should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Injectable solutions should also be protected from light. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include drowsiness, fatigue, muscle weakness, and ataxia (impaired coordination). More serious side effects can include respiratory depression, paradoxical reactions (e.g., excitement, agitation, hallucinations), dependence and withdrawal symptoms (upon abrupt cessation), and anterograde amnesia.
Warnings & Precautions	♦ CNS Depression: Can cause significant CNS depression, including drowsiness, sedation, and impaired mental/physical abilities. Caution patients against driving or operating machinery. ♦ Respiratory Depression: Use with extreme caution in patients with respiratory insufficiency (e.g., COPD, sleep apnea) due to risk of respiratory depression. ♦ Dependence and Withdrawal: Prolonged use can lead to physical and psychological dependence. Abrupt discontinuation can precipitate severe withdrawal symptoms (e.g., seizures, delirium, psychosis). Taper doses gradually. ♦ Abuse Potential: Has abuse potential; use with caution in patients with a history of substance abuse. ♦ Paradoxical Reactions: Excitement, agitation, hallucinations, and rage can occur, especially in children, elderly, or psychiatric patients. ♦ Renal/Hepatic Impairment: Use with caution and adjust dose in patients with liver or kidney dysfunction. ♦ Elderly: More sensitive to CNS depressant effects; use lower doses.
Missed Dose Instructions	For chronic conditions, if a dose of Diazepam is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For acute, as-needed use, this instruction may not apply. Do not stop taking the medication abruptly, especially after prolonged use, due to withdrawal risks.
Overdose Instructions	Overdose can cause severe CNS depression ranging from drowsiness to coma, confusion, impaired coordination, slurred speech, and hypotension. In severe cases, respiratory depression, apnea, and cardiac arrest can occur. Treatment is supportive. Maintain a patent airway and provide respiratory support. Flumazenil, a benzodiazepine receptor antagonist, can reverse the sedative effects but may precipitate withdrawal seizures in dependent patients and should be used with extreme caution. Seek immediate medical attention.
Medicine Interactions	♦ CNS Depressants: Increased risk of CNS depression, sedation, and respiratory depression when co-administered with alcohol, opioids, other benzodiazepines, barbiturates, antihistamines, antidepressants, or antipsychotics. Avoid concomitant use of opioids and benzodiazepines unless absolutely necessary, and if so, use the lowest effective doses for the shortest duration. ♦ CYP3A4/CYP2C19 Inhibitors: Drugs that inhibit these enzymes (e.g., cimetidine, fluvoxamine, fluoxetine, omeprazole, ketoconazole, protease inhibitors) can increase diazepam levels, leading to increased sedation and adverse effects. ♦ CYP3A4 Inducers (e.g., rifampin, carbamazepine, phenytoin, St. John's Wort): May decrease diazepam levels. ♦ Digoxin: Diazepam may increase steady-state plasma digoxin concentrations. ♦ Levodopa: May antagonize the therapeutic effects of levodopa.

Diclofenac (Voltaren)

Purpose/Indication	Diclofenac is a non-steroidal anti-inflammatory drug (NSAID) used to relieve pain, inflammation, and stiffness. It is indicated for a wide range of conditions, including osteoarthritis, rheumatoid arthritis, ankylosing spondylitis, acute pain, menstrual pain (dysmenorrhea), and migraine headaches. Various formulations target specific conditions, such as topical for localized pain or ophthalmic for ocular inflammation.
Method of Action	Diclofenac works by inhibiting cyclooxygenase (COX) enzymes, specifically both COX-1 and COX-2. These enzymes are responsible for the synthesis of prostaglandins, which are key mediators of pain, inflammation, and fever. By reducing prostaglandin production, diclofenac effectively reduces pain, swelling, and redness.
Medication Name & Brand Names	♦ Medication Name: Diclofenac Sodium / Diclofenac Potassium ♦ Brand Names: Voltaren (many formulations), Cataflam, Zipsor, Cambia (oral solution), Solaraze (topical gel), Flector (topical patch), Pennsaid (topical solution), Voltaren Emulgel (topical gel)
Pharmaceutical Forms & Appearance	Diclofenac is available in numerous forms: oral tablets (immediate, delayed, and extended-release), oral capsules, oral powder for solution, topical gels, solutions, patches, ophthalmic solutions, and injectable solutions. Oral tablets vary in color, shape, and imprints. Topical gels are typically translucent.
Dosage & Administration	Dosage varies considerably by indication, formulation, and patient response. Oral doses generally range from 50 mg to 75 mg, 2-3 times daily for immediate-release, or once daily for extended-release. Topical formulations are applied to the affected area, typically 2-4 times daily. It is generally recommended to take oral forms with food or milk to minimize gastrointestinal upset. Use the lowest effective dose for the shortest duration.
Supplied As	Diclofenac is supplied as: oral tablets (e.g., 25 mg, 50 mg, 75 mg, 100 mg), oral capsules, oral powder for solution, topical gels (e.g., 1%, 3%, 10%), topical solutions, transdermal patches, ophthalmic solutions, and injectable solutions.

Contraindications	Diclofenac is contraindicated in patients with a known hypersensitivity (e.g., allergic reactions, asthma, urticaria) to diclofenac, aspirin, or other NSAIDs. It is also contraindicated in the setting of coronary artery bypass graft (CABG) surgery and in patients with active gastrointestinal bleeding or peptic ulcer disease. Severe heart failure is also a contraindication.
Storage & Expiry	Diclofenac oral forms and topical preparations should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., abdominal pain, nausea, indigestion, diarrhea), headache, and dizziness. More serious and potentially life-threatening side effects can include cardiovascular thrombotic events (e.g., heart attack, stroke), gastrointestinal bleeding, ulceration, or perforation, kidney dysfunction, liver injury, and serious skin reactions (e.g., Stevens-Johnson syndrome).
Warnings & Precautions	♦ Cardiovascular Risk: NSAIDs, including diclofenac, can increase the risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may increase with duration of use. Contraindicated for pain after CABG surgery. ♦ Gastrointestinal Risk: Can cause serious gastrointestinal adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. Risk is higher in elderly patients, those with a history of GI bleeding, or concomitant use of other agents. ♦ Renal Effects: Can cause new onset or worsening of renal impairment, especially in dehydrated patients or those with pre-existing kidney disease or heart failure. ♦ Hypertension: Can cause new onset hypertension or worsen pre-existing hypertension. ♦ Hepatic Effects: Liver injury, including severe and fatal cases, can occur. Monitor liver function tests regularly. ♦ Skin Reactions: Serious skin reactions can occur. Discontinue at first appearance of rash. ♦ Asthma Exacerbation: Use with caution in patients with asthma, especially aspirin-sensitive asthma. ♦ Fluid Retention/Edema: Use with caution in patients with heart failure or hypertension.
Missed Dose Instructions	If a dose of Diclofenac is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. For consistent pain and inflammation control, regular dosing is usually preferred.
Overdose Instructions	Symptoms of acute overdose typically include lethargy, drowsiness, nausea, vomiting, epigastric pain, and gastrointestinal bleeding. In severe cases, hypotension, acute renal failure, respiratory depression, and coma may occur. Treatment is supportive and symptomatic. Gastric decontamination with activated charcoal may be considered if ingestion was recent and substantial. Hemodialysis is unlikely to be effective due to high protein binding. Seek immediate medical attention.
Medicine Interactions	♦ Anticoagulants (e.g., warfarin): Increased risk of bleeding; monitor INR closely. ♦ Antiplatelet agents (e.g., aspirin, clopidogrel): Increased risk of bleeding. ♦ Other NSAIDs/Corticosteroids: Increased risk of GI adverse events. ♦ ACE Inhibitors/ARBs/Diuretics: May reduce the antihypertensive and diuretic effects, and increase the risk of renal impairment. ♦ Lithium: May increase serum lithium concentrations and toxicity; monitor lithium levels. ♦ Methotrexate: May increase methotrexate toxicity. ♦ Cyclosporine/Tacrolimus: Increased risk of nephrotoxicity. ♦ CYP2C9 Inhibitors/Inducers: Diclofenac is metabolized by CYP2C9; inhibitors (e.g., fluconazole, amiodarone) can increase diclofenac levels, while inducers (e.g., rifampin) can decrease them.

Diethylcarbamazine (Banocide)

Purpose/Indication	Diethylcarbamazine (DEC) is an anthelmintic medication primarily used to treat certain parasitic worm infections, particularly filariasis. This includes lymphatic filariasis (caused by Wuchereria bancrofti, Brugia malayi, or Brugia timori), loiasis (African eye worm), and tropical pulmonary eosinophilia. It works by killing the larval forms (microfilariae) of the worms, thereby breaking the cycle of infection.
Method of Action	The exact mechanism of action of diethylcarbamazine is not fully understood, but it is believed to act on the microfilariae in multiple ways. It appears to alter their surface membranes, making them more susceptible to the host's immune system (e.g., phagocytosis by white blood cells). It may also interfere with the parasites' arachidonic acid metabolism and directly affect their muscular function, leading to paralysis and easier elimination by the host's immune response.
Medication Name & Brand Names	♦ Medication Name: Diethylcarbamazine Citrate ♦ Brand Names: Hetrazan, Eofil, Banocide Forte (regional)
Pharmaceutical Forms & Appearance	Diethylcarbamazine is primarily available as oral tablets, usually in strengths of 50 mg, 100 mg, or 150 mg. Tablets are typically white or off-white and may be scored.
Dosage & Administration	Dosage is highly individualized based on the specific type of filarial infection, patient weight, and local guidelines. Treatment often starts with a lower dose to mitigate adverse reactions, gradually increasing over several days. It is typically taken orally, usually three times a day, often after meals to reduce gastrointestinal upset. Complete the full prescribed course.
Supplied As	Diethylcarbamazine is supplied as oral tablets (e.g., 50 mg, 100 mg, 150 mg).
Contraindications	Diethylcarbamazine is contraindicated in patients with known hypersensitivity to diethylcarbamazine or its components. Due to the potential for severe inflammatory reactions (Mazzotti reaction), it should be used with extreme caution or contraindicated in patients with high microfilarial loads, particularly in Loa loa infections (risk of encephalopathy) and Onchocerca volvulus (river blindness) due to severe ocular reactions. It is generally contraindicated in pregnancy (treatment deferred until after delivery), in infants, and in patients with severe cardiac or renal disease.
Storage & Expiry	Diethylcarbamazine tablets should be stored at room temperature (typically below 30°C or 86°F), protected from light and moisture. Keep in a tightly closed container and out of reach of children. Always check the specific expiry date on the packaging.
Side Effects	Side effects are common and often result from the immune response to dying parasites, known as the Mazzotti reaction. These include fever, headache, dizziness, nausea, vomiting, joint pain, rash, itching, lymph node swelling, and facial edema. More serious reactions, particularly in heavy infections, can involve eye damage (onchocerciasis) or neurological effects like encephalitis (loiasis).
Warnings & Precautions	♦ Mazzotti Reaction: Patients with high microfilarial loads can experience a severe inflammatory response to dying parasites, which can be life-threatening. Management often involves starting with low doses and may require corticosteroids to mitigate severe reactions. ♦ Ocular Effects: In onchocerciasis, rapid killing of microfilariae can lead to severe and potentially irreversible eye damage. ♦ Encephalopathy: In loiasis, high microfilarial loads can lead to encephalopathy, which can be fatal. Careful monitoring is crucial. ♦ Renal Impairment: Dose reduction is necessary in patients with renal impairment to avoid drug accumulation and increased toxicity. ♦ Cardiac Disease: Use with caution in patients with underlying cardiac conditions. ♦ Concomitant Corticosteroids: Corticosteroids may be co-administered, especially in severe cases, to reduce inflammatory reactions.

Missed Dose Instructions	If a dose of Diethylcarbamazine is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. Adherence to the prescribed regimen is important for effective treatment of parasitic infections.
Overdose Instructions	Overdose symptoms are generally an exaggeration of common side effects, including nausea, vomiting, headache, dizziness, and drowsiness. In severe cases, more pronounced allergic or inflammatory reactions could occur. There is no specific antidote. Treatment is supportive and symptomatic. Gastric decontamination may be considered if a significant oral overdose was recent. Seek immediate medical attention.
Medicine Interactions	♦ Corticosteroids: Concurrent use of corticosteroids may be necessary to manage Mazzotti reactions, but they may theoretically reduce the anti-filarial activity of DEC by suppressing the immune response that aids in parasite clearance. ♦ Urinary Alkalinizers: Drugs that make the urine more alkaline may reduce the urinary elimination of diethylcarbamazine, potentially increasing its levels and side effects. ♦ Urinary Acidifiers: Drugs that make the urine more acidic may increase the elimination of diethylcarbamazine. ♦ Cholinergic Medications, Potassium Channel Blockers, Tricyclic Antidepressants, Beta-blockers: Some sources suggest potential interactions that may alter safety or effectiveness, but comprehensive data is limited. Always inform your doctor of all concomitant medications.

Digoxin (Lanoxin)

Purpose/Indication	Digoxin is a cardiac glycoside used to improve the pumping ability of the heart in patients with chronic heart failure (especially with reduced ejection fraction and symptoms) and to control the ventricular rate in patients with chronic atrial fibrillation or flutter. It helps the heart beat more strongly and efficiently, and in atrial fibrillation, it slows the rapid and irregular heart rhythm.
Method of Action	Digoxin exerts its primary therapeutic effect by inhibiting the sodium-potassium adenosine triphosphatase (Na+/K+-ATPase) pump in cardiac muscle cells. This inhibition leads to an increase in intracellular sodium, which in turn reduces the activity of the sodium-calcium exchanger, resulting in increased intracellular calcium. The elevated intracellular calcium enhances the contractility of the heart muscle (positive inotropic effect). Additionally, digoxin enhances vagal tone, which slows conduction through the atrioventricular (AV) node, thereby decreasing the ventricular rate in atrial fibrillation.
Medication Name & Brand Names	♦ Medication Name: Digoxin ♦ Brand Names: Lanoxin, Lanoxicaps (liquid-filled capsules, less common now), Digitek (US, discontinued)
Pharmaceutical Forms & Appearance	Digoxin is available as oral tablets, oral solution/elixir, and solution for intravenous (IV) injection. Oral tablets are typically small, white, and often scored. The oral solution/elixir is a clear liquid. The injectable solution is clear and colorless.
Dosage & Administration	Dosage is highly individualized and determined by the patient's age, renal function, body weight, and response, often guided by therapeutic drug monitoring (serum digoxin levels). For heart failure, a typical maintenance dose is 0.125 mg once daily, but lower doses may be used. For rate control in atrial fibrillation, a loading dose followed by maintenance dosing may be used. It can be taken with or without food. Avoid abrupt discontinuation.
Supplied As	Digoxin is supplied as: oral tablets (e.g., 62.5 mcg, 125 mcg, 250 mcg), oral solution/elixir (e.g., 50 mcg/mL), and injectable solution (e.g., 0.25 mg/mL, 0.1 mg/mL for pediatric use).
Contraindications	Digoxin is contraindicated in patients with known hypersensitivity to digoxin or any component of the formulation, ventricular fibrillation, ventricular tachycardia, Wolff-Parkinson-White syndrome with atrial fibrillation (unless accessory pathway ablation has occurred), and obstructive cardiomyopathy (HCM) unless used to control atrial fibrillation. It is also contraindicated in patients with digoxin toxicity.
Storage & Expiry	Digoxin tablets and solutions should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Digoxin has a narrow therapeutic index, meaning the difference between an effective dose and a toxic dose is small. Side effects are often signs of toxicity. Common side effects include nausea, vomiting, diarrhea, anorexia, fatigue, headache, and visual disturbances (e.g., blurred vision, yellow/green halos). More serious side effects, indicative of toxicity, include various arrhythmias (e.g., bradycardia, AV block, ventricular arrhythmias), severe nausea/vomiting, confusion, and disorientation.
Warnings & Precautions	♦ Narrow Therapeutic Index: Requires careful dosing and monitoring. Toxicity can be life-threatening. ♦ Digoxin Toxicity: Symptoms include GI upset, vision changes, and most critically, cardiac arrhythmias. Risk factors include hypokalemia, hypomagnesemia, hypercalcemia, renal impairment, hypothyroidism, and drug interactions. Monitor serum digoxin levels, electrolytes, and renal function regularly. ♦ Cardiac Arrhythmias: Can cause new or worsen existing arrhythmias. ♦ Renal Impairment: Digoxin is primarily eliminated by the kidneys; dose adjustment is crucial in kidney disease to prevent accumulation and toxicity. ♦ Elderly: More susceptible to toxicity due to reduced renal function and polypharmacy. ♦ Hypokalemia: Increases the risk of digoxin toxicity. Correct potassium deficits. ♦ Thyroid Dysfunction: Both hypothyroidism and hyperthyroidism can affect digoxin levels and sensitivity.
Missed Dose Instructions	If a dose of Digoxin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose (e.g., within 6 hours of the next dose), skip the missed dose and continue with the regular schedule. Do not take a double dose. If more than one dose is missed, or if you are unsure, contact your healthcare provider. Consistent daily dosing is crucial for maintaining therapeutic levels and preventing toxicity.
Overdose Instructions	Digoxin overdose is life-threatening. Symptoms include severe nausea, vomiting, profound bradycardia, various potentially fatal arrhythmias (e.g., severe AV block, ventricular tachycardia/fibrillation), hyperkalemia (in acute massive overdose), and neurological symptoms. Treatment requires immediate emergency medical attention. Digoxin Immune Fab (DigiFab) is a specific antidote that binds to digoxin, neutralizing its effects. Supportive care, including correction of electrolyte abnormalities (especially hyperkalemia with insulin/glucose), and temporary pacing for bradycardia, are also vital.
Medicine Interactions	Digoxin has numerous significant drug interactions. Many drugs can: ♦ Increase Digoxin Levels (leading to toxicity): Amiodarone, verapamil, diltiazem, quinidine, clarithromycin, erythromycin, cyclosporine, propafenone, spironolactone, some proton pump inhibitors. These require careful monitoring and often a reduction in digoxin dose. ♦ Decrease Digoxin Levels: Antacids, cholestyramine, activated charcoal, rifampin, St. John's Wort. ♦ Increase Risk of Arrhythmias/Toxicity: Diuretics (especially loop or thiazide diuretics causing hypokalemia/hypomagnesemia), calcium (IV calcium can cause arrhythmias), beta-blockers, calcium channel blockers (can cause additive bradycardia/AV block). ♦ Angiotensin-Converting Enzyme (ACE) Inhibitors/Angiotensin Receptor Blockers (ARBs): May decrease potassium levels, increasing digoxin toxicity risk.

Diltiazem (Cardizem)

Purpose/Indication	Diltiazem is a non-dihydropyridine calcium channel blocker used primarily to treat hypertension (high blood pressure), angina pectoris (chest pain), and to control ventricular rate in certain supraventricular tachyarrhythmias like atrial fibrillation and atrial flutter. It works by relaxing blood vessels and slowing the heart rate, which reduces the heart's workload and improves blood flow.

Method of Action	Diltiazem inhibits the influx of extracellular calcium ions across the membranes of cardiac and vascular smooth muscle cells. In the heart, this leads to reduced myocardial contractility, decreased heart rate, and slowed conduction through the SA and AV nodes, which is beneficial for controlling arrhythmias. In vascular smooth muscle, it causes vasodilation of both coronary and peripheral arteries, resulting in decreased peripheral vascular resistance and improved blood flow to the heart, thereby lowering blood pressure and reducing angina.
Medication Name & Brand Names	♦ Medication Name: Diltiazem Hydrochloride ♦ Brand Names: Cardizem (CD, LA, SR), Dilacor XR, Tiazac, Cartia XT, Dilt-XR
Pharmaceutical Forms & Appearance	Diltiazem is available as immediate-release tablets, extended-release capsules or tablets (with various release mechanisms like CD, LA, SR, XT, XR), and solutions for intravenous (IV) injection. Immediate-release tablets are typically white, round, and often scored. Extended-release capsules contain beads and come in various colors and sizes. The injectable solution is clear and colorless.
Dosage & Administration	Dosage varies significantly by indication and formulation. For hypertension, extended-release forms are typically taken once daily, with doses ranging from 120 mg to 360 mg. For angina, immediate-release forms may be taken multiple times a day (e.g., 30-120 mg three or four times daily). IV administration is used for rapid rate control in arrhythmias. Extended-release forms should generally be swallowed whole and not chewed or crushed. It can be taken with or without food.
Supplied As	Diltiazem is supplied as: immediate-release oral tablets (e.g., 30 mg, 60 mg, 90 mg, 120 mg), extended-release oral capsules/tablets (e.g., 60 mg to 420 mg), and injectable solution (e.g., 5 mg/mL).
Contraindications	Diltiazem is contraindicated in patients with known hypersensitivity to diltiazem or any component of the formulation. It is also contraindicated in patients with sick sinus syndrome (unless a functional ventricular pacemaker is in place), second- or third-degree AV block (unless a functional ventricular pacemaker is in place), hypotension (systolic BP <90 mmHg), acute myocardial infarction with pulmonary congestion, and severe bradycardia. Intravenous diltiazem is contraindicated in patients with atrial fibrillation/flutter and an accessory bypass tract (e.g., Wolff-Parkinson-White syndrome).
Storage & Expiry	Diltiazem tablets and capsules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include headache, dizziness, bradycardia (slow heart rate), edema (swelling of ankles/feet), fatigue, flushing, and nausea. More serious but less common side effects can include severe hypotension, severe bradycardia, AV block, worsening of heart failure, and liver injury.
Warnings & Precautions	♦ Cardiac Conduction Abnormalities: Can cause or worsen bradycardia, AV block, and asystole. Use with extreme caution in patients with pre-existing conduction disturbances. ♦ Hypotension: Can cause symptomatic hypotension. ♦ Heart Failure: Use with caution in patients with impaired ventricular function as it can worsen heart failure due to its negative inotropic effect. ♦ Hepatic/Renal Impairment: Use with caution and consider dose reduction in patients with liver or kidney dysfunction. ♦ Abrupt Withdrawal: Avoid abrupt discontinuation, especially in patients with angina, as it may exacerbate symptoms. ♦ Drug Interactions: Numerous significant drug interactions (see interactions).
Missed Dose Instructions	If a dose of Diltiazem is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. Consistent daily dosing is important for effective control of blood pressure, angina, or heart rate.
Overdose Instructions	Overdose can lead to severe hypotension, profound bradycardia, various degrees of AV block, asystole, and cardiogenic shock. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered if oral ingestion was recent. IV fluids, vasopressors (e.g., dopamine, norepinephrine), atropine for bradycardia, and calcium gluconate/chloride (to reverse calcium channel blockade) are often used. Glucagon may also be beneficial. Temporary cardiac pacing may be necessary. Seek immediate medical attention.
Medicine Interactions	♦ Beta-Blockers (e.g., carvedilol, metoprolol): Additive negative effects on heart rate, AV conduction, and myocardial contractility; increased risk of severe bradycardia, AV block, and heart failure. Close monitoring is essential. ♦ Digoxin: Can increase digoxin plasma concentrations, leading to digoxin toxicity; monitor digoxin levels. ♦ CYP3A4 Substrates: Diltiazem is a moderate CYP3A4 inhibitor and can increase plasma concentrations of many drugs metabolized by this enzyme, including: statins (e.g., simvastatin, lovastatin – increased risk of myopathy/rhabdomyolysis), cyclosporine, tacrolimus, carbamazepine, oral midazolam, sildenafil, quinidine, amiodarone. Dose adjustments or alternative agents may be needed. ♦ Amiodarone: Increased risk of bradycardia, AV block, and sinus arrest. ♦ Grapefruit Juice: Can increase diltiazem levels. ♦ Rifampin: Can significantly decrease diltiazem levels.

Diphenhydramine (Benadryl)

Purpose/Indication	Diphenhydramine is a first-generation antihistamine with sedative, anticholinergic, and antiemetic properties. It is widely used to relieve symptoms of seasonal and perennial allergies (e.g., sneezing, runny nose, itchy/watery eyes, itchy throat), to treat insomnia (as a temporary sleep aid), to prevent and treat motion sickness, to manage symptoms of Parkinsonism (due to anticholinergic effects), and to treat or prevent allergic reactions to blood or plasma. It can also be used topically for itching due to insect bites or minor skin irritation.
Method of Action	Diphenhydramine acts as a competitive antagonist of histamine H1 receptors in the peripheral and central nervous system. By blocking these receptors, it prevents histamine from binding and exerting its effects, thereby reducing allergic symptoms. Its sedative properties are due to its ability to readily cross the blood-brain barrier and block central H1 receptors. Its anticholinergic effects contribute to its use in motion sickness and Parkinsonism, while its antiemetic effects are also centrally mediated.
Medication Name & Brand Names	♦ Medication Name: Diphenhydramine Hydrochloride ♦ Brand Names: Benadryl (various formulations), ZzzQuil, Sominex, Dramamine (some formulations), Nytol, Unisom SleepGels
Pharmaceutical Forms & Appearance	Diphenhydramine is available in numerous forms: oral tablets, capsules, liquid-filled capsules, oral solution/syrup, chewable tablets, topical creams/gels/sprays, and solutions for intravenous (IV) or intramuscular (IM) injection. Oral forms vary widely in color and appearance. Liquids are usually clear. Topical creams are white.
Dosage & Administration	Dosage varies by indication and patient age. For adults, typical oral doses are 25 mg to 50 mg every 4-6 hours for allergy symptoms or 50 mg at bedtime for insomnia. For children, it is weight-based. Topical forms are applied as needed. It can be taken with or without food. Use the lowest effective dose.
Supplied As	Diphenhydramine is supplied as: oral tablets (e.g., 25 mg, 50 mg), capsules (e.g., 25 mg, 50 mg), liquid-filled capsules, oral solution/syrup (e.g., 12.5 mg/5 mL), chewable tablets, topical creams/gels/sprays (e.g., 1%, 2%), and injectable solutions (e.g., 50 mg/mL).

MEDICATION | List | D - G | Diphenhydramine (Benadryl)

Contraindications	Diphenhydramine is contraindicated in neonates and premature infants. It is also contraindicated in patients with known hypersensitivity to diphenhydramine or other antihistamines with similar chemical structures. Use with caution or avoid in patients with lower respiratory tract symptoms, including asthma, due to its drying effects.
Storage & Expiry	Diphenhydramine oral forms and topical preparations should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include significant drowsiness, dizziness, dry mouth, blurred vision, urinary retention, and constipation (due to anticholinergic effects). In some individuals, particularly children and elderly, paradoxical excitation, restlessness, or irritability may occur.
Warnings & Precautions	♦ CNS Depression/Sedation: Can cause significant drowsiness and impaired alertness. Caution patients against driving or operating machinery. Avoid concurrent use with alcohol or other CNS depressants. ♦ Anticholinergic Effects: Use with caution in patients with conditions exacerbated by anticholinergic activity, such as narrow-angle glaucoma, prostatic hypertrophy, urinary retention, or gastric outlet obstruction. ♦ Elderly: More susceptible to sedative and anticholinergic side effects (e.g., confusion, falls, urinary retention). Use with caution and lower doses. ♦ Respiratory Conditions: Use with caution in patients with asthma, emphysema, or chronic bronchitis as its drying effects may thicken bronchial secretions and impair expectoration. ♦ Photosensitivity: Can cause increased sensitivity to sunlight; advise patients to use sunscreen. ♦ Topical Use: Avoid applying to large areas of skin, to broken or blistered skin, or for prolonged periods due to risk of systemic absorption and side effects.
Missed Dose Instructions	As Diphenhydramine is often used on an as-needed basis for acute symptoms (allergies, insomnia, motion sickness), missed dose instructions are generally not critical. If a dose is missed, take it when remembered, but do not take a double dose. For regular use (e.g., for Parkinsonism), take the missed dose as soon as remembered, but if it's almost time for the next dose, skip the missed one.
Overdose Instructions	Overdose can lead to severe CNS depression (somnolence, coma), respiratory depression, severe anticholinergic effects (e.g., dry mouth, dilated pupils, flushed skin, urinary retention, intestinal immobility), cardiac arrhythmias, seizures, and hallucinations. In children, excitation and convulsions may be more prominent. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered if oral ingestion was recent. Physostigmine may be used to reverse severe anticholinergic symptoms, but it has risks. Avoid CNS stimulants. Seek immediate medical attention.
Medicine Interactions	♦ CNS Depressants: Enhanced sedative and CNS depressant effects when co-administered with alcohol, opioids, benzodiazepines, barbiturates, other antihistamines, hypnotics, tranquilizers, or antidepressants. Avoid concomitant use. ♦ Anticholinergic Drugs: Increased anticholinergic side effects (e.g., dry mouth, constipation, urinary retention, blurred vision) when co-administered with other anticholinergic agents (e.g., tricyclic antidepressants, antipsychotics, atropine). ♦ Monoamine Oxidase Inhibitors (MAOIs): Can prolong and intensify the anticholinergic and CNS depressant effects of antihistamines; avoid concomitant use.

Dolutegravir (Tivicay)

Purpose/Indication	Dolutegravir is an antiretroviral medication primarily used to treat human immunodeficiency virus type 1 (HIV-1) infection in adults and children. It is indicated as part of a combination regimen with other antiretroviral agents for both treatment-naive and treatment-experienced patients, including those with integrase strand transfer inhibitor (INSTI) resistance (with specific dosing adjustments). It helps to reduce the amount of HIV in the body and improve the immune system.
Method of Action	Dolutegravir is an integrase strand transfer inhibitor (INSTI). It works by selectively blocking the activity of HIV integrase, an enzyme that is essential for HIV replication. Integrase is responsible for integrating viral DNA into the host cell's DNA. By inhibiting this crucial step, dolutegravir prevents the HIV virus from replicating and infecting new cells, thereby reducing the viral load and helping the immune system recover.
Medication Name & Brand Names	♦ Medication Name: Dolutegravir Sodium ♦ Brand Names: Tivicay (single agent), Triumeq (fixed-dose combination with abacavir and lamivudine), Dovato (fixed-dose combination with lamivudine)
Pharmaceutical Forms & Appearance	Dolutegravir is available as oral film-coated tablets. Tivicay tablets are typically yellow, round, and biconvex, with specific imprints indicating the strength (e.g., 50 mg). Fixed-dose combination tablets (Triumeq, Dovato) have their own distinct appearances.
Dosage & Administration	Dosage varies depending on patient characteristics, prior treatment history, and presence of INSTI resistance. For most treatment-naive adults and adolescents, the dose is 50 mg once daily. In patients with INSTI resistance or taking certain interacting medications, the dose may be increased to 50 mg twice daily. It can be taken with or without food. Adherence to the prescribed regimen is critical for treatment success and preventing resistance.
Supplied As	Dolutegravir is supplied as oral film-coated tablets (e.g., 10 mg, 25 mg, 50 mg). It is also available in fixed-dose combination tablets with other antiretrovirals.
Contraindications	Dolutegravir is contraindicated in patients with known hypersensitivity to dolutegravir or any component of the formulation. Co-administration with dofetilide (antiarrhythmic) is contraindicated due to increased dofetilide plasma concentrations and potential for serious or life-threatening adverse reactions.
Storage & Expiry	Dolutegravir tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include insomnia, headache, nausea, diarrhea, and fatigue. More serious but less common side effects can include hypersensitivity reactions (including rash, fever, and organ dysfunction), liver toxicity, and worsening of depression or suicidal ideation (rare). Weight gain has also been observed in some patients on INSTI-based regimens.
Warnings & Precautions	♦ Hypersensitivity Reactions: Severe hypersensitivity reactions (including rash, fever, malaise, myalgia, arthralgia, vesicles, oral lesions, conjunctivitis, facial edema, eosinophilia, hepatitis) have been reported. Discontinue immediately if severe reaction occurs and monitor clinical status. ♦ Hepatotoxicity: Liver toxicity, including cases requiring liver transplant, has been reported. Monitor liver function tests. ♦ Worsening of Depression/Suicidal Ideation: Rare reports, especially in patients with pre-existing psychiatric conditions. ♦ Neural Tube Defects: A potential risk of neural tube defects has been observed when dolutegravir is taken at the time of conception, though subsequent data have shown the risk to be very low and similar to other antiretrovirals. Discuss with women of childbearing potential. ♦ Drug Interactions: Multiple significant drug interactions due to metabolism and drug transporter inhibition (see interactions). ♦ Resistance: Adherence is key to preventing resistance development.
Missed Dose Instructions	If a dose of Dolutegravir is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose (e.g., within 4 hours of the next dose for once-daily dosing), skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is essential for maintaining viral suppression and preventing resistance.

MEDICATION | Medication | D - G

Overdose Instructions	Limited information is available on dolutegravir overdose. Symptoms would likely be an exaggeration of known side effects. Treatment is supportive and symptomatic. There is no specific antidote. Hemodialysis is unlikely to be effective due to high protein binding. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Dofetilide: Co-administration is contraindicated due to significantly increased dofetilide levels and risk of serious cardiac arrhythmias. ♦ Polyvalent Cations: Antacids (aluminum, magnesium), iron supplements, calcium supplements, sucralfate, and buffered medications can significantly reduce dolutegravir absorption. Administer dolutegravir at least 2 hours before or 6 hours after these agents. ♦ Metformin: Dolutegravir can increase metformin levels; dose adjustment of metformin may be necessary, and caution is advised in patients with renal impairment. ♦ Rifampicin: Co-administration significantly decreases dolutegravir levels, often requiring a dose increase of dolutegravir to 50 mg twice daily. ♦ Tipranavir/Ritonavir, Efavirenz, Fosamprenavir/Ritonavir: May require dolutegravir dose adjustment due to decreased dolutegravir levels. ♦ St. John's Wort: May decrease dolutegravir levels; avoid concomitant use.

Donepezil (Aricept)

Purpose/Indication	Donepezil is a cholinesterase inhibitor used to treat mild, moderate, and severe Alzheimer's disease. It helps to improve cognitive function, including memory, thinking, awareness, and the ability to perform daily activities, by increasing the availability of a natural substance in the brain. It does not cure Alzheimer's but can help manage its symptoms.
Method of Action	Donepezil works by reversibly inhibiting the enzyme acetylcholinesterase (AChE) in the brain. AChE is responsible for breaking down acetylcholine, a neurotransmitter crucial for memory, learning, and other cognitive processes. By inhibiting AChE, donepezil increases the concentration of acetylcholine in the synaptic clefts, thereby enhancing cholinergic transmission and improving cognitive function in patients with Alzheimer's disease.
Medication Name & Brand Names	♦ Medication Name: Donepezil Hydrochloride ♦ Brand Names: Aricept, Aricept ODT (oral disintegrating tablet), Donepezil-ODT, Donepezil-XR
Pharmaceutical Forms & Appearance	Donepezil is available as oral tablets, oral disintegrating tablets (ODT), and oral solution. Oral tablets are typically small, white or yellow, round, and often film-coated, with varying imprints. Oral disintegrating tablets dissolve rapidly on the tongue. The oral solution is usually clear.
Dosage & Administration	Dosage is initiated at a low dose (e.g., 5 mg once daily) and gradually increased over several weeks to months to a usual maintenance dose of 10 mg once daily, to minimize side effects. For severe Alzheimer's, a 23 mg once daily dose is available after a period on 10 mg. It is typically taken once daily in the evening, just before bedtime, to mitigate potential sleep disturbances. It can be taken with or without food.
Supplied As	Donepezil is supplied as: oral tablets (e.g., 5 mg, 10 mg, 23 mg), oral disintegrating tablets (e.g., 5 mg, 10 mg), and oral solution (e.g., 1 mg/mL).
Contraindications	Donepezil is contraindicated in patients with known hypersensitivity to donepezil, piperidine derivatives, or any component of the formulation.
Storage & Expiry	Donepezil tablets, ODTs, and oral solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, vomiting, diarrhea, insomnia, muscle cramps, fatigue, and anorexia. More serious but less common side effects can include bradycardia (slow heart rate), syncope (fainting), heart block, seizures, gastrointestinal bleeding, and exacerbation of asthma or COPD.
Warnings & Precautions	♦ Cardiovascular Effects: Can cause bradycardia and heart block, leading to syncope, especially in patients with pre-existing cardiac conduction abnormalities. Use with caution in patients with sick sinus syndrome or other supraventricular conduction conditions. ♦ Gastrointestinal Effects: Can increase gastric acid secretion, potentially leading to ulceration or bleeding. Use with caution in patients with a history of ulcers or those taking NSAIDs. Nausea, vomiting, and diarrhea are common, especially at higher doses. ♦ Cholinergic Effects: Exacerbates conditions that are sensitive to cholinergic activation, such as asthma, COPD, and obstructive pulmonary disease, by increasing bronchial secretions and bronchoconstriction. ♦ Urinary Outflow Obstruction: Use with caution in patients with bladder outflow obstruction. ♦ Seizures: May lower the seizure threshold; use with caution in patients with a history of seizures. ♦ Drug Interactions: Numerous significant drug interactions (see interactions).
Missed Dose Instructions	If a dose of Donepezil is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. If multiple doses are missed, consult a healthcare professional before resuming, as a re-titration from a lower dose may be necessary.
Overdose Instructions	Overdose can lead to a "cholinergic crisis," characterized by severe nausea, vomiting, salivation, sweating, bradycardia, hypotension, collapse, convulsions, muscle weakness (potentially involving respiratory muscles), and increased secretions leading to respiratory distress. Treatment is supportive. Atropine is the antidote for cholinergic crisis. Gastric lavage and activated charcoal may be considered if oral ingestion was recent. Seek immediate medical attention.
Medicine Interactions	♦ Cholinesterase Inhibitors (other): Avoid concomitant use with other cholinesterase inhibitors as it can lead to additive cholinergic effects and increased side effects. ♦ Anticholinergic Drugs: Donepezil may antagonize the effects of anticholinergic medications (e.g., atropine, scopolamine, some antihistamines, tricyclic antidepressants), reducing their effectiveness. ♦ Beta-Blockers/Calcium Channel Blockers: Increased risk of bradycardia and AV block when used concurrently with drugs that slow heart rate. ♦ CYP2D6 & CYP3A4 Inducers: Drugs that induce these enzymes (e.g., rifampin, phenytoin, carbamazepine, phenobarbital, St. John's Wort) can increase donepezil metabolism, leading to decreased donepezil levels and reduced efficacy. ♦ CYP2D6 & CYP3A4 Inhibitors: Drugs that inhibit these enzymes (e.g., quinidine, fluoxetine, paroxetine, ketoconazole, erythromycin) can increase donepezil levels, potentially increasing side effects. ♦ NSAIDs: Increased risk of gastrointestinal bleeding/ulceration.

Doxycycline (Vibramycin)

Purpose/Indication	Doxycycline is a tetracycline antibiotic with a broad spectrum of activity against many bacteria and some parasites. It is used to treat a wide range of infections, including respiratory tract infections, urinary tract infections, skin infections, sexually transmitted infections (e.g., chlamydia, gonorrhea), Lyme disease, malaria prophylaxis, anthrax, and severe acne. It also has anti-inflammatory properties at lower doses.

Method of Action	Doxycycline works by inhibiting bacterial protein synthesis. It reversibly binds to the 30S ribosomal subunit of susceptible bacteria, preventing the attachment of aminoacyl tRNA to the mRNA-ribosome complex. This interference halts the elongation of the peptide chain, thereby inhibiting bacterial growth and replication. It is primarily bacteriostatic.
Medication Name & Brand Names	♦ Medication Name: Doxycycline Hyclate / Doxycycline Monohydrate ♦ Brand Names: Vibramycin, Doryx, Monodox, Oracea (for rosacea), Acticlate, Periostat (for periodontitis)
Pharmaceutical Forms & Appearance	Doxycycline is available as oral capsules (hard or liquid-filled), oral tablets (immediate and delayed-release), and powder for oral suspension. Capsules and tablets vary in color and size. The oral suspension is typically a yellow liquid. It can also be available as an injectable solution for severe cases, though less common.
Dosage & Administration	Dosage varies widely depending on the indication. For most infections, typical adult doses are 100 mg once or twice daily. For malaria prophylaxis, it's 100 mg daily. For acne, lower anti-inflammatory doses (e.g., 20 mg twice daily or 40 mg once daily for Oracea) are used. It should be taken with a full glass of water to reduce the risk of esophageal irritation and generally at least 1 hour before or 2 hours after meals. Avoid taking with dairy products or antacids.
Supplied As	Doxycycline is supplied as: oral capsules (e.g., 50 mg, 100 mg), oral tablets (e.g., 20 mg, 50 mg, 100 mg, 150 mg), delayed-release tablets/capsules, and powder for oral suspension (e.g., 25 mg/5 mL).
Contraindications	Doxycycline is contraindicated in patients with known hypersensitivity to doxycycline or any other tetracycline. It is generally contraindicated in children under 8 years of age due to the risk of permanent tooth discoloration (yellow-grey-brown) and inhibition of bone growth. It is also contraindicated in pregnancy and breastfeeding due to these same effects on the fetus/infant.
Storage & Expiry	Doxycycline capsules, tablets, and oral powder should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging. Once reconstituted, the oral suspension should be used promptly.
Side Effects	Common side effects include gastrointestinal upset (e.g., nausea, vomiting, diarrhea), esophageal irritation/ulceration (especially if taken without enough water or before lying down), photosensitivity (increased sensitivity to sunlight resulting in severe sunburn), and vaginal candidiasis (yeast infection). More serious but less common side effects include increased intracranial pressure (pseudotumor cerebri), tooth discoloration (in children), and liver dysfunction.
Warnings & Precautions	♦ Tooth Discoloration/Bone Growth: Can cause permanent tooth discoloration (yellow-grey-brown) and temporary inhibition of bone growth in children under 8 years of age, and in the second/third trimesters of pregnancy. Avoid use in these populations unless the benefits outweigh the risks in severe or life-threatening conditions. ♦ Photosensitivity: Can cause severe sunburn; advise patients to use sunscreen and protective clothing and avoid prolonged sun exposure. ♦ Esophageal Irritation/Ulceration: Take with a full glass of water and remain upright for at least 30 minutes (or preferably 1 hour) after taking, especially at bedtime. ♦ Increased Intracranial Pressure (Pseudotumor Cerebri): Can cause symptoms like headache, blurred vision, dizziness; discontinue if suspected. ♦ Superinfections: Can lead to overgrowth of non-susceptible organisms, including Clostridioides difficile (causing CDAD) and candidiasis. ♦ Renal Impairment: Unlike some other tetracyclines, doxycycline is primarily excreted non-renally, making it safer for use in patients with renal impairment, but caution is still advised. ♦ Fixed Drug Eruption: Can cause specific skin reactions.
Missed Dose Instructions	If a dose of Doxycycline is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. Complete the full prescribed course of treatment even if symptoms improve.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily gastrointestinal upset (nausea, vomiting, diarrhea) and photosensitivity. Treatment is supportive and symptomatic. Gastric decontamination with activated charcoal may be considered if oral ingestion was recent and substantial. Dialysis is not effective in removing doxycycline from the blood. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Antacids/Dairy Products/Iron/Calcium/Magnesium/Zinc Supplements: These polyvalent cations can significantly chelate doxycycline and reduce its absorption. Administer doxycycline at least 2-3 hours before or after these products. ♦ Oral Contraceptives: While less definitive than with some other antibiotics, some sources suggest tetracyclines may reduce the effectiveness of oral contraceptives; advise patients to consider backup birth control. ♦ Warfarin: May enhance the anticoagulant effect of warfarin; monitor INR closely. ♦ Barbiturates/Carbamazepine/Phenytoin: These anticonvulsants/enzyme inducers can decrease the half-life of doxycycline, potentially reducing its efficacy. Increased doxycycline dosage may be needed. ♦ Methotrexate: May increase methotrexate toxicity. ♦ Penicillins: Tetracyclines are bacteriostatic and can interfere with the bactericidal action of penicillins; avoid concomitant use.

Econazole (Pevaryl)

Purpose/Indication	Econazole is a broad-spectrum imidazole antifungal agent used topically to treat various fungal and yeast infections of the skin. It is indicated for conditions such as tinea pedis (athlete's foot), tinea cruris (jock itch), tinea corporis (ringworm), cutaneous candidiasis, and tinea versicolor. It helps to relieve associated symptoms like itching, redness, and scaling by targeting the fungi directly.
Method of Action	Econazole works by inhibiting the biosynthesis of ergosterol, a crucial component of the fungal cell membrane. It primarily affects the fungal cytochrome P450-dependent enzyme lanosterol 14α-demethylase, which is essential for ergosterol synthesis. By disrupting ergosterol production, it compromises the integrity and permeability of the fungal cell membrane, leading to leakage of essential intracellular components and ultimately, the death of the fungal organism.
Medication Name & Brand Names	♦ Medication Name: Econazole Nitrate ♦ Brand Names: Spectazole, Ecoza (foam), Pevaryl (regional), Ecostatin (regional)
Pharmaceutical Forms & Appearance	Econazole is primarily available in various topical forms: creams, lotions, solutions, and foams. Creams are typically white and opaque. Lotions and solutions are usually white to off-white, and may be slightly viscous. Foams are white, quick-drying formulations.
Dosage & Administration	Dosage and administration vary by specific formulation and infection. For most skin infections, creams, lotions, or solutions are typically applied once daily to the affected area and surrounding skin. For tinea versicolor, application may be twice daily for a shorter duration. Treatment duration usually ranges from 2 to 4 weeks. Always apply a thin layer and gently rub it in, and continue the full course of treatment even if symptoms improve.
Supplied As	Econazole is supplied as: topical creams (e.g., 1%), topical lotions (e.g., 1%), topical solutions (e.g., 1%), and topical foams (e.g., 1%).

Contraindications	Econazole is contraindicated in individuals with known hypersensitivity (allergy) to econazole or any component of the formulation. It is for external use only and should not be applied to the eyes, orally, or intravaginally unless specifically formulated for vaginal use.
Storage & Expiry	Econazole topical formulations should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and freezing. Keep in a tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally localized to the application site and include mild skin irritation, itching, redness, burning, or stinging. Other localized reactions like blistering, scaling, or peeling of the skin may occur. Systemic side effects are rare due to minimal absorption.
Warnings & Precautions	♦ External Use Only: For topical application only. Avoid contact with eyes and mucous membranes. ♦ Irritation/Sensitization: If irritation, sensitization, or worsening of the condition occurs, discontinue use and consult a healthcare professional. ♦ Not for Ophthalmic, Oral, or Intravaginal Use: Not intended for internal use or use in the eyes. If formulated for vaginal use, it will be clearly specified. ♦ Flammability (Foam): The foam formulation may be flammable; avoid use near heat or open flame. ♦ Complete Course: Advise patients to use for the full prescribed treatment period even if symptoms improve, to prevent recurrence.
Missed Dose Instructions	If a dose of topical Econazole is missed, apply it as soon as remembered. However, if it is almost time for the next scheduled application, skip the missed dose and continue with the regular schedule. Do not apply a double amount. Consistency is important for effective treatment of fungal infections.
Overdose Instructions	Overdose with topical econazole is highly unlikely to cause systemic toxicity due to negligible systemic absorption. Accidental oral ingestion may cause mild gastrointestinal upset (nausea, vomiting), but serious systemic effects are not anticipated. Treatment for accidental ingestion is supportive. Seek medical advice if a large amount is ingested or if severe irritation occurs.
Medicine Interactions	No significant systemic drug interactions are commonly reported with topical application of econazole due to its negligible systemic absorption. However, avoid co-application with other topical preparations on the same area unless directed by a healthcare professional, as this could alter absorption or cause irritation.

Enalapril (Vasotec)

Purpose/Indication	Enalapril is an angiotensin-converting enzyme (ACE) inhibitor used to treat hypertension (high blood pressure) and symptomatic heart failure. It is also indicated for the prevention of symptomatic heart failure in asymptomatic left ventricular dysfunction and for the prevention of coronary ischemic events in patients with left ventricular dysfunction. By lowering blood pressure and reducing the heart's workload, it improves cardiovascular outcomes.
Method of Action	Enalapril is a prodrug that is converted in the liver to its active metabolite, enalaprilat. Enalaprilat inhibits the angiotensin-converting enzyme (ACE), which is responsible for converting angiotensin I to angiotensin II. Angiotensin II is a potent vasoconstrictor and stimulates aldosterone secretion, both of which raise blood pressure. By inhibiting ACE, enalaprilat leads to decreased angiotensin II levels, resulting in vasodilation, reduced aldosterone secretion (leading to sodium and water excretion), and consequently, lower blood pressure and reduced cardiac preload and afterload, benefiting heart failure. It also inhibits the breakdown of bradykinin, a vasodilator.
Medication Name & Brand Names	♦ Medication Name: Enalapril Maleate ♦ Brand Names: Vasotec, Epaned (oral solution), Renitec (regional)
Pharmaceutical Forms & Appearance	Enalapril is available as oral tablets and as a powder for oral solution (which needs to be reconstituted). Oral tablets are typically small, white, round or oval, and may be scored, with various imprints indicating strength. The oral solution is a clear liquid after reconstitution. It can also be administered as an intravenous (IV) injection (enalaprilat) for acute settings.
Dosage & Administration	Dosage is individualized based on the patient's condition, renal function, and response. For hypertension, initial doses are typically 2.5 mg to 5 mg once daily, increasing to 10 mg to 40 mg daily in single or divided doses. For heart failure, lower initial doses are used with gradual titration. It can be taken with or without food.
Supplied As	Enalapril is supplied as: oral tablets (e.g., 2.5 mg, 5 mg, 10 mg, 20 mg), and powder for oral solution. Enalaprilat (active form) is supplied as an injectable solution (e.g., 1.25 mg/mL).
Contraindications	Enalapril is contraindicated in patients with known hypersensitivity to enalapril or any other ACE inhibitor. It is also contraindicated in patients with a history of angioedema related to previous ACE inhibitor treatment, hereditary or idiopathic angioedema. Concurrent use with aliskiren in patients with diabetes or renal impairment is contraindicated. It is contraindicated in pregnancy (especially second and third trimesters) due to risk of fetal harm.
Storage & Expiry	Enalapril tablets and oral solution (before reconstitution) should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. The reconstituted oral solution is typically stable for a limited time (e.g., 60 days) when refrigerated. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include cough (dry, persistent), dizziness (especially with the first dose or dose increases due to hypotension), fatigue, and headache. More serious side effects include angioedema (swelling of face, lips, tongue, throat, potentially life-threatening), hypotension, hyperkalemia (high potassium), renal impairment (especially in patients with renal artery stenosis), and liver dysfunction.
Warnings & Precautions	♦ Angioedema: Can cause potentially life-threatening angioedema involving the face, extremities, lips, tongue, glottis, and larynx. Discontinue immediately if symptoms occur. Higher risk in Black patients. ♦ Hypotension: May cause symptomatic hypotension, especially with the first dose, in volume-depleted patients, or those on diuretics. Initial doses should be low, and patients monitored. ♦ Hyperkalemia: Can cause hyperkalemia, especially in patients with renal impairment, diabetes, or those taking potassium-sparing diuretics or potassium supplements. Monitor potassium levels. ♦ Renal Impairment: Can cause acute renal failure, particularly in patients with severe congestive heart failure, renal artery stenosis, or volume depletion. Monitor renal function. ♦ Cough: A persistent dry cough is a common side effect and typically resolves upon discontinuation. ♦ Pregnancy: Use during the second and third trimesters of pregnancy can cause injury and death to the developing fetus; contraindicated. ♦ Neutropenia/Agranulocytosis: Rare but serious hematologic effects.
Missed Dose Instructions	If a dose of Enalapril is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily administration is important for blood pressure and heart failure management.

Overdose Instructions	Overdose symptoms are primarily severe hypotension, often with bradycardia, and potentially acute renal failure. Treatment is supportive. Administer intravenous fluids to support blood pressure. If ingestion was recent, gastric lavage and activated charcoal may be considered. Enalaprilat (the active metabolite) can be removed by hemodialysis. Seek immediate medical attention.
Medicine Interactions	♦ Potassium-Sparing Diuretics/Potassium Supplements/Salt Substitutes: Increased risk of hyperkalemia. Avoid or use with extreme caution and close monitoring of potassium. ♦ NSAIDs: Can reduce the antihypertensive effect of enalapril and increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. ♦ Lithium: May increase serum lithium concentrations and toxicity; monitor lithium levels. ♦ Diuretics: Additive hypotensive effects, particularly with the first dose; consider discontinuing diuretic or reducing initial enalapril dose. ♦ Aliskiren: Contraindicated in patients with diabetes or renal impairment due to increased risk of hyperkalemia, hypotension, and renal impairment. ♦ mTOR Inhibitors (e.g., sirolimus, everolimus): Increased risk of angioedema. ♦ Racecadotril: Increased risk of angioedema.

Epinephrine (EpiPen)

Purpose/Indication	Epinephrine, also known as adrenaline, is a potent sympathomimetic agent used in life-threatening emergencies due to its rapid and widespread effects. Its primary indications include the emergency treatment of severe allergic reactions (anaphylaxis), cardiac arrest, and severe asthma attacks. It is also used in conjunction with local anesthetics to prolong their action and reduce systemic absorption, and for the symptomatic relief of acute bronchospasm.
Method of Action	Epinephrine acts directly on both alpha (α) and beta (β) adrenergic receptors throughout the body. Its alpha_1 receptor activation causes vasoconstriction, which increases blood pressure, reduces swelling, and shunts blood to vital organs during anaphylaxis. Its beta_1 receptor activation increases heart rate and contractility, useful in cardiac arrest. Its beta_2 receptor activation causes bronchodilation, relieving airway constriction in asthma and anaphylaxis. This combination of effects rapidly counteracts the life-threatening symptoms of severe allergic reactions and helps restore circulation.
Medication Name & Brand Names	♦ Medication Name: Epinephrine (Adrenaline) ♦ Brand Names: EpiPen, EpiPen Jr, Auvi-Q, Adrenaclick (auto-injectors), Adrenalin (injectable solution), Primatene Mist (OTC inhaler, historical/some regional)
Pharmaceutical Forms & Appearance	Epinephrine is available as sterile solutions for injection (IM, SC, IV), and as auto-injectors containing a pre-measured dose. Solutions are typically clear and colorless. Auto-injectors are designed for easy, rapid self-administration. It can also be available as an inhaled solution for nebulization.
Dosage & Administration	Dosage varies significantly by indication and route. For anaphylaxis, auto-injectors deliver a fixed dose (e.g., 0.3 mg for adults, 0.15 mg for children) intramuscularly into the thigh. For cardiac arrest, it is typically given intravenously (IV) or intraosseously (IO) at 1 mg every 3-5 minutes. For severe asthma, it can be given subcutaneously. Doses are determined by weight for children. Repeat doses may be necessary.
Supplied As	Epinephrine is supplied as: auto-injectors (e.g., 0.3 mg/0.3 mL, 0.15 mg/0.3 mL), injectable solution vials/ampules (e.g., 1 mg/mL for IM/SC, 0.1 mg/mL for IV use, often diluted), and prefilled syringes.
Contraindications	Epinephrine is generally contraindicated in patients with known hypersensitivity to epinephrine or any component of the formulation, except in life-threatening situations where the benefits outweigh the risks (e.g., anaphylaxis, cardiac arrest). Relative contraindications for non-life-threatening uses include narrow-angle glaucoma, shock (other than anaphylactic shock), organic brain damage, and certain cardiac conditions like significant coronary artery disease, arrhythmias, or hypertension, due to its cardiac stimulant effects.
Storage & Expiry	Epinephrine solutions and auto-injectors should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and extreme heat or cold. Do not refrigerate or freeze. Check the solution periodically for discoloration or particulate matter (should be clear and colorless); if discolored or cloudy, discard. Always check the specific expiry date and replace expired auto-injectors immediately.
Side Effects	Common side effects are generally transient and include anxiety, restlessness, tremor, headache, dizziness, palpitations, rapid heart rate, and pallor. More serious side effects can include ventricular arrhythmias, angina (chest pain), hypertension, cerebral hemorrhage (rare), and pulmonary edema. Injection site reactions may occur.
Warnings & Precautions	♦ Cardiac Effects: Can cause severe cardiac effects including angina, myocardial infarction, ventricular arrhythmias, and hypertension. Use with extreme caution in patients with heart disease, hypertension, or hyperthyroidism. ♦ Use in Anaphylaxis: The benefits of epinephrine in anaphylaxis generally outweigh the risks; it should not be withheld due to concerns about side effects. Seek immediate medical attention after administration. ♦ Injection Site: Intramuscular injection into the anterolateral aspect of the thigh is preferred for auto-injectors; avoid injection into buttocks, hands, or feet due to risk of tissue necrosis. ♦ Diabetes: Can increase blood glucose levels. ♦ Drug Interactions: Numerous significant drug interactions (see interactions). ♦ Proper Administration: Patients/caregivers should be trained on proper auto-injector use.
Missed Dose Instructions	Epinephrine is typically used in acute, emergency situations, often as a single dose or repeated as necessary under medical supervision. Therefore, "missed dose" instructions in the traditional sense do not apply. Its administration is guided by the immediate clinical need.
Overdose Instructions	Overdose can lead to a severe hypertensive crisis, cerebrovascular hemorrhage, pulmonary edema, renal failure, and potentially fatal cardiac arrhythmias (e.g., ventricular fibrillation). Treatment is symptomatic and supportive, usually requiring rapid medical intervention in an emergency setting. Alpha-adrenergic blocking agents (e.g., phentolamine) may be used to counteract severe hypertension, and beta-blockers may be used for tachyarrhythmias (with caution). Vasodilators can help manage hypertension. Seek immediate medical attention.
Medicine Interactions	♦ Beta-Blockers (non-selective, e.g., propranolol): Can block the bronchodilator and vasodilator effects of epinephrine, leading to unopposed alpha-adrenergic effects resulting in severe hypertension and bradycardia (reflex). Use with extreme caution. ♦ Tricyclic Antidepressants (TCAs), MAO Inhibitors (MAOIs), Catechol-O-methyltransferase (COMT) Inhibitors (e.g., entacapone): Can potentiate the pressor and cardiac effects of epinephrine, leading to increased risk of arrhythmias and hypertensive crisis. Use with extreme caution or avoid. ♦ Digoxin/Other Cardiac Glycosides: Increased risk of arrhythmias. ♦ Diuretics: May reduce the pressor response to epinephrine. ♦ Local Anesthetics: Epinephrine is often combined with local anesthetics to prolong their action and reduce systemic absorption, but high doses of epinephrine can increase systemic effects. ♦ Alpha-Adrenergic Blockers: May antagonize the vasoconstrictor and hypertensive effects of epinephrine.

Erythromycin (Ery-Tab)

Purpose/Indication	Erythromycin is a macrolide antibiotic used to treat a wide range of bacterial infections, particularly in patients allergic to penicillin. It is commonly indicated for respiratory tract infections (e.g., pneumonia, bronchitis, Legionnaires' disease), skin and soft tissue infections, pertussis (whooping cough), diphtheria, chlamydial infections, and some sexually transmitted infections. It also has prokinetic properties, occasionally used to promote gastric emptying.

Method of Action	Erythromycin works by inhibiting bacterial protein synthesis. It reversibly binds to the 50S ribosomal subunit of susceptible bacteria, specifically at the P site, thereby blocking the translocation of peptides and inhibiting the assembly of new proteins. This bacteriostatic action prevents the growth and multiplication of bacteria. At higher concentrations or against highly susceptible organisms, it can be bactericidal.
Medication Name & Brand Names	♦ Medication Name: Erythromycin (various salts: base, ethylsuccinate, stearate, lactobionate, gluceptate) ♦ Brand Names: E-Mycin, Ery-Tab, EryPed, Erygel (topical), Akne-mycin (topical), Ilotycin (ophthalmic), Erythrocin (injectable)
Pharmaceutical Forms & Appearance	Erythromycin is available in numerous forms: oral tablets (film-coated, enteric-coated), oral capsules, oral suspensions, topical solutions/gels/ointments, ophthalmic ointments, and solutions for intravenous (IV) injection. Oral tablets vary in color, shape, and imprints. Oral suspensions are typically granular powders that are reconstituted to a liquid. Topical and ophthalmic forms vary in consistency.
Dosage & Administration	Dosage and duration vary significantly by formulation, infection type, severity, and patient factors. Oral doses typically range from 250 mg to 500 mg, 2-4 times daily. It is often recommended to take oral forms on an empty stomach for better absorption, but some formulations are designed to be taken with food to reduce gastrointestinal upset. IV administration is used for severe infections. Complete the full course of treatment.
Supplied As	Erythromycin is supplied as: oral tablets (e.g., 250 mg, 333 mg, 500 mg), oral capsules, granules for oral suspension (e.g., 200 mg/5 mL, 400 mg/5 mL), topical solution/gel/ointment (e.g., 2%), ophthalmic ointment, and powder for intravenous solution.
Contraindications	Erythromycin is contraindicated in patients with known hypersensitivity to erythromycin or any other macrolide or ketolide antibiotic. It is also contraindicated in patients with a history of cholestatic jaundice or hepatic dysfunction associated with prior erythromycin use. Concurrent administration with certain medications, such as cisapride, pimozide, ergotamine, dihydroergotamine, and some statins (e.g., lovastatin, simvastatin), is contraindicated due to risk of serious interactions (e.g., cardiac arrhythmias, rhabdomyolysis).
Storage & Expiry	Erythromycin tablets and powder for suspension (unreconstituted) should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Reconstituted oral suspensions typically require refrigeration (2°C to 8°C or 36°F to 46°F) and are stable for a limited period (e.g., 10-14 days). Topical and ophthalmic preparations are stored at room temperature. Always check the specific product label for precise storage and expiry information.
Side Effects	Common side effects include gastrointestinal upset (e.g., abdominal cramps, nausea, vomiting, diarrhea), which can be dose-related and severe due to its prokinetic activity. Other side effects include headache and rash. More serious but less common side effects can include QT prolongation (a heart rhythm abnormality leading to potential arrhythmias), liver toxicity (cholestatic hepatitis), hearing loss (reversible, dose-related), and Clostridioides difficile-associated diarrhea (CDAD).
Warnings & Precautions	♦ QT Prolongation: Can prolong the QT interval, increasing the risk of potentially fatal arrhythmias (Torsades de Pointes). Use with caution in patients with pre-existing heart conditions, electrolyte disturbances (hypokalemia, hypomagnesemia), or those taking other QT-prolonging drugs. ♦ Hepatotoxicity: Liver dysfunction, including cholestatic hepatitis, has been reported. Monitor liver function tests, especially with prolonged use. ♦ Gastrointestinal Effects: Common and can be severe, leading to non-adherence. Taking with food or using certain formulations may help. ♦ Hearing Loss: Reversible hearing loss has been reported, particularly at high doses or in patients with renal/hepatic impairment. ♦ Clostridioides difficile-Associated Diarrhea (CDAD): Can occur during or after antibiotic therapy. ♦ Infantile Hypertrophic Pyloric Stenosis (IHPS): Associated with risk in infants receiving erythromycin, especially during the first few weeks of life. ♦ Drug Interactions: Numerous significant drug interactions due to strong CYP3A4 inhibition (see interactions).
Missed Dose Instructions	If a dose of Erythromycin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. It's crucial to complete the entire course of antibiotics to ensure eradication of the infection and prevent resistance.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily severe gastrointestinal symptoms (nausea, vomiting, diarrhea, abdominal pain), and potentially hearing loss, QT prolongation, and liver toxicity. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered if oral ingestion was recent. Hemodialysis and peritoneal dialysis are generally not effective. Seek immediate medical attention.
Medicine Interactions	♦ Strong CYP3A4 Substrates: Erythromycin is a potent CYP3A4 inhibitor and can significantly increase levels of drugs metabolized by this enzyme, leading to increased toxicity. Examples include: statins (lovastatin, simvastatin - contraindicated due to rhabdomyolysis risk), carbamazepine, ciclosporin, tacrolimus, sildenafil, theophylline, warfarin, oral midazolam, quinidine, disopyramide, ergot alkaloids (ergotamine, dihydroergotamine - contraindicated due to acute ergotism). ♦ Cisapride/Pimozide: Co-administration is contraindicated due to increased risk of QT prolongation and life-threatening arrhythmias (Torsades de Pointes). ♦ Colchicine: Increased risk of colchicine toxicity, especially in patients with renal or hepatic impairment. ♦ Oral Contraceptives: While less definitive than with some other antibiotics, some sources suggest macrolides may reduce the effectiveness of oral contraceptives; advise patients to consider backup birth control. ♦ Antacids: Some antacids can reduce the absorption of certain erythromycin formulations. ♦ Digoxin: May increase digoxin levels.

Escitalopram (Lexapro)

Purpose/Indication	Escitalopram is a selective serotonin reuptake inhibitor (SSRI) antidepressant used to treat major depressive disorder (MDD) and generalized anxiety disorder (GAD) in adults. It is also sometimes used off-label for other anxiety disorders like panic disorder, social anxiety disorder, and obsessive-compulsive disorder (OCD). It works by helping to restore the balance of a natural substance (serotonin) in the brain.
Method of Action	Escitalopram selectively inhibits the reuptake of serotonin (5-HT) by the presynaptic neuron in the central nervous system. By blocking the serotonin transporter (SERT), it increases the concentration of serotonin in the synaptic cleft, leading to enhanced serotonergic neurotransmission. This increase in serotonin availability is believed to contribute to its antidepressant and anxiolytic effects. Escitalopram is the S-enantiomer of citalopram, and is more potent and selective.
Medication Name & Brand Names	♦ Medication Name: Escitalopram Oxalate ♦ Brand Names: Lexapro, Cipralex (regional)
Pharmaceutical Forms & Appearance	Escitalopram is available as oral tablets and oral solution. Oral tablets are typically white, oval, film-coated, and often scored, with various imprints indicating the strength. The oral solution is a clear, colorless liquid.
Dosage & Administration	Dosage is individualized, typically starting at a low dose (e.g., 10 mg once daily) and gradually increasing based on response and tolerability, up to a maximum of 20 mg once daily. For elderly patients or those with hepatic impairment, a lower maximum dose may be recommended. It can be taken with or without food. Therapeutic effects may take several weeks to become apparent.

Supplied As	Escitalopram is supplied as: oral film-coated tablets (e.g., 5 mg, 10 mg, 20 mg) and oral solution (e.g., 5 mg/5 mL, 1 mg/mL).
Contraindications	Escitalopram is contraindicated in patients with known hypersensitivity to escitalopram, citalopram, or any component of the formulation. It is contraindicated in patients taking monoamine oxidase inhibitors (MAOIs) or within 14 days of discontinuing an MAOI, due to the risk of serotonin syndrome. Co-administration with pimozide (due to QT prolongation) is also contraindicated.
Storage & Expiry	Escitalopram tablets and oral solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, insomnia, diarrhea, constipation, sweating, dizziness, dry mouth, fatigue, and sexual dysfunction (e.g., decreased libido, delayed ejaculation). More serious but less common side effects include serotonin syndrome, QT prolongation, seizures, increased bleeding risk, hyponatremia (low sodium), and suicidal ideation.
Warnings & Precautions	♦ Suicidality Risk: Antidepressants increase the risk of suicidal thoughts and behaviors in children, adolescents, and young adults (up to age 24) with MDD and other psychiatric disorders. Monitor patients closely for clinical worsening, suicidality, or unusual changes in behavior. ♦ Serotonin Syndrome: Potentially life-threatening condition when co-administered with other serotonergic agents (e.g., MAOIs, triptans, fentanyl, lithium, tramadol, St. John's Wort). Symptoms include mental status changes, autonomic instability, neuromuscular abnormalities, and/or GI symptoms. ♦ QT Prolongation: Can cause dose-dependent QT interval prolongation, increasing the risk of Torsades de Pointes. Avoid in patients with congenital long QT syndrome or taking other QT-prolonging drugs. ♦ Seizures: Use with caution in patients with a history of seizures. ♦ Hyponatremia: Can cause clinically significant hyponatremia, particularly in elderly patients or those on diuretics. ♦ Abnormal Bleeding: May increase the risk of bleeding events, especially with concurrent use of NSAIDs, aspirin, or anticoagulants. ♦ Activation of Mania/Hypomania: Use with caution in patients with bipolar disorder. ♦ Discontinuation Syndrome: Abrupt discontinuation can lead to symptoms like dizziness, sensory disturbances, insomnia, agitation; taper dose gradually.
Missed Dose Instructions	If a dose of Escitalopram is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining therapeutic levels and managing symptoms effectively. Do not stop taking the medication abruptly without consulting a doctor due to withdrawal risks.
Overdose Instructions	Overdose symptoms are typically mild to moderate and may include dizziness, tremor, nausea, vomiting, somnolence, tachycardia, and seizures. More severe overdose can lead to serotonin syndrome, QT prolongation, arrhythmias, and coma. Treatment is supportive. Maintain an airway and monitor cardiac and vital signs. Activated charcoal may be considered if ingestion was recent and substantial. There is no specific antidote. Seek immediate medical attention.
Medicine Interactions	♦ Monoamine Oxidase Inhibitors (MAOIs): Concurrent use is contraindicated due to severe, potentially fatal serotonin syndrome. Allow at least 14 days between discontinuing an MAOI and starting escitalopram, and vice versa. ♦ Other Serotonergic Drugs: Increased risk of serotonin syndrome with triptans, tricyclic antidepressants, fentanyl, lithium, tramadol, buspirone, tryptophan, and St. John's Wort. Use with caution. ♦ Pimozide: Co-administration is contraindicated due to increased pimozide levels and potential for QT prolongation and ventricular arrhythmias. ♦ NSAIDs, Aspirin, Warfarin: Increased risk of bleeding. Monitor for signs of bleeding. ♦ Metoprolol: Escitalopram can increase plasma concentrations of metoprolol; monitor metoprolol levels. ♦ Cimetidine/Omeprazole/Esomeprazole: Can increase escitalopram levels. ♦ Alcohol: Avoid alcohol due to additive CNS depressant effects.

Esomeprazole (Nexium)

Purpose/Indication	Esomeprazole is a proton pump inhibitor (PPI) used to reduce the amount of acid produced in the stomach. It is indicated for the treatment of gastroesophageal reflux disease (GERD) including erosive esophagitis, Zollinger-Ellison syndrome, and to reduce the risk of gastric ulcers associated with NSAID use. It is also used in combination with antibiotics to eradicate Helicobacter pylori infection.
Method of Action	Esomeprazole is a proton pump inhibitor, and the S-isomer of omeprazole. It irreversibly binds to and inactivates the H+/K+-ATPase enzyme (the "proton pump") on the secretory surface of parietal cells in the stomach. This enzyme is responsible for the final step in gastric acid production. By blocking the proton pump, esomeprazole significantly reduces gastric acid secretion, regardless of the stimulus, leading to prolonged acid suppression.
Medication Name & Brand Names	♦ Medication Name: Esomeprazole Magnesium / Esomeprazole Strontium ♦ Brand Names: Nexium, Nexium 24HR (OTC), Esomeprazole (generic)
Pharmaceutical Forms & Appearance	Esomeprazole is available as delayed-release capsules, delayed-release tablets, granules for oral suspension, and powder for intravenous (IV) injection. Oral capsules and tablets are often colored (e.g., light purple/pink) and may contain enteric-coated pellets. The oral suspension prepared from granules is typically opaque. The injectable solution is clear.
Dosage & Administration	Dosage varies depending on the condition being treated. For most GERD indications, typical adult doses range from 20 mg to 40 mg once daily. It is usually taken at least 30 to 60 minutes before a meal (preferably breakfast) to maximize its effectiveness, as the proton pumps are activated by food intake. For IV use, it is given once daily. Duration of treatment varies from weeks to months, depending on the condition.
Supplied As	Esomeprazole is supplied as: delayed-release oral capsules (e.g., 20 mg, 40 mg), delayed-release oral tablets (e.g., 20 mg, 40 mg), packets of granules for oral suspension (e.g., 2.5 mg, 5 mg, 10 mg, 20 mg, 40 mg), and powder for intravenous solution (e.g., 20 mg, 40 mg).
Contraindications	Esomeprazole is contraindicated in patients with known hypersensitivity to esomeprazole, substituted benzimidazoles (e.g., omeprazole, lansoprazole), or any component of the formulation. Concurrent use with rilpivirine-containing products is contraindicated due to potential for reduced rilpivirine exposure and loss of virologic response.
Storage & Expiry	Esomeprazole delayed-release capsules/tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. The reconstituted oral suspension should be used promptly. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include headache, nausea, diarrhea, abdominal pain, constipation, and flatulence. Less common but more serious long-term side effects can include increased risk of Clostridioides difficile-associated diarrhea (CDAD), bone fractures (with long-term high dose use), hypomagnesemia (low magnesium), and vitamin B12 deficiency (with prolonged use).

Warnings & Precautions	♦ Serious Gastric Conditions: Symptomatic response to esomeprazole does not preclude the presence of gastric malignancy. ♦ Clostridioides difficile-Associated Diarrhea (CDAD): PPI use may increase the risk of CDAD. Consider diagnosis in patients presenting with diarrhea that does not improve. ♦ Bone Fracture Risk: Long-term and high-dose PPI therapy may increase the risk of hip, wrist, or spine fractures, particularly in the elderly. Use the lowest effective dose for the shortest duration. ♦ Hypomagnesemia: Can occur with prolonged use (usually >3 months). Monitor magnesium levels. ♦ Vitamin B12 Deficiency: Prolonged daily use may lead to vitamin B12 malabsorption. ♦ Kidney Disease: Rarely, acute interstitial nephritis has been observed. ♦ Drug Interactions: Multiple significant drug interactions (see interactions), particularly due to CYP2C19 inhibition. ♦ Rebound Acid Hypersecretion: May occur upon discontinuation.
Missed Dose Instructions	If a dose of Esomeprazole is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing, usually before the first meal, is important for optimal acid control.
Overdose Instructions	Overdose symptoms are generally mild and may include drowsiness, confusion, blurred vision, tachycardia, nausea, sweating, and headache. In rare cases, more severe effects have been reported. There is no specific antidote. Treatment is symptomatic and supportive. Since esomeprazole is highly protein-bound, dialysis is unlikely to be effective. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Rilpivirine-containing products: Co-administration is contraindicated due to potential for reduced rilpivirine exposure and loss of virologic response. ♦ Clopidogrel: Esomeprazole (and omeprazole) can reduce the antiplatelet effect of clopidogrel by inhibiting CYP2C19, which is crucial for clopidogrel activation. Concomitant use is generally discouraged. ♦ Warfarin: May increase INR and risk of bleeding; monitor INR closely. ♦ Digoxin: Increased digoxin absorption, leading to increased digoxin levels and potential toxicity. ♦ Methotrexate: May increase and prolong serum levels of methotrexate and/or its metabolite, potentially leading to toxicity. ♦ Tacrolimus: May increase tacrolimus levels. ♦ Diazepam, Phenytoin, Cilostazol: Esomeprazole is a moderate CYP2C19 inhibitor and can increase levels of drugs metabolized by this enzyme. ♦ Drugs requiring acidic gastric pH for absorption (e.g., iron salts, certain antifungals like ketoconazole, itraconazole, erlotinib): Reduced absorption due to increased gastric pH. ♦ St. John's Wort/Rifampin: May decrease esomeprazole levels.

Ethambutol (Myambutol)

Purpose/Indication	Ethambutol is an antitubercular medication used as a first-line agent in the treatment of active tuberculosis (TB) caused by susceptible strains of Mycobacterium tuberculosis. It is always used in combination with other anti-tuberculosis drugs to prevent the development of resistance and enhance therapeutic efficacy. It helps to stop the growth of the bacteria that cause TB.
Method of Action	Ethambutol works by inhibiting the synthesis of the mycobacterial cell wall. Specifically, it interferes with the enzyme arabinosyl transferase, which is involved in the polymerization of arabinogalactan, an essential component of the mycobacterial cell wall. This disruption leads to impaired cell wall integrity, increased permeability, and ultimately, the inhibition of bacterial growth (bacteriostatic action).
Medication Name & Brand Names	♦ Medication Name: Ethambutol Hydrochloride ♦ Brand Names: Myambutol
Pharmaceutical Forms & Appearance	Ethambutol is available as oral tablets, typically in strengths of 100 mg and 400 mg. Tablets are usually white or off-white, round or oval, and may be scored.
Dosage & Administration	Dosage is typically based on body weight and depends on whether it's daily or intermittent therapy. For adults, a common daily dose is 15 mg/kg orally once daily, often with a maximum of 1000 mg/day. It is always used as part of a multi-drug regimen. It can be taken with or without food. Compliance with the full course of therapy is crucial to prevent drug resistance and treatment failure.
Supplied As	Ethambutol is supplied as oral tablets (e.g., 100 mg, 400 mg).
Contraindications	Ethambutol is contraindicated in patients with known hypersensitivity to ethambutol or any component of the formulation. It is also contraindicated in patients with known optic neuritis due to the risk of exacerbating visual impairment. Additionally, it should not be used in children who are too young to reliably report visual symptoms (e.g., typically under 6 years of age).
Storage & Expiry	Ethambutol tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in a tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	The most significant side effect of ethambutol is ocular toxicity, specifically optic neuritis, which can lead to blurred vision, red-green color blindness, and even irreversible vision loss. Other common side effects include headache, dizziness, nausea, vomiting, abdominal pain, and arthralgia (joint pain).
Warnings & Precautions	♦ Ocular Toxicity (Optic Neuritis): This is the most serious side effect. It is dose-dependent and can lead to irreversible blindness. Baseline and regular (e.g., monthly) ophthalmologic examinations, including visual acuity and red-green color discrimination tests, are mandatory during therapy. Patients should be instructed to report any visual changes immediately. ♦ Renal Impairment: Ethambutol is primarily eliminated by the kidneys. Dose adjustment is required in patients with renal impairment to avoid accumulation and increased risk of toxicity, especially ocular toxicity. ♦ Gout: Can increase serum uric acid levels, potentially exacerbating or precipitating gout attacks. ♦ Liver Dysfunction: Monitor liver function, although hepatotoxicity is less common than with other TB drugs. ♦ Children: Not recommended for children under 6 years of age because they cannot reliably report visual symptoms.
Missed Dose Instructions	Given the critical nature of TB treatment and the importance of adherence to prevent resistance, if a dose of Ethambutol is missed, the healthcare provider managing the patient's TB therapy should be contacted immediately for specific instructions. Do not take a double dose. Consistent daily dosing, as part of the overall regimen, is crucial.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily gastrointestinal upset and, most importantly, severe ocular toxicity (optic neuritis) including vision loss. There is no specific antidote. Treatment is supportive and symptomatic. Gastric decontamination with activated charcoal may be considered if oral ingestion was recent and substantial. Hemodialysis may remove some ethambutol from the blood. Seek immediate medical attention.
Medicine Interactions	♦ Aluminum Salts: Aluminum-containing antacids can significantly reduce the absorption of ethambutol. Administer ethambutol at least 4 hours before or after aluminum-containing antacids. ♦ Other Hepatotoxic Drugs: Concurrent use with other drugs known to cause liver injury (e.g., isoniazid, rifampicin) requires careful monitoring of liver function, though ethambutol itself is less hepatotoxic. ♦ Didanosine: May increase the risk of peripheral neuropathy when co-administered. ♦ No other significant drug interactions are commonly reported, but given its specific toxicities, careful consideration of concurrent medications is always warranted.

Etodolac (Lodine)

Purpose/Indication	Etodolac is a non-steroidal anti-inflammatory drug (NSAID) used to relieve pain, inflammation, and stiffness. It is indicated for the acute and long-term management of osteoarthritis and rheumatoid arthritis, and for the management of acute pain. Its anti-inflammatory and analgesic properties help improve patient comfort and mobility in these conditions.
Method of Action	Etodolac works by reversibly inhibiting cyclooxygenase (COX) enzymes, particularly COX-2, which are primarily responsible for the synthesis of prostaglandins involved in inflammation, pain, and fever. While it has some activity against COX-1, its relatively greater selectivity for COX-2 is thought to contribute to a potentially lower incidence of gastrointestinal side effects compared to non-selective NSAIDs. By reducing prostaglandin production, it reduces pain, swelling, and redness.
Medication Name & Brand Names	♦ Medication Name: Etodolac ♦ Brand Names: Lodine (immediate-release), Lodine XL (extended-release)
Pharmaceutical Forms & Appearance	Etodolac is available as oral capsules and oral tablets (immediate-release and extended-release). Oral capsules and tablets vary in color, shape, and imprints. Immediate-release tablets are typically white or off-white. Extended-release tablets are often film-coated.
Dosage & Administration	Dosage varies depending on the indication. For osteoarthritis and rheumatoid arthritis, the immediate-release form is typically 300 mg to 500 mg two to three times daily, or the extended-release form is 400 mg to 1000 mg once daily. For acute pain, a single dose of 200 mg to 400 mg may be used every 6-8 hours as needed. It can be taken with or without food, but taking it with food or milk may help reduce gastrointestinal upset. Use the lowest effective dose for the shortest duration.
Supplied As	Etodolac is supplied as: oral capsules (e.g., 200 mg, 300 mg), oral tablets (e.g., 400 mg, 500 mg), and extended-release tablets (e.g., 400 mg, 500 mg, 600 mg).
Contraindications	Etodolac is contraindicated in patients with a known hypersensitivity (e.g., allergic reactions, asthma, urticaria) to etodolac, aspirin, or other NSAIDs. It is also contraindicated in the setting of coronary artery bypass graft (CABG) surgery and in patients with active gastrointestinal bleeding or peptic ulcer disease. Severe heart failure is also a contraindication.
Storage & Expiry	Etodolac oral forms should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., nausea, abdominal pain, indigestion, diarrhea, heartburn), dizziness, and headache. More serious and potentially life-threatening side effects can include cardiovascular thrombotic events (e.g., heart attack, stroke), gastrointestinal bleeding, ulceration, or perforation, kidney dysfunction, liver injury, and serious skin reactions (e.g., Stevens-Johnson syndrome).
Warnings & Precautions	♦ Cardiovascular Risk: NSAIDs, including etodolac, can increase the risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may increase with duration of use. Contraindicated for pain after CABG surgery. ♦ Gastrointestinal Risk: Can cause serious gastrointestinal adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. Risk is higher in elderly patients, those with a history of GI bleeding, or concomitant use of other agents. ♦ Renal Effects: Can cause new onset or worsening of renal impairment, especially in dehydrated patients or those with pre-existing kidney disease or heart failure. ♦ Hypertension: Can cause new onset hypertension or worsen pre-existing hypertension. ♦ Hepatic Effects: Liver injury, including severe and fatal cases, can occur. Monitor liver function tests. ♦ Skin Reactions: Serious skin reactions can occur. Discontinue at first appearance of rash. ♦ Asthma Exacerbation: Use with caution in patients with asthma, especially aspirin-sensitive asthma. ♦ Fluid Retention/Edema: Use with caution in patients with heart failure or hypertension.
Missed Dose Instructions	If a dose of Etodolac is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. For consistent pain and inflammation control in chronic conditions, regular dosing is usually preferred.
Overdose Instructions	Symptoms of acute overdose typically include lethargy, drowsiness, nausea, vomiting, epigastric pain, and gastrointestinal bleeding. In severe cases, hypotension, acute renal failure, respiratory depression, and coma may occur. Treatment is supportive and symptomatic. Gastric decontamination with activated charcoal may be considered if ingestion was recent and substantial. Hemodialysis is unlikely to be effective due to high protein binding. Seek immediate medical attention.
Medicine Interactions	♦ Anticoagulants (e.g., warfarin): Increased risk of bleeding; monitor INR closely. ♦ Antiplatelet agents (e.g., aspirin, clopidogrel): Increased risk of bleeding. ♦ Other NSAIDs/Corticosteroids: Increased risk of GI adverse events. ♦ ACE Inhibitors/ARBs/Diuretics: May reduce the antihypertensive and diuretic effects, and increase the risk of renal impairment. ♦ Lithium: May increase serum lithium concentrations and toxicity; monitor lithium levels. ♦ Methotrexate: May increase methotrexate toxicity. ♦ Cyclosporine/Tacrolimus: Increased risk of nephrotoxicity. ♦ Digoxin: May increase digoxin levels. ♦ Furosemide/Thiazide Diuretics: May reduce diuretic efficacy.

Famciclovir (Famvir)

Purpose/Indication	Famciclovir is an antiviral medication used to treat infections caused by herpes viruses. Its primary indications include the treatment of acute herpes zoster (shingles), treatment of recurrent genital herpes, and suppression of recurrent genital herpes. It works by interfering with viral replication, helping to reduce the severity and duration of outbreaks.
Method of Action	Famciclovir is a prodrug of penciclovir. After oral administration, it is rapidly absorbed and extensively converted in the body to penciclovir, which is then phosphorylated by viral thymidine kinase in infected cells to penciclovir triphosphate. Penciclovir triphosphate then competitively inhibits viral DNA polymerase, thereby blocking viral DNA synthesis and inhibiting the replication of herpes simplex virus types 1 and 2 (HSV-1, HSV-2) and varicella-zoster virus (VZV).
Medication Name & Brand Names	♦ Medication Name: Famciclovir ♦ Brand Names: Famvir
Pharmaceutical Forms & Appearance	Famciclovir is available as oral film-coated tablets. Tablets are typically white, round or oval, and may be engraved with the strength.
Dosage & Administration	Dosage varies significantly based on the specific infection, its severity, and patient's renal function. For acute herpes zoster, a common adult dose is 500 mg every 8 hours for 7 days. For recurrent genital herpes, a single dose of 1500 mg or 1000 mg twice daily for 1 day might be used. For suppression, doses are typically 250 mg twice daily. Doses must be adjusted in patients with renal impairment. It can be taken with or without food.
Supplied As	Famciclovir is supplied as oral film-coated tablets (e.g., 125 mg, 250 mg, 500 mg).
Contraindications	Famciclovir is contraindicated in patients with known hypersensitivity to famciclovir, penciclovir, or any component of the formulation.

Storage & Expiry	Famciclovir tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include headache, nausea, diarrhea, and fatigue. More serious but less common side effects can include confusion (especially in elderly patients or those with renal impairment), hallucinations, rash, and, rarely, severe cutaneous reactions or angioedema.
Warnings & Precautions	♦ Renal Impairment: Dose adjustment is crucial in patients with impaired renal function to avoid drug accumulation and increased risk of side effects, particularly central nervous system (CNS) effects like confusion. ♦ CNS Effects: Can cause dizziness, headache, and confusion, particularly in the elderly or renally impaired. Advise caution with activities requiring mental alertness. ♦ Immunocompromised Patients: Effectiveness in immunocompromised patients for certain indications may differ, and longer treatment durations or higher doses might be considered based on clinical judgment. ♦ Transmission: Famciclovir is not a cure for herpes and does not prevent the transmission of herpes to others. Advise patients on safe sex practices.
Missed Dose Instructions	For optimal effectiveness in treating viral infections, it is important to take Famciclovir doses regularly. If a dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Complete the full prescribed course of treatment.
Overdose Instructions	Limited information is available on famciclovir overdose. Symptoms would likely be an exaggeration of known side effects, particularly gastrointestinal upset and CNS effects (e.g., confusion, dizziness). Treatment is supportive and symptomatic. Hemodialysis has been shown to enhance the elimination of penciclovir (the active metabolite) and may be useful in managing overdose, especially in patients with impaired renal function. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Probenecid: Co-administration with probenecid can significantly reduce the renal clearance of penciclovir (active metabolite), leading to increased penciclovir plasma concentrations. Dose adjustment of famciclovir may be necessary, especially in renally impaired patients. ♦ Digoxin: Famciclovir may increase plasma levels of digoxin. ♦ Renally Eliminated Drugs: Use with caution when co-administering with other drugs that are primarily eliminated via active renal tubular secretion, as competition for excretion may occur. No other significant drug interactions are commonly reported, but always consult with a healthcare professional regarding all concomitant medications.

Famotidine (Pepcid)

Purpose/Indication	Famotidine is a histamine-2 (H2) receptor antagonist used to reduce the amount of acid produced in the stomach. It is indicated for the treatment and prevention of various acid-related conditions, including peptic ulcers (gastric and duodenal), gastroesophageal reflux disease (GERD), erosive esophagitis, and Zollinger-Ellison syndrome. It is also commonly used to relieve heartburn and indigestion.
Method of Action	Famotidine competitively inhibits the binding of histamine to the H2 receptors on the gastric parietal cells. Histamine normally stimulates these receptors, leading to the activation of the proton pump and subsequent acid secretion. By blocking the H2 receptors, famotidine effectively reduces both basal and stimulated gastric acid output, as well as pepsin secretion, thereby promoting healing of ulcers and relieving symptoms of acid reflux.
Medication Name & Brand Names	♦ Medication Name: Famotidine ♦ Brand Names: Pepcid, Pepcid AC (OTC), Famotidine (generic)
Pharmaceutical Forms & Appearance	Famotidine is available as oral tablets, chewable tablets, oral suspension, and solution for intravenous (IV) injection. Oral tablets are typically small, white or off-white, and may be film-coated or scored, with various imprints. Chewable tablets may be flavored. The oral suspension is an opaque liquid. The injectable solution is clear and colorless.
Dosage & Administration	Dosage varies depending on the indication, severity, and patient's renal function. For most ulcer conditions, typical adult doses range from 20 mg to 40 mg once daily at bedtime, or twice daily. For heartburn relief, lower doses (e.g., 10 mg) may be taken as needed. It can be taken with or without food. Duration of treatment varies from weeks for acute conditions to long-term for maintenance or chronic conditions.
Supplied As	Famotidine is supplied as: oral tablets (e.g., 10 mg, 20 mg, 40 mg), chewable tablets (e.g., 10 mg, 20 mg), powder for oral suspension (e.g., 40 mg/5 mL after reconstitution), and solution for intravenous injection (e.g., 10 mg/mL, 20 mg/2 mL vials).
Contraindications	Famotidine is contraindicated in patients with known hypersensitivity to famotidine or any component of the formulation. Cross-sensitivity among H2 receptor antagonists (e.g., cimetidine, ranitidine) may occur.
Storage & Expiry	Famotidine tablets and powder for oral suspension (unreconstituted) should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. The reconstituted oral suspension typically requires refrigeration and is stable for a limited period (e.g., 30 days). Always check the specific product label for precise storage and expiry information.
Side Effects	Common side effects are generally mild and include headache, dizziness, constipation, and diarrhea. Less common but more serious side effects include allergic reactions (rash, hives), liver enzyme elevations, and, rarely, blood dyscrasias. Long-term use generally has a good safety profile, but very rarely can be associated with confusion in elderly or renally impaired patients.
Warnings & Precautions	♦ Serious Gastric Conditions: Symptomatic response to famotidine does not preclude the presence of gastric malignancy. Further evaluation may be needed. ♦ Renal Impairment: Dose adjustment is necessary in patients with moderate to severe renal impairment (creatinine clearance <50 mL/min) to prevent drug accumulation and increased risk of side effects. ♦ Elderly: More susceptible to central nervous system side effects (e.g., confusion) due to decreased renal clearance. ♦ Liver Dysfunction: Use with caution in patients with liver impairment. ♦ Cardiac Arrhythmias: Rare reports of QT prolongation and ventricular arrhythmias, particularly with IV administration in patients with renal impairment or rapid infusion.
Missed Dose Instructions	If a dose of Famotidine is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For chronic conditions, consistent daily dosing is important for maintaining acid suppression.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily gastrointestinal upset and, in severe cases, central nervous system effects (e.g., restlessness, confusion, seizures) and cardiac abnormalities (e.g., QT prolongation, bradycardia). Treatment is supportive and symptomatic. Gastric decontamination with activated charcoal may be considered if oral ingestion was recent and substantial. Hemodialysis is minimally effective in removing famotidine. Seek medical attention if a large amount is ingested or severe symptoms occur.

Medicine Interactions	♦ Drugs requiring acidic gastric pH for absorption (e.g., certain antifungals like ketoconazole, itraconazole; atazanavir, some iron salts): Famotidine significantly increases gastric pH, which can reduce the absorption and effectiveness of these medications. Administer these drugs at least 2 hours before or after famotidine. ♦ Tizanidine: Famotidine can increase the plasma concentration of tizanidine (a muscle relaxant), potentially leading to increased adverse effects. ♦ Probenecid: May reduce the renal clearance of famotidine, leading to increased famotidine levels. ♦ Antacids: While generally not a significant interaction for systemic absorption of famotidine, antacids can sometimes be taken with famotidine for immediate symptom relief. However, avoid taking them simultaneously with oral suspension to ensure proper dosing.

Fenoprofen (Nalfon)

Purpose/Indication	Fenoprofen is a non-steroidal anti-inflammatory drug (NSAID) used to relieve pain, inflammation, and stiffness. It is indicated for the acute and long-term management of rheumatoid arthritis and osteoarthritis. It also provides relief for mild to moderate pain, including conditions like dysmenorrhea (menstrual pain).
Method of Action	Fenoprofen works by reversibly inhibiting cyclooxygenase (COX) enzymes, both COX-1 and COX-2. These enzymes are crucial for the synthesis of prostaglandins, which are lipid compounds that play a central role in mediating pain, inflammation, and fever. By reducing prostaglandin production, fenoprofen effectively decreases pain, swelling, and redness associated with inflammatory conditions.
Medication Name & Brand Names	♦ Medication Name: Fenoprofen Calcium ♦ Brand Names: Nalfon (historical, now largely generic)
Pharmaceutical Forms & Appearance	Fenoprofen is primarily available as oral capsules and oral tablets. Capsules are typically white, and tablets are often white or off-white, and may be scored.
Dosage & Administration	Dosage varies depending on the indication and patient response. For rheumatoid arthritis and osteoarthritis, typical adult doses range from 300 mg to 600 mg three to four times daily, with a maximum daily dose often around 3200 mg. For mild to moderate pain, 200 mg every 4-6 hours as needed. It should be taken with food or milk to minimize gastrointestinal upset. Use the lowest effective dose for the shortest duration.
Supplied As	Fenoprofen is supplied as: oral capsules (e.g., 200 mg, 300 mg) and oral tablets (e.g., 600 mg).
Contraindications	Fenoprofen is contraindicated in patients with a known hypersensitivity (e.g., allergic reactions, asthma, urticaria) to fenoprofen, aspirin, or other NSAIDs. It is also contraindicated in the setting of coronary artery bypass graft (CABG) surgery and in patients with active gastrointestinal bleeding or peptic ulcer disease. Severe heart failure is also a contraindication.
Storage & Expiry	Fenoprofen oral forms should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., nausea, dyspepsia, abdominal pain, constipation), headache, and dizziness. More serious and potentially life-threatening side effects can include cardiovascular thrombotic events (e.g., heart attack, stroke), gastrointestinal bleeding, ulceration, or perforation, kidney dysfunction, liver injury, and serious skin reactions (e.g., Stevens-Johnson syndrome).
Warnings & Precautions	♦ Cardiovascular Risk: NSAIDs, including fenoprofen, can increase the risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may increase with duration of use. Contraindicated for pain after CABG surgery. ♦ Gastrointestinal Risk: Can cause serious gastrointestinal adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. Risk is higher in elderly patients, those with a history of GI bleeding, or concomitant use of other agents. ♦ Renal Effects: Can cause new onset or worsening of renal impairment, especially in dehydrated patients or those with pre-existing kidney disease or heart failure. ♦ Hypertension: Can cause new onset hypertension or worsen pre-existing hypertension. ♦ Hepatic Effects: Liver injury, including severe and fatal cases, can occur. Monitor liver function tests. ♦ Skin Reactions: Serious skin reactions can occur. Discontinue at first appearance of rash. ♦ Asthma Exacerbation: Use with caution in patients with asthma, especially aspirin-sensitive asthma. ♦ Fluid Retention/Edema: Use with caution in patients with heart failure or hypertension. ♦ Pregnancy: Avoid use in late pregnancy due to risk of premature closure of the fetal ductus arteriosus.
Missed Dose Instructions	If a dose of Fenoprofen is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. For consistent pain and inflammation control in chronic conditions, regular dosing is usually preferred.
Overdose Instructions	Symptoms of acute overdose typically include lethargy, drowsiness, nausea, vomiting, epigastric pain, and gastrointestinal bleeding. In severe cases, hypotension, acute renal failure, respiratory depression, and coma may occur. Treatment is supportive and symptomatic. Gastric decontamination with activated charcoal may be considered if ingestion was recent and substantial. Hemodialysis is unlikely to be effective due to high protein binding. Seek immediate medical attention.
Medicine Interactions	♦ Anticoagulants (e.g., warfarin): Increased risk of bleeding; monitor INR closely. ♦ Antiplatelet agents (e.g., aspirin, clopidogrel): Increased risk of bleeding. ♦ Other NSAIDs/Corticosteroids: Increased risk of GI adverse events. ♦ ACE Inhibitors/ARBs/Diuretics: May reduce the antihypertensive and diuretic effects, and increase the risk of renal impairment. ♦ Lithium: May increase serum lithium concentrations and toxicity; monitor lithium levels. ♦ Methotrexate: May increase methotrexate toxicity. ♦ Cyclosporine/Tacrolimus: Increased risk of nephrotoxicity. ♦ Digoxin: May increase digoxin levels. ♦ Hydantoins (e.g., phenytoin): May increase plasma levels of hydantoins. ♦ Sulfonylureas: May enhance the hypoglycemic effect.

Fexofenadine (Telfast)

Purpose/Indication	Fexofenadine is a second-generation (non-sedating) antihistamine used to relieve symptoms of seasonal allergic rhinitis (hay fever) and chronic idiopathic urticaria (hives). It effectively reduces symptoms like sneezing, runny nose, itchy or watery eyes, itchy throat, and skin itching and hives, without causing significant drowsiness.
Method of Action	Fexofenadine is a selective peripheral H1-receptor antagonist. It works by blocking the action of histamine at H1 receptors, which are responsible for the symptoms of allergic reactions. Unlike first-generation antihistamines, fexofenadine has poor penetration into the central nervous system, which accounts for its non-sedating profile. It also does not bind significantly to cholinergic or alpha-1 adrenergic receptors, contributing to its favorable side effect profile.
Medication Name & Brand Names	♦ Medication Name: Fexofenadine Hydrochloride ♦ Brand Names: Allegra, Telfast, Fexofenadine (generic)

MEDICATION List D - G - D - G - D - G - D

Pharmaceutical Forms & Appearance	Fexofenadine is available as oral tablets, orally disintegrating tablets (ODT), and oral suspension. Oral tablets are typically peach-colored, oval, and film-coated, often with specific imprints indicating strength. ODTs dissolve rapidly on the tongue. The oral suspension is a white to off-white opaque liquid.
Dosage & Administration	Dosage varies by age and indication. For seasonal allergic rhinitis in adults and children 12 years and older, common doses are 60 mg twice daily or 180 mg once daily. For chronic idiopathic urticaria, 180 mg once daily is typical for adults. For children, a lower dose oral suspension or tablet may be used. It is generally recommended to take fexofenadine with water and to avoid taking it with fruit juices.
Supplied As	Fexofenadine is supplied as: oral tablets (e.g., 30 mg, 60 mg, 120 mg, 180 mg), orally disintegrating tablets (e.g., 30 mg), and oral suspension (e.g., 30 mg/5 mL).
Contraindications	Fexofenadine is contraindicated in patients with known hypersensitivity to fexofenadine or any component of the formulation.
Storage & Expiry	Fexofenadine tablets, ODTs, and oral suspension should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging. The oral suspension should not be frozen.
Side Effects	Common side effects are generally mild and include headache, dizziness, drowsiness (less common than with first-generation antihistamines), and nausea. More serious side effects are rare due to its selective action and minimal CNS penetration.
Warnings & Precautions	♦ Fruit Juice Interaction: Avoid taking fexofenadine with fruit juices (e.g., grapefruit, orange, apple) as they can significantly reduce its absorption and effectiveness. Take with water. ♦ Renal Impairment: Use with caution and consider a reduced dose in patients with impaired renal function, as fexofenadine is primarily eliminated renally. ♦ Elderly: While generally well-tolerated, use with caution in elderly patients due to potentially decreased renal function. ♦ Allergic Reactions: Discontinue use if an allergic reaction occurs.
Missed Dose Instructions	If a dose of Fexofenadine is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Regular dosing is important for consistent symptom control in chronic allergic conditions.
Overdose Instructions	Overdose symptoms are generally mild and may include dizziness, drowsiness, and dry mouth. Significant cardiotoxicity (e.g., QT prolongation, arrhythmias) is rare with fexofenadine overdose due to its highly selective peripheral H1 antagonism and lack of cardiac ion channel effects. Treatment is supportive and symptomatic. Gastric decontamination with activated charcoal may be considered if oral ingestion was recent and substantial. Hemodialysis is not effective. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Antacids (containing aluminum or magnesium): Can significantly reduce the absorption of fexofenadine. Administer fexofenadine at least 2 hours before or after antacids. ♦ Fruit Juices: As mentioned, grapefruit, orange, and apple juices can reduce fexofenadine bioavailability. Avoid taking fexofenadine with these juices. ♦ Erythromycin/Ketoconazole: While these drugs were shown to increase fexofenadine levels in early studies, these increases were generally not associated with increased QTc prolongation or increased adverse events. However, caution is still advised. ♦ P-glycoprotein inhibitors/inducers: As fexofenadine is a substrate of P-glycoprotein, drugs that affect this transporter could theoretically alter its levels, but clinically significant interactions are rare.

Fidaxomicin (Dificid)

Purpose/Indication	Fidaxomicin is a macrolide antibacterial medication specifically indicated for the treatment of Clostridioides difficile-associated diarrhea (CDAD) in adults and pediatric patients aged 6 months and older. It is highly effective in targeting C. difficile bacteria in the gut, helping to resolve diarrhea and reduce the risk of recurrence.
Method of Action	Fidaxomicin is a narrow-spectrum, macrocyclic antibiotic that acts locally in the gastrointestinal tract with minimal systemic absorption. It works by inhibiting bacterial RNA polymerase, thereby disrupting bacterial RNA synthesis and protein synthesis, leading to bacterial death. Its specific targeting of C. difficile results in potent bactericidal activity against the pathogen while largely preserving the normal gut microbiota.
Medication Name & Brand Names	♦ Medication Name: Fidaxomicin ♦ Brand Names: Dificid
Pharmaceutical Forms & Appearance	Fidaxomicin is available as oral film-coated tablets and as granules for oral suspension. Tablets are typically pale yellow to white, oval, and film-coated. The granules for oral suspension, when reconstituted, form a uniform white to off-white suspension.
Dosage & Administration	For adults, the typical dose is 200 mg orally twice daily for 10 days. For pediatric patients, dosing is based on weight. It can be taken with or without food. It is crucial to complete the entire 10-day course of fidaxomicin to ensure eradication of the C. difficile infection and minimize the risk of recurrence.
Supplied As	Fidaxomicin is supplied as: oral film-coated tablets (e.g., 200 mg) and granules for oral suspension (e.g., 40 mg/mL after reconstitution, 50 mg/mL after reconstitution for younger children).
Contraindications	Fidaxomicin is contraindicated in patients with known hypersensitivity to fidaxomicin or any component of the formulation.
Storage & Expiry	Fidaxomicin tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. The granules for oral suspension should be stored in the refrigerator (2°C to 8°C or 36°F to 46°F) after reconstitution and are typically stable for a limited period (e.g., 14 days). Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, vomiting, abdominal pain, and gastrointestinal hemorrhage (often mild). Less common but serious side effects can include hypersensitivity reactions, angioedema, and, very rarely, neutropenia or anemia.
Warnings & Precautions	♦ Hypersensitivity Reactions: Serious hypersensitivity reactions, including angioedema and dyspnea, have been reported. Discontinue immediately if symptoms of a severe reaction occur. ♦ Lack of Systemic Activity: Fidaxomicin has minimal systemic absorption, so it is not effective for systemic infections outside of the gut. It is specifically for C. difficile infection. ♦ Duration of Treatment: The full 10-day course is essential to prevent recurrence, even if symptoms improve earlier. ♦ Pseudomembranous Colitis: If severe, persistent diarrhea develops during or after treatment, evaluate for pseudomembranous colitis and C. difficile (if not already the diagnosis).

Missed Dose Instructions	If a dose of Fidaxomicin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Completing the entire course of therapy is critical for effectively treating C. difficile infection and preventing recurrence.
Overdose Instructions	Due to fidaxomicin's minimal systemic absorption, overdose is unlikely to result in systemic toxicity. Symptoms would likely be an exaggeration of gastrointestinal side effects. There is no specific antidote. Treatment is supportive and symptomatic. Hemodialysis is not expected to be effective in removing fidaxomicin. Seek medical advice if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ P-glycoprotein (P-gp) Inhibitors (e.g., cyclosporine, ketoconazole, verapamil, amiodarone, quinidine): Co-administration with P-gp inhibitors can significantly increase systemic exposure to fidaxomicin (though systemic absorption is still minimal). While the clinical significance of this increase is generally considered low given fidaxomicin's local action, caution may be advised in certain situations, especially in patients with severe underlying conditions. ♦ No other significant drug interactions are commonly reported due to its limited systemic absorption.

Fluconazole (Diflucan)

Purpose/Indication	Fluconazole is an antifungal medication belonging to the triazole class, used to treat a variety of fungal and yeast infections. It is commonly indicated for vaginal candidiasis (yeast infections), oropharyngeal and esophageal candidiasis, cryptococcal meningitis, and systemic candidiasis. It can also be used for the prophylaxis of fungal infections in immunocompromised patients.
Method of Action	Fluconazole works by inhibiting the fungal cytochrome P450 enzyme 14-a demethylase. This enzyme is essential for the demethylation of lanosterol to ergosterol, a crucial component of the fungal cell membrane. By disrupting ergosterol synthesis, fluconazole compromises the integrity and permeability of the fungal cell membrane, leading to leakage of essential cellular components and ultimately, the inhibition of fungal growth (fungistatic effect).
Medication Name & Brand Names	♦ Medication Name: Fluconazole ♦ Brand Names: Diflucan, Fluconazole (generic)
Pharmaceutical Forms & Appearance	Fluconazole is available as oral tablets, oral suspension, and solution for intravenous (IV) injection. Oral tablets are typically white, round or oval, and may be scored, with various imprints indicating strength. The oral suspension is usually a white to off-white powder that is reconstituted to a liquid. The injectable solution is clear and colorless.
Dosage & Administration	Dosage varies widely depending on the type and severity of the fungal infection, patient's renal function, and immune status. For vaginal candidiasis, a single oral dose of 150 mg is common. For other infections, daily doses can range from 50 mg to 400 mg or more, often with a loading dose. It can be taken with or without food. Complete the full prescribed course of treatment.
Supplied As	Fluconazole is supplied as: oral tablets (e.g., 50 mg, 100 mg, 150 mg, 200 mg), powder for oral suspension (e.g., 10 mg/mL, 40 mg/mL after reconstitution), and solution for intravenous injection (e.g., 2 mg/mL).
Contraindications	Fluconazole is contraindicated in patients with known hypersensitivity to fluconazole, other azole antifungals, or any component of the formulation. Co-administration with terfenadine (in multiple-dose fluconazole regimens) or cisapride is contraindicated due to increased risk of serious cardiac arrhythmias.
Storage & Expiry	Fluconazole tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. The powder for oral suspension should be stored dry, and the reconstituted suspension is typically stable for a limited time (e.g., 14 days) at room temperature or refrigerated (check specific label). Always check the specific expiry date on the packaging.
Side Effects	Common side effects include headache, nausea, abdominal pain, diarrhea, and rash. More serious but less common side effects can include elevated liver enzymes, hepatotoxicity (liver injury), QT prolongation, Torsades de Pointes (a type of cardiac arrhythmia), and severe skin reactions (e.g., Stevens-Johnson syndrome, toxic epidermal necrolysis).
Warnings & Precautions	♦ Hepatotoxicity: Can cause severe, and rarely fatal, liver injury. Monitor liver function tests during prolonged therapy. Discontinue if signs/symptoms of liver disease develop. ♦ QT Prolongation/Arrhythmias: Can prolong the QT interval, increasing the risk of serious cardiac arrhythmias (Torsades de Pointes). Use with caution in patients with pre-existing heart conditions, electrolyte imbalances (hypokalemia, hypomagnesemia), or those taking other QT-prolonging drugs. ♦ Renal Impairment: Dose adjustment is required in patients with renal impairment to prevent drug accumulation. ♦ Exfoliative Skin Disorders: Rare but serious skin reactions have been reported; discontinue at first sign of rash. ♦ Adrenal Insufficiency: Rare reports of adrenal insufficiency with azole antifungals. ♦ Pregnancy: Avoid use in pregnancy, particularly high doses or prolonged use, due to potential for birth defects (specifically, a pattern of congenital anomalies similar to Antley-Bixler syndrome has been reported with long-term, high-dose use for coccidioidomycosis).
Missed Dose Instructions	If a dose of Fluconazole is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For effective treatment of fungal infections, consistent dosing and completion of the full course are important.
Overdose Instructions	Overdose symptoms may include hallucinations and paranoid behavior, in addition to exaggerated common side effects like nausea and diarrhea. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered if oral ingestion was recent and substantial. Fluconazole is largely excreted unchanged in urine, and a 3-hour hemodialysis session decreases plasma levels by approximately 50%. Seek immediate medical attention.
Medicine Interactions	♦ Terfenadine/Cisapride: Co-administration is contraindicated due to increased risk of QT prolongation and life-threatening arrhythmias. ♦ CYP2C9/2C19/3A4 Substrates: Fluconazole is a potent inhibitor of CYP2C9 and a moderate inhibitor of CYP2C19 and CYP3A4. It can significantly increase plasma concentrations of many drugs metabolized by these enzymes, leading to increased risk of toxicity. Examples include: warfarin (increased bleeding risk), phenytoin, sulfonylureas (increased hypoglycemia), cyclosporine, tacrolimus, short-acting benzodiazepines (midazolam, triazolam), some statins (e.g., atorvastatin, simvastatin), rifabutin, theophylline. ♦ Hydrochlorothiazide: Can increase fluconazole levels. ♦ Rifampin: Can decrease fluconazole levels. ♦ Oral Contraceptives: May alter the metabolism of oral contraceptives, but the clinical significance is generally considered low.

Fluoxetine (Prozac)

Purpose/Indication	Fluoxetine is a selective serotonin reuptake inhibitor (SSRI) antidepressant used to treat a range of mental health conditions. Its primary indications include major depressive disorder (MDD), obsessive-compulsive disorder (OCD), bulimia nervosa, panic disorder, and premenstrual dysphoric disorder (PMDD). It helps to improve mood, reduce anxiety, and regulate behavior by affecting certain chemical messengers in the brain.
Method of Action	Fluoxetine works by selectively inhibiting the reuptake of serotonin (5-HT) by the presynaptic neuron in the central nervous system. By blocking the serotonin transporter (SERT), it increases the concentration of serotonin in the synaptic cleft, leading to enhanced serotonergic neurotransmission. This increase in serotonin availability is believed to be responsible for its antidepressant, anxiolytic, and anti-obsessive effects. Fluoxetine also has a long half-life due to its active metabolite, norfluoxetine.
Medication Name & Brand Names	♦ Medication Name: Fluoxetine Hydrochloride ♦ Brand Names: Prozac, Sarafem (for PMDD), Prozac Weekly (delayed-release capsule), Fluoxetine (generic)
Pharmaceutical Forms & Appearance	Fluoxetine is available as oral capsules (hard and delayed-release), oral tablets, oral solution, and orally disintegrating tablets (ODT). Capsules vary in color and size. Tablets are typically white or off-white and may be scored. The oral solution is usually a clear liquid.
Dosage & Administration	Dosage is individualized and varies by indication. For MDD, initial doses are typically 10 mg to 20 mg once daily, gradually increasing up to a maximum of 60 mg to 80 mg daily. For bulimia nervosa, 60 mg once daily is common. It can be taken with or without food. Therapeutic effects may take several weeks (4-6 weeks or more) to become fully apparent.
Supplied As	Fluoxetine is supplied as: oral capsules (e.g., 10 mg, 20 mg, 40 mg), delayed-release capsules (e.g., 90 mg for once-weekly dosing), oral tablets (e.g., 10 mg, 20 mg, 60 mg), and oral solution (e.g., 20 mg/5 mL).
Contraindications	Fluoxetine is contraindicated in patients with known hypersensitivity to fluoxetine or any component of the formulation. It is contraindicated in patients taking monoamine oxidase inhibitors (MAOIs) or within 14 days of discontinuing an MAOI, due to the risk of serotonin syndrome. Co-administration with thioridazine (due to QT prolongation and serious arrhythmias) and pimozide (due to QT prolongation) is also contraindicated.
Storage & Expiry	Fluoxetine capsules, tablets, and oral solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include insomnia, headache, nausea, diarrhea, nervousness, anxiety, sexual dysfunction (e.g., decreased libido, delayed ejaculation), and tremor. More serious but less common side effects include serotonin syndrome, suicidal ideation, seizures, increased bleeding risk, hyponatremia (low sodium), and activation of mania/hypomania.
Warnings & Precautions	♦ Suicidality Risk: Antidepressants increase the risk of suicidal thoughts and behaviors in children, adolescents, and young adults (up to age 24) with MDD and other psychiatric disorders. Monitor patients closely for clinical worsening, suicidality, or unusual changes in behavior. ♦ Serotonin Syndrome: Potentially life-threatening condition when co-administered with other serotonergic agents (e.g., MAOIs, triptans, fentanyl, lithium, tramadol, St. John's Wort). Symptoms include mental status changes, autonomic instability, neuromuscular abnormalities, and/or GI symptoms. ♦ QT Prolongation: Can cause QT interval prolongation, and co-administration with thioridazine or pimozide is contraindicated. ♦ Seizures: Use with caution in patients with a history of seizures. ♦ Hyponatremia: Can cause clinically significant hyponatremia, particularly in elderly patients or those on diuretics. ♦ Abnormal Bleeding: May increase the risk of bleeding events, especially with concurrent use of NSAIDs, aspirin, or anticoagulants. ♦ Activation of Mania/Hypomania: Use with caution in patients with bipolar disorder. ♦ Discontinuation Syndrome: Abrupt discontinuation, particularly after long-term use, can lead to symptoms like dizziness, sensory disturbances, insomnia, agitation; taper dose gradually, though fluoxetine's long half-life may make this less severe than with other SSRIs. ♦ Weight Changes: Can cause weight loss, especially initially.
Missed Dose Instructions	If a dose of Fluoxetine is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining therapeutic levels and managing symptoms effectively. Do not stop taking the medication abruptly without consulting a doctor due to withdrawal risks.
Overdose Instructions	Overdose symptoms are typically mild to moderate and may include nausea, vomiting, seizures, sinus tachycardia, somnolence, and rarely, QT prolongation or coma. Fatalities are rare when fluoxetine is taken alone. Treatment is supportive. Maintain an airway and monitor cardiac and vital signs. Activated charcoal may be considered if ingestion was recent and substantial. Due to its large volume of distribution and high protein binding, forced diuresis, dialysis, hemoperfusion, and exchange transfusion are unlikely to be beneficial. Seek immediate medical attention.
Medicine Interactions	♦ Monoamine Oxidase Inhibitors (MAOIs): Concurrent use is contraindicated due to severe, potentially fatal serotonin syndrome. Allow at least 14 days between discontinuing an MAOI and starting fluoxetine, and at least 5 weeks (due to fluoxetine's long half-life) between discontinuing fluoxetine and starting an MAOI. ♦ Other Serotonergic Drugs: Increased risk of serotonin syndrome with triptans, tricyclic antidepressants, fentanyl, lithium, tramadol, buspirone, tryptophan, St. John's Wort. Use with caution. ♦ Thioridazine/Pimozide: Co-administration is contraindicated due to increased levels and risk of QT prolongation and serious arrhythmias. ♦ Drugs Metabolized by CYP2D6: Fluoxetine is a potent CYP2D6 inhibitor and can significantly increase plasma concentrations of drugs metabolized by this enzyme (e.g., tricyclic antidepressants, risperidone, atomoxetine, dextromethorphan, metoprolol, tamoxifen). Dose adjustments may be needed. ♦ NSAIDs, Aspirin, Warfarin: Increased risk of bleeding. Monitor for signs of bleeding. ♦ Alcohol: Avoid alcohol due to additive CNS depressant effects. ♦ Phenytoin: May increase phenytoin levels.

Fluticasone (Flonase)

Purpose/Indication	Fluticasone is a synthetic corticosteroid primarily used for its potent anti-inflammatory and immunosuppressive effects. It is widely indicated for the treatment of asthma (inhaled), allergic and non-allergic rhinitis (nasal spray), and various inflammatory skin conditions such as eczema and psoriasis (topical creams/ointments). It helps to reduce swelling, itching, and allergic reactions in the airways, nasal passages, or on the skin.
Method of Action	Fluticasone works by binding to glucocorticoid receptors in the cytoplasm of target cells. This complex then translocates to the nucleus, where it modulates gene expression. This leads to the upregulation of anti-inflammatory proteins (e.g., lipocortin) and the downregulation of pro-inflammatory mediators (e.g., cytokines, chemokines, adhesion molecules). In the airways, this reduces inflammation, edema, and mucus production. In the nose, it reduces histamine release and inflammatory cell activity. On the skin, it suppresses the immune response and reduces inflammation and pruritus.
Medication Name & Brand Names	♦ Medication Name: Fluticasone Propionate, Fluticasone Furoate ♦ Brand Names: Flovent (HFA, Diskus - inhaled for asthma), Flonase (nasal spray), Veramyst (nasal spray), Cutivate (topical), Flonase Sensimist (nasal spray), Arnuity Ellipta (inhaled for asthma)
Pharmaceutical Forms & Appearance	Fluticasone is available in various forms: metered-dose inhalers (MDIs), dry powder inhalers (DPIs) for oral inhalation; nasal sprays (aqueous suspensions); and topical creams, ointments, and lotions. Inhalers are typically plastic devices containing a canister. Nasal sprays are bottles with an applicator. Topical preparations are white or off-white creams/ointments.

Dosage & Administration	Dosage varies significantly by formulation, indication, and patient age. For asthma, inhaled doses are typically 100 mcg to 1000 mcg daily in divided doses, depending on severity. Nasal sprays are commonly 1-2 sprays per nostril once or twice daily. Topical preparations are applied thinly to the affected skin area once or twice daily. Always follow specific product instructions. For inhaled forms, rinsing the mouth after use is important to prevent oral thrush.
Supplied As	Fluticasone is supplied as: metered-dose inhalers (e.g., 44 mcg, 110 mcg, 220 mcg/puff), dry powder inhalers (e.g., 50 mcg, 100 mcg, 250 mcg/blister), nasal sprays (e.g., 50 mcg/spray, 27.5 mcg/spray), and topical creams/ointments (e.g., 0.05%, 0.005%).
Contraindications	Fluticasone is contraindicated in patients with known hypersensitivity to fluticasone or any component of the formulation. Inhaled fluticasone is contraindicated for the primary treatment of status asthmaticus or other acute episodes of asthma or COPD where intensive measures are required. Topical fluticasone is contraindicated in patients with rosacea, perioral dermatitis, or untreated bacterial, fungal, or viral infections of the skin.
Storage & Expiry	Fluticasone products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from direct sunlight, extreme heat, and freezing. Inhalers should be stored with the mouthpiece down or upright as directed. Always check the specific expiry date on the packaging.
Side Effects	Common side effects for inhaled/nasal forms include headache, throat irritation, hoarseness, cough, and candidiasis (thrush) in the mouth/throat. For topical forms, localized skin reactions like burning, itching, or dryness may occur. Systemic side effects are generally rare with recommended doses but can include adrenal suppression (with high doses or prolonged use), growth retardation in children, and increased risk of cataracts/glaucoma with long-term use.
Warnings & Precautions	♦ Oral Candidiasis (Thrush): Inhaled fluticasone can cause oral candidiasis. Advise patients to rinse mouth with water and spit after each inhaled dose. ♦ Adrenal Suppression: Prolonged use of high doses can lead to systemic corticosteroid effects, including adrenal suppression. Taper doses gradually if discontinuing after prolonged use. ♦ Growth Retardation: Long-term use in children can potentially affect growth; monitor growth. ♦ Immunosuppression: Can increase susceptibility to infections. Avoid exposure to chickenpox or measles if not immune. ♦ Ocular Effects: Long-term use can increase the risk of glaucoma and cataracts. Regular eye exams may be needed. ♦ Bone Mineral Density: Potential for reduced bone mineral density with prolonged use, especially at high doses. ♦ Paradoxical Bronchospasm (Inhaled): Rare but can occur immediately after inhalation; use a short-acting bronchodilator for relief. ♦ Nasal Septal Perforation (Nasal): Rare, but can occur with improper nasal spray use.
Missed Dose Instructions	If a dose of Fluticasone (inhaled, nasal, or topical) is missed, take/apply it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take/apply a double dose. Regular, consistent use is crucial for optimal control of chronic conditions like asthma or allergies.
Overdose Instructions	Acute overdose with fluticasone is generally rare and unlikely to cause life-threatening symptoms due to its low systemic bioavailability and short half-life. Chronic overdose, especially with high doses over prolonged periods, can lead to signs and symptoms of Cushing's syndrome, adrenal suppression, hyperglycemia, and other systemic corticosteroid effects. Treatment is symptomatic and supportive; gradual reduction of the steroid dose under medical supervision is usually indicated. Seek medical advice if an overdose is suspected or severe symptoms occur.
Medicine Interactions	♦ CYP3A4 Inhibitors: Strong CYP3A4 inhibitors (e.g., ritonavir, cobicistat, ketoconazole, itraconazole) can significantly increase systemic exposure to fluticasone, leading to increased risk of systemic corticosteroid side effects (e.g., adrenal suppression, Cushing's syndrome). Co-administration is generally not recommended unless the benefits outweigh the risks, and careful monitoring is required. ♦ No other significant drug interactions are commonly reported due to fluticasone's low systemic absorption from inhaled, nasal, and topical routes at recommended doses.

Fluticasone/Salmeterol (Advair)

Purpose/Indication	Fluticasone/Salmeterol is a combination inhaled medication used for the long-term maintenance treatment of asthma in patients aged 4 years and older, and for the maintenance treatment of airflow obstruction and reduction of exacerbations in patients with chronic obstructive pulmonary disease (COPD). It is not for the relief of acute bronchospasm. This combination helps to control symptoms and improve lung function over time.
Method of Action	This medication combines two active ingredients: Fluticasone, an inhaled corticosteroid (ICS), and Salmeterol, a long-acting beta2-adrenergic agonist (LABA). Fluticasone works locally in the airways as an anti-inflammatory, reducing swelling and mucus production. Salmeterol acts by stimulating beta2-adrenergic receptors in the bronchial smooth muscle, leading to long-lasting bronchodilation and relaxation of the airways. Together, they provide both anti-inflammatory effects and sustained bronchodilation to improve breathing.
Medication Name & Brand Names	♦ Medication Name: Fluticasone Propionate/Salmeterol Xinafoate ♦ Brand Names: Advair Diskus, Advair HFA, AirDuo RespiClick, Wixela Inhub
Pharmaceutical Forms & Appearance	Fluticasone/Salmeterol is available as dry powder inhalers (DPIs) and metered-dose inhalers (MDIs). The DPIs (e.g., Diskus) are typically disc-shaped devices containing blister strips. The MDIs (e.g., HFA) are canisters in plastic actuators. The powder or aerosol contents are white.
Dosage & Administration	Dosage varies by strength and device, and by indication (asthma vs. COPD). It is typically administered as one inhalation twice daily, approximately 12 hours apart. For asthma, different strengths are available, and the dose is individualized. For COPD, a specific strength (e.g., 250/50 mcg) is generally used. It should be used consistently every day, even when feeling well. It is not for acute symptom relief.
Supplied As	Fluticasone/Salmeterol is supplied as: dry powder inhalers (e.g., Advair Diskus: 100/50 mcg, 250/50 mcg, 500/50 mcg per actuation; AirDuo RespiClick: 55/14 mcg, 113/14 mcg, 232/14 mcg per actuation) and metered-dose inhalers (e.g., Advair HFA: 45/21 mcg, 115/21 mcg, 230/21 mcg per actuation).
Contraindications	Fluticasone/Salmeterol is contraindicated in patients with known hypersensitivity to fluticasone, salmeterol, or any component of the formulation. It is also contraindicated as primary treatment of status asthmaticus or other acute episodes of asthma or COPD requiring intensive measures. LABA monotherapy (without an ICS) is contraindicated in asthma.
Storage & Expiry	Fluticasone/Salmeterol inhalers should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from direct sunlight, extreme heat, and freezing. Store dry powder inhalers in a dry place. MDIs should be kept with the mouthpiece down or upright as directed. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include upper respiratory tract infection, pharyngitis, oral candidiasis (thrush), headache, voice changes/hoarseness, and muscle pain. More serious but less common side effects associated with LABAs include increased risk of asthma-related death (with LABA monotherapy), cardiovascular effects (tachycardia, palpitations), and paradoxical bronchospasm. ICS-related systemic effects (e.g., adrenal suppression, bone mineral density loss) are rare with usual doses.

MEDICATION MEDICATION MEDICATION List D - G D - G D - G

Warnings & Precautions	♦ LABA Black Box Warning (Asthma): LABA-containing products (like Advair) increase the risk of asthma-related death. This risk is greater in patients not also using an inhaled corticosteroid. Therefore, it should not be used as monotherapy for asthma and only for patients whose asthma is not adequately controlled on an ICS alone or who require both an ICS and a LABA. ♦ Acute Bronchospasm: Not for acute relief of bronchospasm. A short-acting beta-agonist (SABA) should be prescribed for rescue. ♦ Oral Candidiasis: Risk of thrush; advise patients to rinse mouth with water and spit after each dose. ♦ Adrenal Suppression: Can cause systemic corticosteroid effects; monitor for adrenal suppression with high doses or prolonged use. ♦ Immunosuppression: Increased susceptibility to infections. ♦ Cardiovascular Effects: Use with caution in patients with cardiovascular disorders, hypertension, or arrhythmias. ♦ Paradoxical Bronchospasm: Immediately discontinue if bronchospasm worsens. ♦ Ocular Effects: Increased risk of glaucoma and cataracts with long-term use. ♦ Hypokalemia/Hyperglycemia: Can occur rarely.
Missed Dose Instructions	If a dose of Fluticasone/Salmeterol is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose (e.g., within 6 hours of the next 12-hour dose), skip the missed dose and continue with the regular schedule. Do not take a double dose. Regular, consistent use is critical for effective long-term control of asthma and COPD.
Overdose Instructions	Overdose symptoms are primarily related to salmeterol overstimulation of beta-adrenergic receptors, including tachycardia, arrhythmias (e.g., ventricular), tremors, headache, palpitations, and hypertension. Fluticasone overdose effects are generally related to chronic use leading to Cushingoid features or adrenal suppression. Treatment is supportive and symptomatic. Cardio-selective beta-blockers (with extreme caution in asthma/COPD due to bronchospasm risk) may be considered for cardiovascular effects. Seek immediate medical attention.
Medicine Interactions	♦ Strong CYP3A4 Inhibitors (e.g., ritonavir, ketoconazole, itraconazole, clarithromycin, cobicistat): Can significantly increase systemic exposure to both fluticasone and salmeterol, leading to increased risk of systemic corticosteroid side effects (e.g., adrenal suppression, Cushing's syndrome) and cardiovascular effects (e.g., QT prolongation, tremors) from salmeterol. Co-administration is generally not recommended unless benefits outweigh risks and careful monitoring is required. ♦ Beta-Blockers (non-selective, e.g., propranolol): Can block the bronchodilator effect of salmeterol and may cause severe bronchospasm in asthma patients. Avoid concomitant use. Cardioselective beta-blockers should be used with caution. ♦ Diuretics (non-potassium-sparing): The ECG changes and/or hypokalemia that may result from beta-agonists can be acutely worsened by non-potassium-sparing diuretics (e.g., loop or thiazide diuretics), especially with high doses. ♦ Other Sympathomimetics: Additive effects, increased risk of cardiovascular adverse events. ♦ Tricyclic Antidepressants/MAO Inhibitors: Can potentiate the cardiovascular effects of salmeterol. Use with extreme caution.

Fluticasone/Salmeterol (Advair)

Furosemide (Lasix)

Purpose/Indication	Furosemide is a potent loop diuretic used to treat edema (fluid retention) associated with congestive heart failure, liver cirrhosis, and kidney disease. It is also indicated for the management of hypertension (high blood pressure), especially in patients with renal impairment, and for the treatment of acute pulmonary edema. It works by increasing the excretion of excess fluid and salts from the body.
Method of Action	Furosemide primarily acts on the ascending limb of the loop of Henle in the kidney, where it inhibits the sodium-potassium-chloride ($Na+/K+/2Cl-$) co-transporter. By blocking this transporter, it prevents the reabsorption of these ions, leading to a significant increase in their excretion, along with water. This results in potent diuresis (increased urine output), rapid onset of action, and removal of excess fluid from the body. It also has a mild venodilating effect.
Medication Name & Brand Names	♦ Medication Name: Furosemide ♦ Brand Names: Lasix, Salix (historical/regional), Furosemide (generic)
Pharmaceutical Forms & Appearance	Furosemide is available as oral tablets, oral solution, and solution for intravenous (IV) or intramuscular (IM) injection. Oral tablets are typically white, round, and scored, with various imprints indicating strength. The oral solution is usually clear and colorless or light yellow. The injectable solution is clear and colorless.
Dosage & Administration	Dosage varies widely depending on the indication, severity of edema, and patient's renal function. For edema, initial adult oral doses are typically 20 mg to 80 mg once or twice daily, titrating up to a maximum of 600 mg daily. For hypertension, lower doses (e.g., 20 mg to 40 mg twice daily) may be used. IV administration is used for rapid diuresis or in acute settings. It can be taken with or without food, but consistency is recommended.
Supplied As	Furosemide is supplied as: oral tablets (e.g., 20 mg, 40 mg, 80 mg), oral solution (e.g., 10 mg/mL, 40 mg/5 mL), and solution for intravenous/intramuscular injection (e.g., 10 mg/mL).
Contraindications	Furosemide is contraindicated in patients with known hypersensitivity to furosemide or sulfonamides (though cross-reactivity is rare), in patients with anuria (absence of urine production), and in patients with hepatic coma or severe electrolyte depletion until the condition is improved.
Storage & Expiry	Furosemide tablets and oral solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. The injectable solution should be protected from light. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include electrolyte imbalances (e.g., hypokalemia, hyponatremia, hypochloremia, hypomagnesemia, hypocalcemia), dehydration, hypotension (dizziness, lightheadedness), and increased urination. More serious side effects can include ototoxicity (hearing impairment, tinnitus, particularly with rapid IV infusion or high doses), allergic reactions, pancreatitis, and gout.
Warnings & Precautions	♦ Fluid and Electrolyte Imbalances: Can cause significant fluid and electrolyte depletion (especially hypokalemia, hyponatremia, hypomagnesemia). Monitor electrolytes regularly. Advise patients on diet or supplements if needed. ♦ Hypotension: Risk of symptomatic hypotension, especially with initial doses, rapid diuresis, or in dehydrated patients. ♦ Ototoxicity: Can cause transient or permanent hearing impairment/tinnitus, especially with high doses, rapid IV infusion, or in patients with renal impairment or concurrent use of other ototoxic drugs. ♦ Sulfonamide Allergy: While cross-reactivity is rare, use with caution in patients with a history of sulfonamide allergy. ♦ Renal Impairment: Use with caution and monitor renal function. Can worsen pre-existing renal dysfunction or lead to acute renal failure, especially in volume-depleted states. ♦ Gout: Can increase serum uric acid levels and precipitate gout attacks. ♦ Diabetes: May increase blood glucose levels; monitor diabetics closely.
Missed Dose Instructions	If a dose of Furosemide is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For once-daily dosing, avoid taking a missed dose too late in the day to prevent nocturia (nighttime urination).

Furosemide (Lasix)

Overdose Instructions	Overdose symptoms are primarily related to severe dehydration and electrolyte imbalances, including profound diuresis leading to hypovolemia, hypotension, electrolyte depletion (especially hypokalemia, hypochloremia), and associated symptoms like dizziness, weakness, muscle cramps, and cardiac arrhythmias. Treatment is supportive and symptomatic. Focus on fluid and electrolyte replacement. Hemodialysis is generally not effective in removing furosemide. Seek immediate medical attention.
Medicine Interactions	♦ Aminoglycoside Antibiotics (e.g., gentamicin): Increased risk of ototoxicity and nephrotoxicity. Avoid concomitant use or monitor closely. ♦ Other Ototoxic Drugs (e.g., cisplatin): Additive ototoxicity risk. ♦ Digoxin: Increased risk of digoxin toxicity due to hypokalemia caused by furosemide. Monitor potassium and digoxin levels. ♦ Lithium: Furosemide can reduce renal clearance of lithium, leading to increased lithium levels and toxicity. Monitor lithium levels closely. ♦ NSAIDs: Can reduce the diuretic and antihypertensive effects of furosemide and increase the risk of renal impairment. ♦ ACE Inhibitors/ARBs: Increased risk of severe hypotension with initial doses, especially in patients already on diuretics. ♦ Corticosteroids: Increased risk of hypokalemia. ♦ Antihypertensive Agents: Additive hypotensive effects. ♦ Sucralfate: Can reduce the absorption of furosemide; separate administration by at least 2 hours. ♦ Phenytoin: May reduce the diuretic effect of furosemide.

Gabapentin (Neurontin)

Purpose/Indication	Gabapentin is an anticonvulsant and neuropathic pain agent used to treat various neurological conditions. Its primary indications include the management of postherpetic neuralgia (nerve pain after shingles) in adults, and as an adjunct therapy for partial onset seizures with or without secondary generalization in adults and children 3 years and older. It is also commonly used off-label for other neuropathic pain conditions, restless legs syndrome, and anxiety disorders.
Method of Action	The precise mechanism of action of gabapentin is not fully understood, but it is believed to involve binding to the α2−δ (alpha-2-delta) subunit of voltage-dependent calcium channels in the central nervous system. This binding modulates the release of several neurotransmitters, including glutamate, norepinephrine, and substance P. This effect is thought to contribute to its anticonvulsant and analgesic properties by reducing neuronal excitability and pain signaling. It does not bind to GABA receptors directly.
Medication Name & Brand Names	♦ Medication Name: Gabapentin ♦ Brand Names: Neurontin, Gralise (extended-release for postherpetic neuralgia), Horizant (extended-release for restless legs syndrome and postherpetic neuralgia)
Pharmaceutical Forms & Appearance	Gabapentin is available as oral capsules, oral tablets (immediate and extended-release), and oral solution. Capsules vary in color and size. Tablets vary in shape and color, often white or off-white, and may be scored. The oral solution is a clear, colorless liquid.
Dosage & Administration	Dosage is highly individualized, starting at a low dose and gradually titrated upwards to achieve therapeutic effect while minimizing side effects. For neuropathic pain, initial doses are typically 300 mg once daily at bedtime, increasing to 300 mg three times daily, with a maximum often around 1800-3600 mg daily in divided doses. For seizures, doses can be higher. Dosing frequency is often three times daily due to its short half-life, but extended-release forms allow once-daily dosing. It can be taken with or without food.
Supplied As	Gabapentin is supplied as: oral capsules (e.g., 100 mg, 300 mg, 400 mg), oral tablets (e.g., 300 mg, 600 mg, 800 mg), extended-release tablets (e.g., Gralise 300 mg, 600 mg; Horizant 300 mg, 600 mg), and oral solution (e.g., 250 mg/5 mL).
Contraindications	Gabapentin is contraindicated in patients with known hypersensitivity to gabapentin or any component of the formulation.
Storage & Expiry	Gabapentin capsules, tablets, and oral solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include dizziness, somnolence (drowsiness), fatigue, ataxia (impaired coordination), peripheral edema (swelling of extremities), and blurred vision. More serious but less common side effects include suicidal thoughts/behavior, hypersensitivity reactions (e.g., DRESS syndrome), respiratory depression (especially with opioids or in patients with respiratory risk factors), and behavioral changes in children.
Warnings & Precautions	♦ Suicidality Risk: Antiepileptic drugs (AEDs), including gabapentin, increase the risk of suicidal thoughts or behavior. Monitor patients for new or worsening depression, suicidal thoughts, or unusual changes in mood or behavior. ♦ Dizziness/Somnolence/Ataxia: Can cause significant central nervous system (CNS) depression. Advise caution with activities requiring mental alertness (e.g., driving, operating machinery), especially during initial titration. ♦ Respiratory Depression: Serious, life-threatening respiratory depression can occur, particularly when co-administered with opioids or other CNS depressants, or in patients with underlying respiratory compromise. Use with extreme caution. ♦ Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) / Hypersensitivity: Potentially fatal, multi-organ hypersensitivity reactions can occur. Discontinue immediately if symptoms (e.g., rash, fever, lymphadenopathy, organ involvement) are suspected. ♦ Renal Impairment: Dose adjustment is required in patients with renal impairment to prevent drug accumulation and toxicity. ♦ Withdrawal Seizures: Do not discontinue gabapentin abruptly in patients receiving it for seizures due to the risk of increased seizure frequency. Taper gradually over at least 1 week. ♦ Abuse Potential: Gabapentin can be abused or misused, especially by individuals with a history of substance abuse. Monitor patients for signs of misuse.
Missed Dose Instructions	If a dose of Gabapentin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For chronic conditions, consistent dosing is important for maintaining therapeutic effect and preventing breakthrough symptoms. Do not stop abruptly.
Overdose Instructions	Overdose symptoms are typically lethargy, somnolence, ataxia, slurred speech, ptosis, diarrhea, and double vision. Respiratory depression may occur, especially with co-ingestion of other CNS depressants. Treatment is supportive and symptomatic. Gastric decontamination with activated charcoal may be considered if oral ingestion was recent and substantial. Hemodialysis can remove gabapentin from the plasma and may be useful in patients with severe renal impairment or life-threatening overdose. Seek immediate medical attention.
Medicine Interactions	♦ Opioids/Other CNS Depressants (e.g., benzodiazepines, alcohol): Increased risk of respiratory depression, profound sedation, hypotension, and coma. Concomitant use should be avoided or used with extreme caution, with reduced doses and close monitoring. ♦ Antacids (containing aluminum or magnesium): Can reduce the absorption of gabapentin. Administer gabapentin at least 2 hours after antacids. ♦ Hydrocodone/Morphine: Gabapentin may increase the plasma concentrations of hydrocodone and morphine. ♦ Naproxen: Can increase the plasma concentration of gabapentin. ♦ No significant interactions with common antiepileptic drugs (e.g., phenytoin, carbamazepine, valproate, phenobarbital) or oral contraceptives.

Glipizide (Glucotrol)

Purpose/Indication	Glipizide is an oral sulfonylurea antidiabetic medication used to manage blood glucose levels in adults with type 2 diabetes mellitus. It is typically used when diet and exercise alone are insufficient to achieve adequate glycemic control. It helps the body produce and use its own insulin more effectively, thereby lowering blood sugar.
Method of Action	Glipizide works primarily by stimulating insulin release from the beta cells of the pancreatic islets. It binds to a specific receptor on the pancreatic beta-cell membrane (the sulfonylurea receptor SUR1, which is part of the ATP-sensitive potassium channel), leading to the closure of potassium channels. This depolarization of the beta cell opens voltage-dependent calcium channels, resulting in an influx of calcium that triggers the secretion of insulin. It also may increase insulin sensitivity in peripheral tissues and reduce hepatic glucose production.
Medication Name & Brand Names	♦ Medication Name: Glipizide ♦ Brand Names: Glucotrol (immediate-release), Glucotrol XL (extended-release), Glipizide (generic)
Pharmaceutical Forms & Appearance	Glipizide is available as immediate-release oral tablets and extended-release oral tablets. Immediate-release tablets are typically white, round or oval, and may be scored. Extended-release tablets are often film-coated and may maintain their shape during transit through the GI tract.
Dosage & Administration	Dosage is individualized, typically starting at a low dose (e.g., 5 mg once daily for immediate-release, 5 mg to 10 mg once daily for extended-release) and gradually titrated upwards based on blood glucose response, usually up to a maximum of 20 mg to 40 mg daily. Immediate-release glipizide should be taken approximately 30 minutes before a meal to maximize insulin release in response to food. Extended-release glipizide should be taken with breakfast.
Supplied As	Glipizide is supplied as: immediate-release oral tablets (e.g., 5 mg, 10 mg) and extended-release oral tablets (e.g., 2.5 mg, 5 mg, 10 mg).
Contraindications	Glipizide is contraindicated in patients with known hypersensitivity to glipizide or other sulfonylureas. It is also contraindicated in patients with type 1 diabetes mellitus or diabetic ketoacidosis, as it requires functioning pancreatic beta cells. It is generally not recommended during pregnancy or breastfeeding.
Storage & Expiry	Glipizide tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	The most common and significant side effect is hypoglycemia (low blood sugar), which can be severe. Other common side effects include nausea, diarrhea, abdominal pain, headache, and dizziness. Less common side effects can include allergic skin reactions, cholestatic jaundice, and, rarely, blood dyscrasias.
Warnings & Precautions	♦ Hypoglycemia: The primary risk is hypoglycemia, which can be severe and prolonged. Patients must be educated on symptoms, management, and prevention of hypoglycemia. Risk is increased with skipped meals, alcohol intake, strenuous exercise, or renal/hepatic impairment. ♦ Cardiovascular Mortality: Some older sulfonylureas were associated with increased cardiovascular mortality; while not definitively established for glipizide, caution is advised. ♦ Renal/Hepatic Impairment: Use with caution and consider dose reduction in patients with impaired renal or hepatic function, as accumulation can increase the risk of hypoglycemia. ♦ G6PD Deficiency: Patients with G6PD deficiency are at increased risk of hemolytic anemia with sulfonylurea treatment. ♦ Loss of Glycemic Control: Over time, the effectiveness of glipizide may decrease due to progression of the underlying diabetes. ♦ Fixed Drug Eruption: Can cause specific skin reactions.
Missed Dose Instructions	If a dose of Glipizide (immediate-release) is missed, take it as soon as remembered if it is still well before your next meal. However, if it is almost time for your next scheduled dose or meal, skip the missed dose and continue with the regular schedule. Do not take a double dose. For extended-release, if a dose is missed, take it with the next meal. Consistent timing with meals is important to reduce hypoglycemia risk.
Overdose Instructions	Overdose primarily leads to severe and prolonged hypoglycemia. Symptoms can range from mild (tremor, sweating, hunger, nervousness, confusion) to severe (seizures, coma, brain damage, death). Treatment involves immediate administration of glucose (oral glucose for conscious patients, IV dextrose for unconscious patients). Hospitalization and prolonged monitoring are necessary due to the potential for recurrence of hypoglycemia. Glucagon may be administered. Seek immediate medical attention.
Medicine Interactions	♦ Drugs that Enhance Hypoglycemic Effect (Increased Hypoglycemia Risk): Beta-blockers (can mask hypoglycemia symptoms), alcohol, NSAIDs, salicylates, sulfonamides, chloramphenicol, probenecid, coumarins, monoamine oxidase inhibitors (MAOIs), quinolones, fibrates, fluconazole, azole antifungals (e.g., miconazole), certain antidepressants (SSRIs). ♦ Drugs that Reduce Hypoglycemic Effect (Increased Hyperglycemia Risk): Thiazide diuretics, corticosteroids, phenothiazines, thyroid hormones, estrogens, oral contraceptives, phenytoin, nicotinic acid, sympathomimetics, calcium channel blockers. ♦ Colesevelam: Can reduce the absorption of glipizide. Administer glipizide at least 4 hours before colesevelam. ♦ Beta-Blockers: Can mask the symptoms of hypoglycemia (e.g., tremor, tachycardia), making it harder for patients to recognize low blood sugar.

Glyburide (Diabeta)

Purpose/Indication	Glyburide is an oral sulfonylurea antidiabetic medication used to manage blood glucose levels in adults with type 2 diabetes mellitus. It is typically prescribed when diet and exercise alone are insufficient to achieve adequate glycemic control. It helps the body produce and release more insulin, thereby lowering blood sugar.
Method of Action	Glyburide works primarily by stimulating insulin release from the beta cells of the pancreatic islets. It binds to a specific receptor on the pancreatic beta-cell membrane (the sulfonylurea receptor SUR1), leading to the closure of ATP-sensitive potassium channels. This closure depolarizes the cell membrane, which opens voltage-dependent calcium channels, resulting in a rapid influx of calcium ions that triggers the secretion of insulin. It may also enhance peripheral glucose utilization and reduce hepatic glucose production.
Medication Name & Brand Names	♦ Medication Name: Glyburide (also known as Glibenclamide in many regions), Glyburide Micronized ♦ Brand Names: Diabeta, Glynase PresTab (micronized), Euglucon (regional), Glyburide (generic)
Pharmaceutical Forms & Appearance	Glyburide is available as oral tablets, including both non-micronized and micronized formulations. Tablets are typically white or off-white, round or oval, and may be scored, with various imprints indicating strength. Micronized tablets are generally smaller.
Dosage & Administration	Dosage is individualized, typically starting at a low dose (e.g., 2.5 mg to 5 mg once daily for non-micronized, 1.25 mg to 2.5 mg once daily for micronized) and gradually titrated upwards based on blood glucose response, usually up to a maximum of 20 mg daily (non-micronized) or 12 mg daily (micronized). It should be taken with breakfast or the first main meal of the day to maximize insulin release in response to food and reduce the risk of hypoglycemia.
Supplied As	Glyburide is supplied as: non-micronized oral tablets (e.g., 1.25 mg, 2.5 mg, 5 mg) and micronized oral tablets (e.g., 1.5 mg, 3 mg, 6 mg).

Contraindications	Glyburide is contraindicated in patients with known hypersensitivity to glyburide, other sulfonylureas, or sulfonamide derivatives. It is also contraindicated in patients with type 1 diabetes mellitus or diabetic ketoacidosis, as it requires functioning pancreatic beta cells. It is generally not recommended during pregnancy or breastfeeding. Concurrent use with bosentan is contraindicated.
Storage & Expiry	Glyburide tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	The most common and significant side effect is hypoglycemia (low blood sugar), which can be severe and prolonged. Other common side effects include nausea, heartburn, abdominal pain, headache, and dizziness. Less common side effects can include allergic skin reactions, cholestatic jaundice, and, rarely, blood dyscrasias or hyponatremia.
Warnings & Precautions	♦ Hypoglycemia: The primary risk is hypoglycemia, which can be severe, prolonged, and life-threatening. Patients must be educated on symptoms, management, and prevention of hypoglycemia. Risk is increased with skipped meals, alcohol intake, strenuous exercise, or renal/hepatic impairment. ♦ Cardiovascular Mortality: Some older sulfonylureas were associated with increased cardiovascular mortality. While not definitively established for glyburide, caution is advised. ♦ Renal/Hepatic Impairment: Use with caution and consider dose reduction in patients with impaired renal or hepatic function, as accumulation can significantly increase the risk of severe hypoglycemia. Glyburide is generally not recommended as a first-line agent in elderly patients or those with moderate to severe renal impairment. ♦ G6PD Deficiency: Patients with G6PD deficiency are at increased risk of hemolytic anemia with sulfonylurea treatment. ♦ Loss of Glycemic Control: Over time, the effectiveness of glyburide may decrease due to progression of the underlying diabetes. ♦ Hypersensitivity: Rare, but serious allergic reactions can occur.
Missed Dose Instructions	If a dose of Glyburide is missed, take it as soon as remembered if it is still with or just before your next meal. However, if it is almost time for your next scheduled meal or dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent timing with meals is important to reduce the risk of hypoglycemia.
Overdose Instructions	Overdose primarily leads to severe and prolonged hypoglycemia. Symptoms can range from mild (tremor, sweating, hunger, nervousness, confusion) to severe (seizures, coma, brain damage, death). Treatment involves immediate administration of glucose (oral glucose for conscious patients, IV dextrose for unconscious patients). Hospitalization and prolonged monitoring (e.g., 24-72 hours) are necessary due to the potential for recurrence of hypoglycemia. Glucagon may be administered. Seek immediate medical attention.
Medicine Interactions	♦ Bosentan: Concurrent use is contraindicated due to increased risk of liver enzyme elevations and potential for reduced efficacy of both agents. ♦ Drugs that Enhance Hypoglycemic Effect (Increased Hypoglycemia Risk): Beta-blockers (can mask hypoglycemia symptoms), alcohol, NSAIDs, salicylates, sulfonamides, chloramphenicol, probenecid, coumarins (warfarin), monoamine oxidase inhibitors (MAOIs), quinolones, fibrates, fluconazole, azole antifungals (e.g., miconazole), certain antidepressants (SSRIs). ♦ Drugs that Reduce Hypoglycemic Effect (Increased Hyperglycemia Risk): Thiazide diuretics, corticosteroids, phenothiazines, thyroid hormones, estrogens, oral contraceptives, phenytoin, nicotinic acid, sympathomimetics, calcium channel blockers. ♦ Colesevelam: Can reduce the absorption of glyburide. Administer glyburide at least 4 hours before colesevelam. ♦ Beta-Blockers: Can mask the symptoms of hypoglycemia (e.g., tremor, tachycardia), making it harder for patients to recognize low blood sugar.

Griseofulvin (Gris-Peg)

Purpose/Indication	Griseofulvin is an oral antifungal medication specifically used to treat dermatophyte fungal infections of the skin, hair, and nails. It is effective against tinea infections (ringworm) such as tinea corporis, tinea capitis, tinea pedis (athlete's foot), tinea cruris (jock itch), tinea unguium (onychomycosis), and tinea barbae. It is used when topical antifungal agents are ineffective or inappropriate, particularly for widespread or difficult-to-treat infections.
Method of Action	Griseofulvin works by interfering with fungal cell division. It deposits in keratin precursor cells and binds to keratin, making newly formed keratin resistant to fungal invasion. Within the fungal cell, it binds to microtubules, disrupting mitotic spindle formation and inhibiting cell division (fungistatic action). It also impairs nucleic acid synthesis. This action allows healthy, uninfected cells to grow, pushing out the infected cells.
Medication Name & Brand Names	♦ Medication Name: Griseofulvin (microsize and ultramicrosize) ♦ Brand Names: Grifulvin V (microsize), Gris-PEG (ultramicrosize), Fulvicin P/G (ultramicrosize), Griseofulvin (generic)
Pharmaceutical Forms & Appearance	Griseofulvin is available as oral tablets and oral suspension. Tablets are typically white or off-white, and may be scored. The oral suspension is usually a white to off-white liquid. Ultramicrosize formulations are generally available in lower strengths but offer better absorption than microsize.
Dosage & Administration	Dosage and duration of treatment vary significantly depending on the infection type, location, and patient's age and weight. Treatment courses are often prolonged, ranging from 2-4 weeks for skin infections, 4-8 weeks for hair and nail infections, and up to several months (e.g., 6-12 months for toenails). It is usually taken once or twice daily. For best absorption, especially of the microsize form, it should be taken with a fatty meal.
Supplied As	Griseofulvin is supplied as: oral tablets (e.g., microsize 250 mg, 500 mg; ultramicrosize 125 mg, 165 mg, 250 mg, 330 mg), and oral suspension (e.g., 125 mg/5 mL).
Contraindications	Griseofulvin is contraindicated in patients with known hypersensitivity to griseofulvin or any component of the formulation. It is also contraindicated in patients with porphyria, severe liver disease, or hepatocellular failure. It is contraindicated in pregnancy and should not be used in men planning paternity within 6 months of treatment, due to potential for teratogenicity.
Storage & Expiry	Griseofulvin tablets and oral suspension should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include headache (especially early in treatment), gastrointestinal upset (e.g., nausea, vomiting, diarrhea), rash, and photosensitivity. More serious but less common side effects include hepatotoxicity (liver injury), allergic reactions (including severe skin reactions), leucopenia (low white blood cell count), and peripheral neuritis.
Warnings & Precautions	♦ Hepatotoxicity: Can cause liver dysfunction, including severe cases. Monitor liver function tests periodically, especially with prolonged use. ♦ Photosensitivity: Can cause increased sensitivity to sunlight. Advise patients to use sun protection (sunscreen, protective clothing). ♦ Pregnancy/Reproductive Risk: Contraindicated in pregnancy due to teratogenic effects. Men should avoid paternity during and for at least 6 months after treatment due to potential effects on spermatogenesis. Advise effective contraception for women of childbearing potential during and for one month after treatment. ♦ Cross-Reactivity: Possible cross-sensitivity with penicillin due to fungal origin. ♦ Blood Dyscrasias: Rare reports of leukopenia; monitor blood counts periodically. ♦ Renal Impairment: Use with caution in patients with renal impairment. ♦ Alcohol Interaction: May enhance the effects of alcohol, causing flushing, tachycardia, and impaired coordination. Avoid alcohol during treatment.

Missed Dose Instructions	If a dose of Griseofulvin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing and completing the entire, often prolonged, course of treatment are crucial for successful fungal eradication and preventing recurrence.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily gastrointestinal upset, headache, rash, and potential for more severe hepatotoxicity or central nervous system effects (e.g., confusion). Treatment is supportive and symptomatic. Gastric decontamination with activated charcoal may be considered if oral ingestion was recent and substantial. Griseofulvin is largely metabolized in the liver, and dialysis is not expected to be effective in removing it. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Oral Contraceptives: Griseofulvin can decrease the effectiveness of oral contraceptives, potentially leading to breakthrough bleeding or unintended pregnancy. Advise alternative or additional non-hormonal contraception during and for one month after treatment. ♦ Warfarin: Griseofulvin can decrease the anticoagulant effect of warfarin. Monitor INR closely and adjust warfarin dose as needed. ♦ Barbiturates: Phenobarbital and other barbiturates can decrease the absorption of griseofulvin, leading to reduced effectiveness. ♦ Alcohol: May cause a disulfiram-like reaction (flushing, nausea, vomiting, tachycardia) and enhance the effects of alcohol. Avoid alcohol during treatment. ♦ Salicylates: May decrease absorption of griseofulvin.

Guaifenesin (Mucinex)

Purpose/Indication	Guaifenesin is an expectorant used to relieve chest congestion and coughs caused by the common cold, bronchitis, and other upper respiratory tract infections. It helps to thin and loosen mucus in the airways, making it easier to cough up and clear from the lungs. It is often found in combination cold and cough preparations.
Method of Action	Guaifenesin is believed to work by increasing the volume and decreasing the viscosity of secretions in the respiratory tract. While the exact mechanism is not fully understood, it is thought to stimulate goblet cells and serous glands in the bronchial mucosa, leading to increased production of thinner, less tenacious mucus. This action makes coughs more productive and aids in the clearance of phlegm.
Medication Name & Brand Names	♦ Medication Name: Guaifenesin ♦ Brand Names: Mucinex (often extended-release), Robitussin Chest Congestion, Cheratussin, Humibid (historical), Guaifenesin (generic)
Pharmaceutical Forms & Appearance	Guaifenesin is available as oral tablets (immediate and extended-release), oral capsules, oral solution, and oral syrup. Tablets vary in shape and color, often white or off-white. Syrups and solutions are typically clear or colored liquids. It is very frequently found in combination products with other cough/cold medications.
Dosage & Administration	Dosage varies by age and formulation (immediate-release vs. extended-release). For adults and children 12 years and older, immediate-release doses are typically 200 mg to 400 mg every 4 hours as needed, with a maximum daily dose of 2400 mg. Extended-release forms (e.g., Mucinex) are typically 600 mg to 1200 mg every 12 hours. It can be taken with or without food. Adequate hydration is important to help thin mucus.
Supplied As	Guaifenesin is supplied as: immediate-release oral tablets (e.g., 200 mg, 400 mg), extended-release oral tablets (e.g., 600 mg, 1200 mg), oral capsules (e.g., 200 mg, 300 mg), oral solution/syrup (e.g., 100 mg/5 mL, 200 mg/5 mL).
Contraindications	Guaifenesin is contraindicated in patients with known hypersensitivity to guaifenesin or any component of the formulation.
Storage & Expiry	Guaifenesin tablets, capsules, and oral solutions/syrups should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and include nausea, vomiting, stomach upset, dizziness, and headache. These are often transient and can be minimized by taking the medication with food. Serious side effects are rare with guaifenesin used alone.
Warnings & Precautions	♦ Persistent Cough: Do not use for chronic persistent cough associated with smoking, asthma, emphysema, or chronic bronchitis unless directed by a doctor. Consult a healthcare professional if cough persists for more than 7 days, recurs, or is accompanied by fever, rash, or persistent headache. ♦ Children: Always follow age-appropriate dosing guidelines. For children under 4 years of age, consult a doctor before use. ♦ Hydration: Encourage adequate fluid intake to help thin mucus. ♦ Masking Symptoms: Be aware that guaifenesin primarily provides symptomatic relief and does not treat the underlying cause of the cough or congestion.
Missed Dose Instructions	As Guaifenesin is often used for symptomatic relief as needed, strict "missed dose" instructions are less critical. If a dose is missed, take it when remembered if symptoms warrant. However, if it's almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose.
Overdose Instructions	Overdose with guaifenesin alone is generally associated with gastrointestinal discomfort (nausea, vomiting), but serious toxicity is rare. Ingesting very large amounts may cause kidney stones (rarely), especially with chronic high-dose abuse. Treatment is supportive and symptomatic. Gastric decontamination may be considered if a very large overdose was recent. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ No significant drug interactions are commonly reported with guaifenesin when used alone at recommended doses. ♦ However, it is frequently found in combination products. When using combination products, check for interactions related to other ingredients (e.g., decongestants, cough suppressants, antihistamines).

H - M

Any medications starting with H through to M.

Hydrochlorothiazide (Microzide)

Purpose/Indication	Hydrochlorothiazide (HCTZ) is a thiazide diuretic commonly used to treat hypertension (high blood pressure) and edema (fluid retention) associated with conditions like congestive heart failure, liver cirrhosis, and kidney disease. It helps the body eliminate excess fluid and salt, which in turn reduces blood pressure and swelling. It is frequently used alone or in combination with other antihypertensive agents.

MEDICATION

Medication

H - M - H

Hydrochlorothiazide (Microzide)

Method of Action	Hydrochlorothiazide works primarily by inhibiting the reabsorption of sodium and chloride ions in the distal convoluted tubule of the kidney. By blocking the Na+/Cl− co-transporter, it increases the excretion of sodium, chloride, and water, leading to increased urine output (diuresis). It also causes a small increase in potassium and magnesium excretion, and a decrease in calcium excretion. Its antihypertensive effect is thought to involve reduced plasma volume and a direct vasodilator effect.
Medication Name & Brand Names	♦ Medication Name: Hydrochlorothiazide (HCTZ) ♦ Brand Names: Microzide, Esidrix (historical), Hydrochlorothiazide (generic) (Often found in combination products like HCTZ/Lisinopril, HCTZ/Valsartan)
Pharmaceutical Forms & Appearance	Hydrochlorothiazide is primarily available as oral tablets and oral capsules. Tablets are typically small, white, and often scored, with various imprints indicating strength. Capsules are usually clear or colored, containing white powder.
Dosage & Administration	Dosage varies depending on the indication. For hypertension, typical adult doses range from 12.5 mg to 50 mg once daily. For edema, initial doses may be 25 mg to 100 mg once or twice daily. It can be taken with or without food, but taking it with food may help reduce stomach upset. It is generally recommended to take it in the morning to avoid nighttime urination.
Supplied As	Hydrochlorothiazide is supplied as: oral tablets (e.g., 12.5 mg, 25 mg, 50 mg) and oral capsules (e.g., 12.5 mg). It is also widely available in fixed-dose combination tablets with other antihypertensive agents.
Contraindications	Hydrochlorothiazide is contraindicated in patients with known hypersensitivity to hydrochlorothiazide, other sulfonamide-derived drugs, or any component of the formulation. It is also contraindicated in patients with anuria (absence of urine production).
Storage & Expiry	Hydrochlorothiazide tablets and capsules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include electrolyte imbalances (e.g., hypokalemia, hyponatremia, hypomagnesemia, hypercalcemia), dizziness, lightheadedness (due to orthostatic hypotension), headache, and increased urination. Less common but more serious side effects can include allergic reactions (rash, photosensitivity), pancreatitis, blood dyscrasias, and, rarely, acute myopia and secondary angle-closure glaucoma.
Warnings & Precautions	♦ Fluid and Electrolyte Imbalances: Can cause significant fluid and electrolyte depletion, particularly hypokalemia (low potassium). Monitor electrolytes regularly. Advise patients on diet or supplements if needed. ♦ Hypotension: Risk of symptomatic hypotension, especially with initial doses or in volume-depleted patients. ♦ Renal Impairment: Use with caution in patients with severe renal impairment as thiazides may be less effective and can precipitate azotemia. Not effective if creatinine clearance is very low. ♦ Hepatic Impairment: Use with caution in patients with impaired hepatic function or progressive liver disease, as minor fluid and electrolyte alterations can precipitate hepatic coma. ♦ Sulfonamide Allergy: Patients with a history of sulfonamide allergy may have cross-reactivity, though rare. ♦ Photosensitivity: Can cause increased sensitivity to sunlight. Advise patients to use sun protection. ♦ Gout: Can increase serum uric acid levels and precipitate gout attacks. ♦ Diabetes: May increase blood glucose levels and worsen glycemic control; monitor diabetics closely. ♦ Acute Myopia and Secondary Angle-Closure Glaucoma: Rare idiosyncratic reactions that can lead to permanent vision loss; discontinue immediately if symptoms occur. ♦ Skin Cancer Risk: Recent studies suggest a potential increased risk of non-melanoma skin cancer (basal cell carcinoma, squamous cell carcinoma) with increasing cumulative doses of HCTZ. Advise patients to limit sun exposure and perform regular skin examinations.
Missed Dose Instructions	If a dose of Hydrochlorothiazide is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. To avoid nighttime urination, it's best to take the medication in the morning.
Overdose Instructions	Overdose symptoms are primarily related to severe dehydration and electrolyte imbalances, including profound diuresis leading to hypovolemia, hypotension, electrolyte depletion (especially hypokalemia, hyponatremia), and associated symptoms like dizziness, weakness, muscle cramps, and cardiac arrhythmias. Treatment is supportive and symptomatic. Focus on fluid and electrolyte replacement. Hemodialysis is not effective in removing hydrochlorothiazide. Seek immediate medical attention.
Medicine Interactions	♦ Lithium: HCTZ can reduce the renal clearance of lithium, leading to increased lithium levels and toxicity. Monitor lithium levels closely. ♦ NSAIDs: Can reduce the diuretic and antihypertensive effects of HCTZ and increase the risk of renal impairment. ♦ Corticosteroids: Increased risk of hypokalemia. ♦ Digoxin: Increased risk of digoxin toxicity due to hypokalemia. Monitor potassium and digoxin levels. ♦ Antidiabetic agents (e.g., insulin, oral hypoglycemics): HCTZ can increase blood glucose levels, potentially requiring adjustment of antidiabetic medication. ♦ Cholestyramine/Colestipol: Can reduce the absorption of HCTZ; administer HCTZ at least 1 hour before or 4 hours after these bile acid sequestrants. ♦ Other Antihypertensive Agents: Additive hypotensive effects. ♦ Alcohol/Barbiturates/Narcotics: Increased risk of orthostatic hypotension. ♦ Non-depolarizing Skeletal Muscle Relaxants: May prolong their effects.

Hydrocodone/Acetaminophen (Vicodin)

Purpose/Indication	Hydrocodone/Acetaminophen is a combination analgesic used to relieve moderate to severe pain. Hydrocodone is an opioid pain reliever that works on the central nervous system, and acetaminophen (paracetamol) is a non-opioid pain reliever and fever reducer that enhances the analgesic effects of the opioid. This combination provides comprehensive pain relief for acute or chronic conditions where non-opioid options are insufficient.
Method of Action	Hydrocodone, an opioid agonist, binds to mu-opioid receptors in the central nervous system, mimicking the effects of endogenous opioids. This binding inhibits pain signaling pathways, alters pain perception, and produces analgesia, sedation, and euphoria. Acetaminophen's exact mechanism of action is not fully understood, but it is believed to involve inhibition of prostaglandin synthesis in the central nervous system and possibly activation of descending serotonergic pathways, contributing to its analgesic and antipyretic effects without significant anti-inflammatory action.
Medication Name & Brand Names	♦ Medication Name: Hydrocodone Bitartrate/Acetaminophen ♦ Brand Names: Vicodin, Norco, Lortab, Xodol, Zohydro ER (hydrocodone only), Tylenol with Codeine (different opioid), Hydrocodone/APAP (generic)
Pharmaceutical Forms & Appearance	Hydrocodone/Acetaminophen is primarily available as oral tablets and oral solutions/syrups. Tablets vary in shape, color, and imprints depending on the strength and manufacturer (e.g., white, yellow, or orange, often oval or capsule-shaped). The oral solution/syrup is typically a clear or colored liquid.
Dosage & Administration	Dosage is individualized based on pain severity, patient response, and tolerance, using the lowest effective dose for the shortest duration. Typical adult doses range from 2.5 mg to 10 mg of hydrocodone combined with 300 mg to 325 mg of acetaminophen, taken every 4-6 hours as needed for pain. The maximum daily dose of acetaminophen should not exceed 4000 mg (or 3000 mg in some guidelines/preparations) to avoid liver toxicity. Take with food or milk if stomach upset occurs.

Supplied As	Hydrocodone/Acetaminophen is supplied as: oral tablets (various strengths, e.g., 5 mg/325 mg, 7.5 mg/325 mg, 10 mg/325 mg of hydrocodone/acetaminophen) and oral solution/syrup (e.g., 7.5 mg/325 mg per 15 mL).
Contraindications	Hydrocodone/Acetaminophen is contraindicated in patients with known hypersensitivity to hydrocodone, acetaminophen, or any component of the formulation. It is also contraindicated in patients with significant respiratory depression, acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment, and known or suspected paralytic ileus. Use in children under 12 years (and under 18 for tonsillectomy/adenoidectomy) is generally contraindicated.
Storage & Expiry	Hydrocodone/Acetaminophen tablets and solutions/syrups should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed, child-resistant containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include dizziness, drowsiness, lightheadedness, nausea, vomiting, constipation, and headache. More serious side effects can include respiratory depression, liver damage (due to acetaminophen), addiction, dependence, withdrawal symptoms, severe allergic reactions (including skin reactions like SJS), and adrenal insufficiency.
Warnings & Precautions	♦ Addiction, Abuse, Misuse: Opioids carry a significant risk of addiction, abuse, and misuse, which can lead to overdose and death. Assess patient risk factors and monitor for signs of abuse. ♦ Respiratory Depression: Serious, life-threatening, or fatal respiratory depression can occur, especially with initiation or re-initiation of therapy. Monitor patients closely, especially those with respiratory compromise. ♦ Accidental Ingestion: Accidental ingestion by children can be fatal. Keep out of reach of children. ♦ Neonatal Opioid Withdrawal Syndrome: Prolonged use during pregnancy can result in NAS in the newborn. ♦ Hepatotoxicity (Acetaminophen): Acetaminophen can cause severe, potentially fatal liver injury, especially at doses exceeding the maximum recommended daily dose. Avoid other acetaminophen-containing products. ♦ CNS Depression: Causes significant CNS depression. Advise caution with driving or operating machinery. Avoid concurrent use of alcohol or other CNS depressants. ♦ Adrenal Insufficiency: Chronic opioid use can cause adrenal insufficiency. ♦ Serotonin Syndrome: Rare but serious risk when co-administered with other serotonergic drugs (e.g., SSRIs, SNRIs). ♦ GI Effects: Risk of severe constipation and paralytic ileus. ♦ Hypotension: Can cause severe hypotension. ♦ Drug-Drug Interactions: Many significant interactions due to both components. ♦ Withdrawal: Do not discontinue abruptly after prolonged use.
Missed Dose Instructions	Hydrocodone/Acetaminophen is typically taken as needed for pain. If a scheduled dose is missed, take it as soon as remembered if pain warrants. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Adhere to the prescribed dosing interval to avoid excessive acetaminophen intake.
Overdose Instructions	Overdose is a medical emergency. Symptoms of hydrocodone overdose include severe respiratory depression, pinpoint pupils, extreme drowsiness progressing to stupor or coma, limp muscles, cold/clammy skin, and potentially circulatory collapse. Acetaminophen overdose can cause severe liver damage, initially presenting with nausea, vomiting, sweating, and malaise, progressing to jaundice, confusion, and liver failure. Naloxone is the antidote for opioid overdose; N-acetylcysteine (NAC) is the antidote for acetaminophen overdose. Seek immediate emergency medical help.
Medicine Interactions	♦ Other CNS Depressants (e.g., alcohol, benzodiazepines, other opioids, sedatives, hypnotics, tranquilizers): Increased risk of respiratory depression, profound sedation, coma, and death. Avoid concomitant use or use with extreme caution, with reduced doses of one or both agents. ♦ CYP3A4 Inhibitors (e.g., ketoconazole, clarithromycin, ritonavir): Can increase hydrocodone plasma levels, leading to increased opioid effects and respiratory depression. ♦ CYP3A4 Inducers (e.g., rifampin, carbamazepine, phenytoin): Can decrease hydrocodone plasma levels, leading to reduced efficacy. ♦ Serotonergic Drugs (e.g., SSRIs, SNRIs, triptans, TCAs, tramadol, MAOIs): Increased risk of serotonin syndrome. ♦ Anticholinergic Drugs: Increased risk of urinary retention and severe constipation/paralytic ileus. ♦ Diuretics: Opioids can reduce the diuretic effect of diuretics. ♦ Drugs affecting gastric emptying: May alter absorption. ♦ Naloxone: Precipitates withdrawal in opioid-dependent patients. ♦ Acetaminophen Interactions: Warfarin (increased bleeding risk with chronic high acetaminophen doses), other hepatotoxic drugs.

Hydrocortisone (oral) (Cortef)

Purpose/Indication	Oral hydrocortisone is a corticosteroid medication used to treat a wide range of inflammatory, allergic, and autoimmune conditions. Its primary indications include replacement therapy for adrenal insufficiency (e.g., Addison's disease, congenital adrenal hyperplasia), treatment of severe allergic reactions, various rheumatologic disorders, dermatologic conditions, respiratory diseases (e.g., severe asthma), and certain hematologic and neoplastic disorders. It works by reducing inflammation and suppressing the immune system.
Method of Action	Hydrocortisone is a glucocorticoid that works by binding to intracellular glucocorticoid receptors. This complex then translocates to the nucleus, where it modulates gene expression by either upregulating the production of anti-inflammatory proteins or downregulating the synthesis of pro-inflammatory mediators (e.g., prostaglandins, leukotrienes, cytokines). This leads to widespread anti-inflammatory, immunosuppressive, and anti-allergic effects, as well as influencing metabolism and fluid balance.
Medication Name & Brand Names	♦ Medication Name: Hydrocortisone (oral) ♦ Brand Names: Cortef, Hydrocortone (historical/regional), Hydrocortisone (generic)
Pharmaceutical Forms & Appearance	Oral hydrocortisone is available as tablets. Tablets are typically white, round, and may be scored, with various imprints indicating strength.
Dosage & Administration	Dosage is highly individualized, depending on the condition being treated, its severity, and patient response. For adrenal insufficiency, typical adult replacement doses range from 10 mg to 30 mg daily, often divided into two or three doses, with higher doses during stress. For inflammatory conditions, doses can range from 20 mg to 240 mg daily, or even higher, and are often tapered over time. It can be taken with food or milk to reduce stomach upset.
Supplied As	Oral hydrocortisone is supplied as: oral tablets (e.g., 5 mg, 10 mg, 20 mg).
Contraindications	Oral hydrocortisone is generally contraindicated in patients with systemic fungal infections, except when used as replacement therapy for adrenal insufficiency. It is also contraindicated in patients with known hypersensitivity to hydrocortisone or any component of the formulation. Live or live-attenuated vaccines are generally contraindicated during immunosuppressive doses of corticosteroids.
Storage & Expiry	Hydrocortisone tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects with short-term use include increased appetite, weight gain, fluid retention, insomnia, and mood changes (e.g., irritability, euphoria). Long-term or high-dose use can lead to more serious effects such as Cushing's syndrome, adrenal suppression, osteoporosis, hyperglycemia/diabetes, increased susceptibility to infection, hypertension, peptic ulcers, thin skin, muscle weakness, and cataracts/glaucoma.

MEDICATION

Warnings & Precautions	♦ Adrenal Suppression: Prolonged use can suppress the body's natural cortisol production, leading to adrenal insufficiency upon abrupt discontinuation. Doses should be tapered gradually. During stress (surgery, illness), increased doses may be needed. ♦ Immunosuppression: Increases susceptibility to and masks symptoms of infection. Avoid exposure to chickenpox or measles if not immune. Live vaccines are contraindicated during immunosuppressive doses. ♦ Cushing's Syndrome: Chronic high-dose use can lead to iatrogenic Cushing's syndrome. ♦ Osteoporosis: Increased risk of bone mineral density loss and fractures with long-term use. ♦ Hyperglycemia/Diabetes: Can elevate blood glucose levels; monitor diabetics closely. ♦ Gastrointestinal Effects: Increased risk of peptic ulcer, bleeding, and perforation, especially with concurrent NSAID use. ♦ Cardiovascular Effects: Can cause fluid retention, hypertension, and worsen heart failure. ♦ Psychiatric Disturbances: Can cause mood swings, insomnia, anxiety, depression, or psychosis. ♦ Ocular Effects: Increased risk of cataracts and glaucoma with long-term use. ♦ Growth Retardation: Can inhibit growth in children; monitor growth. ♦ Hypokalemia: Can cause potassium depletion. ♦ Thyroid Function: Corticosteroid metabolism may be altered in hypo- or hyperthyroid states.
Missed Dose Instructions	For chronic replacement therapy (e.g., Addison's disease), if a dose of oral Hydrocortisone is missed, take it as soon as remembered. If it's close to the next dose, take the missed dose and spread the next dose out a bit or take a slightly reduced next dose. Never double a dose. For inflammatory conditions with a tapered dose, follow the doctor's specific instructions. Patients on chronic therapy should carry medical identification indicating their steroid dependence.
Overdose Instructions	Acute overdose with oral hydrocortisone is rarely life-threatening but can exacerbate known side effects, particularly gastrointestinal upset, fluid retention, and electrolyte imbalances. Chronic overdose leads to signs and symptoms of Cushing's syndrome and adrenal suppression. Treatment is supportive and symptomatic. Gradual reduction of the steroid dose under medical supervision is indicated for chronic overdose. Seek medical advice if an overdose is suspected or severe symptoms occur.
Medicine Interactions	♦ CYP3A4 Inducers (e.g., rifampin, phenytoin, barbiturates, carbamazepine): Can increase the metabolism of hydrocortisone, reducing its effectiveness. Increased hydrocortisone dose may be needed. ♦ CYP3A4 Inhibitors (e.g., ketoconazole, itraconazole, clarithromycin, ritonavir, cobicistat): Can decrease the metabolism of hydrocortisone, increasing its plasma levels and risk of systemic side effects. Reduced hydrocortisone dose may be needed. ♦ NSAIDs: Increased risk of gastrointestinal ulceration and bleeding. Avoid concurrent use or use with extreme caution. ♦ Diuretics (potassium-depleting, e.g., thiazides, loop diuretics): Increased risk of severe hypokalemia. Monitor potassium levels. ♦ Warfarin: Effects on warfarin can be variable; monitor INR closely. ♦ Antidiabetic Agents (e.g., insulin, oral hypoglycemics): Corticosteroids can increase blood glucose levels, requiring adjustment of antidiabetic medication. ♦ Live Vaccines: Contraindicated during immunosuppressive doses of corticosteroids. ♦ Immunosuppressants (e.g., cyclosporine): Enhanced immunosuppression; cyclosporine levels may be increased. ♦ Cholestyramine/Colestipol: May reduce absorption of oral hydrocortisone.

Hydrocortisone (topical) (Cortaid)

Purpose/Indication	Topical hydrocortisone is a low-potency corticosteroid used to reduce inflammation, itching, and redness associated with various skin conditions. It is commonly indicated for mild to moderate eczema (atopic dermatitis), contact dermatitis, insect bites, rashes, and other inflammatory dermatoses. It provides symptomatic relief by calming the immune response in the skin.
Method of Action	Topical hydrocortisone works by diffusing across cell membranes and binding to intracellular glucocorticoid receptors in the skin cells. This binding initiates a cascade of events that modulates gene expression, leading to the synthesis of anti-inflammatory proteins (e.g., lipocortins) and the inhibition of pro-inflammatory mediators (e.g., prostaglandins, leukotrienes, cytokines). This results in vasoconstriction, decreased capillary permeability, and reduced migration of immune cells to the affected area, thereby suppressing inflammation, itching, and redness.
Medication Name & Brand Names	♦ Medication Name: Hydrocortisone (topical) ♦ Brand Names: Cortaid, Cortizone-10, Dermacort, Hydrocortisone (generic)
Pharmaceutical Forms & Appearance	Topical hydrocortisone is widely available in various forms, including creams, ointments, lotions, solutions, gels, and sprays. Creams are typically white and semi-solid, ointments are greasy and translucent, and lotions/solutions are more fluid. The appearance can vary slightly depending on the base and concentration.
Dosage & Administration	Dosage and frequency of application vary based on the specific formulation, concentration, and severity of the condition. Generally, a thin layer is applied to the affected skin area one to four times daily, or as directed by a healthcare professional. It should be gently rubbed into the skin until absorbed. Avoid covering the treated area with occlusive dressings unless specifically advised, as this can increase systemic absorption. Wash hands before and after application.
Supplied As	Topical hydrocortisone is supplied in tubes, jars, or bottles of various sizes, in concentrations ranging from 0.5% (OTC) to 2.5% (prescription strength). Examples include: creams (0.5%, 1%, 2.5%), ointments (0.5%, 1%, 2.5%), lotions (1%, 2.5%), and solutions.
Contraindications	Topical hydrocortisone is generally contraindicated in patients with known hypersensitivity to hydrocortisone or any component of the formulation. It should not be used on skin areas affected by untreated bacterial, fungal, or viral infections (e.g., herpes simplex, varicella), rosacea, or perioral dermatitis, as corticosteroids can worsen these conditions.
Storage & Expiry	Topical hydrocortisone products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from excessive heat or freezing. Keep containers tightly closed. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are usually localized and include burning, itching, irritation, dryness, and folliculitis at the application site. With prolonged or excessive use, especially on thin skin or with occlusion, more serious local side effects can occur, such as skin thinning (atrophy), striae (stretch marks), telangiectasias (spider veins), acneiform eruptions, and hypopigmentation. Systemic side effects (e.g., adrenal suppression) are rare with low-potency hydrocortisone but can occur with extensive, long-term use on large surface areas, with occlusion, or in children.
Warnings & Precautions	♦ Systemic Absorption: Although minimal, systemic absorption can occur, leading to reversible hypothalamic-pituitary-adrenal (HPA) axis suppression, especially with prolonged use, high doses, occlusion, or in children. ♦ Skin Infections: Can mask or worsen existing skin infections. If infection is present, appropriate anti-infective therapy should be used concurrently. ♦ Pediatric Use: Children may absorb proportionally larger amounts due to a higher skin surface area to body weight ratio, increasing the risk of systemic side effects. Use the least amount for the shortest duration. ♦ Ocular Use: Avoid contact with eyes due to potential for cataracts and glaucoma, though very rare with topical use. ♦ Not for Certain Conditions: Avoid use on rosacea, perioral dermatitis, or acne due to potential worsening. ♦ Duration of Use: Use for the shortest duration necessary to control symptoms. Long-term continuous use, even of low potency, can lead to skin atrophy.
Missed Dose Instructions	If a dose of topical Hydrocortisone is missed, apply it as soon as remembered. However, if it is almost time for the next scheduled application, skip the missed dose and continue with the regular schedule. Do not apply a double dose. Consistent application as prescribed is important for managing chronic inflammatory skin conditions.

Overdose Instructions	Acute overdose with topical hydrocortisone is highly unlikely to cause immediate severe systemic toxicity due to very limited systemic absorption. Chronic excessive use, especially of high doses, on large body surface areas, or under occlusion, can lead to signs of hypercorticism (e.g., Cushing's syndrome features) and reversible HPA axis suppression. Treatment involves gradual withdrawal of the steroid under medical supervision. Seek medical advice if chronic overuse symptoms appear or if accidental ingestion occurs.
Medicine Interactions	♦ No significant drug interactions are commonly reported with topical hydrocortisone due to its minimal systemic absorption. ♦ However, if systemic absorption were to become significant (e.g., with very high doses, extensive application to damaged skin, or prolonged use under occlusion), theoretical interactions similar to oral corticosteroids with strong CYP3A4 inhibitors (e.g., ritonavir, ketoconazole) could occur, leading to increased systemic effects of hydrocortisone. This is exceptionally rare with typical topical use.

Hydroxychloroquine (Plaquenil)

Purpose/Indication	Hydroxychloroquine is an antimalarial and immunomodulatory medication used to treat and prevent malaria, and to manage autoimmune diseases such as systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). In autoimmune conditions, it helps to reduce inflammation, pain, and stiffness, and can help prevent disease flares and organ damage.
Method of Action	The exact mechanism of action in autoimmune diseases is not fully understood but is thought to involve several pathways. Hydroxychloroquine concentrates in acidic intracellular organelles, such as lysosomes, increasing their pH and inhibiting the activity of various enzymes and protein processing. This can interfere with antigen presentation, cytokine production (e.g., IL-1, IL-6, TNF-a), and T-cell activation. It also inhibits Toll-like receptor (TLR) signaling, particularly TLR7 and TLR9, reducing the inflammatory response. In malaria, it interferes with the parasite's ability to metabolize heme.
Medication Name & Brand Names	♦ Medication Name: Hydroxychloroquine Sulfate ♦ Brand Names: Plaquenil, Hydroxychloroquine (generic)
Pharmaceutical Forms & Appearance	Hydroxychloroquine is available as oral film-coated tablets. Tablets are typically white or off-white, round, and may be engraved with the strength.
Dosage & Administration	Dosage varies by indication and patient response. For autoimmune diseases, common adult doses are 200 mg to 400 mg daily, often taken once daily or divided into two doses. Dosing for malaria prevention or treatment is different. It can be taken with food or milk to minimize gastrointestinal upset. Consistent daily use is important for therapeutic effects in autoimmune conditions, which may take several weeks or months to become apparent.
Supplied As	Hydroxychloroquine is supplied as: oral film-coated tablets (e.g., 200 mg).
Contraindications	Hydroxychloroquine is contraindicated in patients with known hypersensitivity to 4-aminoquinoline compounds (e.g., chloroquine) or any component of the formulation. It is also contraindicated in patients with pre-existing maculopathy of the eye or with a history of retinopathy associated with 4-aminoquinoline treatment. Porphyria is also a contraindication.
Storage & Expiry	Hydroxychloroquine tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., nausea, abdominal cramps, diarrhea), headache, dizziness, and rash. The most serious and significant side effect is ocular toxicity, specifically retinopathy (damage to the retina), which can lead to irreversible vision loss. Other serious but less common side effects include cardiomyopathy (heart muscle damage), hypoglycemia, psychiatric effects, and blood disorders.
Warnings & Precautions	♦ Ocular Toxicity (Retinopathy): The most critical warning. Can cause irreversible retinal damage, visual field defects, and color vision changes. Risk is increased with higher daily doses, longer duration of therapy, pre-existing retinal disease, and renal/hepatic impairment. Baseline and regular (e.g., annual after 5 years or for high-risk patients) comprehensive ophthalmologic examinations, including visual field testing and optical coherence tomography (OCT), are crucial. Patients must be educated on visual symptoms and to report them immediately. ♦ Cardiovascular Effects: Rare reports of cardiomyopathy and QT prolongation, especially with concomitant QT-prolonging drugs. Use with caution in patients with heart disease or taking other QT-prolonging agents. ♦ Hypoglycemia: Can cause severe hypoglycemia, including loss of consciousness. Monitor blood glucose, especially in diabetic patients. ♦ Neuropsychiatric Effects: Can cause nervousness, irritability, psychosis, and suicidal thoughts. ♦ Hematologic Effects: Rare reports of bone marrow suppression (anemia, leukopenia, thrombocytopenia). Monitor blood counts periodically. ♦ Myopathy/Neuropathy: Can cause skeletal muscle weakness or peripheral neuropathy. ♦ Psoriasis/Porphyria: Can exacerbate these conditions. ♦ Children: Children are particularly sensitive to the toxic effects; use with extreme caution.
Missed Dose Instructions	For chronic autoimmune conditions, if a dose of Hydroxychloroquine is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining therapeutic effects.
Overdose Instructions	Overdose is highly dangerous and can be rapidly fatal, particularly in children. Symptoms include headache, dizziness, drowsiness, visual disturbances, cardiovascular collapse, cardiac arrhythmias (especially QT prolongation, ventricular fibrillation), and seizures. Treatment is supportive and symptomatic. Gastric decontamination (e.g., activated charcoal) should be initiated immediately if recent. Correct electrolyte abnormalities. Antidysrhythmics (e.g., diazepam for seizures) and vasopressors may be needed. Continuous cardiac monitoring is essential. Seek immediate emergency medical help.
Medicine Interactions	♦ Digoxin: Hydroxychloroquine can increase plasma digoxin levels. Monitor digoxin levels. ♦ Insulin/Oral Hypoglycemic Agents: Can potentiate the hypoglycemic effect of these drugs, increasing the risk of hypoglycemia. Monitor blood glucose. ♦ Drugs Known to Prolong QT Interval (e.g., amiodarone, tricyclic antidepressants, certain antipsychotics): Increased risk of ventricular arrhythmias. Use with caution. ♦ Methotrexate: Increased risk of hepatotoxicity. ♦ Cyclosporine: May increase cyclosporine levels. ♦ Antacids (containing aluminum or magnesium): Can reduce the absorption of hydroxychloroquine. Administer hydroxychloroquine at least 4 hours before or after antacids. ♦ Mefloquine: Increased risk of seizures. ♦ Amiodarone: Increased risk of cardiac arrhythmias. ♦ Vaccines: Can reduce the antibody response to some vaccines.

Ibandronate (Boniva)

Purpose/Indication	Ibandronate is a bisphosphonate medication used to prevent and treat osteoporosis in postmenopausal women. It helps to increase bone mineral density and reduce the risk of vertebral (spine) fractures. It is also used to treat hypercalcemia of malignancy (high blood calcium due to cancer) and bone metastases in certain cancers, which helps to reduce skeletal-related events.
Method of Action	Ibandronate works by selectively binding to bone mineral, particularly at sites of active bone remodeling. It is then internalized by osteoclasts (cells responsible for bone resorption). Once inside, it inhibits the activity of farnesyl pyrophosphate synthase, an enzyme critical for osteoclast function and survival. This leads to a decrease in osteoclast activity, thereby inhibiting bone resorption and promoting a net increase in bone mass.

MEDICATION
Medication
H - M - H - M - H - M -

Medication Name & Brand Names	♦ Medication Name: Ibandronate Sodium ♦ Brand Names: Boniva (oral and IV), Ibandronate (generic)
Pharmaceutical Forms & Appearance	Ibandronate is available as oral tablets and solution for intravenous (IV) injection. Oral tablets are typically white, oval-shaped, and film-coated. The IV solution is clear and colorless.
Dosage & Administration	For osteoporosis, the usual oral dose is 150 mg once a month, taken on the same day each month, or 2.5 mg once daily. For IV administration for osteoporosis, it's 3 mg every 3 months. For oncology indications, IV dosing varies. Oral tablets must be taken with a full glass of plain water (not mineral water or other beverages) at least 60 minutes before the first food, drink, or other medication of the day. Patients must remain upright for at least 60 minutes after taking the oral dose to minimize esophageal irritation.
Supplied As	Ibandronate is supplied as: oral film-coated tablets (e.g., 2.5 mg, 150 mg) and pre-filled syringes for intravenous injection (e.g., 3 mg/3 mL).
Contraindications	Ibandronate is contraindicated in patients with known hypersensitivity to ibandronate or any component of the formulation. Oral forms are contraindicated in patients with uncorrected hypocalcemia, abnormalities of the esophagus that delay esophageal emptying (e.g., stricture, achalasia), and inability to stand or sit upright for at least 60 minutes.
Storage & Expiry	Ibandronate tablets and IV solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., dyspepsia, esophagitis, abdominal pain, diarrhea), musculoskeletal pain, and headache. More serious but less common side effects include esophageal reactions (ulcers, erosions), osteonecrosis of the jaw (ONJ), atypical femoral fractures, severe bone/joint/muscle pain, and ocular inflammation.
Warnings & Precautions	♦ Esophageal Reactions (Oral Forms): Can cause esophageal irritation, ulceration, or erosion, rarely leading to bleeding or stricture. Follow administration instructions precisely (full glass of water, upright for 60 mins, nothing else by mouth). Discontinue if esophageal symptoms worsen. ♦ Osteonecrosis of the Jaw (ONJ): Rare but serious risk, particularly with IV bisphosphonates, higher doses, cancer, dental procedures, or poor oral hygiene. Dental examination before starting therapy is recommended. Avoid invasive dental procedures during treatment if possible. ♦ Atypical Femur Fractures: Rare but serious risk of unusual fractures in the femur with long-term bisphosphonate use. Evaluate new thigh/groin pain. ♦ Musculoskeletal Pain: Severe and occasionally incapacitating bone, joint, and/or muscle pain has been reported. Discontinue if symptoms occur. ♦ Hypocalcemia: Must correct pre-existing hypocalcemia and other mineral and bone metabolism disturbances before initiating therapy. Ensure adequate intake of calcium and Vitamin D. ♦ Renal Impairment: Not recommended for patients with severe renal impairment (creatinine clearance < 30 mL/min). ♦ Asthma Exacerbation: May exacerbate asthma in aspirin-sensitive patients.
Missed Dose Instructions	♦ Monthly Oral Dose: If the monthly dose is missed and the next scheduled dose is more than 7 days away, take one 150 mg tablet the morning after it is remembered. Then return to the original monthly schedule. If the next scheduled dose is within 7 days, skip the missed dose and wait until the next regularly scheduled dose. Do not take two 150 mg tablets in the same week. ♦ Daily Oral Dose: If a daily dose is missed, skip it and resume the usual schedule the next morning. Do not take a double dose.
Overdose Instructions	Oral overdose can result in hypocalcemia, hypophosphatemia, and upper gastrointestinal adverse events such as upset stomach, dyspepsia, esophagitis, gastritis, or ulcer. Milk or antacids may be given to bind ibandronate. Emesis should not be induced, and the patient should remain fully upright. IV overdose may lead to hypocalcemia and hypophosphatemia. Treatment is supportive. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Calcium-Containing Products, Antacids, Iron, Magnesium, Other Oral Medications: Significantly interfere with the absorption of oral ibandronate. Do not take any other oral medications, including vitamins, calcium, or antacids, for at least 60 minutes after taking ibandronate. ♦ Aspirin/NSAIDs: Increased risk of upper gastrointestinal adverse events with concurrent use, especially with oral bisphosphonates. ♦ Proton Pump Inhibitors (PPIs) / H2-Blockers: Chronic use may potentially contribute to ONJ or reduce the efficacy of bisphosphonates, although specific interactions with ibandronate are not well-established. ♦ Thalidomide: May increase risk of ONJ in multiple myeloma patients when combined with bisphosphonates.

Ibandronate (Boniva)

Ibuprofen (Advil)

Purpose/Indication	Ibuprofen is a non-steroidal anti-inflammatory drug (NSAID) widely used to relieve mild to moderate pain, reduce fever, and alleviate inflammation. It is indicated for conditions such as headache, dental pain, menstrual pain (dysmenorrhea), muscle aches, arthritis (rheumatoid arthritis, osteoarthritis), and to reduce fever associated with common colds or flu.
Method of Action	Ibuprofen works by reversibly inhibiting cyclooxygenase (COX) enzymes, specifically both COX-1 and COX-2. These enzymes are responsible for the synthesis of prostaglandins, which are lipid compounds that play a crucial role in mediating pain, inflammation, and fever. By blocking prostaglandin production, ibuprofen reduces inflammatory responses, thereby decreasing pain, swelling, and redness, and lowering body temperature.
Medication Name & Brand Names	♦ Medication Name: Ibuprofen ♦ Brand Names: Advil, Motrin, Nurofen, Brufen, Ibuprofen (generic)
Pharmaceutical Forms & Appearance	Ibuprofen is available in various oral forms (tablets, capsules, chewable tablets, oral suspension, oral drops) and topical forms (creams, gels). Oral tablets/capsules vary in color, shape, and size, often with specific imprints. Oral liquids are typically flavored suspensions or syrups. Topical preparations are usually clear or white.
Dosage & Administration	Dosage varies by age, indication, and formulation. For adults and children 12 years and older, common oral doses for pain/fever are 200 mg to 400 mg every 4-6 hours as needed, with a maximum daily dose typically 1200 mg (OTC) to 3200 mg (prescription). For children, dosing is based on weight. It should be taken with food, milk, or a full glass of water to minimize gastrointestinal upset. Use the lowest effective dose for the shortest duration.
Supplied As	Ibuprofen is supplied as: oral tablets (e.g., 200 mg, 400 mg, 600 mg, 800 mg), oral capsules/softgels (e.g., 200 mg), chewable tablets (e.g., 100 mg), oral suspension/syrup (e.g., 100 mg/5 mL), oral drops (e.g., 50 mg/1.25 mL), and topical creams/gels (e.g., 5%, 10%).
Contraindications	Ibuprofen is contraindicated in patients with a known hypersensitivity (e.g., allergic reactions, asthma, urticaria, rhinitis) to ibuprofen, aspirin, or other NSAIDs. It is also contraindicated in the setting of coronary artery bypass graft (CABG) surgery, and in patients with active gastrointestinal bleeding or peptic ulcer disease. Severe heart failure and severe renal/hepatic impairment are also contraindications.

Storage & Expiry	Ibuprofen products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in tightly closed containers. Oral suspensions should be shaken well before use. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., nausea, dyspepsia, abdominal pain, diarrhea, heartburn), headache, and dizziness. More serious and potentially life-threatening side effects can include cardiovascular thrombotic events (e.g., heart attack, stroke), gastrointestinal bleeding, ulceration, or perforation, kidney dysfunction, liver injury, and serious skin reactions (e.g., Stevens-Johnson syndrome).
Warnings & Precautions	♦ Cardiovascular Risk: NSAIDs, including ibuprofen, can increase the risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may increase with duration of use. Contraindicated for pain after CABG surgery. ♦ Gastrointestinal Risk: Can cause serious gastrointestinal adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. Risk is higher in elderly patients, those with a history of GI bleeding, or concomitant use of other agents. ♦ Renal Effects: Can cause new onset or worsening of renal impairment, especially in dehydrated patients, those with pre-existing kidney disease, heart failure, or concurrent use of diuretics/ACE inhibitors. ♦ Hypertension: Can cause new onset hypertension or worsen pre-existing hypertension. ♦ Hepatic Effects: Liver injury, including severe and fatal cases, can occur. Monitor liver function tests. ♦ Skin Reactions: Serious skin reactions can occur. Discontinue at first appearance of rash. ♦ Asthma Exacerbation: Use with caution in patients with asthma, especially aspirin-sensitive asthma. ♦ Fluid Retention/Edema: Use with caution in patients with heart failure or hypertension. ♦ Pregnancy: Avoid use in late pregnancy (third trimester) due to risk of premature closure of the fetal ductus arteriosus and kidney dysfunction. ♦ Bleeding Risk: May inhibit platelet aggregation; use with caution in bleeding disorders or with anticoagulants.
Missed Dose Instructions	Ibuprofen is often taken as needed for pain or fever. If a dose is missed, take it when remembered if symptoms warrant, adhering to the recommended dosing interval (e.g., not sooner than 4-6 hours from the last dose). However, if it's almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose.
Overdose Instructions	Overdose symptoms vary but can include nausea, vomiting, epigastric pain, lethargy, drowsiness, dizziness, tinnitus, headache, nystagmus, and gastrointestinal bleeding. In severe cases, acute renal failure, hypotension, respiratory depression, metabolic acidosis, and coma may occur. Treatment is supportive and symptomatic. Gastric decontamination (e.g., activated charcoal) may be considered if oral ingestion was recent and substantial. Hemodialysis is unlikely to be effective due to high protein binding. Seek immediate medical attention.
Medicine Interactions	♦ Anticoagulants (e.g., warfarin): Increased risk of bleeding; monitor INR closely. ♦ Antiplatelet agents (e.g., aspirin, clopidogrel): Increased risk of bleeding, especially GI bleeding. Avoid concomitant regular aspirin use for anti-inflammatory effects. ♦ Other NSAIDs/Corticosteroids: Increased risk of GI adverse events. ♦ ACE Inhibitors/ARBs/Diuretics: May reduce the antihypertensive and diuretic effects, and increase the risk of renal impairment, especially in elderly or dehydrated patients. ♦ Lithium: May increase serum lithium concentrations and toxicity; monitor lithium levels. ♦ Methotrexate: May increase methotrexate toxicity. ♦ Cyclosporine/Tacrolimus: Increased risk of nephrotoxicity. ♦ Digoxin: May increase digoxin levels. ♦ SSRIs: Increased risk of GI bleeding. ♦ Alcohol: Increased risk of GI bleeding and liver damage.

Imiquimod (Aldara)

Purpose/Indication	Imiquimod is a topical immune response modifier used to treat various dermatological conditions. It is indicated for the treatment of external genital and perianal warts (condyloma acuminata), actinic keratosis (AK) on the face and scalp, and superficial basal cell carcinoma (sBCC) in adults. It works by stimulating the body's immune system to clear the abnormal cells or viral infections.
Method of Action	Imiquimod acts as a toll-like receptor 7 (TLR7) agonist. When applied topically, it stimulates immune cells (such as macrophages, dendritic cells, and monocytes) to release various cytokines, including interferon-alpha (IFN-a), tumor necrosis factor-a (TNF-a), and interleukins (e.g., IL-1, IL-6, IL-8, IL-12). These cytokines enhance the local cellular immune response, leading to the destruction of virally infected cells (warts) or cancerous cells (AK, sBCC).
Medication Name & Brand Names	♦ Medication Name: Imiquimod ♦ Brand Names: Aldara, Zyclara, Imiquimod (generic)
Pharmaceutical Forms & Appearance	Imiquimod is available as a topical cream. It is typically a white to slightly yellow cream. It is supplied in single-use sachets (small packets) to ensure hygienic application and proper dosing.
Dosage & Administration	Dosage and application frequency vary significantly by indication. For external genital/perianal warts, it's typically applied 3 times per week at bedtime and left on for 6-10 hours, then washed off. For actinic keratosis, it's usually applied 2 times per week for 16 weeks. For superficial basal cell carcinoma, it's applied 5 times per week for 6 weeks. Always apply a thin layer to the affected area only, avoiding healthy skin. Wash hands before and after application.
Supplied As	Imiquimod is supplied as: 5% cream in single-use packets (e.g., Aldara) and 3.75% cream in a pump dispenser (e.g., Zyclara).
Contraindications	Imiquimod is contraindicated in patients with known hypersensitivity to imiquimod or any component of the formulation. It is not for ophthalmic, oral, or intravaginal use.
Storage & Expiry	Imiquimod cream should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Do not freeze. Store in tightly closed containers or the original sachets. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are local skin reactions at the application site, including erythema (redness), erosion, flaking, scabbing, swelling, itching, and burning. These reactions are expected as part of the immune response. Systemic side effects are less common but can include headache, fatigue, flu-like symptoms (e.g., fever, body aches), and nausea.
Warnings & Precautions	♦ Local Skin Reactions: Severe local skin reactions (e.g., intense redness, erosions, ulcerations, weeping) are common and expected, but can be severe. Temporary discontinuation may be necessary. Inform patients about these expected reactions. ♦ Systemic Reactions: Flu-like symptoms (fever, fatigue, body aches) can occur, especially with extensive application or during the first few weeks of treatment. ♦ Immunosuppression: Use with caution in immunocompromised patients due to limited data. ♦ Sun Exposure: Advise patients to avoid or minimize sun exposure, as imiquimod may increase sensitivity to sunburn. ♦ Avoid Mucous Membranes/Open Wounds: Not for internal use. Avoid contact with eyes, mouth, or other mucous membranes. Do not apply to broken or open skin until healed. ♦ Sexual Activity: Not a cure for warts and does not prevent transmission. Avoid sexual contact while the cream is on the skin. ♦ Children: Safety and effectiveness not established for all indications in pediatric populations; use with caution.
Missed Dose Instructions	If a dose of Imiquimod is missed, apply it as soon as remembered. However, do not apply a double dose to make up for the missed one. Continue with the regular application schedule. Consistent application as prescribed is important for achieving optimal results.

Overdose Instructions	Topical overdose is unlikely to cause serious systemic effects due to minimal percutaneous absorption. However, application of excessive amounts or application over large areas could potentially lead to increased local skin reactions and/or systemic effects like fever, fatigue, or flu-like symptoms. Treatment is symptomatic and supportive. Discontinue use. Accidental oral ingestion of a sachet or two is unlikely to be harmful but may cause nausea or vomiting; larger ingestions should be reported to a poison control center. Seek medical advice if an overdose is suspected or severe symptoms occur.
Medicine Interactions	♦ No significant drug interactions are commonly reported with topical imiquimod due to its minimal systemic absorption. ♦ Theoretically, its immune-stimulating effects could interact with systemic immunosuppressants, but this is not well-established clinically with topical use.

Indomethacin (Indocin)

Purpose/Indication	Indomethacin is a potent non-steroidal anti-inflammatory drug (NSAID) used to relieve moderate to severe pain, inflammation, and stiffness. It is primarily indicated for conditions such as rheumatoid arthritis, osteoarthritis, ankylosing spondylitis, acute painful shoulder (bursitis/tendinitis), and acute gouty arthritis. It is also used to close a patent ductus arteriosus (PDA) in premature infants.
Method of Action	Indomethacin works by potently inhibiting cyclooxygenase (COX) enzymes, both COX-1 and COX-2. By blocking these enzymes, it prevents the synthesis of prostaglandins, which are key mediators of pain, inflammation, and fever. Its strong anti-inflammatory properties contribute to its effectiveness in various inflammatory and pain conditions.
Medication Name & Brand Names	♦ Medication Name: Indomethacin ♦ Brand Names: Indocin (capsules, suspension, suppository), Tivorbex (capsules), Indomethacin (generic)
Pharmaceutical Forms & Appearance	Indomethacin is available as oral capsules (immediate and extended-release), oral suspension, rectal suppositories, and solution for intravenous (IV) injection. Oral capsules are typically blue and white, or clear and white, varying in size. The oral suspension is usually a clear to light yellow liquid. Rectal suppositories are whitish, torpedo-shaped. The IV solution is clear and colorless.
Dosage & Administration	Dosage varies by indication, severity of condition, and patient response. For inflammatory arthritis, typical oral doses range from 25 mg to 50 mg two to three times daily, with a maximum generally 200 mg per day. For acute gout, higher initial doses may be used. It should be taken immediately after meals or with food, or with antacids, to minimize gastrointestinal upset. Rectal suppositories can be used when oral administration is not feasible.
Supplied As	Indomethacin is supplied as: oral capsules (e.g., 25 mg, 50 mg), extended-release oral capsules (e.g., 75 mg), oral suspension (e.g., 25 mg/5 mL), rectal suppositories (e.g., 50 mg), and powder for solution for intravenous injection (e.g., 1 mg vial).
Contraindications	Indomethacin is contraindicated in patients with a known hypersensitivity (e.g., allergic reactions, asthma, urticaria) to indomethacin, aspirin, or other NSAIDs. It is also contraindicated in the setting of coronary artery bypass graft (CABG) surgery, in patients with active gastrointestinal bleeding or peptic ulcer disease, severe renal impairment, or severe heart failure. Rectal suppositories are contraindicated in patients with active proctitis or recent rectal bleeding.
Storage & Expiry	Indomethacin oral forms and suppositories should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. The oral suspension should be shaken well before use. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., nausea, dyspepsia, abdominal pain, diarrhea), headache, dizziness, and somnolence. More serious and potentially life-threatening side effects can include severe gastrointestinal bleeding, ulceration, or perforation, cardiovascular thrombotic events (e.g., heart attack, stroke), kidney dysfunction, liver injury, severe skin reactions, and central nervous system effects (e.g., confusion, psychosis, seizures).
Warnings & Precautions	♦ Cardiovascular Risk: NSAIDs, including indomethacin, can increase the risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may increase with duration of use. ♦ Gastrointestinal Risk: Can cause serious gastrointestinal adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. Risk is higher in elderly patients, those with a history of GI bleeding, or concomitant use of other agents. ♦ Renal Effects: Can cause new onset or worsening of renal impairment, especially in dehydrated patients, those with pre-existing kidney disease, heart failure, or concurrent use of diuretics/ACE inhibitors. ♦ CNS Effects: Can cause significant CNS side effects such as headache, dizziness, vertigo, and confusion. Use with caution in patients with psychiatric history, epilepsy, or Parkinson's disease. ♦ Hypertension: Can cause new onset hypertension or worsen pre-existing hypertension. ♦ Hepatic Effects: Liver injury, including severe and fatal cases, can occur. Monitor liver function tests. ♦ Skin Reactions: Serious skin reactions can occur. Discontinue at first appearance of rash. ♦ Asthma Exacerbation: Use with caution in patients with asthma, especially aspirin-sensitive asthma. ♦ Fluid Retention/Edema: Use with caution in patients with heart failure or hypertension. ♦ Pregnancy: Avoid use in late pregnancy (third trimester) due to risk of premature closure of the fetal ductus arteriosus and kidney dysfunction. ♦ Bleeding Risk: May inhibit platelet aggregation; use with caution in bleeding disorders or with anticoagulants. ♦ Hyperkalemia: Can cause hyperkalemia, especially in patients with diabetes or renal insufficiency
Missed Dose Instructions	If a dose of Indomethacin is missed, take it as soon as remembered if symptoms warrant, adhering to the recommended dosing interval (e.g., not too close to the next scheduled dose). However, if it's almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent dosing is important for chronic conditions like arthritis.
Overdose Instructions	Overdose symptoms can include nausea, vomiting, epigastric pain, lethargy, drowsiness, dizziness, tinnitus, headache, nystagmus, and gastrointestinal bleeding. In severe cases, acute renal failure, hypotension, respiratory depression, metabolic acidosis, and coma may occur. Treatment is supportive and symptomatic. Gastric decontamination (e.g., activated charcoal) may be considered if oral ingestion was recent and substantial. Hemodialysis is unlikely to be effective due to high protein binding. Seek immediate medical attention.
Medicine Interactions	♦ Anticoagulants (e.g., warfarin): Increased risk of bleeding; monitor INR closely. ♦ Antiplatelet agents (e.g., aspirin, clopidogrel): Increased risk of bleeding, especially GI bleeding. Avoid concomitant regular aspirin use for anti-inflammatory effects. ♦ Other NSAIDs/Corticosteroids: Increased risk of GI adverse events. ♦ ACE Inhibitors/ARBs/Diuretics (especially furosemide, thiazides): May reduce the antihypertensive and diuretic effects, and significantly increase the risk of renal impairment, especially in elderly or dehydrated patients. ♦ Lithium: Potent inhibition of lithium excretion, leading to significantly increased serum lithium concentrations and toxicity. Monitor lithium levels extremely closely. ♦ Methotrexate: May increase methotrexate toxicity. ♦ Cyclosporine/Tacrolimus: Increased risk of nephrotoxicity. ♦ Digoxin: May increase digoxin levels. ♦ Beta-Blockers: May reduce the antihypertensive effect of beta-blockers. ♦ Potassium-Sparing Diuretics: Increased risk of hyperkalemia. ♦ SSRIs: Increased risk of GI bleeding. ♦ Alcohol: Increased risk of GI bleeding and CNS effects.

Insulin Glargine (Lantus)

Purpose/Indication	Insulin glargine is a long-acting recombinant human insulin analog used to improve glycemic control in adults and children with type 1 diabetes mellitus and adults with type 2 diabetes mellitus. It provides a constant, peakless basal insulin level over 24 hours, helping to maintain blood glucose levels between meals and overnight. It is typically used once daily in conjunction with rapid-acting insulin at meal times (for type 1) or other oral antidiabetic agents (for type 2).

Method of Action	Insulin glargine is designed for prolonged action and a smooth concentration/time profile without a pronounced peak. After subcutaneous injection, its low solubility at physiological pH (compared to regular insulin) causes it to precipitate, forming micro-precipitates in the subcutaneous tissue. From these micro-precipitates, small amounts of insulin glargine are slowly and continuously released into the bloodstream over approximately 24 hours, providing a consistent basal insulin supply to regulate glucose metabolism.
Medication Name & Brand Names	♦ Medication Name: Insulin Glargine ♦ Brand Names: Lantus, Toujeo, Basaglar, Semglee
Pharmaceutical Forms & Appearance	Insulin glargine is a sterile, clear, colorless solution for subcutaneous injection. It is supplied in vials, cartridges (for reusable pens), and pre-filled pens.
Dosage & Administration	Dosage is highly individualized and determined by a healthcare professional based on the patient's blood glucose levels, lifestyle, and other medications. It is typically administered once daily at the same time each day (e.g., bedtime or morning). It is given by subcutaneous injection into the abdominal wall, thigh, or deltoid. Injection sites should be rotated within the same region. It must never be mixed with other insulins or solutions, and should not be administered intravenously or intramuscularly.
Supplied As	Insulin glargine is supplied as: 100 units/mL (U-100) in 10 mL vials, 3 mL cartridges (for reusable pens), and 3 mL pre-filled pens (e.g., SoloStar, KwikPen). A more concentrated form, 300 units/mL (U-300), is also available (e.g., Toujeo).
Contraindications	Insulin glargine is contraindicated during episodes of hypoglycemia. It is also contraindicated in patients with known hypersensitivity to insulin glargine or any component of the formulation.
Storage & Expiry	Unopened insulin glargine vials, cartridges, and pens should be stored in a refrigerator (2°C to 8°C or 36°F to 46°F), protected from light and direct heat. Do not freeze. Once opened or in-use, it can be stored at room temperature (below 30°C or 86°F) for a specific duration (e.g., 28-56 days, check specific product leaflet), protected from direct heat and light. Always check the specific expiry date on the packaging.
Side Effects	The most common and significant side effect is hypoglycemia (low blood sugar). Other common side effects include injection site reactions (e.g., pain, redness, itching, swelling), lipodystrophy (fat accumulation or atrophy at injection site with improper rotation), weight gain, and peripheral edema. Serious but rare side effects include severe allergic reactions and hypokalemia.
Warnings & Precautions	♦ Hypoglycemia: The most common and serious adverse effect. Patients must be educated on symptoms, management, and prevention of hypoglycemia. Risk is increased with too much insulin, missed meals, increased exercise, or concurrent use of certain medications. ♦ Hypersensitivity Reactions: Severe, life-threatening, generalized allergy, including anaphylaxis, can occur. ♦ Injection Site Reactions/Lipodystrophy: Proper rotation of injection sites is crucial to prevent and manage lipodystrophy. ♦ Never Share Pens: Insulin pens are for single-patient use only. Sharing pens can lead to transmission of blood-borne pathogens. ♦ Medication Errors: Check insulin label carefully before administration to avoid mix-ups with other insulins. Do not dilute or mix with other insulins. ♦ Fluid Retention/Heart Failure: Thiazolidinediones (TZDs) in combination with insulin may cause dose-related fluid retention, potentially exacerbating or leading to heart failure. ♦ Hypokalemia: Insulin can cause a shift of potassium into cells, potentially leading to hypokalemia. Monitor potassium in at-risk patients. ♦ Renal/Hepatic Impairment: Insulin requirements may be altered in patients with renal or hepatic impairment.
Missed Dose Instructions	If a dose of Insulin Glargine is missed, it should be taken as soon as remembered. However, if it's close to the time for the next scheduled dose, patients should consult their healthcare provider for guidance. Do not take a double dose to compensate for a missed one, as this increases the risk of hypoglycemia. Consistent daily administration at the same time is key for maintaining steady basal insulin levels.
Overdose Instructions	Overdose primarily leads to severe and prolonged hypoglycemia. Symptoms can range from mild (tremor, sweating, hunger, nervousness, confusion) to severe (seizures, coma, brain damage, death). Treatment involves immediate administration of glucose (oral glucose for conscious patients, IV dextrose for unconscious patients). Hospitalization and prolonged monitoring are necessary due to the long duration of action of insulin glargine. Glucagon may be administered. Seek immediate emergency medical help.
Medicine Interactions	♦ Drugs that May Increase Hypoglycemic Effect (Increased Hypoglycemia Risk): Oral antidiabetic agents, ACE inhibitors, angiotensin receptor blockers (ARBs), disopyramide, fibrates, fluoxetine, MAO inhibitors, pentoxifylline, pramlintide, propoxyphene, salicylates, somatostatin analogs (e.g., octreotide), sulfonamide antibiotics. ♦ Drugs that May Decrease Hypoglycemic Effect (Increased Hyperglycemia Risk): Corticosteroids, niacin, diuretics (especially thiazides, loop diuretics), sympathomimetics (e.g., albuterol, epinephrine, terbutaline), thyroid hormones, atypical antipsychotics (e.g., olanzapine, clozapine), protease inhibitors. ♦ Beta-Blockers (non-selective): Can mask symptoms of hypoglycemia (e.g., tremor, tachycardia) and delay recovery from hypoglycemia. ♦ Alcohol: Can potentiate the hypoglycemic effect of insulin. ♦ Pioglitazone/Rosiglitazone (TZDs): Increased risk of fluid retention and heart failure when combined with insulin.

Insulin (Lispro, Regular) (Humalog)

Purpose/Indication	Insulin Lispro is a rapid-acting human insulin analog used to improve glycemic control in adults and children with type 1 and type 2 diabetes mellitus. It is primarily taken immediately before or after a meal to control the post-meal rise in blood glucose and can also be used for correction of high blood sugar between meals. Its quick onset and short duration of action make it suitable for a flexible dosing regimen.
Method of Action	Insulin Lispro is a genetically engineered form of human insulin where two amino acids (proline and lysine) have been inverted, preventing its aggregation into hexamers upon injection. This structural change allows it to be rapidly absorbed from the subcutaneous injection site into the bloodstream. Once in circulation, it binds to insulin receptors on cells, facilitating glucose uptake into tissues (muscle, adipose), suppressing hepatic glucose production, and promoting the conversion of glucose to glycogen, thereby lowering blood glucose levels. Its action typically begins within 15-30 minutes, peaks in 30-90 minutes, and lasts 3-5 hours.
Medication Name & Brand Names	♦ Medication Name: Insulin Lispro ♦ Brand Names: Humalog, Admelog, Lyumjev (ultra rapid-acting)
Pharmaceutical Forms & Appearance	Insulin Lispro is a clear, colorless solution for subcutaneous injection. It is supplied in vials, cartridges (for reusable pens), and pre-filled pens. Lyumjev, an ultra rapid-acting formulation, is also a clear, colorless solution.
Dosage & Administration	Dosage is highly individualized and determined by a healthcare professional based on blood glucose levels, carbohydrate intake, and activity. It is typically administered by subcutaneous injection within 15 minutes before a meal or immediately after a meal. For Lyumjev, it can be taken at the start of a meal or up to 20 minutes after starting a meal. Injection sites should be rotated within the same region (abdomen, thigh, deltoid, or buttock). It can be used in insulin pumps.
Supplied As	Insulin Lispro is supplied as: 100 units/mL (U-100) in 10 mL vials, 3 mL cartridges (e.g., KwikPens, Junior KwikPens for reusable pens), and 3 mL pre-filled pens. Lyumjev is available as 100 units/mL and 200 units/mL.

MEDICATION

List

H - M

Insulin (Lispro, Regular) (Humalog)

Contraindications	Insulin Lispro is contraindicated during episodes of hypoglycemia. It is also contraindicated in patients with known hypersensitivity to insulin lispro or any component of the formulation.
Storage & Expiry	Unopened insulin lispro vials, cartridges, and pens should be stored in a refrigerator (2°C to 8°C or 36°F to 46°F), protected from light and direct heat. Do not freeze. Once opened or in-use, it can be stored at room temperature (below 30°C or 86°F) for a specific duration (e.g., 28 days for Humalog, check specific product leaflet). Always check the specific expiry date on the packaging.
Side Effects	The most common and significant side effect is hypoglycemia (low blood sugar). Other common side effects include injection site reactions (e.g., pain, redness, itching, swelling), lipodystrophy (fat accumulation or atrophy at injection site with improper rotation), weight gain, and peripheral edema. Serious but rare side effects include severe allergic reactions and hypokalemia.
Warnings & Precautions	♦ Hypoglycemia: The most common and serious adverse effect. Patients must be educated on symptoms, management, and prevention of hypoglycemia. Risk is increased with too much insulin, delayed/missed meals after injection, increased exercise, or concurrent use of certain medications. ♦ Hypersensitivity Reactions: Severe, life-threatening, generalized allergy, including anaphylaxis, can occur. ♦ Injection Site Reactions/Lipodystrophy: Proper rotation of injection sites is crucial to prevent and manage lipodystrophy. ♦ Never Share Pens: Insulin pens are for single-patient use only. Sharing pens can lead to transmission of blood-borne pathogens. ♦ Medication Errors: Check insulin label carefully before administration to avoid mix-ups with other insulins. Do not dilute or mix with other insulins in pump reservoirs. ♦ Fluid Retention/Heart Failure: Thiazolidinediones (TZDs) in combination with insulin may cause dose-related fluid retention, potentially exacerbating or leading to heart failure. ♦ Hypokalemia: Insulin can cause a shift of potassium into cells, potentially leading to hypokalemia. Monitor potassium in at-risk patients.
Missed Dose Instructions	Since Insulin Lispro is typically dosed around meals, if a pre-meal dose is missed or a patient forgets to eat after taking it, they should monitor their blood sugar and consider taking the dose immediately after eating, or correct hyperglycemia later, under guidance from their healthcare provider. Due to its rapid action, delayed administration significantly reduces its meal-time effect. Do not double a dose.
Overdose Instructions	Overdose primarily leads to severe and prolonged hypoglycemia. Symptoms can range from mild (tremor, sweating, hunger, nervousness, confusion) to severe (seizures, coma, brain damage, death). Treatment involves immediate administration of glucose (oral glucose for conscious patients, IV dextrose for unconscious patients). Glucagon may be administered. Hospitalization and monitoring may be necessary depending on the severity. Seek immediate emergency medical help.
Medicine Interactions	♦ Drugs that May Increase Hypoglycemic Effect (Increased Hypoglycemia Risk): Oral antidiabetic agents, ACE inhibitors, angiotensin receptor blockers (ARBs), disopyramide, fibrates, fluoxetine, MAO inhibitors, pentoxifylline, pramlintide, propoxyphene, salicylates, somatostatin analogs (e.g., octreotide), sulfonamide antibiotics. ♦ Drugs that May Decrease Hypoglycemic Effect (Increased Hyperglycemia Risk): Corticosteroids, niacin, diuretics (especially thiazides, loop diuretics), sympathomimetics (e.g., albuterol, epinephrine, terbutaline), thyroid hormones, atypical antipsychotics (e.g., olanzapine, clozapine), protease inhibitors. ♦ Beta-Blockers (non-selective): Can mask symptoms of hypoglycemia (e.g., tremor, tachycardia) and delay recovery from hypoglycemia. ♦ Alcohol: Can potentiate the hypoglycemic effect of insulin. ♦ Pioglitazone/Rosiglitazone (TZDs): Increased risk of fluid retention and heart failure when combined with insulin.

Irbesartan (Avapro)

Purpose/Indication	Irbesartan is an angiotensin II receptor blocker (ARB) used to treat hypertension (high blood pressure) and to protect the kidneys in patients with type 2 diabetes and nephropathy (kidney disease) who also have hypertension. By effectively lowering blood pressure, it reduces the risk of cardiovascular events like stroke and heart attack. In diabetic nephropathy, it helps slow the progression of kidney disease.
Method of Action	Irbesartan selectively blocks the binding of angiotensin II to the AT1 (angiotensin II type 1) receptors found in various tissues, including vascular smooth muscle and the adrenal glands. Angiotensin II is a potent vasoconstrictor and a key component of the renin-angiotensin-aldosterone system (RAAS), which plays a central role in blood pressure regulation and fluid balance. By blocking AT1 receptors, irbesartan inhibits the vasoconstrictive and aldosterone-secreting effects of angiotensin II, leading to vasodilation, reduced systemic vascular resistance, and decreased sodium and water retention, all of which contribute to lowering blood pressure.
Medication Name & Brand Names	♦ Medication Name: Irbesartan ♦ Brand Names: Avapro, Aprovel (regional), Irbesartan (generic) (Often found in combination with hydrochlorothiazide: Avalide, Co-Aprovel)
Pharmaceutical Forms & Appearance	Irbesartan is available as oral tablets. Tablets are typically white or off-white, often oval-shaped, and may be scored, with various imprints indicating strength.
Dosage & Administration	Dosage is individualized based on blood pressure response. For hypertension, the usual adult starting dose is 150 mg once daily, which can be increased to 300 mg once daily if needed. For diabetic nephropathy, the target maintenance dose is generally 300 mg once daily. It can be taken with or without food. Consistent daily administration is important for optimal blood pressure control.
Supplied As	Irbesartan is supplied as: oral tablets (e.g., 75 mg, 150 mg, 300 mg). It is also commonly available in fixed-dose combination tablets with hydrochlorothiazide.
Contraindications	Irbesartan is contraindicated in patients with known hypersensitivity to irbesartan or any component of the formulation. It is also contraindicated in combination with aliskiren in patients with diabetes or moderate to severe renal impairment (GFR < 60 mL/min/1.73 m2). Use during pregnancy (especially second and third trimesters) is contraindicated due to risk of fetal injury or death.
Storage & Expiry	Irbesartan tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include dizziness, lightheadedness (due to hypotension), headache, and fatigue. Less common but more serious side effects can include hyperkalemia (high potassium levels), kidney dysfunction or failure, angioedema (swelling of face, lips, throat), and rhabdomyolysis (rarely).

Warnings & Precautions	♦ Fetal Toxicity: Can cause fetal harm or death when administered to pregnant women, particularly in the second and third trimesters. Discontinue as soon as pregnancy is detected. ♦ Hypotension: Can cause symptomatic hypotension, especially in volume-depleted patients (e.g., those on high-dose diuretics). Correct volume depletion before initiating therapy. ♦ Renal Impairment/Deterioration: Can cause changes in renal function, including acute renal failure, particularly in patients with severe congestive heart failure, pre-existing renal disease, or renal artery stenosis. Monitor renal function periodically. ♦ Hyperkalemia: Risk of hyperkalemia, especially in patients with renal impairment, diabetes, or those concurrently taking potassium-sparing diuretics, potassium supplements, or other drugs that increase potassium. Monitor serum potassium levels. ♦ Angioedema: Rare but potentially life-threatening swelling of the face, lips, tongue, and throat. Discontinue immediately if symptoms occur. ♦ Dual RAAS Blockade: Concomitant use of ARBs, ACE inhibitors, or aliskiren (especially in diabetes or renal impairment) increases the risk of hypotension, hyperkalemia, and renal dysfunction; generally avoid.
Missed Dose Instructions	If a dose of Irbesartan is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining optimal blood pressure control.
Overdose Instructions	Overdose symptoms are primarily related to exaggerated hypotensive effects (dizziness, lightheadedness, syncope) and possibly tachycardia or bradycardia. Treatment is supportive and symptomatic. If ingestion was recent, gastric decontamination (e.g., activated charcoal) may be considered. Intravenous fluids may be administered to correct hypotension. Irbesartan is not removed by hemodialysis. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Potassium-Sparing Diuretics (e.g., spironolactone, triamterene, amiloride), Potassium Supplements, Salt Substitutes (containing potassium): Increased risk of hyperkalemia. Monitor potassium levels closely. ♦ NSAIDs (Non-Steroidal Anti-inflammatory Drugs): Can reduce the antihypertensive effect of irbesartan and increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. Monitor renal function. ♦ Lithium: Irbesartan can increase serum lithium concentrations and toxicity. Monitor lithium levels. ♦ Aliskiren: Concomitant use is contraindicated in patients with diabetes or moderate to severe renal impairment due to increased risk of hyperkalemia, hypotension, and renal impairment. ♦ Dual RAAS Blockade (e.g., with ACE inhibitors): Generally not recommended due to increased risk of adverse events without clear additional benefit.

Isoniazid (Nydrazid)

Purpose/Indication	Isoniazid (INH) is an antibiotic primarily used for the treatment and prevention of tuberculosis (TB). It is a first-line drug for active tuberculosis, typically used in combination with other anti-tuberculosis medications, and is also effective as monotherapy for latent tuberculosis infection (LTBI) to prevent progression to active disease. Its purpose is to kill or inhibit the growth of Mycobacterium tuberculosis.
Method of Action	Isoniazid is a prodrug that is activated by the catalase-peroxidase enzyme (KatG) of Mycobacterium tuberculosis. Once activated, it interferes with mycobacterial cell wall synthesis by inhibiting the synthesis of mycolic acids, which are essential components of the mycobacterial cell wall. This leads to the disruption of the cell wall and eventually cell death, making it bactericidal against rapidly dividing M. tuberculosis and bacteriostatic against slowly growing bacilli.
Medication Name & Brand Names	♦ Medication Name: Isoniazid (INH) ♦ Brand Names: Nydrazid (historical/regional), Isoniazid (generic)
Pharmaceutical Forms & Appearance	Isoniazid is available as oral tablets and oral syrup, and historically as a solution for injection (though parenteral forms are less common now). Tablets are typically white, round, and often scored. The syrup is usually a clear, colorless to light yellow liquid.
Dosage & Administration	Dosage varies for active TB treatment versus LTBI prevention, and by patient age and weight. For active TB, it's typically 5 mg/kg daily (maximum 300 mg) or 15 mg/kg (maximum 900 mg) two to three times weekly, always in combination with other drugs. For LTBI, it's typically 300 mg daily for 6-9 months, or 900 mg once weekly with rifapentine for 12 weeks. It can be taken with or without food, but taking it with food may reduce gastrointestinal upset. Pyridoxine (Vitamin B6) supplementation is often co-administered to prevent peripheral neuropathy.
Supplied As	Isoniazid is supplied as: oral tablets (e.g., 100 mg, 300 mg) and oral syrup (e.g., 50 mg/5 mL).
Contraindications	Isoniazid is contraindicated in patients with known hypersensitivity to isoniazid or any component of the formulation. It is also contraindicated in patients with a history of previous isoniazid-associated liver injury or severe adverse reactions to isoniazid (e.g., drug-induced fever, chills, arthritis).
Storage & Expiry	Isoniazid tablets and syrup should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include elevated liver enzymes (asymptomatic), peripheral neuropathy (tingling, numbness, pain in hands/feet), and gastrointestinal upset (e.g., nausea, vomiting). More serious but less common side effects include severe hepatotoxicity (drug-induced hepatitis, which can be fatal), severe hypersensitivity reactions (e.g., rash, fever), optic neuritis, and blood dyscrasias.
Warnings & Precautions	♦ Hepatotoxicity: The most significant and potentially fatal adverse effect. Risk is increased with age (especially > 35 years), daily alcohol consumption, pre-existing liver disease, and concurrent use of other hepatotoxic drugs. Monitor liver function tests (ALT, AST) periodically, especially in high-risk patients. Patients should be educated on symptoms of liver injury (e.g., fatigue, weakness, loss of appetite, nausea, vomiting, dark urine, jaundice, pale stools) and advised to seek immediate medical attention if they occur. ♦ Peripheral Neuropathy: Common side effect due to interference with pyridoxine metabolism. Risk is higher in malnourished patients, alcoholics, diabetics, HIV-infected individuals, pregnant women, and patients with renal failure. Pyridoxine (Vitamin B6) supplementation is strongly recommended for all patients on isoniazid, especially those at high risk. ♦ CNS Effects: Can cause seizures, optic neuritis, dizziness, and psychosis. ♦ Hypersensitivity Reactions: Discontinue immediately if severe allergic reactions or drug-induced fever, chills, or rash occur. ♦ Alcohol: Concurrent use of alcohol increases the risk of hepatotoxicity. Advise patients to limit or avoid alcohol. ♦ Renal Impairment: Dose adjustment may be needed in severe renal impairment. ♦ Drug Resistance: Adherence to the full course of therapy and combination regimens is critical to prevent the development of drug-resistant M. tuberculosis.
Missed Dose Instructions	Adherence is crucial for the effectiveness of tuberculosis treatment and prevention. If a dose of Isoniazid is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. If multiple doses are missed, inform the healthcare provider, as this may require a re-evaluation of the treatment regimen.
Overdose Instructions	Isoniazid overdose is a medical emergency and can be life-threatening. Symptoms typically appear within 30 minutes to 3 hours and can include nausea, vomiting, dizziness, slurred speech, hyperreflexia, visual hallucinations, and, characteristically, repetitive generalized seizures (often refractory to conventional anticonvulsants) and severe metabolic acidosis. Treatment involves supportive care, gastric decontamination (if recent), and crucially, administration of large doses of pyridoxine (Vitamin B6) intravenously to counteract the neurotoxic effects. Hemodialysis may be used to remove isoniazid and correct acidosis. Seek immediate emergency medical help.

Medicine Interactions	♦ Carbamazepine, Phenytoin, Valproic Acid, Diazepam: Isoniazid can inhibit the metabolism of these drugs, leading to increased plasma concentrations and potential toxicity (e.g., increased CNS side effects, sedation, hepatotoxicity). Monitor drug levels and adjust doses as needed. ♦ Antacids (containing aluminum): Can reduce the absorption of isoniazid. Administer isoniazid at least 1 hour before antacids. ♦ Alcohol: Increased risk of isoniazid-induced hepatotoxicity. ♦ Disulfiram: Concurrent use can lead to central nervous system effects (e.g., ataxia, psychosis). Avoid concomitant use. ♦ Ketoconazole: Concurrent use can decrease ketoconazole concentrations. ♦ Cycloserine: Increased risk of CNS side effects (e.g., dizziness, drowsiness). ♦ Acetaminophen: Increased risk of hepatotoxicity with chronic high acetaminophen doses. ♦ Oral Contraceptives: May decrease efficacy of oral contraceptives (rarely).

Itraconazole (Sporanox)

Purpose/Indication	Itraconazole is an antifungal medication used to treat various systemic and superficial fungal infections. It is indicated for blastomycosis, histoplasmosis, aspergillosis (invasive and non-invasive), and onychomycosis (fungal nail infections) unresponsive to topical agents. It is also used for candidiasis (oral, esophageal, vulvovaginal), tinea infections, and other serious fungal infections where other antifungals are not appropriate.
Method of Action	Itraconazole is a triazole antifungal that works by inhibiting the fungal cytochrome P450-dependent enzyme 14-a-demethylase. This enzyme is crucial for the synthesis of ergosterol, an essential component of the fungal cell membrane. By blocking ergosterol synthesis, itraconazole disrupts the integrity and permeability of the fungal cell membrane, leading to inhibition of fungal growth (fungistatic effect) and eventual cell death.
Medication Name & Brand Names	♦ Medication Name: Itraconazole ♦ Brand Names: Sporanox (capsules, oral solution), Onmel (capsules for onychomycosis), Tolsura (capsules), Itraconazole (generic)
Pharmaceutical Forms & Appearance	Itraconazole is available as oral capsules and oral solution. Capsules are typically blue and white, with various imprints. The oral solution is a clear, yellowish liquid. Different formulations (capsules vs. solution) have different absorption characteristics and should not be interchanged on a milligram-for-milligram basis.
Dosage & Administration	Dosage and duration vary significantly by indication and severity of infection. For systemic infections, typical adult doses range from 100 mg to 400 mg daily. For onychomycosis, pulse dosing (e.g., 200 mg twice daily for one week, then three weeks off, repeated for several cycles) is common. Capsules should be taken immediately after a full meal to maximize absorption. The oral solution should be taken without food, as absorption is enhanced in the fasted state.
Supplied As	Itraconazole is supplied as: oral capsules (e.g., 100 mg), oral solution (e.g., 10 mg/mL).
Contraindications	Itraconazole is contraindicated in patients with known hypersensitivity to itraconazole or any component of the formulation. It is also strictly contraindicated in patients with congestive heart failure (CHF) or a history of CHF, unless the benefits clearly outweigh the risks due to its potential to worsen heart failure. Concurrent use with numerous drugs that are potent CYP3A4 substrates and/or prolong the QT interval is also contraindicated due to serious and potentially fatal interactions (e.g., certain statins, oral midazolam, cisapride, dofetilide, quinidine).
Storage & Expiry	Itraconazole capsules and oral solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. The oral solution should not be frozen. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., nausea, vomiting, abdominal pain, diarrhea), headache, dizziness, and rash. More serious side effects include hepatotoxicity (liver damage, including fatal cases), congestive heart failure, peripheral neuropathy, severe allergic reactions (e.g., Stevens-Johnson syndrome), hypokalemia, and visual disturbances.
Warnings & Precautions	♦ Congestive Heart Failure (CHF): Can cause or exacerbate CHF. Contraindicated in patients with CHF or a history of CHF unless the benefit clearly outweighs the risk. Discontinue if signs/symptoms of CHF develop. ♦ Hepatotoxicity: Can cause severe and potentially fatal liver injury. Monitor liver function tests (ALT, AST) periodically, especially with prolonged use or in patients with pre-existing liver disease. Discontinue if signs of liver disease develop. ♦ Drug Interactions: Extensive metabolism via CYP3A4 makes it prone to numerous significant drug interactions. Many are contraindicated due to risk of serious adverse events (e.g., QT prolongation, rhabdomyolysis). Thoroughly review concomitant medications. ♦ Peripheral Neuropathy: Can cause or worsen peripheral neuropathy. Discontinue if symptoms of neuropathy develop. ♦ Hearing Loss: Transient or permanent hearing loss has been reported. ♦ Hypokalemia: Can cause hypokalemia. ♦ Visual Disturbances: Blurred vision, diplopia, and photophobia may occur. ♦ Absorption Differences: Capsules and oral solution are not bioequivalent; do not interchange without dose adjustment. Capsules require gastric acidity for absorption; oral solution is better absorbed in a fasted state. ♦ Renal/Hepatic Impairment: Use with caution and consider dose adjustment in patients with renal or hepatic impairment.
Missed Dose Instructions	If a dose of Itraconazole is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining effective drug levels, especially for serious fungal infections.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily gastrointestinal upset and potentially signs of more severe hepatotoxicity or cardiac effects. Treatment is supportive and symptomatic. There is no specific antidote. Itraconazole is not removed by hemodialysis. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Many Contraindicated Interactions (Strong CYP3A4 Inhibitor): Due to potent CYP3A4 inhibition, co-administration with many drugs is contraindicated due to risk of significantly increased plasma levels and toxicity of the co-administered drug. Examples include: certain statins (lovastatin, simvastatin), oral midazolam, triazolam, cisapride, dofetilide, quinidine, pimozide, ergot alkaloids (e.g., ergotamine, dihydroergotamine), ranolazine, ticagrelor, ivabradine, felodipine. ♦ Gastric Acid Reducers (e.g., antacids, H2-blockers, PPIs): Significantly reduce the absorption of itraconazole capsules. Administer antacids at least 1 hour before or 2 hours after itraconazole capsules. Avoid H2-blockers/PPIs if possible, or take capsules with an acidic beverage (e.g., cola). Note: Oral solution absorption is not affected by gastric pH. ♦ CYP3A4 Inducers (e.g., rifampin, phenytoin, phenobarbital, carbamazepine): Can significantly reduce itraconazole plasma levels, leading to reduced efficacy. Avoid concomitant use. ♦ Digoxin: Increased digoxin levels; monitor digoxin levels. ♦ Calcium Channel Blockers (e.g., dihydropyridines, verapamil): Increased levels of CCBs, increased risk of edema and CHF. ♦ Oral Hypoglycemic Agents: Enhanced hypoglycemic effect. ♦ Warfarin: Increased anticoagulant effect; monitor INR. ♦ Immunosuppressants (e.g., cyclosporine, tacrolimus, sirolimus): Increased levels of immunosuppressants; monitor drug levels. ♦ Colchicine: Increased colchicine toxicity.

Ivermectin (Stromectol)

Purpose/Indication	Ivermectin is an antiparasitic medication used to treat various parasitic infections in humans. Its primary indications include strongyloidiasis (threadworm infection) of the intestinal tract and onchocerciasis (river blindness). It is also used off-label or for scabies and lice infestations, particularly in cases resistant to conventional topical treatments.

Method of Action	Ivermectin acts by binding with high affinity to glutamate-gated chloride channels, which are present in invertebrate nerve and muscle cells of parasites. This binding leads to an increase in the permeability of the cell membrane to chloride ions, resulting in hyperpolarization of the cell and subsequent paralysis and death of the parasite. Ivermectin does not readily cross the mammalian blood-brain barrier, which contributes to its relative safety in humans.
Medication Name & Brand Names	♦ Medication Name: Ivermectin ♦ Brand Names: Stromectol (oral), Soolantra (topical for rosacea), Sklice (topical for lice), Ivermectin (generic)
Pharmaceutical Forms & Appearance	Ivermectin is available as oral tablets and various topical formulations (cream for rosacea, lotion for head lice). Oral tablets are typically white, round, and may be scored, with specific imprints. Topical creams and lotions are typically white to off-white.
Dosage & Administration	Dosage is dependent on the indication and the patient's weight, generally administered as a single oral dose for parasitic infections. For strongyloidiasis, it's typically 200 μg/kg as a single dose. For onchocerciasis, it's 150 μg/kg as a single dose, repeated every 3, 6, or 12 months. It should be taken with a full glass of water on an empty stomach (at least 1 hour before or 2 hours after a meal) for better absorption. For topical forms, follow product-specific instructions.
Supplied As	Ivermectin is supplied as: oral tablets (e.g., 3 mg), topical cream (1%), and topical lotion (0.5%).
Contraindications	Ivermectin is contraindicated in patients with known hypersensitivity to ivermectin or any component of the formulation. It is generally not recommended for use in pregnant or breastfeeding women unless absolutely necessary and the potential benefits outweigh the risks.
Storage & Expiry	Ivermectin tablets and topical formulations should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and temporary, and often related to the dying parasites, including dizziness, nausea, diarrhea, pruritus (itching), rash, and asthenia (weakness). For onchocerciasis, Mazzotti reaction (fever, headache, myalgia, arthralgia, skin rash, pruritus, edema) can occur due to the death of microfilariae. More serious but less common side effects include orthostatic hypotension, seizures (rare), and liver function abnormalities (rare).
Warnings & Precautions	♦ Neurological Effects: Can cause dizziness and somnolence. Use with caution in patients with conditions affecting the blood-brain barrier (e.g., meningitis, trypanosomiasis). ♦ Mazzotti Reaction: For onchocerciasis, expect transient, mild to moderate reactions (fever, rash, headache, joint/muscle pain, lymphadenopathy) due to microfilarial destruction. These are usually self-limiting but can be severe. ♦ Pregnancy/Lactation: Generally avoid unless the need is clear. Small amounts are excreted in breast milk. ♦ Children: Safety and efficacy in children weighing less than 15 kg have not been established. ♦ Concurrent Medical Conditions: Use with caution in patients with hepatic impairment. ♦ Not for Viral Infections.
Missed Dose Instructions	Ivermectin is often given as a single dose for parasitic infections. If a single dose is missed, take it as soon as remembered. For regimens involving multiple doses over time (e.g., for onchocerciasis), follow the specific dosing schedule. Consistent adherence is important for parasitic eradication.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, including rash, edema, headache, dizziness, asthenia, nausea, vomiting, diarrhea, and abdominal pain. More severe symptoms could include convulsions, ataxia, dyspnea, and paralytic effects. Treatment is supportive and symptomatic. Gastric decontamination (e.g., activated charcoal) may be considered if oral ingestion was recent. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ CNS Depressants (e.g., benzodiazepines, barbiturates, alcohol): Potential for increased CNS depression due to additive effects, though less common than with other antiparasitics. ♦ Warfarin: Isolated reports suggest possible enhancement of anticoagulant effect; monitor INR closely if co-administered, though data is limited. ♦ No other significant or commonly reported drug interactions are well-established for ivermectin. The primary concern for interactions is with other agents that affect the CNS or blood-brain barrier.

Kanamycin (Kantrex)

Purpose/Indication	Kanamycin is an aminoglycoside antibiotic primarily used to treat serious bacterial infections caused by susceptible Gram-negative bacteria. Its use is limited due to potential toxicity and the availability of newer agents. It is typically reserved for severe infections such as complicated urinary tract infections, bacteremia, septicemia, and some respiratory and skin infections, often when other less toxic antibiotics are ineffective or contraindicated. In some regions, it might be used in multi-drug resistant tuberculosis (MDR-TB) regimens.
Method of Action	Kanamycin exerts its bactericidal effect by irreversibly binding to the 30S ribosomal subunit of susceptible bacteria. This binding interferes with the initiation complex for protein synthesis, causes misreading of the mRNA template, and promotes premature termination of polypeptide chains. The resulting production of abnormal or non-functional proteins disrupts essential bacterial functions, leading to bacterial cell death.
Medication Name & Brand Names	♦ Medication Name: Kanamycin Sulfate ♦ Brand Names: Kantrex (historical, largely discontinued in many regions), Kanamycin (generic)
Pharmaceutical Forms & Appearance	Kanamycin is primarily available as a sterile powder for reconstitution into a solution for intravenous (IV) or intramuscular (IM) injection. It may also be found in some topical or ophthalmic preparations, but systemic use is the main consideration. The powder is typically white or off-white. The reconstituted solution is clear and colorless to pale yellow.
Dosage & Administration	Dosage is highly individualized and based on patient weight, renal function, and the severity and type of infection. It is usually administered by slow intravenous infusion or intramuscular injection. Typical adult doses for systemic infections are 15 mg/kg/day, divided into 2-3 doses. Dosing must be adjusted carefully in patients with impaired renal function, and therapeutic drug monitoring (measuring peak and trough levels) is often employed to optimize efficacy and minimize toxicity. The duration of therapy depends on the infection.
Supplied As	Kanamycin is supplied as: sterile powder for solution for injection (e.g., 500 mg, 1 g, 75 mg/2 mL vial for pediatric use).
Contraindications	Kanamycin is contraindicated in patients with known hypersensitivity to kanamycin or any other aminoglycoside antibiotic. It is also contraindicated in patients with pre-existing hearing loss or vestibular dysfunction, or severe renal impairment, unless the benefits clearly outweigh the very high risks and close monitoring is possible.
Storage & Expiry	Kanamycin powder for injection should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light. Once reconstituted, the solution should be used promptly or stored according to manufacturer guidelines (e.g., refrigerated for up to 24-48 hours depending on diluent). Always check the specific expiry date on the packaging.

Side Effects	Common side effects include injection site pain. However, kanamycin is well-known for serious and often irreversible toxicities. The most significant side effects are ototoxicity (damage to the inner ear, leading to hearing loss or vestibular dysfunction, often irreversible) and nephrotoxicity (kidney damage, ranging from mild dysfunction to acute renal failure). Other side effects include neuromuscular blockade (leading to respiratory depression or paralysis), hypersensitivity reactions, and gastrointestinal disturbances.
Warnings & Precautions	♦ Ototoxicity: Can cause irreversible bilateral or unilateral hearing loss (cochlear damage) and vestibular dysfunction. Risk is increased with higher doses, prolonged therapy, pre-existing renal impairment, advanced age, dehydration, and concomitant ototoxic drugs. Audiometric monitoring and vestibular function tests are essential before and during therapy. ♦ Nephrotoxicity: Can cause acute tubular necrosis, leading to acute kidney injury. Risk factors are similar to ototoxicity. Monitor renal function (serum creatinine, BUN, urine output) closely throughout treatment. Dosage adjustments are crucial. ♦ Neuromuscular Blockade: Can cause severe and prolonged respiratory depression or paralysis, especially in patients with neuromuscular disorders (e.g., myasthenia gravis) or those receiving neuromuscular blocking agents. ♦ Pregnancy: Aminoglycosides can cause fetal ototoxicity; generally avoided unless essential. ♦ Hydration: Maintain good hydration to prevent nephrotoxicity. ♦ Therapeutic Drug Monitoring (TDM): Monitoring peak and trough serum concentrations is strongly recommended to ensure therapeutic levels while minimizing toxicity. ♦ Concurrent Use with other toxic drugs: Avoid or use with extreme caution with other ototoxic, nephrotoxic, or neuromuscular blocking agents.
Missed Dose Instructions	Given the critical nature of serious infections and the need for precise dosing with aminoglycosides, missed doses should be reported to the healthcare provider immediately. Dosing regimens are usually timed to achieve specific peak and trough levels; missing a dose can impact efficacy and/or alter the drug's accumulation. Do not double a dose.
Overdose Instructions	Overdose with kanamycin typically manifests as severe ototoxicity, nephrotoxicity, and/or neuromuscular blockade (respiratory paralysis). Treatment is supportive and symptomatic. Hemodialysis or peritoneal dialysis can help remove kanamycin from the blood, especially in cases of severe renal impairment or life-threatening toxicity. Calcium salts may reverse neuromuscular blockade. Mechanical ventilation may be required for respiratory depression. Seek immediate emergency medical help.
Medicine Interactions	♦ Nephrotoxic Drugs (e.g., ciclosporin, amphotericin B, platinum-based chemotherapy like cisplatin, NSAIDs, vancomycin, loop diuretics): Significantly increased risk of nephrotoxicity. Avoid concurrent use or monitor renal function extremely closely. ♦ Ototoxic Drugs (e.g., loop diuretics like furosemide, ethacrynic acid; cisplatin, vancomycin): Significantly increased risk of ototoxicity. Avoid concurrent use or monitor hearing closely. ♦ Neuromuscular Blocking Agents (e.g., succinylcholine, rocuronium): Increased and prolonged neuromuscular blockade, leading to increased risk of respiratory depression or paralysis. Monitor closely. ♦ Other Aminoglycosides: Do not administer concurrently due to additive toxicity. ♦ Cephalosporins (especially cephalothin): Increased risk of nephrotoxicity with concomitant use. ♦ Potent Diuretics (e.g., furosemide): Can increase aminoglycoside levels and enhance ototoxicity.

Ketoconazole (Nizoral)

Purpose/Indication	Ketoconazole is an antifungal medication available in both topical and oral forms, though oral use is highly restricted due to significant safety concerns. Topically, it's widely used to treat superficial fungal infections of the skin like tinea corporis, tinea cruris, tinea pedis, and tinea versicolor, as well as seborrheic dermatitis. Oral ketoconazole is reserved for serious systemic fungal infections when alternative therapies are not available or tolerated, and for certain endocrine conditions like Cushing's syndrome off-label due to its ability to inhibit steroid synthesis.
Method of Action	Ketoconazole is an azole antifungal that inhibits the fungal cytochrome P450-dependent enzyme 14-a-demethylase. This enzyme is crucial for the biosynthesis of ergosterol, a primary component of the fungal cell membrane. By blocking ergosterol synthesis, ketoconazole disrupts the structure and function of the fungal cell membrane, leading to increased permeability, leakage of cellular contents, and inhibition of fungal growth (fungistatic) or cell death (fungicidal at higher concentrations).
Medication Name & Brand Names	♦ Medication Name: Ketoconazole ♦ Brand Names: Nizoral (oral, shampoo, cream), Extina (foam), Ketoconazole (generic)
Pharmaceutical Forms & Appearance	Ketoconazole is available as oral tablets, topical creams, topical gels, topical foams, and shampoos. Oral tablets are typically white, round, and may be scored. Topical creams are white and semi-solid, gels are clear, foams are white, and shampoos are typically orange-red.
Dosage & Administration	♦ Topical: Applied once or twice daily to the affected skin area for varying durations, depending on the infection. Shampoos are typically used 2-3 times per week for seborrheic dermatitis or tinea versicolor, then tapered. ♦ Oral: Due to significant risks, oral ketoconazole use is highly restricted. For severe systemic fungal infections, typical adult doses are 200 mg once daily, which may be increased to 400 mg daily if needed. Oral tablets require gastric acidity for absorption; take with food or an acidic beverage. Always adhere strictly to a healthcare professional's prescription for oral use.
Supplied As	Ketoconazole is supplied as: oral tablets (e.g., 200 mg), topical cream (2%), topical gel (2%), topical foam (2%), and shampoo (1%, 2%).
Contraindications	♦ Oral: Contraindicated in patients with acute or chronic liver disease, and concomitant use with numerous drugs that are potent CYP3A4 substrates and/or prolong the QT interval due to serious and potentially fatal interactions (e.g., certain statins, oral midazolam, cisapride, dofetilide, quinidine). Not for use in non-life-threatening fungal infections where safer alternatives exist. ♦ Topical: Contraindicated in patients with known hypersensitivity to ketoconazole or any component of the formulation.
Storage & Expiry	Ketoconazole products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	♦ Oral: The most significant side effects are severe hepatotoxicity (liver damage, including fatal cases) and adrenal insufficiency. Other common side effects include nausea, vomiting, abdominal pain, diarrhea, headache, and dizziness. Less common but serious effects include QT prolongation and severe allergic reactions. ♦ Topical: Local skin reactions like burning, itching, irritation, dry skin, and erythema are common but generally mild. Systemic side effects are rare with topical use.
Warnings & Precautions	♦ Oral: BLACK BOX WARNINGS: Severe hepatotoxicity (including fatal cases) has occurred. Not for use in fungal meningitis or for non-life-threatening infections. Use only when alternative antifungal therapies are not available or tolerated. Concomitant use with specific drugs that can cause QT prolongation and/or significant CYP3A4 inhibition is strictly contraindicated. Risk of adrenal insufficiency. Monitor liver function tests and adrenal function carefully. ♦ Topical: For external use only. Avoid contact with eyes. Discontinue if irritation develops. Minimal systemic absorption but caution with large surface areas or broken skin.

Missed Dose Instructions	♦ Oral: Adherence is critical for systemic fungal infections. If an oral dose is missed, take it as soon as remembered. However, if it's almost time for the next dose, skip the missed dose and continue the regular schedule. Do not double doses. Consult healthcare provider if multiple doses are missed. ♦ Topical: If a topical application is missed, apply it as soon as remembered. Then continue with the regular schedule. Do not apply a double amount.
Overdose Instructions	♦ Oral: Overdose can lead to exacerbation of side effects, particularly severe gastrointestinal upset, hepatotoxicity, and potentially adrenal insufficiency. Treatment is supportive and symptomatic. Gastric decontamination may be considered if recent. Ketoconazole is not removed by hemodialysis. Seek immediate medical attention. ♦ Topical: Acute topical overdose is highly unlikely to cause systemic toxicity due to minimal absorption. Excessive local application might increase skin irritation. Treatment is symptomatic.
Medicine Interactions	♦ Oral: Numerous Contraindicated Interactions (Potent CYP3A4 Inhibitor): Due to potent CYP3A4 inhibition, co-administration with many drugs is strictly contraindicated due to risk of significantly increased plasma levels and toxicity. Examples include: certain statins (lovastatin, simvastatin, atorvastatin), oral midazolam, triazolam, cisapride, dofetilide, quinidine, pimozide, ergot alkaloids, ranolazine, ticagrelor, ivabradine, felodipine. Refer to comprehensive drug interaction checker. ♦ Gastric Acid Reducers (e.g., antacids, H2-blockers, PPIs): Significantly reduce the absorption of oral ketoconazole. Administer antacids at least 1 hour before or 2 hours after ketoconazole. Avoid H2-blockers/PPIs if possible, or take with an acidic beverage (e.g., cola). ♦ CYP3A4 Inducers (e.g., rifampin, phenytoin, phenobarbital, carbamazepine): Can significantly reduce ketoconazole plasma levels, leading to reduced efficacy. Avoid concomitant use. ♦ Warfarin: Increased anticoagulant effect; monitor INR. ♦ Immunosuppressants (e.g., cyclosporine, tacrolimus, sirolimus): Increased levels of immunosuppressants; monitor drug levels. ♦ Digoxin, sulfonylureas, corticosteroids, calcium channel blockers, HIV protease inhibitors, certain oncology drugs: Levels may be increased; monitor and adjust doses. ♦ Topical: Systemic drug interactions are extremely rare and generally not clinically significant with topical formulations due to minimal absorption.

Ketorolac (Toradol)

Purpose/Indication	Ketorolac is a potent non-steroidal anti-inflammatory drug (NSAID) primarily used for the short-term (typically up to 5 days) management of moderately severe acute pain that requires analgesia at the opioid level. It is often used post-operatively or for acute musculoskeletal injuries when a non-opioid alternative is desired. It is available in oral, injectable (IM/IV), nasal, and ophthalmic forms, but systemic use for pain is generally restricted to short durations due to risk of serious side effects.
Method of Action	Ketorolac works by inhibiting cyclooxygenase (COX) enzymes, both COX-1 and COX-2, thereby preventing the synthesis of prostaglandins. Prostaglandins are lipid compounds that play a central role in mediating pain, inflammation, and fever. By reducing prostaglandin production, ketorolac effectively decreases inflammation, pain sensation, and swelling, providing potent analgesic effects.
Medication Name & Brand Names	♦ Medication Name: Ketorolac Tromethamine ♦ Brand Names: Toradol (injectable, oral, nasal), Acular (ophthalmic), Sprix (nasal), Ketorolac (generic)
Pharmaceutical Forms & Appearance	Ketorolac is available as oral tablets, solution for intramuscular (IM) and intravenous (IV) injection, nasal spray, and ophthalmic solution. Oral tablets are typically small, white or off-white, and often round or oval. The injectable solution is clear and colorless to pale yellow. The nasal spray is a clear solution. Ophthalmic solution is clear.
Dosage & Administration	Dosage and route of administration depend on the severity of pain and patient characteristics, with a maximum duration of 5 days for systemic use. For adults, typical IM/IV doses are 30 mg or 60 mg as a single dose, or 15-30 mg every 6 hours, not exceeding 120 mg/day for IM/IV and 40 mg/day for oral/nasal. Oral therapy usually follows injectable therapy. Take oral doses with food or milk to minimize GI upset. It is crucial to always use the lowest effective dose for the shortest possible duration.
Supplied As	Ketorolac is supplied as: oral tablets (e.g., 10 mg), solution for IM/IV injection (e.g., 15 mg/mL, 30 mg/mL, 60 mg/2mL), nasal spray (e.g., 15.75 mg/spray), and ophthalmic solution (e.g., 0.5%).
Contraindications	Ketorolac is strictly contraindicated for chronic use, in patients with a history of serious gastrointestinal bleeding or peptic ulcer disease, advanced renal impairment, cerebrovascular bleeding, or bleeding diatheses. It is also contraindicated in the setting of coronary artery bypass graft (CABG) surgery, before major surgery (due to bleeding risk), in women in labor and delivery, and in patients with known hypersensitivity to ketorolac, aspirin, or other NSAIDs. Concomitant use with other NSAIDs, aspirin, or probenecid is also contraindicated.
Storage & Expiry	Ketorolac products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light. Keep in tightly closed containers. Ophthalmic and nasal solutions should be protected from freezing. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., nausea, dyspepsia, abdominal pain, diarrhea), headache, dizziness, and injection site pain. More serious and potentially life-threatening side effects (which are emphasized due to its potent nature) include severe gastrointestinal bleeding, ulceration, or perforation, acute kidney injury, cardiovascular thrombotic events (e.g., heart attack, stroke), severe allergic reactions (including anaphylaxis, serious skin reactions), and liver injury.
Warnings & Precautions	♦ BLACK BOX WARNINGS: ♦ GI Risk: Increased risk of serious GI adverse events including bleeding, ulceration, and perforation of stomach or intestines, which can be fatal. Risk increases with duration. ♦ Cardiovascular Risk: Increased risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may increase with duration. Contraindicated for pain after CABG surgery. ♦ Renal Risk: Can cause new onset or worsening of renal impairment, including acute renal failure. Contraindicated in advanced renal disease. ♦ Bleeding Risk: Can cause increased bleeding risk due to antiplatelet effects. Contraindicated before major surgery and in patients with bleeding disorders. ♦ Duration of Use: Limited to 5 days for combined (oral, IM, IV) duration in adults due to increased risk of serious adverse events with prolonged use. ♦ Children: Not recommended for children under 16 years. ♦ Hepatic Effects: Liver injury, including severe and fatal cases, can occur. ♦ Hypertension: Can cause new onset hypertension or worsen pre-existing hypertension. ♦ Fluid Retention/Edema: Use with caution in patients with heart failure or hypertension. ♦ Asthma Exacerbation: Use with caution in patients with asthma, especially aspirin-sensitive asthma. ♦ Pregnancy: Avoid use in late pregnancy (third trimester).
Missed Dose Instructions	Ketorolac is typically used for short-term, acute pain. If a scheduled dose is missed, take it when remembered if pain warrants, adhering to the recommended dosing interval. Do not exceed the maximum daily dose or the 5-day treatment limit. Do not double a dose.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, including severe gastrointestinal upset, metabolic acidosis, renal dysfunction, lethargy, drowsiness, nausea, vomiting, epigastric pain, and potentially more severe GI bleeding, acute renal failure, and respiratory depression. Treatment is supportive and symptomatic. Gastric decontamination (e.g., activated charcoal) may be considered if oral ingestion was recent and substantial. Hemodialysis is unlikely to be effective due to high protein binding. Seek immediate emergency medical help.

Medicine Interactions	♦ Anticoagulants (e.g., warfarin) & Antiplatelet agents (e.g., aspirin, clopidogrel): Significantly increased risk of bleeding. Concurrent use is generally contraindicated. ♦ Other NSAIDs: Concomitant use is contraindicated due to additive GI and renal toxicity, and no additional benefit. ♦ Probenecid: Significantly increases ketorolac plasma levels and half-life; concomitant use is contraindicated. ♦ Lithium: Increases serum lithium concentrations and toxicity; monitor lithium levels closely. ♦ Methotrexate: Increases methotrexate toxicity. ♦ ACE Inhibitors/ARBs/Diuretics: May reduce the antihypertensive and diuretic effects, and significantly increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. ♦ Corticosteroids: Increased risk of GI ulceration and bleeding. ♦ SSRIs: Increased risk of GI bleeding. ♦ Pentoxifylline: Increased risk of bleeding. ♦ Alcohol: Increased risk of GI bleeding and liver damage.

Labetalol (Normodyne)

Purpose/Indication	Labetalol is a combined alpha (α1) and beta (β1, β2) adrenergic blocker used to treat hypertension (high blood pressure). It is particularly useful for managing severe hypertension, hypertensive emergencies, and hypertension in pregnancy (including pre-eclampsia), as it rapidly lowers blood pressure without significantly affecting heart rate or cardiac output. It is also used in the long-term management of chronic hypertension.
Method of Action	Labetalol acts as a non-selective beta-adrenergic blocker (blocking β1 and β2 receptors) and a selective alpha-1 adrenergic blocker. By blocking β1 receptors in the heart, it reduces heart rate and myocardial contractility, decreasing cardiac output. Blockade of β2 receptors causes some bronchoconstriction. Crucially, its α1 blockade leads to vasodilation of peripheral blood vessels, reducing total peripheral resistance. The combination of these actions results in a reduction in blood pressure with less reflex tachycardia compared to pure vasodilators, and without the profound bradycardia seen with pure beta-blockers.
Medication Name & Brand Names	♦ Medication Name: Labetalol Hydrochloride ♦ Brand Names: Normodyne (historical), Trandate (historical), Labetalol (generic)
Pharmaceutical Forms & Appearance	Labetalol is available as oral tablets and solution for intravenous (IV) injection. Oral tablets are typically white, round, or capsule-shaped, and may be scored, with various imprints. The IV solution is clear and colorless.
Dosage & Administration	Dosage varies significantly by route and indication. For oral hypertension, initial adult doses are typically 100 mg twice daily, increasing gradually to a usual maintenance range of 200 mg to 400 mg twice daily, with a maximum of 1200 mg to 2400 mg per day. For hypertensive emergencies, IV bolus doses (e.g., 20 mg initially, then 40-80 mg every 10-20 minutes) or continuous IV infusion are used. Oral doses can be taken with or without food, but food may enhance bioavailability.
Supplied As	Labetalol is supplied as: oral tablets (e.g., 100 mg, 200 mg, 300 mg) and solution for intravenous injection (e.g., 5 mg/mL in 20 mL vials, 20 mg/4 mL pre-filled syringes).
Contraindications	Labetalol is contraindicated in patients with known hypersensitivity to labetalol or any component of the formulation. It is also contraindicated in patients with bronchial asthma, overt cardiac failure, greater than first-degree heart block (unless a pacemaker is in place), cardiogenic shock, and severe bradycardia.
Storage & Expiry	Labetalol tablets and IV solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Do not freeze IV solution. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include dizziness, fatigue, nausea, headache, and orthostatic hypotension (dizziness upon standing). Due to its alpha-blocking effects, transient scalp tingling may occur with initial doses. More serious side effects include symptomatic bradycardia, heart block, worsening heart failure, bronchospasm, and liver injury.
Warnings & Precautions	♦ Hypotension/Orthostatic Hypotension: Can cause symptomatic postural hypotension, especially with initial doses or IV administration. Patients should be advised to rise slowly. ♦ Bradycardia/Heart Block/Heart Failure: Can exacerbate bradycardia, heart block, or precipitate/worsen heart failure. Use with caution in patients with cardiac disease. Discontinue if signs of cardiac failure appear. ♦ Bronchospasm: As a non-selective beta-blocker, it can cause bronchospasm, particularly in patients with asthma or COPD. Avoid in patients with bronchial asthma. ♦ Hepatic Injury: Rare but serious liver injury, including fatal cases, has been reported. Monitor liver function periodically. ♦ Perioperative Risk: Risk of exaggerated hypotensive response with certain anesthetics. Inform anesthetist of labetalol use. ♦ Diabetes: Can mask symptoms of hypoglycemia (e.g., tachycardia) and prolong recovery from hypoglycemia. Use with caution in diabetic patients. ♦ Thyrotoxicosis: Can mask symptoms of hyperthyroidism. Abrupt withdrawal can precipitate thyroid storm. ♦ Pheochromocytoma: Use with caution as it has both alpha and beta blocking activity. An alpha-blocker should be initiated prior to any beta-blocker. ♦ Abrupt Withdrawal: Do not abruptly discontinue therapy in patients with coronary artery disease, as it can exacerbate angina or precipitate myocardial infarction. Taper dose gradually over 1-2 weeks.
Missed Dose Instructions	For chronic hypertension, if a dose of Labetalol (oral) is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining blood pressure control.
Overdose Instructions	Overdose symptoms are primarily related to exaggerated pharmacological effects, including severe hypotension, profound bradycardia, heart block, cardiac failure, bronchospasm, and possibly seizures. Treatment is supportive and symptomatic. For severe bradycardia or heart block, atropine, glucagon, or a pacemaker may be needed. For hypotension, IV fluids and vasopressors are indicated. Bronchospasm may require beta-agonists. Labetalol is not effectively removed by hemodialysis. Seek immediate emergency medical help.
Medicine Interactions	♦ Other Antihypertensives: Additive hypotensive effects. Dose adjustment may be needed. ♦ Calcium Channel Blockers (e.g., verapamil, diltiazem): Increased risk of bradycardia, heart block, and hypotension. Use with caution. ♦ Digoxin: Can increase digoxin levels; monitor digoxin levels. ♦ Beta-Agonists (e.g., albuterol, epinephrine): Labetalol can blunt the bronchodilator effects of beta-agonists. ♦ NSAIDs: May reduce the antihypertensive effect of labetalol. ♦ Cimetidine: May increase labetalol bioavailability. ♦ Tricyclic Antidepressants (TCAs): Increased risk of tremor. ♦ Anesthetics (general): May potentiate the hypotensive effect of labetalol. Inform anesthetist of labetalol use. ♦ MAO Inhibitors: Concurrent use generally not recommended due to possible severe hypertension or hypotension.

Laxatives (Bisacodyl) (Dulcolax)

Purpose/Indication	Bisacodyl is a stimulant laxative used for the short-term relief of occasional constipation and for bowel preparation before medical procedures (e.g., colonoscopy, surgery). It promotes bowel movements by directly stimulating the muscles in the intestines, helping to produce a bowel movement usually within 6-12 hours for oral forms, and 15-60 minutes for rectal forms.

Method of Action	Bisacodyl acts primarily by directly stimulating the nerve endings in the colonic mucosa. This stimulation increases peristalsis (muscle contractions) of the colon, accelerating the movement of stool through the intestines. It also increases the accumulation of water and electrolytes in the colonic lumen, which helps to soften the stool and facilitate its passage, making it easier to evacuate.
Medication Name & Brand Names	♦ Medication Name: Bisacodyl ♦ Brand Names: Dulcolax, Correctol, Feen-a-Mint, Bisacodyl (generic)
Pharmaceutical Forms & Appearance	Bisacodyl is available as oral tablets (enteric-coated) and rectal suppositories. Oral tablets are typically small, yellow or pink, and sugar-coated or enteric-coated to prevent dissolution in the stomach. Rectal suppositories are whitish, torpedo-shaped.
Dosage & Administration	For occasional constipation, the usual adult oral dose is 5-15 mg once daily, preferably at bedtime. For rectal suppositories, the usual adult dose is 10 mg once daily. For bowel preparation, higher doses may be used as directed by a healthcare professional. Oral tablets should be swallowed whole and not chewed or crushed. Do not take within 1 hour of antacids, milk, or dairy products, as this can cause the enteric coating to dissolve prematurely, leading to stomach irritation.
Supplied As	Bisacodyl is supplied as: enteric-coated oral tablets (e.g., 5 mg), and rectal suppositories (e.g., 10 mg).
Contraindications	Bisacodyl is contraindicated in patients with known hypersensitivity to bisacodyl or any component of the formulation. It is also contraindicated in patients with acute abdominal pain, appendicitis, intestinal obstruction, undiagnosed rectal bleeding, severe dehydration, or inflammatory bowel disease (e.g., Crohn's disease, ulcerative colitis).
Storage & Expiry	Bisacodyl tablets and suppositories should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Suppositories should be kept cool, but generally do not require refrigeration. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include abdominal discomfort, cramping, nausea, diarrhea, and rectal irritation (with suppositories). Prolonged or excessive use can lead to electrolyte imbalances (e.g., hypokalemia), fluid loss, dehydration, and laxative dependence or "lazy bowel" syndrome, where the bowel becomes reliant on laxatives for function.
Warnings & Precautions	♦ Short-term Use Only: Intended for short-term relief of occasional constipation. Prolonged daily use can lead to dependence, electrolyte imbalance, and loss of normal bowel function. ♦ Fluid and Electrolyte Imbalance: Excessive use can lead to significant fluid and electrolyte disturbances, particularly hypokalemia and dehydration. ♦ Abdominal Pain: Do not use if severe abdominal pain, nausea, or vomiting is present, as these may indicate a serious condition. ♦ Rectal Bleeding: Discontinue use and consult a doctor if rectal bleeding occurs or if a bowel movement does not occur after use. ♦ Children: Use in children should only be under medical supervision. ♦ Swallow Tablets Whole: Do not chew, crush, or break enteric-coated tablets to avoid stomach irritation. ♦ Avoid Milk/Antacids: Do not take within one hour of milk, dairy products, or antacids due to premature dissolution of the enteric coating.
Missed Dose Instructions	Bisacodyl is typically used as needed for constipation. If a dose is missed, take it when remembered if constipation persists and it is within the recommended dosing interval. However, do not double a dose. For bowel preparation, adhere strictly to the prescribed regimen.
Overdose Instructions	Overdose symptoms are primarily severe abdominal cramping, pain, and profuse watery diarrhea, leading to significant fluid and electrolyte losses (especially hypokalemia). Chronic overdose can result in steatorrhea, kidney stones, and bone damage. Treatment is supportive and symptomatic, focusing on fluid and electrolyte replacement. In severe cases, intravenous fluids may be needed. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Antacids, Milk, Dairy Products: Can cause the enteric coating of oral bisacodyl tablets to dissolve prematurely, leading to gastric or duodenal irritation, cramping, and vomiting. Do not administer within 1 hour of taking bisacodyl. ♦ Diuretics (especially loop or thiazide diuretics) and Corticosteroids: Increased risk of electrolyte imbalance (particularly hypokalemia) when combined with long-term or excessive use of bisacodyl due to enhanced potassium loss. ♦ Cardiac Glycosides (e.g., digoxin): Hypokalemia induced by laxative abuse can potentiate the effects of cardiac glycosides, increasing the risk of toxicity. ♦ Other Laxatives: Concomitant use with other laxatives can increase the risk of adverse effects, including severe dehydration and electrolyte imbalance.

Levetiracetam (Keppra)

Purpose/Indication	Levetiracetam is an antiepileptic drug (AED) used to treat various types of seizures in adults and children. It is indicated for the adjunctive treatment of partial-onset seizures, myoclonic seizures in patients with juvenile myoclonic epilepsy, and primary generalized tonic-clonic seizures. It can also be used as monotherapy for partial-onset seizures in certain cases.
Method of Action	The precise mechanism of action of levetiracetam is not fully understood, but it differs from that of other antiepileptic drugs. It is believed to exert its anticonvulsant effects by modulating synaptic vesicle glycoprotein 2A (SV2A), a protein found on presynaptic vesicles. This interaction is thought to reduce neurotransmitter release, thereby stabilizing neuronal activity and preventing excessive neuronal firing without directly affecting traditional ion channels or neurotransmitter receptors.
Medication Name & Brand Names	♦ Medication Name: Levetiracetam ♦ Brand Names: Keppra (immediate-release and extended-release), Elepsia XR, Roweepra, Levetiracetam (generic)
Pharmaceutical Forms & Appearance	Levetiracetam is available as oral tablets (immediate and extended-release), oral solution, and solution for intravenous (IV) injection. Oral tablets vary in color and shape (e.g., blue, yellow, white, oval), often with specific imprints. The oral solution is a clear, colorless to yellowish liquid. The IV solution is clear and colorless.
Dosage & Administration	Dosage is individualized based on seizure type, patient age, renal function, and response, typically starting low and titrating upwards. For adults, common starting doses for immediate-release tablets are 500 mg twice daily, increasing to usual maintenance doses of 1000 mg to 3000 mg twice daily. Extended-release tablets are given once daily. The oral solution is used for patients who cannot swallow tablets. IV administration is an alternative for patients temporarily unable to take oral medication.
Supplied As	Levetiracetam is supplied as: oral immediate-release tablets (e.g., 250 mg, 500 mg, 750 mg, 1000 mg), oral extended-release tablets (e.g., 500 mg, 750 mg), oral solution (e.g., 100 mg/mL), and solution for intravenous injection (e.g., 500 mg/5 mL vial, 1500 mg/15 mL vial).
Contraindications	Levetiracetam is contraindicated in patients with known hypersensitivity to levetiracetam or any component of the formulation.
Storage & Expiry	Levetiracetam tablets, oral solution, and IV solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.

Side Effects	Common side effects include somnolence (drowsiness), asthenia (weakness), dizziness, behavioral abnormalities (e.g., irritability, aggression, mood swings, anxiety, depression), and nasopharyngitis. More serious but less common side effects include psychiatric and behavioral changes (including psychotic symptoms, suicidal ideation), hematologic abnormalities (e.g., neutropenia, leukopenia), coordination difficulties, and Stevens-Johnson syndrome (rare).
Warnings & Precautions	♦ Neuropsychiatric Adverse Reactions: Can cause behavioral abnormalities (e.g., agitation, hostility, anxiety, apathy, mood swings, depression, psychosis), and suicidal ideation/behavior. Monitor patients for these changes. Advise patients and caregivers to report new or worsening psychiatric symptoms. ♦ Somnolence and Ataxia: Can cause dose-related drowsiness and coordination difficulties. Advise caution with driving or operating machinery, especially during initiation or dose escalation. ♦ Withdrawal Seizures: Antiepileptic drugs should generally not be discontinued abruptly, as this can increase seizure frequency. Taper dose gradually. ♦ Renal Impairment: Requires dose adjustment in patients with impaired renal function due to renal elimination. Monitor renal function. ♦ Hematologic Abnormalities: Rare reports of decreased red blood cell count, white blood cell count, and platelet count. Monitor complete blood counts periodically. ♦ Stevens-Johnson Syndrome (SJS)/Toxic Epidermal Necrolysis (TEN): Rare but serious and potentially fatal skin reactions have been reported. Discontinue at first sign of rash unless clearly not drug-related. ♦ Pregnancy: Data suggests risk of major congenital malformations and adverse pregnancy outcomes; use only if benefits outweigh risks.
Missed Dose Instructions	For chronic seizure management, if a dose of Levetiracetam is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is very important for maintaining seizure control.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, including somnolence, agitation, aggression, decreased level of consciousness, respiratory depression, and coma. Treatment is supportive and symptomatic. There is no specific antidote. Hemodialysis can remove approximately 50% of levetiracetam from the body. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ No significant or widely reported drug-drug interactions with levetiracetam, unlike many other AEDs. Levetiracetam is minimally metabolized by the CYP450 system and does not significantly induce or inhibit these enzymes. ♦ Methotrexate: Decreased clearance of methotrexate has been reported with concomitant levetiracetam, leading to increased methotrexate concentrations. Monitor methotrexate levels. ♦ Oral Contraceptives: Levetiracetam does not appear to affect the efficacy of oral contraceptives. ♦ Other Antiepileptic Drugs: No significant pharmacokinetic interactions with commonly used AEDs. However, additive CNS depressant effects (e.g., somnolence, dizziness) can occur if taken with other CNS depressants or alcohol.

Levofloxacin (Levaquin)

Purpose/Indication	Levofloxacin is a fluoroquinolone antibiotic used to treat a wide range of bacterial infections. It is indicated for infections such as community-acquired pneumonia, acute bacterial exacerbation of chronic bronchitis, acute bacterial sinusitis, urinary tract infections (complicated and uncomplicated), pyelonephritis, chronic bacterial prostatitis, complicated skin and skin structure infections, and inhalational anthrax (post-exposure). Its broad spectrum makes it effective against various Gram-positive and Gram-negative bacteria.
Method of Action	Levofloxacin works by inhibiting bacterial DNA gyrase (topoisomerase II) and topoisomerase IV, enzymes essential for bacterial DNA replication, transcription, repair, and recombination. By blocking these enzymes, levofloxacin causes breaks in bacterial DNA, leading to cell death (bactericidal action). This mechanism distinguishes it from other antibiotic classes and contributes to its broad spectrum of activity.
Medication Name & Brand Names	♦ Medication Name: Levofloxacin ♦ Brand Names: Levaquin (USA - brand discontinued but widely known), Tavanic (regional), Levofloxacin (generic)
Pharmaceutical Forms & Appearance	Levofloxacin is available as oral tablets, an oral solution, and a solution for intravenous (IV) infusion. Oral tablets are typically film-coated, oblong, and may vary in color (e.g., yellowish-white) and imprint depending on strength. The oral solution is clear and colorless to yellowish. The IV solution is clear and pale yellow.
Dosage & Administration	Dosage varies significantly by indication, patient's renal function, and type of infection, typically ranging from 250 mg to 750 mg once daily. For uncomplicated UTIs, 250 mg once daily for 3 days is common. For community-acquired pneumonia, 500 mg or 750 mg once daily for 5-14 days. For skin infections, 500 mg once daily for 7-14 days. IV and oral dosages are typically interchangeable. Oral tablets can be taken with or without food. Avoid taking with antacids, iron supplements, or dairy products due to absorption interference. Complete the full prescribed course.
Supplied As	Levofloxacin is supplied as: oral tablets (e.g., 250 mg, 500 mg, 750 mg), oral solution (e.g., 25 mg/mL), and solution for intravenous infusion (e.g., 250 mg/50 mL, 500 mg/100 mL, 750 mg/150 mL in flexible containers).
Contraindications	Levofloxacin is strictly contraindicated in patients with known hypersensitivity to levofloxacin, other fluoroquinolones, or any component of the formulation. It is also contraindicated in patients with a history of tendinitis or tendon rupture associated with fluoroquinolone use.
Storage & Expiry	Levofloxacin oral tablets, oral solution, and IV solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light. Oral solution should not be refrigerated. IV solutions should be protected from excessive heat and freezing. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, diarrhea, headache, insomnia, and dizziness. More serious and often emphasized side effects (due to black box warnings) include tendinitis and tendon rupture, peripheral neuropathy, and central nervous system effects. Other serious but less common side effects include QT prolongation, Clostridioides difficile-associated diarrhea (CDAD), hypoglycemia/hyperglycemia, and severe hypersensitivity reactions (e.g., anaphylaxis, Stevens-Johnson Syndrome).
Warnings & Precautions	♦ BLACK BOX WARNING: Tendinitis and Tendon Rupture: Fluoroquinolones, including levofloxacin, are associated with an increased risk of tendinitis and tendon rupture in all ages. This risk is higher in older patients, those on corticosteroids, and those with kidney, heart, or lung transplants. Discontinue at the first sign of tendon pain or inflammation. ♦ BLACK BOX WARNING: Peripheral Neuropathy: Fluoroquinolones can cause peripheral neuropathy, a potentially permanent nerve damage, which can occur rapidly. Discontinue if symptoms of neuropathy (pain, burning, tingling, numbness, weakness) develop. ♦ BLACK BOX WARNING: Central Nervous System Effects: Fluoroquinolones are associated with an increased risk of psychiatric adverse reactions (e.g., hallucinations, anxiety, depression, suicidal thoughts) and seizures. Use with caution in patients with CNS disorders. ♦ BLACK BOX WARNING: Exacerbation of Myasthenia Gravis: Fluoroquinolones may exacerbate muscle weakness in patients with myasthenia gravis. Avoid in patients with a known history of myasthenia gravis. ♦ Aortic Aneurysm and Dissection: Increased risk reported, especially in elderly patients. Use with caution in patients with a history of aortic aneurysm. ♦ QT Prolongation: Can prolong the QT interval on ECG, increasing the risk of potentially fatal arrhythmias (torsades de pointes). Avoid in patients with known QT prolongation, uncorrected hypokalemia/hypomagnesemia, or concomitant Class IA/III antiarrhythmics. ♦ Hypoglycemia/Hyperglycemia: Can cause severe blood sugar disturbances, especially in diabetic patients. Monitor blood glucose. ♦ Photosensitivity: Can cause moderate to severe photosensitivity reactions. Advise patients to avoid excessive sun exposure and use sunscreen. ♦ Clostridioides difficile-associated Diarrhea (CDAD): Can occur. ♦ Renal Impairment: Dose adjustment is necessary. ♦ Drug Resistance: Use responsibly and reserve for appropriate indications.

Missed Dose Instructions	If a dose of Levofloxacin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Completing the full prescribed course of antibiotics is crucial for effective bacterial eradication and preventing the development of drug resistance and relapse of infection.
Overdose Instructions	Overdose symptoms are typically exaggerated side effects, including CNS effects (confusion, dizziness, seizures), prolonged QT interval, and gastrointestinal upset (nausea, vomiting). There is no specific antidote for levofloxacin. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Maintain adequate hydration. ECG monitoring is important. Levofloxacin is not effectively removed by hemodialysis or peritoneal dialysis. Seek immediate emergency medical help.
Medicine Interactions	♦ Antacids (containing magnesium, aluminum), Sucralfate, Didanosine (chewable/buffered tablets), Iron Supplements, Zinc Supplements: Form insoluble chelates with levofloxacin, significantly reducing its absorption. Administer levofloxacin at least 2 hours before or 2 hours after these agents. ♦ Dairy Products: Can reduce oral absorption due to calcium content. Take levofloxacin at least 2 hours before or after consuming dairy products. ♦ Warfarin: May enhance the anticoagulant effect of warfarin, increasing the risk of bleeding. Monitor INR closely. ♦ Antiarrhythmics (Class IA e.g., quinidine, procainamide; Class III e.g., amiodarone, sotalol), Tricyclic Antidepressants, Macrolides, Antipsychotics: Increased risk of QT prolongation and torsades de pointes. Avoid concomitant use. ♦ NSAIDs (Non-Steroidal Anti-inflammatory Drugs): May increase the risk of CNS stimulation and convulsive seizures when used concurrently with fluoroquinolones. ♦ Corticosteroids: Concomitant use significantly increases the risk of tendinitis and tendon rupture. ♦ Cyclosporine: May increase cyclosporine levels. ♦ Oral Hypoglycemics (e.g., sulfonylureas, insulin): Can cause dysglycemia (hypoglycemia or hyperglycemia), sometimes severe. Monitor blood glucose closely. ♦ Cimetidine/Probenecid: Can reduce renal clearance of levofloxacin, potentially increasing its levels and adverse effects. ♦ Theophylline: May increase theophylline levels.

Levothyroxine (Synthroid)

Purpose/Indication	Levothyroxine is a synthetic thyroid hormone (T4) used primarily for thyroid hormone replacement therapy. It is indicated for the treatment of hypothyroidism (underactive thyroid gland) of any etiology, including primary (thyroidal), secondary (pituitary), and tertiary (hypothalamic) hypothyroidism, and subclinical hypothyroidism. It is also used as an adjunct to surgery and radioiodine therapy in the management of thyroid-stimulating hormone (TSH)-dependent well-differentiated thyroid cancer (to suppress TSH production) and for diffuse goiter.
Method of Action	Levothyroxine sodium is a synthetic form of L-thyroxine (T4), which is identical to the naturally occurring hormone produced by the thyroid gland. Once administered, it is deiodinated in peripheral tissues to form L-triiodothyronine (T3), the active form of thyroid hormone. T3 then enters the cell nucleus and binds to thyroid hormone receptors, which then bind to DNA and activate gene transcription. This process regulates various cellular metabolic processes, including metabolism, growth, and development, thereby restoring normal thyroid function.
Medication Name & Brand Names	♦ Medication Name: Levothyroxine Sodium ♦ Brand Names: Synthroid, Levoxyl, Euthyrox, Unithroid, Tirosint, Levothyroxine (generic)
Pharmaceutical Forms & Appearance	Levothyroxine is available as oral tablets, oral capsules (gelatin-based), and oral solution. Tablets vary widely in color, shape, and imprint depending on the manufacturer and strength, often with different colors for different strengths. Capsules are typically softgels. The oral solution is clear and colorless.
Dosage & Administration	Dosage is highly individualized and determined by the patient's age, weight, cardiovascular status, concomitant medications, and especially TSH levels. It is typically administered once daily in the morning, preferably 30-60 minutes before breakfast, on an empty stomach, and at least 4 hours apart from calcium, iron, antacids, or other medications that can interfere with absorption. Adherence to a consistent administration time and method is crucial for stable hormone levels.
Supplied As	Levothyroxine is supplied as: oral tablets (numerous strengths, e.g., 25 mcg to 300 mcg), oral capsules (e.g., 13 mcg to 150 mcg), and oral solution (e.g., 20 mcg/mL, 100 mcg/mL). (mcg & µg = micrograms)
Contraindications	Levothyroxine is contraindicated in patients with known hypersensitivity to levothyroxine or any component of the formulation. It is also contraindicated in patients with uncorrected adrenal insufficiency (unless adequately treated), untreated thyrotoxicosis, or acute myocardial infarction.
Storage & Expiry	Levothyroxine tablets, capsules, and solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging. Due to sensitivity to light, moisture, and temperature, improper storage can reduce potency.
Side Effects	Side effects are generally related to excessive dosage and symptoms of hyperthyroidism (overactive thyroid). Common side effects include palpitations, tachycardia, arrhythmias, tremors, nervousness, insomnia, weight loss, heat intolerance, excessive sweating, and diarrhea. Serious but less common side effects can include angina, myocardial infarction, heart failure, seizures, and osteoporosis (with long-term overtreatment).
Warnings & Precautions	♦ Cardiac Toxicity: Use with extreme caution in patients with cardiovascular disease (e.g., angina, arrhythmias, coronary artery disease, hypertension, elderly patients), as thyroid hormone replacement can exacerbate or precipitate cardiac symptoms. Start with low doses and titrate slowly. ♦ Adrenal Insufficiency: Must be corrected before initiating levothyroxine therapy, as thyroid hormone replacement can precipitate an acute adrenal crisis. ♦ Thyrotoxicosis: Avoid overtreatment, as it can lead to symptoms of hyperthyroidism, reduce bone mineral density (leading to osteoporosis), and increase cardiovascular risk. Regular monitoring of TSH and free T4 levels is crucial. ♦ Diabetes Mellitus: Thyroid hormone replacement may increase blood glucose levels and insulin requirements. Monitor diabetic patients closely. ♦ Myxedema Coma: IV levothyroxine is preferred for this life-threatening hypothyroid state. ♦ Other Conditions: Use with caution in patients with pituitary insufficiency, malabsorption syndromes, or those undergoing surgery. ♦ Infertility: Untreated hypothyroidism can cause infertility. ♦ Brand Consistency: Patients should generally stick to the same brand and formulation of levothyroxine due to potential differences in bioavailability, which could affect TSH levels. Any change should be monitored with TSH testing.
Missed Dose Instructions	If a dose of Levothyroxine is missed, take it as soon as remembered. However, if it's close to the time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Taking two doses in one day may temporarily elevate thyroid hormone levels. Consistent daily administration is critical for maintaining stable thyroid hormone levels.
Overdose Instructions	Acute or chronic overdose symptoms are indicative of hyperthyroidism, including palpitations, tachycardia, arrhythmias, tremors, nervousness, insomnia, excessive sweating, heat intolerance, weight loss, and diarrhea. In severe cases, cardiovascular complications (angina, myocardial infarction, heart failure), seizures, or even death can occur. Treatment is supportive and symptomatic. Beta-blockers may be used to control cardiovascular symptoms. Antithyroid drugs (e.g., propylthiouracil) may be considered in severe cases, but their benefit is limited due to the slow onset of action. Gastric decontamination (e.g., activated charcoal) may be considered if recent. Seek immediate emergency medical help.

Medicine Interactions	♦ Calcium Carbonate, Iron Supplements, Antacids (aluminum- or magnesium-containing), Sucralfate, Bile Acid Sequestrants (e.g., cholestyramine, colestipol), Proton Pump Inhibitors (PPIs), Soy Products: These can significantly decrease the absorption of levothyroxine from the GI tract. Administer levothyroxine at least 4 hours apart from these agents (and often longer for some, like bile acid sequestrants). ♦ Thyroid Hormone Binding Proteins (e.g., estrogens, oral contraceptives, selective estrogen receptor modulators): Can increase serum thyroid binding globulin (TBG) levels, requiring an increase in levothyroxine dose. ♦ CYP450 Inducers (e.g., rifampin, phenytoin, carbamazepine, phenobarbital): Can increase the metabolism of levothyroxine, potentially requiring a higher dose. ♦ Anticoagulants (e.g., warfarin): Thyroid hormones can enhance the anticoagulant effect of warfarin, increasing bleeding risk. Monitor INR closely and adjust warfarin dose. ♦ Beta-Blockers: May reduce the effect of beta-blockers, particularly those that inhibit T4 to T3 conversion (e.g., propranolol). ♦ Antidiabetic Agents (e.g., insulin, oral hypoglycemics): Levothyroxine can increase blood glucose levels, potentially requiring an increase in antidiabetic medication dosage. ♦ Amiodarone: Can cause both hypothyroidism and hyperthyroidism, and can affect thyroid hormone metabolism. ♦ Sertraline, Chloral Hydrate, Furosemide (high dose): May displace thyroid hormones from binding proteins.

Linezolid (Zyvox)

Purpose/Indication	Linezolid is an oxazolidinone antibiotic used to treat serious infections caused by susceptible Gram-positive bacteria, particularly those resistant to other antibiotics. It is indicated for nosocomial pneumonia, community-acquired pneumonia, complicated skin and skin structure infections, and vancomycin-resistant Enterococcus faecium (VRE) infections. It is a crucial agent against methicillin-resistant Staphylococcus aureus (MRSA) and VRE.
Method of Action	Linezolid acts by inhibiting bacterial protein synthesis through a unique mechanism. It binds to the 23S ribosomal RNA of the 50S ribosomal subunit, preventing the formation of the 70S initiation complex, which is essential for bacterial translation. This action leads to a bacteriostatic effect against many Gram-positive organisms (e.g., enterococci, staphylococci) and a bactericidal effect against some (e.g., streptococci), preventing bacterial growth and replication.
Medication Name & Brand Names	♦ Medication Name: Linezolid ♦ Brand Names: Zyvox, Linezolid (generic)
Pharmaceutical Forms & Appearance	Linezolid is available as oral tablets, oral suspension, and solution for intravenous (IV) infusion. Oral tablets are typically white to off-white, film-coated, and oval-shaped, with various imprints. The oral suspension is an orange-flavored, white to off-white opaque liquid. The IV solution is clear and colorless to pale yellow.
Dosage & Administration	Dosage is typically 600 mg every 12 hours for adults, regardless of the route of administration (oral or IV). It can be given with or without food. Duration of therapy varies by infection type and severity, usually ranging from 10 to 28 days. No dosage adjustment is required for mild to moderate renal or hepatic impairment, but caution and close monitoring are advised in severe cases.
Supplied As	Linezolid is supplied as: oral film-coated tablets (e.g., 600 mg), oral suspension (e.g., 100 mg/5 mL powder for reconstitution), and solution for intravenous infusion (e.g., 2 mg/mL in 300 mL flexible bags).
Contraindications	Linezolid is contraindicated in patients with known hypersensitivity to linezolid or any component of the formulation. It is also contraindicated in patients currently taking or who have taken monoamine oxidase inhibitors (MAOIs) within two weeks, due to the risk of serotonin syndrome.
Storage & Expiry	Linezolid tablets and IV solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light. Oral suspension powder should be stored at room temperature, and once reconstituted, the suspension is stable for a specific period (e.g., 21 days) when stored at room temperature. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include diarrhea, headache, nausea, vomiting, constipation, and taste alteration. More serious but less common side effects include myelosuppression (e.g., thrombocytopenia, anemia, leukopenia), peripheral and optic neuropathy (especially with prolonged use), serotonin syndrome, lactic acidosis, and C. difficile-associated diarrhea.
Warnings & Precautions	♦ Myelosuppression: Can cause reversible myelosuppression (thrombocytopenia, anemia, leukopenia, pancytopenia), particularly with prolonged use (more than 2 weeks). Complete blood counts should be monitored weekly, especially in patients at increased risk. ♦ Peripheral and Optic Neuropathy: Reported with prolonged linezolid use (usually > 28 days). Patients should be advised to report changes in vision or sensation (e.g., numbness, tingling). Monitor visual function if signs occur. ♦ Serotonin Syndrome: Linezolid is a reversible, non-selective MAOI. Concurrent use with serotonergic agents (e.g., SSRIs, SNRIs, TCAs, triptans, tramadol, meperidine) can lead to serotonin syndrome. Avoid co-administration; if unavoidable, monitor closely. ♦ Lactic Acidosis: Cases of lactic acidosis have been reported. Monitor for symptoms (e.g., nausea, vomiting, abdominal pain, hyperventilation). ♦ Hypoglycemia: Can cause hypoglycemia in diabetic patients taking insulin or oral hypoglycemic agents. ♦ Clostridioides difficile-associated diarrhea (CDAD): Can occur with nearly all antibacterial agents, including linezolid. ♦ Hypertension: May cause a reversible increase in blood pressure due to its MAOI activity; caution with pressor agents. ♦ Children: Safety and efficacy in pediatric patients are similar to adults, but careful monitoring is warranted.
Missed Dose Instructions	For chronic infections requiring regular dosing, if a dose of Linezolid is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent dosing is crucial for effective antibiotic therapy.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, including increased gastrointestinal upset, headache, and potential for more severe myelosuppression, neuropathy, or serotonin syndrome. Treatment is supportive and symptomatic. There is no specific antidote. Hemodialysis may remove some linezolid, but it is not highly effective. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Monoamine Oxidase Inhibitors (MAOIs) and Serotonergic Agents (e.g., SSRIs, SNRIs, TCAs, triptans, tramadol, meperidine, dextromethorphan): Concomitant use is contraindicated or requires extreme caution due to the risk of serotonin syndrome (fever, rigidity, myoclonus, autonomic instability, mental status changes). Allow a 2-week washout period before starting linezolid after an MAOI. ♦ Vasopressors (e.g., dopamine, epinephrine, norepinephrine): Linezolid may potentiate the pressor effects of these agents due to its MAOI activity, potentially leading to increased blood pressure. Dose reduction of vasopressors may be needed. ♦ Tyramine-containing Foods/Beverages: Advise patients to avoid large quantities of tyramine-rich foods (e.g., aged cheese, fermented meats, tap beers, red wine) due to potential for hypertensive crisis, though the risk is lower than with irreversible MAOIs. ♦ Pseudoephedrine/Phenylpropanolamine: Increased risk of hypertension. ♦ Rifampin: Can decrease linezolid concentrations, potentially reducing efficacy. Consider alternative antibiotics if possible.

Lisinopril (Zestril)

Purpose/Indication	Lisinopril is an angiotensin-converting enzyme (ACE) inhibitor used primarily to treat hypertension (high blood pressure) and heart failure. It is also indicated to improve survival following a heart attack (acute myocardial infarction) and to slow the progression of kidney disease in patients with diabetes and hypertension who have early signs of kidney damage (microalbuminuria).

Method of Action	Lisinopril inhibits the angiotensin-converting enzyme (ACE), which is responsible for converting angiotensin I to angiotensin II. Angiotensin II is a powerful vasoconstrictor and stimulates aldosterone secretion. By blocking ACE, lisinopril reduces the production of angiotensin II, leading to vasodilation, decreased peripheral vascular resistance, and reduced sodium and water retention. It also decreases the breakdown of bradykinin, a vasodilator, further contributing to its blood pressure-lowering effects.
Medication Name & Brand Names	♦ Medication Name: Lisinopril ♦ Brand Names: Prinivil, Zestril, Lisinopril (generic) (Often found in combination with hydrochlorothiazide: Zestoretic, Prinzide)
Pharmaceutical Forms & Appearance	Lisinopril is available as oral tablets. Tablets vary in color, shape, and imprint depending on the manufacturer and strength (e.g., pink, white, yellow, round, oval), and are often scored.
Dosage & Administration	Dosage is individualized based on the patient's condition, blood pressure response, and renal function. For hypertension, the usual adult starting dose is 10 mg once daily, with a maintenance range typically 20 mg to 40 mg once daily. For heart failure, lower initial doses are used (e.g., 2.5 mg to 5 mg daily). It can be taken with or without food. Consistent daily administration is important for optimal blood pressure control.
Supplied As	Lisinopril is supplied as: oral tablets (e.g., 2.5 mg, 5 mg, 10 mg, 20 mg, 30 mg, 40 mg). It is also commonly available in fixed-dose combination tablets with hydrochlorothiazide.
Contraindications	Lisinopril is contraindicated in patients with known hypersensitivity to lisinopril, any other ACE inhibitor, or any component of the formulation. It is also contraindicated in patients with a history of angioedema related to previous ACE inhibitor treatment, hereditary or idiopathic angioedema, and concomitant use with aliskiren in patients with diabetes or moderate to severe renal impairment (GFR < 60 mL/min/1.73 m2). Use during pregnancy (especially second and third trimesters) is contraindicated due to risk of fetal injury or death.
Storage & Expiry	Lisinopril tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include persistent dry cough, dizziness, headache, and fatigue. More serious but less common side effects can include angioedema (swelling of face, lips, tongue, throat), hyperkalemia (high potassium levels), kidney dysfunction or failure, and severe hypotension.
Warnings & Precautions	♦ Fetal Toxicity: Can cause fetal harm or death when administered to pregnant women, particularly in the second and third trimesters. Discontinue as soon as pregnancy is detected. ♦ Angioedema: Can cause potentially life-threatening angioedema of the face, extremities, lips, tongue, glottis, and/or larynx. If angioedema involving the tongue, glottis, or larynx occurs, it can be fatal. Discontinue immediately and provide appropriate treatment. Higher risk in Black patients. ♦ Hypotension: Can cause symptomatic hypotension, especially with the first dose in volume-depleted patients (e.g., those on high-dose diuretics) or those with severe heart failure. Correct volume depletion before initiating therapy. ♦ Renal Impairment/Deterioration: Can cause changes in renal function, including acute renal failure, particularly in patients with severe congestive heart failure, pre-existing renal disease, or bilateral renal artery stenosis. Monitor renal function periodically. ♦ Hyperkalemia: Risk of hyperkalemia, especially in patients with renal impairment, diabetes, or those concurrently taking potassium-sparing diuretics, potassium supplements, or other drugs that increase potassium. Monitor serum potassium levels. ♦ Cough: A persistent, non-productive, dry cough is a common side effect, which resolves upon discontinuation. ♦ Hepatic Failure: Rare cases of cholestatic jaundice progressing to fulminant hepatic necrosis, sometimes fatal, have been reported. Discontinue if jaundice or marked elevations of liver enzymes develop. ♦ Neutropenia/Agranulocytosis: Rare, but can occur, especially in patients with renal impairment or collagen vascular disease. Monitor blood counts. ♦ Dual RAAS Blockade: Concomitant use of ACE inhibitors, ARBs, or aliskiren (especially in diabetes or renal impairment) increases the risk of hypotension, hyperkalemia, and renal dysfunction; generally avoid.
Missed Dose Instructions	If a dose of Lisinopril is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining optimal blood pressure control.
Overdose Instructions	Overdose symptoms are primarily related to exaggerated hypotensive effects (severe dizziness, lightheadedness, syncope) and possibly electrolyte disturbances (hyperkalemia) or renal failure. Treatment is supportive and symptomatic. If ingestion was recent, gastric decontamination (e.g., activated charcoal) may be considered. Intravenous fluids and vasopressors may be administered to correct hypotension. Lisinopril can be removed by hemodialysis. Seek immediate emergency medical help.
Medicine Interactions	♦ Potassium-Sparing Diuretics (e.g., spironolactone, triamterene, amiloride), Potassium Supplements, Salt Substitutes (containing potassium): Significantly increased risk of severe hyperkalemia. Avoid concurrent use or monitor potassium levels extremely closely. ♦ NSAIDs (Non-Steroidal Anti-inflammatory Drugs): Can reduce the antihypertensive effect of lisinopril and increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. Monitor renal function. ♦ Lithium: ACE inhibitors can increase serum lithium concentrations and toxicity. Monitor lithium levels. ♦ Diuretics: Can cause excessive blood pressure drop (hypotension), especially with the first dose of lisinopril. Diuretics may need to be stopped or reduced before starting lisinopril. ♦ Aliskiren: Concomitant use is contraindicated in patients with diabetes or moderate to severe renal impairment due to increased risk of hyperkalemia, hypotension, and renal impairment. ♦ Dual RAAS Blockade (e.g., with ARBs): Generally not recommended due to increased risk of adverse events without clear additional benefit. ♦ Gold (parenteral): Nitritoid reactions (facial flushing, nausea, vomiting, hypotension) have been reported rarely in patients receiving injectable gold and concomitant ACE inhibitors. ♦ mTOR Inhibitors (e.g., everolimus, sirolimus, temsirolimus): Increased risk of angioedema with concomitant use. ♦ Racecadotril: Increased risk of angioedema with concomitant use. ♦ Insulin/Oral Hypoglycemics: Increased risk of hypoglycemia, especially at initiation of lisinopril. Monitor blood glucose.

Loperamide (Imodium)

Purpose/Indication	Loperamide is an opioid-receptor agonist used to control and relieve the symptoms of acute non-specific diarrhea, including traveler's diarrhea. It is also used to reduce the volume of discharge from ileostomies and in the symptomatic management of chronic diarrhea associated with inflammatory bowel disease, often as an adjunct to specific therapy.
Method of Action	Loperamide acts directly on the opioid receptors in the intestinal wall, primarily the mu (μ) opioid receptors. By binding to these receptors, it decreases the activity of the myenteric plexus, leading to a reduction in intestinal motility and propulsive peristalsis. This allows more time for water and electrolytes to be absorbed from the gut, reducing the frequency and fluidity of bowel movements. It also increases the tone of the anal sphincter, helping to reduce incontinence.
Medication Name & Brand Names	♦ Medication Name: Loperamide Hydrochloride ♦ Brand Names: Imodium, Imodium A-D, Diamode, Anti-Diarrheal, Loperamide (generic)
Pharmaceutical Forms & Appearance	Loperamide is available as oral tablets, capsules, chewable tablets, and oral solution/liquid. Tablets and capsules vary in color and shape (e.g., white, green, round, oval), often with specific imprints. Oral solutions are typically clear or flavored liquids.

Dosage & Administration	For acute diarrhea in adults and children 12 years and older, the initial dose is typically 4 mg (two 2 mg capsules/tablets) orally, followed by 2 mg after each loose stool, not exceeding 8 mg to 16 mg in 24 hours (depending on specific product and region). For children under 12, dosing is based on weight or age and should be done under medical supervision. Loperamide is intended for short-term use; do not use for more than 2 days for acute diarrhea without consulting a doctor.
Supplied As	Loperamide is supplied as: oral capsules (e.g., 2 mg), oral tablets (e.g., 2 mg), chewable tablets (e.g., 2 mg), and oral solution/liquid (e.g., 1 mg/5 mL).
Contraindications	Loperamide is contraindicated in patients with known hypersensitivity to loperamide or any component of the formulation. It is also contraindicated in conditions where inhibition of peristalsis should be avoided, such as suspected or confirmed bacterial enterocolitis (e.g., Clostridioides difficile infection), acute dysentery (characterized by fever and blood in stool), acute ulcerative colitis, or bacterial infections of the bowel where inhibition of peristalsis could lead to toxic megacolon or worsen the underlying condition.
Storage & Expiry	Loperamide tablets, capsules, and oral solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and include constipation, dizziness, nausea, and abdominal cramps. More serious but less common side effects can include severe constipation, paralytic ileus (bowel obstruction), toxic megacolon (especially in severe colitis), and rarely, serious cardiac events (QT prolongation, Torsades de Pointes) with high doses.
Warnings & Precautions	♦ Cardiac Events (High Doses): Serious cardiac adverse reactions (QT prolongation, Torsades de Pointes, other ventricular arrhythmias) have been reported with abuse, misuse, or high doses of loperamide, sometimes leading to death. Do not exceed the recommended dose. ♦ Diarrhea with Fever/Blood in Stool: Do not use if you have a fever or blood/mucus in your stool, as this may indicate a serious bacterial infection or other condition where delaying stool passage could be harmful. ♦ Acute Dysentery/Bacterial Enterocolitis/C. difficile: Contraindicated in these conditions as it can worsen the underlying infection or lead to toxic megacolon. ♦ Hepatic Impairment: Use with caution in patients with hepatic impairment, as it may lead to relative overdose and CNS toxicity due to reduced metabolism. ♦ Dehydration: Diarrhea itself can cause dehydration and electrolyte depletion; adequate fluid and electrolyte replacement are important. ♦ Children: Not recommended for children under 6 years due to risk of ileus and CNS depression. Use with caution in older children and only as directed. ♦ Abuse Potential: While generally having low CNS penetration at therapeutic doses, very high doses can produce opioid-like effects, leading to abuse and dependence, and dangerous cardiac risks.
Missed Dose Instructions	Loperamide is typically taken as needed for diarrhea symptoms. If a dose is missed, take it when the next loose stool occurs, adhering to the maximum daily dose and the recommended dosing interval (e.g., not exceeding the maximum daily dose or using for more than 2 days without medical advice).
Overdose Instructions	Overdose symptoms are similar to opioid overdose, including constipation, CNS depression (drowsiness, stupor, coma), miosis (pinpoint pupils), respiratory depression, and severe cardiac abnormalities (QT prolongation, Torsades de Pointes, cardiac arrest). Children are particularly sensitive to CNS and respiratory depression. Treatment is supportive. Naloxone can reverse opioid effects but may require repeated doses due to loperamide's long duration of action. Gastric lavage and activated charcoal may be considered. Continuous ECG monitoring is essential for potential cardiac arrhythmias. Seek immediate emergency medical help.
Medicine Interactions	♦ CYP3A4/CYP2C8 Inhibitors (e.g., quinidine, ritonavir, ketoconazole, itraconazole, gemfibrozil): Can increase plasma concentrations of loperamide, potentially increasing CNS effects or cardiac risks. Use with caution. ♦ Other CNS Depressants (e.g., opioids, sedatives, tranquilizers, alcohol): Additive CNS depressant effects; increased drowsiness or dizziness. ♦ P-glycoprotein Inhibitors (e.g., quinidine, ritonavir): Can increase loperamide absorption and distribution to the CNS, increasing the risk of CNS depression. ♦ Cholestyramine: May reduce loperamide absorption; administer at different times. ♦ Saquinavir: Loperamide may reduce saquinavir absorption.

Loratadine (Claritin)

Purpose/Indication	Loratadine is a second-generation (non-sedating) antihistamine used to relieve symptoms associated with seasonal allergic rhinitis (hay fever), such as sneezing, runny nose, itchy or watery eyes, and itchy throat or nose. It is also indicated for the symptomatic relief of chronic idiopathic urticaria (hives), reducing itching and the size and number of hives. It provides 24-hour relief with once-daily dosing.
Method of Action	Loratadine is a selective peripheral histamine H1-receptor antagonist. It works by blocking the action of histamine, a substance released by the body during an allergic reaction. By preventing histamine from binding to H1-receptors in peripheral tissues, loratadine alleviates allergic symptoms such as itching, sneezing, rhinorrhea (runny nose), and watery eyes, without causing significant drowsiness due to its poor penetration of the blood-brain barrier.
Medication Name & Brand Names	♦ Medication Name: Loratadine ♦ Brand Names: Claritin, Alavert, Claratyne (regional), Loratadine (generic)
Pharmaceutical Forms & Appearance	Loratadine is available as oral tablets, orally disintegrating tablets (ODT), chewable tablets, and oral syrup. Tablets are typically white, round, or oval, with specific imprints. ODTs are white and dissolve rapidly on the tongue. Chewable tablets may be colored and flavored. The oral syrup is a clear, colorless to yellowish liquid.
Dosage & Administration	For adults and children 6 years and older, the usual dose is 10 mg once daily. For children aged 2-5 years, a lower dose (e.g., 5 mg daily) is typically used. It can be taken with or without food. Consistent daily administration is important for continuous symptom control. Do not exceed the recommended dose.
Supplied As	Loratadine is supplied as: oral tablets (e.g., 10 mg), orally disintegrating tablets (e.g., 10 mg), chewable tablets (e.g., 5 mg), and oral syrup (e.g., 1 mg/mL).
Contraindications	Loratadine is contraindicated in patients with known hypersensitivity to loratadine, desloratadine (its active metabolite), or any component of the formulation.
Storage & Expiry	Loratadine products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from excessive moisture and heat. Keep in tightly closed containers. Oral syrup should be protected from freezing. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and include headache, somnolence (drowsiness, though less than first-generation antihistamines), fatigue, dry mouth, and nausea. Serious side effects are rare but can include severe hypersensitivity reactions (e.g., anaphylaxis, angioedema), and very rarely, liver dysfunction or cardiovascular effects (e.g., tachycardia, palpitations, though not typically QT prolongation at therapeutic doses).

Warnings & Precautions	♦ Hepatic/Renal Impairment: Use with caution and consider dose adjustment in patients with severe hepatic impairment or severe renal impairment (creatinine clearance < 30 mL/min), as drug clearance may be reduced, increasing exposure. ♦ Phenylketonuria (PKU): Orally disintegrating tablets and chewable tablets may contain phenylalanine (aspartame), which is a concern for patients with PKU. ♦ Drug Interactions: While generally having fewer significant interactions than first-generation antihistamines, caution should be exercised with concurrent use of medications that inhibit CYP3A4 or CYP2D6, as this can increase loratadine levels. ♦ Elderly: While generally well-tolerated, use with caution in elderly patients who may be more susceptible to adverse effects. ♦ Driving/Operating Machinery: Although less sedating than first-generation antihistamines, individuals should assess their response before engaging in activities requiring mental alertness.
Missed Dose Instructions	Loratadine is typically taken once daily. If a dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing helps maintain continuous symptom control.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, including somnolence, tachycardia, and headache. In children, extrapyramidal symptoms and palpitations have been reported. Treatment is supportive and symptomatic. Gastric decontamination (e.g., activated charcoal) may be considered if recent. Loratadine is not significantly removed by hemodialysis. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ CYP3A4 and CYP2D6 Inhibitors (e.g., ketoconazole, itraconazole, erythromycin, cimetidine, fluvoxamine): Concomitant use with these inhibitors can increase plasma concentrations of loratadine and its active metabolite (desloratadine). While typically not clinically significant at recommended doses, this could potentially increase the risk of adverse effects. ♦ Alcohol and other CNS Depressants: Although loratadine is generally non-sedating, additive sedative effects could theoretically occur, but are less likely than with first-generation antihistamines. Caution is still advised. ♦ Grapefruit Juice: May inhibit CYP3A4, potentially increasing loratadine levels.

Lorazepam (Ativan)

Purpose/Indication	Lorazepam is a benzodiazepine used primarily for the short-term management of anxiety disorders, anxiety associated with depressive symptoms, and insomnia due to anxiety. It is also a first-line treatment for status epilepticus (a medical emergency involving continuous seizures), and is used for pre-anesthetic medication to induce sedation, reduce anxiety, and produce anterograde amnesia.
Method of Action	Lorazepam enhances the effect of gamma-aminobutyric acid (GABA), the primary inhibitory neurotransmitter in the brain. It binds to specific benzodiazepine receptors on the GABA-A receptor complex, increasing the frequency of chloride channel opening. This allows more chloride ions to enter the neuron, leading to hyperpolarization and reduced neuronal excitability, thereby producing anxiolytic (anti-anxiety), sedative, hypnotic, anticonvulsant, and muscle relaxant effects.
Medication Name & Brand Names	♦ Medication Name: Lorazepam ♦ Brand Names: Ativan, Lorazepam (generic)
Pharmaceutical Forms & Appearance	Lorazepam is available as oral tablets, oral solution, and solution for intravenous (IV) or intramuscular (IM) injection. Oral tablets are typically white, round, or oblong, and may be scored, with various imprints. The oral solution is a clear, colorless liquid. The injectable solution is clear and colorless.
Dosage & Administration	Dosage is highly individualized and varies by indication, patient age, and response. For anxiety, typical oral doses range from 1 mg to 4 mg daily in divided doses. For insomnia, 2-4 mg at bedtime. For status epilepticus, IV doses of 2 mg to 4 mg are given, repeated as needed. For pre-anesthesia, IM or IV doses are used. Oral doses can be taken with or without food. Avoid abrupt discontinuation due to withdrawal risk.
Supplied As	Lorazepam is supplied as: oral tablets (e.g., 0.5 mg, 1 mg, 2 mg), oral solution (e.g., 2 mg/mL), and solution for intravenous or intramuscular injection (e.g., 2 mg/mL, 4 mg/mL in vials or pre-filled syringes).
Contraindications	Lorazepam is contraindicated in patients with known hypersensitivity to lorazepam or any benzodiazepine, or any component of the formulation. It is also contraindicated in patients with acute narrow-angle glaucoma or severe respiratory insufficiency (except when managing acute seizures under close monitoring). Concomitant use with opioids may lead to profound sedation, respiratory depression, coma, and death.
Storage & Expiry	Lorazepam tablets, oral solution, and injectable solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. The injectable solution should be protected from freezing. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include sedation, drowsiness, dizziness, weakness, unsteadiness, and ataxia (impaired coordination). More serious side effects include respiratory depression (especially with IV use or high doses), paradoxical reactions (e.g., excitement, aggression), dependence and withdrawal symptoms (especially with prolonged use), and anterograde amnesia.
Warnings & Precautions	♦ CNS Depression/Sedation: Can cause significant CNS depression, including drowsiness, reduced alertness, and impaired coordination. Advise caution with driving or operating machinery. ♦ Respiratory Depression: Can cause respiratory depression, especially with IV use, high doses, or concomitant use of other CNS depressants (e.g., opioids, alcohol). Use with extreme caution in patients with respiratory compromise (e.g., COPD, sleep apnea). ♦ Concomitant Opioid Use: BLACK BOX WARNING: Concomitant use with opioids significantly increases the risk of profound sedation, respiratory depression, coma, and death. Reserve for use when alternative treatment options are inadequate. Monitor for signs of respiratory depression and sedation. ♦ Dependence and Withdrawal: Prolonged use can lead to physical and psychological dependence. Abrupt discontinuation can precipitate severe withdrawal symptoms (e.g., seizures, hallucinations, tremor, anxiety, insomnia, psychosis), especially with high doses or long-term use. Taper dose gradually. ♦ Paradoxical Reactions: Excitement, agitation, hostility, and hallucinations can rarely occur, especially in children and the elderly. ♦ Elderly Patients: More susceptible to CNS depressant effects (drowsiness, ataxia) and paradoxical reactions. Use lowest effective dose. ♦ Hepatic/Renal Impairment: Use with caution and consider dose adjustment in patients with severe hepatic or renal impairment. ♦ Abuse Potential: Has abuse potential; use with caution in patients with a history of substance abuse. ♦ Depression/Suicidal Ideation: Use with caution in patients with depression; may exacerbate symptoms.
Missed Dose Instructions	For chronic anxiety or insomnia, if a dose of Lorazepam is missed, take it as soon as remembered if symptoms warrant. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Missing doses regularly, especially with long-term use, can contribute to withdrawal symptoms.
Overdose Instructions	Overdose symptoms are typically an exaggeration of the pharmacological effects, including somnolence, confusion, diminished reflexes, slurred speech, ataxia, hypotension, and profound CNS and respiratory depression, which can progress to coma and death. Treatment is supportive and symptomatic. Flumazenil, a benzodiazepine receptor antagonist, can reverse the effects but should be used with extreme caution, especially in patients on chronic benzodiazepine therapy or with co-ingestions of other proconvulsant drugs, as it can precipitate acute withdrawal or seizures. Gastric decontamination may be considered if recent. Seek immediate emergency medical help.

Medicine Interactions	♦ Opioids: BLACK BOX WARNING: Profound sedation, respiratory depression, coma, and death. Avoid concomitant use unless absolutely necessary; if so, use lowest effective doses and monitor closely. ♦ Other CNS Depressants (e.g., alcohol, barbiturates, antidepressants, antipsychotics, antihistamines, muscle relaxants, anesthetics): Additive CNS depressant effects; increased sedation and respiratory depression. Avoid or use with extreme caution. ♦ Valproic Acid, Probenecid: Can inhibit the metabolism of lorazepam, leading to increased plasma concentrations and enhanced CNS effects. Reduce lorazepam dose. ♦ Theophylline, Aminophylline: Can reduce the sedative effects of benzodiazepines. ♦ Clozapine: Can cause profound sedation, hypotension, and respiratory depression. Use with extreme caution. ♦ Digoxin: May increase digoxin levels. ♦ Disulfiram: May inhibit lorazepam metabolism.

Losartan (Cozaar)

Purpose/Indication	Losartan is an angiotensin II receptor blocker (ARB) primarily used to treat hypertension (high blood pressure) to reduce the risk of stroke, heart attack, and death from cardiovascular causes. It is also indicated for the treatment of diabetic nephropathy (kidney disease) in patients with type 2 diabetes and a history of hypertension, aiming to slow the progression of kidney disease. It is often used as an alternative for patients who develop a cough with ACE inhibitors.
Method of Action	Losartan works by selectively blocking the binding of angiotensin II to the AT1 (angiotensin II type 1) receptors found in various tissues, including vascular smooth muscle, adrenal glands, and kidneys. Angiotensin II is a potent vasoconstrictor and a key hormone in the renin-angiotensin-aldosterone system (RAAS) responsible for regulating blood pressure and fluid balance. By blocking AT1 receptors, losartan prevents angiotensin II from causing vasoconstriction, aldosterone release, and sodium/water retention, leading to vasodilation, reduced systemic vascular resistance, and decreased blood pressure. It is also metabolized to an active metabolite, E-
Medication Name & Brand Names	♦ Medication Name: Losartan Potassium ♦ Brand Names: Cozaar, Losartan (generic) (Often found in combination with hydrochlorothiazide: Hyzaar, Cozaar Comp.)
Pharmaceutical Forms & Appearance	Losartan is available as oral tablets. Tablets are typically white or off-white, often oval or round, and may be scored, with various imprints indicating strength.
Dosage & Administration	Dosage is individualized based on blood pressure response and patient tolerability. For hypertension, the usual adult starting dose is 50 mg once daily, which can be increased to 100 mg once daily if needed. For diabetic nephropathy, the starting dose is 50 mg once daily, with a target maintenance dose of 100 mg once daily. It can be taken with or without food. Consistent daily administration is important for optimal blood pressure control.
Supplied As	Losartan is supplied as: oral tablets (e.g., 25 mg, 50 mg, 100 mg). It is also commonly available in fixed-dose combination tablets with hydrochlorothiazide.
Contraindications	Losartan is contraindicated in patients with known hypersensitivity to losartan or any component of the formulation. It is also contraindicated in combination with aliskiren in patients with diabetes or moderate to severe renal impairment (GFR < 60 mL/min/1.73 m2). Use during pregnancy (especially second and third trimesters) is strictly contraindicated due to risk of fetal injury or death.
Storage & Expiry	Losartan tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include dizziness, lightheadedness (due to hypotension), upper respiratory tract infection, and fatigue. Less common but more serious side effects can include hyperkalemia (high potassium levels), kidney dysfunction or failure, angioedema (swelling of face, lips, throat), and rhabdomyolysis (rarely). Unlike ACE inhibitors, a persistent dry cough is much less common.
Warnings & Precautions	♦ Fetal Toxicity: Can cause fetal harm or death when administered to pregnant women, particularly in the second and third trimesters. Discontinue as soon as pregnancy is detected. ♦ Hypotension: Can cause symptomatic hypotension, especially in volume-depleted patients (e.g., those on high-dose diuretics) or those with severe heart failure. Correct volume depletion before initiating therapy. ♦ Renal Impairment/Deterioration: Can cause changes in renal function, including acute renal failure, particularly in patients with severe congestive heart failure, pre-existing renal disease, or renal artery stenosis. Monitor renal function periodically. ♦ Hyperkalemia: Risk of hyperkalemia, especially in patients with renal impairment, diabetes, or those concurrently taking potassium-sparing diuretics, potassium supplements, or other drugs that increase potassium. Monitor serum potassium levels. ♦ Angioedema: Rare but potentially life-threatening swelling of the face, lips, tongue, and throat. Discontinue immediately if symptoms occur. While less common than with ACE inhibitors, it can still occur. ♦ Dual RAAS Blockade: Concomitant use of ARBs, ACE inhibitors, or aliskiren (especially in diabetes or renal impairment) increases the risk of hypotension, hyperkalemia, and renal dysfunction; generally avoid. ♦ Hepatic Impairment: Use with caution in patients with hepatic impairment, as plasma concentrations of losartan may be increased.
Missed Dose Instructions	If a dose of Losartan is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining optimal blood pressure control.
Overdose Instructions	Overdose symptoms are primarily related to exaggerated hypotensive effects (severe dizziness, lightheadedness, syncope) and possibly tachycardia or bradycardia. Treatment is supportive and symptomatic. If ingestion was recent, gastric decontamination (e.g., activated charcoal) may be considered. Intravenous fluids and vasopressors may be administered to correct hypotension. Losartan and its active metabolite are not removed by hemodialysis. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Potassium-Sparing Diuretics (e.g., spironolactone, triamterene, amiloride), Potassium Supplements, Salt Substitutes (containing potassium): Significantly increased risk of hyperkalemia. Avoid concurrent use or monitor potassium levels extremely closely. ♦ NSAIDs (Non-Steroidal Anti-inflammatory Drugs): Can reduce the antihypertensive effect of losartan and increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. Monitor renal function. ♦ Lithium: Losartan can increase serum lithium concentrations and toxicity. Monitor lithium levels. ♦ Aliskiren: Concomitant use is contraindicated in patients with diabetes or moderate to severe renal impairment due to increased risk of hyperkalemia, hypotension, and renal impairment. ♦ Dual RAAS Blockade (e.g., with ACE inhibitors): Generally not recommended due to increased risk of adverse events without clear additional benefit. ♦ Rifampin, Fluconazole: May affect levels of losartan and its active metabolite. Rifampin may decrease levels, while fluconazole may increase levels.

Malathion (Ovide)

Purpose/Indication	Malathion is an organophosphate insecticide used topically to treat head lice (Pediculus humanus capitis) and their nits (eggs) in patients 6 years of age and older. It is typically reserved for cases where other less toxic treatments (like permethrin) have failed or are not appropriate, due to its classification as a potent anticholinesterase.

Method of Action	Malathion is an organophosphate that acts as a cholinesterase inhibitor. Once absorbed by the lice and their eggs, malathion is metabolized into malaoxon, its active metabolite. Malaoxon irreversibly binds to and inactivates acetylcholinesterase, an enzyme essential for breaking down acetylcholine in the nervous system of insects. This leads to an accumulation of acetylcholine, causing continuous stimulation of nerve and muscle cells, resulting in paralysis and death of the lice.
Medication Name & Brand Names	♦ Medication Name: Malathion Lotion ♦ Brand Names: Ovide (most common), Malathion (generic)
Pharmaceutical Forms & Appearance	Malathion is primarily available as a topical lotion for external use. It is typically a clear, colorless to yellowish, alcoholic solution.
Dosage & Administration	For head lice, apply enough lotion to cover dry hair and scalp thoroughly, ensuring all hair and scalp are saturated. Allow the hair to air dry naturally (do not use a hairdryer, as the product is flammable). Leave on hair for 8 to 12 hours, then wash hair and scalp thoroughly with a non-medicated shampoo. Remove dead lice and nits with a fine-toothed comb. A second application may be needed if live lice are still present after 7-9 days.
Supplied As	Malathion is supplied as: topical lotion (e.g., 0.5% or 0.9% malathion in an alcoholic vehicle) in bottles (e.g., 59 mL or 60 mL).
Contraindications	Malathion is contraindicated in patients with known hypersensitivity to malathion or any component of the formulation. It is also contraindicated in children younger than 6 years due to increased risk of absorption and systemic toxicity. Avoid use on irritated, broken, or inflamed skin.
Storage & Expiry	Malathion lotion should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from heat and open flame, as it is flammable. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and localized, including scalp irritation (e.g., burning, stinging, itching), dry skin, and mild eye irritation if contact occurs. More serious side effects, though rare with proper topical use, can include systemic toxicity symptoms characteristic of organophosphate poisoning (e.g., increased sweating, lacrimation, salivation, miosis, nausea, vomiting, abdominal cramps, diarrhea, muscle tremors, respiratory distress, seizures), especially with excessive application or accidental ingestion.
Warnings & Precautions	♦ Flammability: Malathion lotion is flammable due to its alcohol content. Do not use or dry hair with heat sources (e.g., hair dryers, curling irons, open flames, cigarettes) during application or while hair is wet with the lotion. Apply in a well-ventilated area. ♦ Systemic Absorption/Toxicity: Although topical absorption is generally low, systemic toxicity (cholinesterase inhibition symptoms) can occur, especially with excessive application, prolonged contact, broken skin, or in young children. Symptoms include headache, dizziness, nausea, abdominal cramps, and blurred vision. Discontinue if symptoms of systemic toxicity occur. ♦ Eye Contact: Avoid contact with eyes. If contact occurs, flush immediately with water. ♦ Oral Ingestion: Harmful if swallowed. Keep out of reach of children and pets. ♦ Irritated Skin: Do not apply to open wounds, cuts, or severely irritated skin to prevent increased systemic absorption. ♦ Cholinesterase Monitoring: In rare cases of suspected systemic toxicity or prolonged exposure, plasma cholinesterase levels may be monitored. ♦ Resistance: Improper or overuse can contribute to the development of lice resistance.
Missed Dose Instructions	Malathion for head lice is typically a single application, potentially with a second application 7-9 days later if live lice remain. If the first application was not performed correctly or effectively, repeat as directed. For the second application, if missed, apply as soon as remembered if live lice are still present, maintaining the 7-9 day interval from the initial application if possible, or consult a healthcare professional.
Overdose Instructions	Overdose from topical malathion is rare but can result in systemic organophosphate poisoning symptoms due to significant absorption. Symptoms include increased sweating, lacrimation, salivation, miosis (pinpoint pupils), nausea, vomiting, diarrhea, abdominal cramps, muscle weakness, tremors, respiratory distress, bradycardia, and potentially seizures or coma. Treatment involves immediate medical attention. Atropine is the primary antidote for cholinergic symptoms, and pralidoxime chloride (2-PAM) may also be used to reactivate cholinesterase. Supportive care, including respiratory support, may be necessary. Contaminated skin should be thoroughly washed. Seek immediate emergency medical help.
Medicine Interactions	♦ Other Cholinesterase Inhibitors: Concomitant use with other cholinesterase inhibitors (e.g., certain medications for Alzheimer's disease like donepezil, rivastigmine, galantamine) or neuromuscular blocking agents (e.g., succinylcholine) could theoretically increase the risk of systemic cholinergic toxicity. However, given the topical route and limited systemic absorption, this interaction is generally considered low risk for typical use. ♦ No other significant or commonly reported systemic drug interactions are well-established for topical malathion.

Mebendazole (Vermox)

Purpose/Indication	Mebendazole is an anthelmintic (anti-worm) medication used to treat a variety of parasitic worm infections in the gastrointestinal tract. It is highly effective against common infections such as pinworm (enterobiasis), roundworm (ascariasis), hookworm (ancylostomiasis, necatoriasis), and whipworm (trichuriasis). Its purpose is to eradicate the worms from the digestive system.
Method of Action	Mebendazole works by selectively and irreversibly inhibiting the formation of microtubules in the intestinal cells of the parasites. Microtubules are crucial for glucose uptake and other vital cellular processes in the worms. By disrupting microtubule formation, mebendazole impairs the worm's ability to absorb glucose, leading to depletion of its glycogen stores, reduction in ATP synthesis, and ultimately, starvation and death of the parasite. It has a relatively low systemic absorption in humans.
Medication Name & Brand Names	♦ Medication Name: Mebendazole ♦ Brand Names: Vermox, Emverm, Mebendazole (generic)
Pharmaceutical Forms & Appearance	Mebendazole is available as oral tablets (chewable or regular) and oral suspension. Tablets are typically white or off-white, often round, and may be chewable. The oral suspension is a white to off-white liquid.
Dosage & Administration	Dosage varies depending on the type of worm infection. For pinworms, a single dose of 100 mg orally is typical, which may be repeated in 2-3 weeks to prevent re-infection. For roundworm, hookworm, and whipworm, the usual dose is 100 mg twice daily for 3 days, or 500 mg as a single dose for heavy infestations. It can be taken with or without food, but taking it with a fatty meal may slightly increase absorption.
Supplied As	Mebendazole is supplied as: oral chewable tablets (e.g., 100 mg, 500 mg) and oral suspension (e.g., 100 mg/5 mL).
Contraindications	Mebendazole is contraindicated in patients with known hypersensitivity to mebendazole or any component of the formulation. It is also generally contraindicated in children under 2 years of age due to reports of convulsions in this age group.

Storage & Expiry	Mebendazole tablets and oral suspension should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Oral suspension should not be frozen. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and include abdominal pain, diarrhea, and flatulence, especially with heavy worm infestations. More serious but rare side effects can include transient neutropenia (decreased white blood cells), agranulocytosis (severe reduction in white blood cells), hepatitis, and hypersensitivity reactions (e.g., rash, Stevens-Johnson syndrome).
Warnings & Precautions	♦ Children Under 2 Years: Not recommended for children younger than 2 years due to reports of convulsions. Use in this age group only if the potential benefit justifies the potential risk. ♦ Myelosuppression: Rare cases of neutropenia and agranulocytosis have been reported, particularly with higher doses and prolonged treatment duration. Monitor blood counts in such cases. ♦ Hepatotoxicity: Very rare cases of hepatitis and abnormal liver function tests have been reported. Monitor liver function if prolonged use or high doses are necessary. ♦ Absorption: Absorption is variable. Taking with a fatty meal can increase absorption. ♦ Pregnancy/Breastfeeding: Use in pregnancy only if clearly needed. Minimal excretion into breast milk, but caution is advised. ♦ Hygiene Measures: Advise patients on proper hygiene to prevent re-infection, especially for pinworm (e.g., handwashing, cleaning bedding).
Missed Dose Instructions	For single-dose treatments (e.g., pinworm), if the dose is missed, take it as soon as remembered. For multi-dose regimens (e.g., for hookworm, roundworm, whipworm), if a dose is missed, take it as soon as remembered. If it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not double a dose. Completing the full course of treatment is important for effective eradication.
Overdose Instructions	In cases of accidental or intentional overdose, symptoms can include abdominal cramps, nausea, vomiting, and diarrhea. With very high doses or prolonged use, more serious effects like myelosuppression, alopecia, and hepatitis have been reported. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered if ingestion was recent. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Cimetidine: May inhibit the metabolism of mebendazole, leading to increased plasma concentrations. This is generally not clinically significant with typical short-term use, but could be relevant for prolonged or high-dose regimens. ♦ Phenytoin, Carbamazepine: These enzyme inducers may decrease mebendazole plasma concentrations, potentially reducing its efficacy. Concurrent use should be avoided or monitored closely, and an alternative anthelmintic considered. ♦ Metronidazole: Concurrent use of mebendazole and metronidazole has been associated with an increased risk of Stevens-Johnson syndrome/toxic epidermal necrolysis; concomitant use should be avoided if possible. ♦ No other significant or commonly reported drug interactions are well-established for mebendazole with typical short-term use.

Mefenamic Acid (Ponstel)

Purpose/Indication	Mefenamic acid is a non-steroidal anti-inflammatory drug (NSAID) primarily used for the short-term (typically up to 7 days) relief of mild to moderate pain, including muscular pain, traumatic pain, dental pain, and post-operative pain. It is particularly effective and frequently indicated for the treatment of primary dysmenorrhea (menstrual pain) due to its specific action on prostaglandin synthesis, often starting at the onset of menstrual flow.
Method of Action	Mefenamic acid exerts its analgesic, anti-inflammatory, and antipyretic effects by inhibiting the cyclooxygenase (COX) enzymes, both COX-1 and COX-2. This inhibition leads to a reduction in the synthesis of prostaglandins, which are key mediators of pain, inflammation, and fever. In the context of dysmenorrhea, it inhibits prostaglandin synthesis in the uterus, reducing uterine contractions and associated pain.
Medication Name & Brand Names	♦ Medication Name: Mefenamic Acid ♦ Brand Names: Ponstel (historical, largely discontinued in some regions), Ponstan (common in many regions), Mefenamic Acid (generic)
Pharmaceutical Forms & Appearance	Mefenamic acid is primarily available as oral capsules or tablets. Capsules are typically blue and white, sometimes with specific imprints. Tablets may vary in color and shape.
Dosage & Administration	For adults and adolescents 14 years and older, the typical initial dose is 500 mg orally, followed by 250 mg every 6 hours as needed. The maximum recommended duration of treatment is generally 7 days, particularly for acute pain, and 2-3 days for dysmenorrhea, starting at the onset of menstrual flow. It should be taken with food, milk, or antacids to minimize gastrointestinal upset.
Supplied As	Mefenamic acid is supplied as: oral capsules (e.g., 250 mg) and oral tablets (e.g., 500 mg).
Contraindications	Mefenamic acid is contraindicated in patients with known hypersensitivity to mefenamic acid, aspirin, or other NSAIDs. It is also contraindicated in patients with a history of bronchospasm, asthma, rhinitis, or urticaria precipitated by aspirin or other NSAIDs, active gastrointestinal bleeding or peptic ulcer disease, severe renal impairment, or severe hepatic impairment. Concomitant use in the setting of coronary artery bypass graft (CABG) surgery is also contraindicated.
Storage & Expiry	Mefenamic acid capsules/tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., nausea, vomiting, abdominal pain, dyspepsia, diarrhea – which can be prominent), headache, and dizziness. More serious side effects, though less common with short-term use, include severe gastrointestinal bleeding, ulceration, or perforation, acute kidney injury, cardiovascular thrombotic events (e.g., heart attack, stroke), liver injury, and severe allergic reactions (including anaphylaxis, serious skin reactions).
Warnings & Precautions	♦ GI Risk: Like other NSAIDs, it carries a risk of serious gastrointestinal adverse events including bleeding, ulceration, and perforation, which can be fatal. This risk increases with duration of use, higher doses, and in certain patient populations (elderly, history of GI disease). ♦ Cardiovascular Risk: Can increase the risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may increase with duration. Contraindicated for pain after CABG surgery. ♦ Renal Effects: Can cause new onset or worsening of renal impairment, including acute renal failure. Use with caution in patients with pre-existing renal disease, heart failure, or dehydration. ♦ Hepatic Effects: Liver injury, including severe and fatal cases, can occur. Monitor liver function in prolonged use. ♦ Hematologic Effects: Can cause anemia and other blood dyscrasias. ♦ Hypersensitivity Reactions: Can cause severe allergic reactions, including anaphylaxis and serious skin reactions (e.g., Stevens-Johnson syndrome). Discontinue at first sign of rash or allergic reaction. ♦ Hypertension: Can cause new onset hypertension or worsen pre-existing hypertension. ♦ Fluid Retention/Edema: Use with caution in patients with heart failure or hypertension. ♦ Asthma Exacerbation: Use with caution in patients with asthma, especially aspirin-sensitive asthma. ♦ Pregnancy: Avoid use in late pregnancy (third trimester) due to risk of premature closure of fetal ductus arteriosus. ♦ Duration of Use: Recommended for short-term use only (maximum 7 days) to minimize risk of serious side effects.
Missed Dose Instructions	Mefenamic acid is typically used as needed for pain. If a dose is missed, take it when remembered if pain warrants, adhering to the recommended dosing interval (e.g., every 6 hours) and the maximum daily dose. Do not exceed the maximum daily dose or the recommended treatment duration (e.g., 7 days). Do not double a dose.

Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily severe gastrointestinal upset (nausea, vomiting, abdominal pain, diarrhea), drowsiness, and potentially more severe GI bleeding, acute renal failure, or even seizures. Treatment is supportive and symptomatic. Gastric decontamination (e.g., activated charcoal) may be considered if oral ingestion was recent and substantial. Hemodialysis is unlikely to be effective due to high protein binding. Seek immediate emergency medical help.
Medicine Interactions	♦ Anticoagulants (e.g., warfarin) & Antiplatelet agents (e.g., aspirin, clopidogrel): Significantly increased risk of bleeding. Concurrent use should be approached with extreme caution, and close monitoring of coagulation parameters (e.g., INR) is essential. ♦ Other NSAIDs: Concomitant use is generally not recommended due to additive GI and renal toxicity, and no additional therapeutic benefit. ♦ Lithium: Increases serum lithium concentrations and toxicity; monitor lithium levels closely. ♦ Methotrexate: Increases methotrexate toxicity. ♦ ACE Inhibitors/ARBs/Diuretics: May reduce the antihypertensive and diuretic effects, and significantly increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. ♦ Corticosteroids: Increased risk of GI ulceration and bleeding. ♦ SSRIs: Increased risk of GI bleeding. ♦ Oral Hypoglycemics: Can potentiate the effects of sulfonylurea oral hypoglycemic agents, increasing the risk of hypoglycemia. Monitor blood glucose. ♦ Cyclosporine/Tacrolimus: Increased risk of nephrotoxicity.

Meloxicam (Mobic)

Purpose/Indication	Meloxicam is a non-steroidal anti-inflammatory drug (NSAID) primarily used for the symptomatic treatment of osteoarthritis, rheumatoid arthritis, and juvenile rheumatoid arthritis (in older children). It helps relieve pain, stiffness, and swelling associated with these chronic inflammatory conditions. Its purpose is to provide long-term management of inflammatory pain.
Method of Action	Meloxicam acts by inhibiting the synthesis of prostaglandins, which are key mediators of pain, inflammation, and fever. It does this by primarily inhibiting the cyclooxygenase-2 (COX-2) enzyme more selectively than COX-1, especially at lower doses. While it has some COX-1 inhibitory activity, its relative COX-2 selectivity is thought to provide anti-inflammatory effects with a potentially lower risk of gastrointestinal side effects compared to non-selective NSAIDs.
Medication Name & Brand Names	♦ Medication Name: Meloxicam ♦ Brand Names: Mobic, Mobicox (regional), Vivlodex, Anjeso (injectable), Meloxicam (generic)
Pharmaceutical Forms & Appearance	Meloxicam is available as oral tablets, orally disintegrating tablets (ODT), oral suspension, and solution for intravenous (IV) injection. Oral tablets are typically light yellow, round, or oblong, and often scored, with various imprints. The oral suspension is a pale yellow liquid. The IV solution is clear and colorless to pale yellow.
Dosage & Administration	Dosage varies by indication and patient response. For osteoarthritis, the usual adult oral dose is 7.5 mg once daily, which may be increased to a maximum of 15 mg once daily. For rheumatoid arthritis, the dose is generally 15 mg once daily. For IV use, the dose is typically 30 mg once daily. It can be taken with or without food, but taking it with food or milk may help reduce gastrointestinal upset. Use the lowest effective dose for the shortest duration consistent with treatment goals.
Supplied As	Meloxicam is supplied as: oral tablets (e.g., 7.5 mg, 15 mg), orally disintegrating tablets (e.g., 7.5 mg, 15 mg), oral suspension (e.g., 7.5 mg/5 mL), and solution for intravenous injection (e.g., 30 mg/mL).
Contraindications	Meloxicam is contraindicated in patients with known hypersensitivity to meloxicam, aspirin, or other NSAIDs. It is also contraindicated in patients with a history of asthma, urticaria, or allergic-type reactions after taking aspirin or other NSAIDs, active gastrointestinal bleeding or peptic ulcer disease, severe renal impairment (unless on dialysis), severe hepatic impairment, or in the setting of coronary artery bypass graft (CABG) surgery.
Storage & Expiry	Meloxicam tablets, oral suspension, and IV solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., dyspepsia, nausea, abdominal pain, diarrhea), headache, dizziness, and edema. More serious side effects, though less common with short-term use or lower doses, include gastrointestinal bleeding, ulceration, or perforation, acute kidney injury, cardiovascular thrombotic events (e.g., heart attack, stroke), liver injury, severe allergic reactions (e.g., anaphylaxis, serious skin reactions), and hypertension.
Warnings & Precautions	♦ BLACK BOX WARNINGS: ♦ Cardiovascular Thrombotic Events: NSAIDs, including meloxicam, increase the risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may occur early in treatment and may increase with duration of use. Contraindicated for pain after CABG surgery. ♦ Gastrointestinal Risk: NSAIDs, including meloxicam, increase the risk of serious gastrointestinal adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. These events can occur at any time during use and without warning symptoms. Elderly patients and those with a history of peptic ulcer disease or GI bleeding are at greater risk. ♦ Renal Effects: Can cause new onset or worsening of renal impairment, including acute renal failure. Use with caution in patients with pre-existing renal disease, heart failure, liver dysfunction, or dehydration. ♦ Hypertension: Can cause new onset hypertension or worsen pre-existing hypertension. Monitor blood pressure closely. ♦ Fluid Retention/Edema: Use with caution in patients with heart failure or hypertension. ♦ Hepatic Effects: Liver injury, including severe and fatal cases, can occur. Monitor liver function in prolonged use. ♦ Anaphylactoid Reactions: Can occur in patients without known prior exposure. ♦ Asthma Exacerbation: Use with caution in patients with asthma, especially aspirin-sensitive asthma. ♦ Pregnancy: Avoid use in late pregnancy (third trimester) due to risk of premature closure of fetal ductus arteriosus. ♦ Elderly: Increased risk of serious adverse effects, especially GI bleeding and renal dysfunction. Use lowest effective dose.
Missed Dose Instructions	For chronic conditions like arthritis, if a dose of Meloxicam is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing helps manage symptoms.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily severe gastrointestinal upset (nausea, vomiting, abdominal pain), drowsiness, and potentially more severe GI bleeding, acute renal failure, and seizures. Treatment is supportive and symptomatic. Gastric decontamination (e.g., activated charcoal) may be considered if oral ingestion was recent and substantial. Hemodialysis is unlikely to be effective due to high protein binding. Seek immediate emergency medical help.
Medicine Interactions	♦ Anticoagulants (e.g., warfarin) & Antiplatelet agents (e.g., aspirin, clopidogrel): Significantly increased risk of bleeding. Concurrent use should be approached with extreme caution, and close monitoring of coagulation parameters (e.g., INR) is essential. ♦ Other NSAIDs: Concomitant use is generally not recommended due to additive GI and renal toxicity, and no additional therapeutic benefit. ♦ Lithium: Increases serum lithium concentrations and toxicity; monitor lithium levels closely. ♦ Methotrexate: Increases methotrexate toxicity. ♦ ACE Inhibitors/ARBs/Diuretics: May reduce the antihypertensive and diuretic effects, and significantly increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. ♦ Corticosteroids: Increased risk of GI ulceration and bleeding. ♦ SSRIs: Increased risk of GI bleeding. ♦ Cyclosporine/Tacrolimus: Increased risk of nephrotoxicity. ♦ Colestyramine: May increase meloxicam clearance. ♦ Furosemide/Thiazide Diuretics: May reduce diuretic and antihypertensive effects.

Metformin (Glucophage)

MEDICATION

List

H - M - H - M - H - M

Metformin (Glucophage)

Purpose/Indication	Metformin is an oral antidiabetic medication primarily used to manage type 2 diabetes mellitus, often as a first-line therapy, especially in overweight or obese individuals. It helps to lower elevated blood glucose levels by improving insulin sensitivity and reducing glucose production. It can also be used off-label for polycystic ovary syndrome (PCOS) to manage insulin resistance and related symptoms.
Method of Action	Metformin's primary mechanism of action is to decrease hepatic glucose production (gluconeogenesis and glycogenolysis) by inhibiting the mitochondrial respiratory chain in liver cells, which activates AMP-activated protein kinase (AMPK). It also improves insulin sensitivity by increasing glucose uptake and utilization in peripheral tissues (muscle and fat), and to a lesser extent, reduces intestinal absorption of glucose. Unlike sulfonylureas, it does not stimulate insulin secretion from pancreatic beta cells, thus rarely causing hypoglycemia as monotherapy.
Medication Name & Brand Names	♦ Medication Name: Metformin Hydrochloride ♦ Brand Names: Glucophage (immediate-release), Glucophage XR (extended-release), Fortamet (extended-release), Glumetza (extended-release), Riomet (oral solution), Metformin (generic)
Pharmaceutical Forms & Appearance	Metformin is available as oral tablets (immediate-release and extended-release) and oral solution. Immediate-release tablets are typically white, round or oval, and may be scored, with various imprints. Extended-release tablets vary in color and shape (often oblong) and may have a ghost tablet in the stool due to the non-absorbable matrix. The oral solution is a clear, colorless to pale yellow liquid.
Dosage & Administration	Dosage is individualized, starting low and titrating up to minimize gastrointestinal side effects. For immediate-release, typical adult starting doses are 500 mg once or twice daily, taken with meals, increasing to a maximum of 2000-2550 mg daily in divided doses. Extended-release forms are typically taken once daily with the evening meal. Take with food to reduce GI upset. Regular monitoring of glycemic control (HbA1c) and renal function is essential.
Supplied As	Metformin is supplied as: oral immediate-release tablets (e.g., 500 mg, 850 mg, 1000 mg), oral extended-release tablets (e.g., 500 mg, 750 mg, 1000 mg), and oral solution (e.g., 500 mg/5 mL).
Contraindications	Metformin is strictly contraindicated in patients with severe renal impairment (e.g., eGFR < 30 mL/min/1.73 m2), metabolic acidosis (including diabetic ketoacidosis), and acute or chronic metabolic acidosis with or without hypoxemia. It is also contraindicated in patients with hypersensitivity to metformin and during acute conditions with potential for renal dysfunction, such as dehydration, shock, acute myocardial infarction, or severe infection.
Storage & Expiry	Metformin tablets and oral solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal disturbances like nausea, vomiting, diarrhea, abdominal pain, and flatulence, especially during initiation or dose escalation. A metallic taste is also common. More serious but rare side effects include lactic acidosis (a life-threatening metabolic complication), and vitamin B12 deficiency (with long-term use).
Warnings & Precautions	♦ BLACK BOX WARNING: Lactic Acidosis: A rare, but serious and potentially fatal metabolic complication due to metformin accumulation. Risk factors include renal impairment, concomitant use of certain drugs (e.g., topiramate, zonisamide), acute congestive heart failure, severe infection, dehydration, liver impairment, excessive alcohol intake, and acute myocardial infarction. Discontinue metformin if lactic acidosis is suspected. ♦ Renal Function: Renal function (eGFR) should be assessed before initiating metformin and at least annually thereafter. Discontinue if eGFR falls below 30 mL/min/1.73 m2. Dose adjustment is required for eGFR 30-45 mL/min/1.73 m2. ♦ Hypoglycemia: While rare as monotherapy, risk increases when combined with other antidiabetic agents (e.g., sulfonylureas, insulin). ♦ Vitamin B12 Deficiency: Long-term use of metformin is associated with a decrease in vitamin B12 levels, which can lead to peripheral neuropathy or megaloblastic anemia. Monitor B12 levels periodically, especially in patients with pre-existing risk factors. ♦ Iodinated Contrast Media: Temporarily discontinue metformin at the time of or prior to iodinated contrast imaging procedures in patients with an eGFR between 30 and 60 mL/min/1.73 m2, or with a history of liver disease, alcoholism, or heart failure, or who will be administered intra-arterial iodinated contrast. Re-evaluate eGFR 48 hours after the procedure and restart metformin only if renal function is stable. ♦ Alcohol Intake: Avoid excessive alcohol intake, as it can potentiate the effects of metformin on lactate metabolism. ♦ Surgical Procedures: Metformin should be temporarily discontinued for any surgical procedure that requires restriction of food and fluid intake. ♦ Cardiac Function: Use with caution in patients with unstable or acute congestive heart failure.
Missed Dose Instructions	If a dose of Metformin (immediate-release) is missed, take it as soon as remembered with food. If it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For extended-release, take the missed dose with the next meal. Consistent daily administration with meals is important for optimal glucose control and to minimize GI side effects.
Overdose Instructions	Overdose of metformin can lead to severe lactic acidosis, which is a medical emergency. Symptoms include malaise, myalgia, respiratory distress, somnolence, and abdominal distress (e.g., severe nausea, vomiting, diarrhea). Hypothermia, hypotension, and resistant bradyarrhythmias may occur. Treatment is urgent, supportive, and involves correcting acidosis. Hemodialysis is the most effective method for removing lactate and metformin from the blood. Seek immediate emergency medical help.
Medicine Interactions	♦ Alcohol: Potentiates the effect of metformin on lactate metabolism, increasing the risk of lactic acidosis. Avoid excessive alcohol intake. ♦ Iodinated Contrast Media: Increased risk of lactic acidosis. Temporarily discontinue metformin as per guidelines. ♦ Carbonic Anhydrase Inhibitors (e.g., topiramate, zonisamide, acetazolamide, dichlorphenamide): Can increase the risk of lactic acidosis. Monitor patients closely if co-administered. ♦ Cationic Drugs (e.g., amiloride, cimetidine, digoxin, procainamide, quinidine, trimethoprim, ranitidine, vancomycin): These drugs are eliminated by renal tubular secretion and may compete with metformin for renal tubular transport, potentially increasing metformin plasma concentrations. Monitor glycemic control and adverse effects. ♦ Drugs Affecting Renal Function (e.g., NSAIDs, ACE inhibitors, ARBs, diuretics): Can impair renal function, potentially increasing the risk of lactic acidosis. Monitor renal function closely. ♦ Drugs Affecting Glycemic Control (e.g., corticosteroids, diuretics, thyroid hormones, oral contraceptives, phenothiazines, sympathetic mimetics): May decrease blood glucose control, requiring adjustment of metformin dose. ♦ Nifedipine: May increase metformin absorption. ♦ Glyburide: Metformin may decrease glyburide AUC, but interaction is not considered clinically significant.

MEDICATION

Medication

M -

Metoprolol (Lopressor)

Purpose/Indication	Metoprolol is a beta-blocker primarily used to treat hypertension (high blood pressure), angina pectoris (chest pain), and to improve survival after a heart attack (myocardial infarction). It is also indicated for the management of heart failure (specifically the extended-release form, metoprolol succinate) and for the prophylaxis of migraine headaches. It works by reducing the heart's workload and oxygen demand.
Method of Action	Metoprolol is a cardioselective beta-1 (β1)-adrenergic receptor blocker. It primarily antagonizes β1 receptors in the heart, leading to decreased heart rate, reduced myocardial contractility, and decreased cardiac output, thereby lowering blood pressure. It also reduces renin release from the kidneys. At higher doses, its β1 selectivity may diminish, and it can affect β2 receptors in the bronchi and peripheral blood vessels.

Medication Name & Brand Names	♦ Medication Name: Metoprolol Tartrate (immediate-release), Metoprolol Succinate (extended-release) ♦ Brand Names: Lopressor (tartrate), Toprol-XL (succinate), Betaloc (regional), Metoprolol (generic)
Pharmaceutical Forms & Appearance	Metoprolol is available as oral tablets (immediate-release and extended-release) and solution for intravenous (IV) injection. Immediate-release tablets (tartrate) are typically white, round, and may be scored. Extended-release tablets (succinate) are often white, oval, and may be scored. The IV solution is clear and colorless.
Dosage & Administration	Dosage varies significantly by formulation, indication, and patient response. For hypertension, immediate-release doses typically start at 50-100 mg daily in divided doses, while extended-release starts at 25-50 mg once daily. For angina, similar daily doses are used. For heart failure, metoprolol succinate is initiated at very low doses (e.g., 12.5-25 mg daily) and titrated slowly over weeks. Take with or immediately after meals for consistent absorption. Do not crush or chew extended-release tablets.
Supplied As	Metoprolol is supplied as: oral immediate-release tablets (e.g., 25 mg, 50 mg, 100 mg), oral extended-release tablets (e.g., 25 mg, 50 mg, 100 mg, 200 mg), and solution for intravenous injection (e.g., 1 mg/mL in 5 mL vials).
Contraindications	Metoprolol is contraindicated in patients with known hypersensitivity to metoprolol or other beta-blockers, or any component of the formulation. It is also contraindicated in severe bradycardia, greater than first-degree heart block (unless a pacemaker is in place), cardiogenic shock, decompensated heart failure requiring intravenous inotropes, and sick sinus syndrome (unless a pacemaker is in place).
Storage & Expiry	Metoprolol tablets and IV solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include fatigue, dizziness, bradycardia (slow heart rate), lightheadedness, nausea, and dry mouth. More serious side effects can include profound bradycardia, heart block, worsening heart failure, bronchospasm (especially at higher doses or in susceptible individuals), and mask symptoms of hypoglycemia.
Warnings & Precautions	♦ Abrupt Withdrawal: Do not abruptly discontinue therapy, especially in patients with coronary artery disease (CAD), as it can exacerbate angina, precipitate myocardial infarction, or lead to ventricular arrhythmias. Taper dose gradually over 1-2 weeks. ♦ Heart Failure: Beta-blockers can worsen heart failure in some patients. Initiate therapy cautiously and monitor closely. Contraindicated in decompensated heart failure. ♦ Bronchospastic Disease: While cardioselective, high doses or individual sensitivity can cause bronchospasm. Use with caution and lowest effective dose in patients with asthma or COPD; generally avoid in severe cases. ♦ Diabetes: Can mask symptoms of hypoglycemia (e.g., tachycardia, palpitations) and may prolong hypoglycemic episodes. Use with caution in diabetic patients. ♦ Pheochromocytoma: Beta-blockers should not be used alone in pheochromocytoma; an alpha-blocker should be initiated prior to beta-blockade to prevent paradoxical hypertension. ♦ Thyrotoxicosis: Can mask symptoms of hyperthyroidism. Abrupt withdrawal can precipitate thyroid storm. ♦ Peripheral Vascular Disease: May precipitate or aggravate symptoms of arterial insufficiency. ♦ Surgery: Inform anesthetist of beta-blocker use due to potential for exaggerated hypotension. ♦ Renal/Hepatic Impairment: Use with caution; dose adjustments may be needed for severe hepatic impairment.
Missed Dose Instructions	If a dose of Metoprolol is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining stable control of blood pressure or heart rate.
Overdose Instructions	Overdose symptoms are primarily related to exaggerated pharmacological effects, including severe bradycardia, hypotension, heart block, cardiac failure, bronchospasm, and possibly seizures. Treatment is supportive and symptomatic. Atropine for bradycardia, glucagon for refractory bradycardia/hypotension, IV fluids for hypotension, and vasopressors if needed. Bronchospasm may require beta-agonists. Metoprolol is not significantly removed by hemodialysis. Seek immediate emergency medical help.
Medicine Interactions	♦ Other Antihypertensives/Diuretics: Additive hypotensive effects. Monitor blood pressure closely. ♦ Calcium Channel Blockers (e.g., verapamil, diltiazem): Increased risk of bradycardia, heart block, and hypotension. Use with caution. ♦ Digoxin: Increased risk of bradycardia and AV block. Monitor heart rate and ECG. ♦ MAO Inhibitors: Concurrent use generally not recommended due to possible severe hypertension or hypotension. ♦ Clonidine: If discontinuing clonidine, beta-blocker should be tapered first to avoid rebound hypertension. ♦ Reserpine/Other Catecholamine-Depleting Drugs: May cause additive hypotensive and bradycardic effects. ♦ NSAIDs: May reduce the antihypertensive effect of metoprolol. ♦ CYP2D6 Inhibitors (e.g., fluoxetine, paroxetine, quinidine, propafenone, bupropion, amiodarone): Can increase metoprolol plasma levels and enhance its effects. Monitor for increased beta-blockade. ♦ Insulin/Oral Hypoglycemics: Can mask signs of hypoglycemia. ♦ General Anesthetics: May cause additive myocardial depression and hypotension.

Metronidazole (Flagyl)

Purpose/Indication	Metronidazole is an antibiotic and antiprotozoal medication used to treat a wide range of infections caused by anaerobic bacteria and certain parasites. It is commonly indicated for bacterial vaginosis, trichomoniasis, giardiasis, amebiasis, Clostridioides difficile-associated diarrhea (CDAD), and serious anaerobic infections (e.g., intra-abdominal infections, skin and soft tissue infections, bone and joint infections). It can also be used topically for rosacea.
Method of Action	Metronidazole is a nitroimidazole derivative. It enters the bacterial or protozoal cell, where its nitro group is reduced by microbial enzymes, creating highly reactive cytotoxic free radicals and reduced nitro compounds. These reactive intermediates damage the organism's DNA, inhibiting nucleic acid synthesis and leading to microbial cell death. This selective reduction in anaerobic conditions makes it effective against anaerobes and certain parasites, as aerobic cells lack the necessary enzymes for this reduction.
Medication Name & Brand Names	♦ Medication Name: Metronidazole ♦ Brand Names: Flagyl (oral, IV), Flagyl ER (extended-release), MetroGel (topical), Noritate (topical), Metrogel-Vaginal (vaginal gel), Metronidazole (generic)
Pharmaceutical Forms & Appearance	Metronidazole is available as oral tablets (immediate and extended-release), oral suspension, solution for intravenous (IV) infusion, topical cream/gel/lotion, and vaginal gel. Oral tablets are typically white or off-white, often round or oblong, and may be scored. The oral suspension is a flavored, white to off-white liquid. The IV solution is clear and colorless to pale yellow. Topical and vaginal gels are translucent to opaque.
Dosage & Administration	Dosage varies widely depending on the infection type, severity, and formulation. For common infections, oral doses range from 250 mg to 750 mg, administered two or three times daily, or a single high dose (e.g., 2 grams for trichomoniasis). IV administration is used for severe infections. Topical and vaginal forms are applied directly to the affected area, typically once or twice daily. Oral doses can be taken with food to reduce gastrointestinal upset.
Supplied As	Metronidazole is supplied as: oral immediate-release tablets (e.g., 250 mg, 500 mg), oral extended-release tablets (e.g., 750 mg), oral suspension (e.g., 200 mg/5 mL), solution for intravenous infusion (e.g., 500 mg/100 mL bags), topical cream/gel/lotion (e.g., 0.75%, 1%), and vaginal gel (e.g., 0.75%).

Contraindications	Metronidazole is contraindicated in patients with known hypersensitivity to metronidazole, other nitroimidazole derivatives, or any component of the formulation. Oral and IV forms are contraindicated during the first trimester of pregnancy for trichomoniasis. Concomitant use of disulfiram within the past 2 weeks is a contraindication due to risk of psychotic reactions. Concomitant use of alcohol or propylene glycol during and for at least 3 days after metronidazole therapy is contraindicated due to a disulfiram-like reaction.
Storage & Expiry	Metronidazole tablets, oral suspension, IV solution, topical, and vaginal products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light (especially IV bags) and moisture. Keep in tightly closed containers. Oral suspension should not be frozen. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, vomiting, diarrhea, abdominal pain, metallic taste, headache, and dizziness. More serious side effects, though less common, include peripheral neuropathy (especially with prolonged or high-dose use), seizures, encephalopathy (rarely), aseptic meningitis (rarely), neutropenia, pancreatitis, and severe allergic reactions (e.g., rash, Stevens-Johnson syndrome). A disulfiram-like reaction (flushing, nausea, vomiting, tachycardia) can occur with alcohol.
Warnings & Precautions	♦ Alcohol Interaction: BLACK BOX WARNING: Disulfiram-like reaction with alcohol. Advise patients to avoid alcohol or products containing alcohol/propylene glycol during therapy and for at least 3 days after discontinuation. ♦ Neurological Effects: Seizures and peripheral neuropathy (e.g., numbness, tingling, pain in extremities) have been reported, especially with prolonged or high-dose therapy. Discontinue if symptoms occur. Cases of aseptic meningitis and encephalopathy (including cerebellar symptoms) have also been reported. ♦ Disulfiram Interaction: Psychotic reactions can occur with concurrent use. Avoid co-administration. ♦ Hepatic Impairment: Use with caution and consider dose reduction in patients with severe hepatic impairment, as drug clearance may be reduced. ♦ Blood Dyscrasias: Cases of neutropenia and leukopenia have been reported. Monitor blood counts, especially with prolonged therapy. ♦ Candida Superinfection: May cause candidal overgrowth. ♦ Pregnancy: While generally considered safe in the second and third trimesters, avoid use in the first trimester for trichomoniasis. Consider risks vs. benefits for other infections. ♦ Renal Impairment: While not renally cleared, metabolites can accumulate; use with caution.
Missed Dose Instructions	If a dose of Metronidazole (oral) is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Completing the full course of therapy is crucial for effective infection eradication and to prevent resistance.
Overdose Instructions	Overdose symptoms are typically an exaggeration of known side effects, including severe gastrointestinal upset, ataxia, nausea, vomiting, and disorientation. With very high doses or prolonged use, more serious neurological effects like peripheral neuropathy, seizures, and encephalopathy can occur. Treatment is supportive and symptomatic. There is no specific antidote. Hemodialysis can remove some metronidazole. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Alcohol/Propylene Glycol: Contraindicated: Disulfiram-like reaction (flushing, nausea, vomiting, abdominal cramps, headache, palpitations, tachycardia). Avoid during and for at least 3 days after therapy. ♦ Disulfiram: Contraindicated: Psychotic reactions. Avoid concomitant use within 2 weeks of disulfiram. ♦ Warfarin and other Oral Anticoagulants: Potentiates the anticoagulant effect, increasing bleeding risk. Monitor INR frequently and adjust anticoagulant dose. ♦ Lithium: Can increase serum lithium concentrations and lead to toxicity. Monitor lithium levels. ♦ Cimetidine: May prolong the half-life and decrease the clearance of metronidazole, increasing plasma concentrations. ♦ Phenobarbital, Phenytoin: May decrease metronidazole plasma concentrations (due to enzyme induction) and increase phenytoin levels. ♦ Busulfan: May increase busulfan plasma concentrations, increasing risk of toxicity. ♦ Fluorouracil: May increase fluorouracil systemic exposure. ♦ Tacrolimus: Increased tacrolimus levels reported with concurrent use. ♦ Mebendazole: Concurrent use has been associated with increased risk of Stevens-Johnson syndrome/toxic epidermal necrolysis (rare). Avoid if possible.

Miconazole (Monistat)

Purpose/Indication	Miconazole is an antifungal medication used to treat various fungal and yeast infections of the skin (e.g., athlete's foot, jock itch, ringworm), nails, and mucous membranes (e.g., vaginal yeast infections, oral thrush). It is effective against dermatophytes (tinea infections) and yeasts, particularly Candida species.
Method of Action	Miconazole is an imidazole antifungal agent. It primarily works by inhibiting the biosynthesis of ergosterol, a vital component of fungal cell membranes. By interfering with ergosterol synthesis, miconazole disrupts the integrity and permeability of the fungal cell membrane, leading to leakage of essential intracellular components and ultimately fungal cell death. It also inhibits certain fungal enzymes and can increase oxidative stress within the fungal cell.
Medication Name & Brand Names	♦ Medication Name: Miconazole Nitrate ♦ Brand Names: Monistat (vaginal cream/suppository), Daktarin (topical cream, oral gel, powder - regional), Micatin (topical cream), Desenex (topical powder/spray - regional), Miconazole (generic)
Pharmaceutical Forms & Appearance	Miconazole is available in various topical forms, including creams, powders, sprays, solutions, and vaginal suppositories/creams. Oral gels are also available for oral thrush. Topical creams are typically white, smooth, and opaque. Vaginal suppositories are usually white or off-white. Oral gels are translucent and flavored.
Dosage & Administration	Dosage and administration vary significantly by the affected area and formulation. For skin infections, apply a thin layer of cream/lotion/powder to the affected area and surrounding skin, typically once or twice daily for 2-4 weeks. For vaginal yeast infections, vaginal cream or suppositories are inserted once daily at bedtime for 1-7 days, depending on strength. For oral thrush, the oral gel is applied to the affected areas in the mouth, usually after meals. Always wash hands before and after application.
Supplied As	Miconazole is supplied as: topical creams (e.g., 2%), topical powders/sprays (e.g., 2%), vaginal creams (e.g., 2%), vaginal suppositories (e.g., 100 mg, 200 mg, 1200 mg), and oral gels (e.g., 2%).
Contraindications	Miconazole is contraindicated in patients with known hypersensitivity to miconazole, other imidazole antifungals, or any component of the formulation.
Storage & Expiry	Miconazole products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and excessive heat. Keep in tightly closed containers. Oral gels should not be frozen. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and localized, including skin irritation, itching, burning, redness, or dryness at the application site. For vaginal forms, mild vaginal burning, itching, or irritation may occur. For oral gel, nausea, vomiting, and taste alteration can occur. Systemic side effects are rare due to minimal absorption.

Warnings & Precautions	♦ For External/Local Use Only: Topical and vaginal preparations are for external/local use only. Do not ingest. ♦ Avoid Eye Contact: Avoid contact with eyes. If contact occurs, flush thoroughly with water. ♦ Irritated/Broken Skin: Use with caution on severely irritated or broken skin, as it may increase local irritation. ♦ Allergic Reactions: Discontinue use if irritation or sensitization occurs. Rarely, severe allergic reactions (e.g., rash, swelling) can occur. ♦ Pregnancy/Breastfeeding: Generally considered safe for topical/vaginal use during pregnancy and breastfeeding, but consult a healthcare professional. Oral gel has higher systemic absorption; discuss with doctor. ♦ Complete Full Course: Patients should complete the full prescribed course of treatment, even if symptoms improve, to prevent recurrence. ♦ Oral Anticoagulants (for Oral Gel): Miconazole oral gel has significant systemic absorption and can potentiate the effects of oral anticoagulants. Monitor INR and adjust warfarin dose.
Missed Dose Instructions	For topical or vaginal miconazole, if a dose is missed, apply it as soon as remembered. If it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not double a dose. Consistency is important for effective treatment. For oral gel, if a dose is missed, apply it as soon as remembered.
Overdose Instructions	Overdose from topical or vaginal miconazole is unlikely due to minimal systemic absorption. In case of accidental oral ingestion of a large amount, symptoms are generally gastrointestinal upset (nausea, vomiting, diarrhea). Treatment is supportive and symptomatic. Gastric decontamination may be considered if a significant amount was ingested recently. For oral gel, higher systemic absorption could lead to more pronounced effects, especially with interacting medications. Seek medical advice if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Oral Anticoagulants (e.g., warfarin): IMPORTANT for Oral Gel: Miconazole oral gel, due to its systemic absorption, can significantly potentiate the effect of oral anticoagulants, increasing the risk of bleeding. Monitor INR (International Normalized Ratio) closely and adjust warfarin dose as necessary. This interaction is less significant with topical or vaginal miconazole forms due to minimal systemic absorption, but caution is still advised. ♦ Phenytoin/Fosphenytoin: Miconazole, particularly the oral gel, may increase plasma concentrations of phenytoin. Monitor phenytoin levels. ♦ Sulfonylureas (e.g., glipizide, glyburide): Miconazole may enhance the hypoglycemic effect of sulfonylureas. Monitor blood glucose. ♦ Cyclosporine, Tacrolimus, Sirolimus: Miconazole can increase the plasma concentrations of these immunosuppressants. Monitor levels closely. ♦ Statins (e.g., simvastatin, lovastatin): Miconazole (oral gel) can increase statin levels, potentially increasing risk of myopathy/rhabdomyolysis. Avoid co-administration of oral gel with simvastatin/lovastatin.

Morphine (MS Contin)

Purpose/Indication	Morphine is a potent opioid analgesic used for the management of moderate to severe acute and chronic pain, especially when other analgesics are insufficient. It is also used in palliative care for pain relief, for relief of dyspnea (shortness of breath) in acute left ventricular failure and pulmonary edema, and as a pre-operative medication to provide sedation and anxiety relief.
Method of Action	Morphine is a pure opioid agonist that primarily acts on mu (μ) opioid receptors in the central nervous system (CNS). By binding to these receptors, it mimics the effects of endogenous opioids (endorphins), leading to inhibition of pain signal transmission, altered perception of pain, and activation of descending inhibitory pain pathways. This action results in potent analgesia, sedation, euphoria, and respiratory depression, as well as effects on the gastrointestinal tract (constipation) and cough reflex.
Medication Name & Brand Names	♦ Medication Name: Morphine Sulfate ♦ Brand Names: MS Contin (sustained-release tablets), Kadian (extended-release capsules), Roxanol (oral solution), Astramorph (injectable), Duramorph (injectable), Oramorph (oral solution - regional), Morphine (generic)
Pharmaceutical Forms & Appearance	Morphine is available in numerous forms: oral tablets (immediate-release, controlled-release, extended-release), oral solutions/syrups, rectal suppositories, and solutions for injection (intravenous, intramuscular, subcutaneous, epidural, intrathecal). Oral tablets vary widely in color, shape, and imprint depending on strength and formulation. Injectable solutions are typically clear and colorless.
Dosage & Administration	Dosage is highly individualized and depends on the route, patient's pain severity, opioid tolerance, and renal/hepatic function. For acute pain, immediate-release oral doses typically start at 10-30 mg every 4 hours, or IV doses of 2-10 mg every 2-4 hours. Controlled-release forms are given less frequently (e.g., every 8-24 hours). Administer oral forms with food to reduce nausea. Long-term use requires careful titration and monitoring due to tolerance and dependence.
Supplied As	Morphine is supplied as: oral immediate-release tablets (e.g., 15 mg, 30 mg), oral controlled/extended-release tablets/capsules (e.g., 15 mg to 200 mg), oral solutions (e.g., 10 mg/5 mL, 20 mg/mL), rectal suppositories (e.g., 5 mg, 10 mg, 20 mg, 30 mg), and solutions for injection (e.g., 1 mg/mL, 2 mg/mL, 4 mg/mL, 10 mg/mL, 15 mg/mL in vials, ampules, or pre-filled syringes).
Contraindications	Morphine is contraindicated in patients with known hypersensitivity to morphine or other opioids. It is also contraindicated in patients with significant respiratory depression, acute or severe bronchial asthma (in an unmonitored setting or in the absence of resuscitative equipment), paralytic ileus (bowel obstruction), severe CNS depression, and acute alcohol intoxication. Use is also contraindicated in patients with suspected or known gastrointestinal obstruction, including paralytic ileus.
Storage & Expiry	Morphine products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed, child-resistant containers. Injectable solutions should be protected from freezing. Due to its status as a controlled substance, specific storage and handling regulations apply. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, vomiting, constipation, drowsiness, dizziness, sedation, itching, and urinary retention. More serious side effects include respiratory depression (potentially fatal), severe hypotension, bradycardia, CNS depression, addiction, dependence, and withdrawal symptoms upon abrupt discontinuation. Serotonin syndrome can occur with concomitant use of serotonergic drugs.

Warnings & Precautions	♦ BLACK BOX WARNINGS: Addiction, Abuse, Misuse: Morphine exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess risk before prescribing and monitor for signs of abuse and addiction. ♦ Respiratory Depression: BLACK BOX WARNING: Serious, life-threatening, or fatal respiratory depression may occur. Monitor closely, especially during initiation and dose escalation. Risk increased with concurrent CNS depressants. ♦ Concomitant Opioid Use with Benzodiazepines/Other CNS Depressants: BLACK BOX WARNING: Concomitant use with benzodiazepines or other CNS depressants (including alcohol) may result in profound sedation, respiratory depression, coma, and death. Reserve for use when alternative treatment options are inadequate. ♦ Neonatal Opioid Withdrawal Syndrome (NOWS): BLACK BOX WARNING (for prolonged use during pregnancy): Prolonged use during pregnancy can result in NOWS, which may be life-threatening if not recognized and treated. ♦ Cytochrome P450 3A4 Interaction: BLACK BOX WARNING (for oral forms): Concomitant use with CYP3A4 inhibitors (or discontinuation of CYP3A4 inducers) can result in increased morphine plasma concentrations and potentially fatal respiratory depression. ♦ Adrenal Insufficiency: Can cause adrenal insufficiency. ♦ Severe Hypotension: Can cause severe hypotension, especially in patients whose ability to maintain blood pressure is compromised. ♦ GI Effects: Risk of severe constipation, paralytic ileus. Use with caution in patients with pre-existing GI conditions. ♦ Head Injury/Increased Intracranial Pressure: Can obscure the clinical course and elevate cerebrospinal fluid pressure. ♦ Drug Dependence: Physical dependence can develop with prolonged use. Abrupt discontinuation will lead to withdrawal symptoms. Taper gradually. ♦ Renal/Hepatic Impairment: Metabolites can accumulate, increasing effects and risk of toxicity. Use with caution and lower doses. ♦ Elderly/Debilitated Patients: More susceptible to respiratory depression and other adverse effects. Use lowest effective dose. ♦ Serotonin Syndrome: Potentially life-threatening, with concomitant use of serotonergic drugs.
Missed Dose Instructions	For scheduled pain management (e.g., controlled-release morphine), if a dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For immediate-release or as-needed dosing, take when pain recurs, but adhere to prescribed frequency limits. Consistent dosing is crucial for pain control and minimizing withdrawal symptoms.
Overdose Instructions	Overdose symptoms are characterized by respiratory depression (decreased respiratory rate and depth, Cheyne-Stokes respiration), extreme somnolence progressing to stupor or coma, constricted pupils (miosis), cold and clammy skin, skeletal muscle flaccidity, and sometimes bradycardia, hypotension, and pulmonary edema. Severe overdose can lead to circulatory collapse, cardiac arrest, and death. Treatment involves immediate medical attention, with primary focus on restoring respiration. Naloxone, an opioid antagonist, is the antidote and should be administered immediately. Repeated doses may be required due to morphine's longer duration of action. Supportive measures, including oxygen, IV fluids, and vasopressors, are essential. Seek immediate emergency medical help.
Medicine Interactions	♦ CNS Depressants (e.g., benzodiazepines, other opioids, alcohol, sedatives, hypnotics, general anesthetics, tricyclic antidepressants, phenothiazines): BLACK BOX WARNING: Potentiation of respiratory depression, profound sedation, coma, and death. Avoid concomitant use; if necessary, use lowest effective doses and shortest duration, monitoring closely. ♦ MAO Inhibitors: Can cause severe, unpredictable reactions (e.g., excitation, depression, rigidity, hyperpyrexia, convulsions). Avoid concomitant use and for 14 days after MAOI discontinuation. ♦ Serotonergic Drugs (e.g., SSRIs, SNRIs, TCAs, triptans, tramadol, linezolid): Increased risk of serotonin syndrome. Monitor for symptoms. ♦ Muscle Relaxants: Enhanced neuromuscular blocking action; increased risk of respiratory depression. ♦ Diuretics: May reduce the diuretic effect. ♦ Anticholinergics: Increased risk of urinary retention and severe constipation/paralytic ileus. ♦ Mixed Agonist/Antagonist Opioid Analgesics (e.g., pentazocine, nalbuphine, butorphanol): Can precipitate withdrawal symptoms in opioid-dependent patients or reduce analgesic effect. ♦ Cimetidine: May enhance respiratory depression. ♦ Ritonavir: Can increase plasma morphine concentrations.

Moxifloxacin (Avelox)

Purpose/Indication	Moxifloxacin is a fluoroquinolone antibiotic used to treat various bacterial infections, including acute bacterial sinusitis, acute bacterial exacerbation of chronic bronchitis, community-acquired pneumonia, complicated and uncomplicated skin and skin structure infections, and complicated intra-abdominal infections. It is also used for plague. Due to significant safety concerns, it is generally reserved for situations where other safer antibiotics are ineffective or contraindicated.
Method of Action	Moxifloxacin exerts its bactericidal effect by inhibiting bacterial topoisomerase II (DNA gyrase) and topoisomerase IV, essential enzymes for DNA replication, transcription, repair, and recombination in bacteria. By interfering with these enzymes, moxifloxacin prevents bacterial DNA unwinding and separation, leading to DNA strand breakage and ultimately bacterial cell death. It has a broad spectrum of activity against both Gram-positive and Gram-negative bacteria, as well as atypical organisms.
Medication Name & Brand Names	♦ Medication Name: Moxifloxacin Hydrochloride ♦ Brand Names: Avelox (oral, IV), Vigamox (ophthalmic solution), Moxifloxacin (generic)
Pharmaceutical Forms & Appearance	Moxifloxacin is available as oral tablets, solution for intravenous (IV) infusion, and ophthalmic solution. Oral tablets are typically pale yellow to pinkish-yellow, film-coated, and oblong, with specific imprints. The IV solution is clear and yellowish. The ophthalmic solution is clear and colorless to pale yellow.
Dosage & Administration	Dosage is typically 400 mg once daily for most infections, regardless of oral or IV route. Duration of therapy varies by infection type and severity, usually ranging from 5 to 21 days. It can be taken with or without food. The ophthalmic solution is administered as drops into the affected eye. No dosage adjustment is usually needed for renal impairment, but caution is advised in severe hepatic impairment.
Supplied As	Moxifloxacin is supplied as: oral film-coated tablets (e.g., 400 mg), solution for intravenous infusion (e.g., 400 mg/250 mL flexible bags), and ophthalmic solution (e.g., 0.5% in 3 mL droptainers).
Contraindications	Moxifloxacin is contraindicated in patients with known hypersensitivity to moxifloxacin, other quinolones, or any component of the formulation. It is also contraindicated in patients with a history of tendon disorders related to quinolone use, or in patients with known QT prolongation or a history of Torsades de Pointes.
Storage & Expiry	Moxifloxacin tablets, IV solution, and ophthalmic solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light (especially IV bags) and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, diarrhea, abdominal pain, dizziness, headache, and insomnia. More serious side effects include tendonitis and tendon rupture (including Achilles tendon), peripheral neuropathy (nerve damage), central nervous system effects (e.g., seizures, psychosis), QT prolongation and Torsades de Pointes, liver injury, and Clostridioides difficile-associated diarrhea (CDAD).

Warnings & Precautions	♦ BLACK BOX WARNINGS: Tendinitis, Tendon Rupture, Peripheral Neuropathy, CNS Effects, Exacerbation of Myasthenia Gravis: ♦ Tendinitis and Tendon Rupture: Increased risk of tendinitis and tendon rupture, occurring at any age, but higher risk in elderly, concomitant corticosteroid use, and organ transplant recipients. Discontinue at first sign of pain, inflammation, or rupture. ♦ Peripheral Neuropathy: Can cause peripheral neuropathy, potentially irreversible, manifesting as pain, burning, tingling, numbness, or weakness. Discontinue if symptoms occur. ♦ Central Nervous System Effects: Can cause CNS adverse reactions including seizures, increased intracranial pressure, psychosis, anxiety, depression, confusion, and hallucinations. Use with caution in patients with CNS disorders. ♦ Exacerbation of Myasthenia Gravis: Can exacerbate muscle weakness in patients with myasthenia gravis. Avoid use. ♦ QT Prolongation: Can prolong the QT interval, potentially leading to Torsades de Pointes. Avoid in patients with known QT prolongation, hypokalemia, or concomitant use of other QT-prolonging drugs. ♦ Hypoglycemia/Hyperglycemia: Can cause severe alterations in blood glucose, including hypoglycemia and hyperglycemia, especially in diabetic patients taking insulin or oral hypoglycemics. Monitor blood glucose. ♦ Aortic Aneurysm and Dissection: Increased risk reported, especially in elderly. Use with caution in patients with known aneurysmal disease. ♦ Hepatotoxicity: Cases of severe hepatotoxicity, including fatal cases, have been reported. ♦ Photosensitivity: Can cause moderate to severe photosensitivity reactions. Advise patients to avoid excessive sun exposure. ♦ Clostridioides difficile-associated diarrhea (CDAD): Can occur. ♦ Resistance: Use should be reserved for specific indications due to increasing fluoroquinolone resistance and serious adverse effects.
Missed Dose Instructions	If a dose of Moxifloxacin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Completing the full course of therapy is crucial for effective infection eradication and to prevent resistance.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, including severe GI upset, CNS effects (dizziness, confusion, tremor, seizures), and QT prolongation. Treatment is supportive and symptomatic. Gastric decontamination (e.g., activated charcoal) may be considered if recent. Monitor ECG for QT prolongation. Hemodialysis is not effective in removing moxifloxacin. Seek immediate emergency medical help.
Medicine Interactions	♦ QT-Prolonging Drugs (e.g., Class IA and III antiarrhythmics, tricyclic antidepressants, macrolides, antipsychotics): Concomitant use significantly increases the risk of QT prolongation and Torsades de Pointes. Avoid co-administration. ♦ Antacids (aluminum-, magnesium-containing), Sucralfate, Didanosine, Iron Supplements, Zinc Supplements, Multivitamins (containing divalent or trivalent cations): These agents can chelate moxifloxacin and significantly reduce its oral absorption. Administer moxifloxacin at least 4 hours before or 8 hours after these products. ♦ Corticosteroids: Concomitant use increases the risk of tendinitis and tendon rupture. ♦ Warfarin: May enhance the anticoagulant effect of warfarin, increasing bleeding risk. Monitor INR closely. ♦ Antidiabetic Agents (e.g., insulin, sulfonylureas): Increased risk of blood glucose disturbances (hypoglycemia or hyperglycemia). Monitor blood glucose levels. ♦ Theophylline: While generally not a significant interaction with moxifloxacin, other fluoroquinolones have interacted with theophylline. Monitor. ♦ NSAIDs: Concomitant use may increase the risk of CNS stimulation and convulsive seizures. ♦ Drugs affecting renal function: Indirectly increase risk of adverse events if they impair moxifloxacin elimination.

N - Q

Any medications starting with N through to Q.

Nabumetone (Relafen)

Purpose/Indication	Nabumetone is a non-steroidal anti-inflammatory drug (NSAID) used for the long-term management of signs and symptoms of osteoarthritis and rheumatoid arthritis. It helps to reduce inflammation, swelling, stiffness, and pain associated with these chronic joint conditions.
Method of Action	Nabumetone is a prodrug that is converted in the liver to its active metabolite, 6-methoxy-2-naphthylacetic acid (6-MNA). This active metabolite, like other NSAIDs, works by inhibiting cyclooxygenase (COX-1 and COX-2) enzymes. This inhibition reduces the synthesis of prostaglandins, which are key mediators of pain and inflammation. Its prodrug nature and relatively long half-life allow for once-daily dosing.
Medication Name & Brand Names	♦ Medication Name: Nabumetone ♦ Brand Names: Relafen (historical, may not be widely available), Relafen DS (historical, may not be widely available), Nabumetone (generic)
Pharmaceutical Forms & Appearance	Nabumetone is available as oral tablets. Tablets are typically white to off-white, often coated, and may be in various shapes (e.g., modified capsule-shaped), with specific imprints indicating strength (e.g., 500 mg, 750 mg).
Dosage & Administration	For adults, the usual initial dose for osteoarthritis and rheumatoid arthritis is 1000 mg orally once a day, typically at bedtime. The dose can be adjusted as needed, with a usual maximum of 2000 mg per day, given as a single dose or in two divided doses. It can be taken with or without food, but taking it with food or milk may help reduce gastrointestinal upset. Use the lowest effective dose for the shortest duration possible.
Supplied As	Nabumetone is supplied as: oral tablets (e.g., 500 mg, 750 mg, 1000 mg).
Contraindications	Nabumetone is contraindicated in patients with known hypersensitivity to nabumetone, aspirin, or other NSAIDs. It is also contraindicated in patients with a history of asthma, urticaria, or other allergic-type reactions precipitated by aspirin or other NSAIDs, active gastrointestinal bleeding or peptic ulcer disease, severe renal impairment, or in the setting of coronary artery bypass graft (CABG) surgery.
Storage & Expiry	Nabumetone tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed, light-resistant containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., abdominal pain, nausea, dyspepsia, diarrhea, constipation, flatulence), headache, dizziness, and skin rash/itching. More serious side effects include severe gastrointestinal bleeding, ulceration, or perforation, acute kidney injury, cardiovascular thrombotic events (e.g., heart attack, stroke), liver injury, and severe allergic reactions (including anaphylaxis, serious skin reactions).

Warnings & Precautions	♦ BLACK BOX WARNINGS: Cardiovascular Thrombotic Events & Gastrointestinal Risk: Nabumetone, like other NSAIDs, carries an increased risk of serious cardiovascular thrombotic events (e.g., heart attack, stroke) and serious gastrointestinal adverse events (e.g., bleeding, ulceration, perforation), which can be fatal. This risk may increase with duration of use. Avoid use in the setting of CABG surgery. ♦ Renal Effects: Can cause new onset or worsening of renal impairment, including acute renal failure. Use with caution in patients with pre-existing renal disease, heart failure, liver dysfunction, or dehydration. ♦ Hypertension: Can cause new onset hypertension or worsen pre-existing hypertension. Monitor blood pressure closely. ♦ Fluid Retention/Edema: Use with caution in patients with heart failure or hypertension. ♦ Hepatic Effects: Liver injury, including severe and fatal cases, can occur. Monitor liver function in prolonged use. ♦ Anaphylactoid Reactions: Can occur in patients without known prior exposure. ♦ Asthma Exacerbation: Use with caution in patients with asthma, especially aspirin-sensitive asthma. ♦ Pregnancy: Avoid use in late pregnancy (after 20 weeks gestation), particularly in the third trimester, due to risk of premature closure of fetal ductus arteriosus and potential fetal renal dysfunction. ♦ Elderly: Increased risk of serious adverse effects, especially GI bleeding and renal dysfunction. Use lowest effective dose. ♦ Photosensitivity: May cause more reactions to sun exposure than expected.
Missed Dose Instructions	If a dose of Nabumetone is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for chronic conditions like arthritis.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily severe gastrointestinal upset (nausea, vomiting, abdominal pain), drowsiness, and potentially more severe GI bleeding, acute renal failure, or even seizures. Treatment is supportive and symptomatic. Gastric decontamination (e.g., activated charcoal) may be considered if oral ingestion was recent and substantial. Hemodialysis is unlikely to be useful due to high protein binding. Seek immediate emergency medical help.
Medicine Interactions	♦ Anticoagulants (e.g., warfarin) & Antiplatelet agents (e.g., aspirin, clopidogrel): Significantly increased risk of bleeding. Concurrent use should be approached with extreme caution, and close monitoring of coagulation parameters (e.g., INR) is essential. ♦ Other NSAIDs: Concomitant use is generally not recommended due to additive GI and renal toxicity, and no additional therapeutic benefit. ♦ Lithium: Increases serum lithium concentrations and toxicity; monitor lithium levels closely. ♦ Methotrexate: Increases methotrexate toxicity. ♦ ACE Inhibitors/ARBs/Diuretics: May reduce the antihypertensive and diuretic effects, and significantly increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. ♦ Corticosteroids: Increased risk of GI ulceration and bleeding. ♦ SSRIs: Increased risk of GI bleeding. ♦ Cyclosporine/Tacrolimus: Increased risk of nephrotoxicity. ♦ Digoxin: May increase digoxin levels. ♦ Phenytoin: May increase phenytoin levels.

Naloxone (Narcan)

Purpose/Indication	Naloxone is an opioid antagonist used to rapidly reverse opioid overdose. Its primary indications include the complete or partial reversal of opioid depression, including respiratory depression, caused by natural, synthetic, or semi-synthetic opioids. It is a life-saving medication used in emergency situations to restore normal breathing in individuals experiencing an opioid overdose.
Method of Action	Naloxone works by competitively binding to opioid receptors (mu, kappa, and delta, with highest affinity for mu receptors) in the central nervous system, thereby displacing opioids from these receptors. This action reverses the effects of opioids, including respiratory depression, sedation, and analgesia. Because it has a higher affinity for opioid receptors than most opioids, it can rapidly reverse even severe overdose symptoms.
Medication Name & Brand Names	♦ Medication Name: Naloxone Hydrochloride ♦ Brand Names: Narcan (nasal spray, injectable), Evzio (auto-injector - phased out in some regions), Naloxone (generic)
Pharmaceutical Forms & Appearance	Naloxone is available as an injectable solution (for intravenous, intramuscular, or subcutaneous administration) and as a nasal spray. The injectable solution is typically clear and colorless. The nasal spray is a device that delivers a single dose of clear solution into one nostril.
Dosage & Administration	Dosage varies based on the route of administration, severity of overdose, and patient response. For opioid overdose reversal in an emergency setting, typical adult doses are 0.4 mg to 2 mg administered IV, IM, or SC, which may be repeated every 2-3 minutes as needed until respiratory function improves. The nasal spray usually comes as a single-use device delivering 4 mg (or 2 mg in some formulations) into one nostril. Due to its short half-life, repeat doses may be required, especially with long-acting opioids.
Supplied As	Naloxone is supplied as: solution for injection (e.g., 0.4 mg/mL, 1 mg/mL, 2 mg/mL in ampules, vials, or prefilled syringes), and nasal spray (e.g., 2 mg/spray, 4 mg/spray).
Contraindications	Naloxone is contraindicated in patients with known hypersensitivity to naloxone or any component of the formulation. There are no other absolute contraindications in an emergency opioid overdose situation, as the potential benefit of reversing life-threatening respiratory depression generally outweighs any theoretical risks.
Storage & Expiry	Naloxone injection and nasal spray should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light. Do not freeze. Keep in the original packaging. Always check the specific expiry date on the packaging. Some products may tolerate brief excursions outside recommended temperatures, but prolonged exposure should be avoided.
Side Effects	Side effects are often related to the rapid reversal of opioid effects and can include opioid withdrawal symptoms (nausea, vomiting, diarrhea, sweating, shivering, body aches, restlessness, irritability, anxiety, piloerection), hypertension, tachycardia, and pulmonary edema (rare). In some cases, severe agitation and aggression may occur.
Warnings & Precautions	♦ Rapid Opioid Withdrawal: Rapid reversal of opioid effects can precipitate an acute opioid withdrawal syndrome, characterized by severe body aches, diarrhea, abdominal cramps, piloerection ("goosebumps"), nausea, vomiting, nervousness, restlessness, irritability, shivering or trembling, muscle spasms, weakness, tachycardia, and increased blood pressure. This can be very distressing for the patient and may be dangerous in patients with cardiovascular disease. ♦ Short Duration of Action: Naloxone has a shorter half-life than many opioids. Therefore, repeated doses may be necessary, and continuous monitoring for recurrent respiratory depression is essential for several hours after initial reversal, especially with long-acting opioids. ♦ Cardiovascular Effects: Rapid reversal can lead to sudden increases in blood pressure, heart rate, and pulmonary edema. Use with caution in patients with pre-existing cardiovascular disease. ♦ Non-Opioid Overdose: Naloxone is ineffective in reversing respiratory depression caused by non-opioid drugs. ♦ Dependence: Naloxone does not produce opioid dependence or cause tolerance. ♦ In Emergency Situations: Administration by laypersons (e.g., family members, first responders) is often crucial and encouraged in opioid overdose emergencies. Training on proper use is vital.
Missed Dose Instructions	Naloxone is an acute, emergency medication. A "missed dose" is not applicable in the typical sense. It is administered when opioid overdose symptoms are present. If a dose is administered and symptoms of opioid overdose reappear, or do not fully resolve, repeat doses should be given as per guidelines (e.g., every 2-3 minutes) until emergency medical services arrive or breathing normalizes.

Naloxone (Narcan)	
Overdose Instructions	Overdose with naloxone is extremely rare and typically results from inadvertent administration of excessively high doses. Symptoms of naloxone overdose are generally not well-defined, as it does not produce opioid-like effects. However, extremely high doses could theoretically exacerbate withdrawal symptoms or cardiovascular side effects. There is no specific antidote for naloxone overdose. Treatment would be supportive and symptomatic. Given its primary use in reversing life-threatening opioid overdose, the risks associated with naloxone overdose are generally minimal compared to the benefits.
Medicine Interactions	♦ Opioids (e.g., morphine, fentanyl, oxycodone, heroin): Naloxone's primary interaction is to antagonize the effects of opioids, leading to their reversal. The degree of reversal depends on the dose of naloxone, the opioid involved, and the degree of opioid dependence. ♦ Buprenorphine: Reversal of buprenorphine-induced respiratory depression may require higher or repeated doses of naloxone due to buprenorphine's high receptor affinity and long duration of action. ♦ No significant direct drug-drug interactions beyond its opioid antagonism are generally reported, as it does not undergo significant metabolism by common cytochrome P450 enzymes. Its rapid action and elimination also limit complex interactions.

Naproxen (Aleve)

Purpose/Indication	Naproxen is a non-steroidal anti-inflammatory drug (NSAID) used to relieve mild to moderate pain, inflammation, and fever. It is widely indicated for conditions such as arthritis (rheumatoid arthritis, osteoarthritis, ankylosing spondylitis), juvenile arthritis, tendinitis, bursitis, acute gout, and primary dysmenorrhea (menstrual pain). It also provides temporary relief of aches and pains associated with the common cold, headache, toothache, and minor injuries.
Method of Action	Naproxen exerts its therapeutic effects by reversibly inhibiting the cyclooxygenase (COX) enzymes, both COX-1 and COX-2. This inhibition leads to a significant reduction in the synthesis of prostaglandins, which are lipid compounds that play a crucial role as mediators of pain, inflammation, and fever. By reducing prostaglandin production, naproxen effectively alleviates pain, reduces swelling, and lowers elevated body temperature.
Medication Name & Brand Names	♦ Medication Name: Naproxen (non-prescription), Naproxen Sodium (non-prescription & prescription), Naproxen (prescription) ♦ Brand Names: Aleve (OTC), Naprosyn (prescription), Anaprox (prescription), Naproxen (generic)
Pharmaceutical Forms & Appearance	Naproxen is available as oral tablets (immediate-release and extended-release), delayed-release tablets, oral suspension, and rectal suppositories. Tablets vary in color, shape, and imprint depending on the manufacturer and strength (e.g., blue, white, round, oval), often scored. The oral suspension is a clear to slightly cloudy liquid.
Dosage & Administration	Dosage varies by indication, patient age, and form (immediate vs. extended release). For adults, typical doses range from 250 mg to 500 mg orally twice daily (for prescription forms) or 220 mg (naproxen sodium) every 8 to 12 hours as needed (for OTC forms). Extended-release forms are usually once daily. For dysmenorrhea, an initial dose of 500 mg followed by 250 mg every 6-8 hours as needed. It should be taken with food, milk, or antacids to minimize gastrointestinal upset. Use the lowest effective dose for the shortest duration.
Supplied As	Naproxen is supplied as: oral tablets (e.g., 220 mg, 250 mg, 375 mg, 500 mg, 550 mg), delayed-release tablets (e.g., 375 mg, 500 mg), extended-release tablets (e.g., 375 mg, 500 mg, 750 mg), oral suspension (e.g., 125 mg/5 mL), and rectal suppositories (e.g., 500 mg).
Contraindications	Naproxen is contraindicated in patients with known hypersensitivity to naproxen, aspirin, or other NSAIDs. It is also contraindicated in patients with a history of bronchospasm, asthma, rhinitis, or urticaria precipitated by aspirin or other NSAIDs, active gastrointestinal bleeding or peptic ulcer disease, severe renal impairment, or in the setting of coronary artery bypass graft (CABG) surgery.
Storage & Expiry	Naproxen tablets, suspension, and suppositories should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (e.g., nausea, vomiting, abdominal pain, dyspepsia, heartburn, constipation), headache, dizziness, and mild swelling (edema). More serious side effects, though less common with short-term use, include severe gastrointestinal bleeding, ulceration, or perforation, acute kidney injury, cardiovascular thrombotic events (e.g., heart attack, stroke), liver injury, and severe allergic reactions (e.g., anaphylaxis, serious skin reactions).
Warnings & Precautions	♦ BLACK BOX WARNINGS: Cardiovascular Thrombotic Events & Gastrointestinal Risk: Naproxen, like other NSAIDs, carries an increased risk of serious cardiovascular thrombotic events (e.g., heart attack, stroke) and serious gastrointestinal adverse events (e.g., bleeding, ulceration, perforation), which can be fatal. This risk may increase with duration of use. Avoid use in the setting of CABG surgery. ♦ Renal Effects: Can cause new onset or worsening of renal impairment, including acute renal failure. Use with caution in patients with pre-existing renal disease, heart failure, liver dysfunction, or dehydration. ♦ Hypertension: Can cause new onset hypertension or worsen pre-existing hypertension. Monitor blood pressure closely. ♦ Fluid Retention/Edema: Use with caution in patients with heart failure or hypertension. ♦ Hepatic Effects: Liver injury, including severe and fatal cases, can occur. Monitor liver function in prolonged use. ♦ Anaphylactoid Reactions: Can occur in patients without known prior exposure. ♦ Asthma Exacerbation: Use with caution in patients with asthma, especially aspirin-sensitive asthma. ♦ Pregnancy: Avoid use in late pregnancy (after 20 weeks gestation), particularly in the third trimester, due to risk of premature closure of fetal ductus arteriosus and potential fetal renal dysfunction. ♦ Elderly: Increased risk of serious adverse effects, especially GI bleeding and renal dysfunction. Use lowest effective dose. ♦ Skin Reactions: Can cause serious skin adverse reactions (e.g., exfoliative dermatitis, Stevens-Johnson Syndrome, toxic epidermal necrolysis). Discontinue at first appearance of rash.
Missed Dose Instructions	For scheduled conditions (e.g., arthritis), if a dose of Naproxen is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For as-needed use, take when pain recurs, adhering to dosage limits.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily severe gastrointestinal upset (nausea, vomiting, abdominal pain), drowsiness, and potentially more severe GI bleeding, acute renal failure, or even seizures. Treatment is supportive and symptomatic. Gastric decontamination (e.g., activated charcoal) may be considered if oral ingestion was recent and substantial. Hemodialysis is unlikely to be effective due to high protein binding. Seek immediate emergency medical help.
Medicine Interactions	♦ Anticoagulants (e.g., warfarin) & Antiplatelet agents (e.g., aspirin, clopidogrel): Significantly increased risk of bleeding. Concurrent use should be approached with extreme caution, and close monitoring of coagulation parameters (e.g., INR) is essential. ♦ Other NSAIDs: Concomitant use is generally not recommended due to additive GI and renal toxicity, and no additional therapeutic benefit. ♦ Lithium: Increases serum lithium concentrations and toxicity; monitor lithium levels closely. ♦ Methotrexate: Increases methotrexate toxicity. ♦ ACE Inhibitors/ARBs/Diuretics: May reduce the antihypertensive and diuretic effects, and significantly increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. ♦ Corticosteroids: Increased risk of GI ulceration and bleeding. ♦ SSRIs: Increased risk of GI bleeding. ♦ Cyclosporine/Tacrolimus: Increased risk of nephrotoxicity. ♦ Digoxin: May increase digoxin levels. ♦ Phenytoin: May increase phenytoin levels. ♦ Beta-blockers: May reduce the antihypertensive effect.

Nifepidine (Procardia)

MEDICATION | Medication List | N - Q | Nifepidine (Procardia)

Purpose/Indication	Nifedipine is a dihydropyridine calcium channel blocker primarily used for the management of hypertension (high blood pressure) and chronic stable angina pectoris (chest pain). Extended-release formulations are preferred for these long-term conditions. It is also used to treat Prinzmetal's (variant) angina and, in some cases, Raynaud's phenomenon. Its purpose is to relax blood vessels, thereby lowering blood pressure and increasing blood flow to the heart.
Method of Action	Nifedipine works by inhibiting the influx of extracellular calcium ions across the cell membranes of vascular smooth muscle and, to a lesser extent, cardiac muscle. This selective inhibition primarily affects the L-type voltage-gated calcium channels in arterial smooth muscle, leading to potent peripheral and coronary vasodilation. This vasodilation reduces systemic vascular resistance, thereby lowering blood pressure, and improves myocardial oxygen supply by dilating coronary arteries, relieving angina. Unlike non-dihydropyridines, it has minimal direct effect on cardiac conduction or contractility at therapeutic doses.
Medication Name & Brand Names	♦ Medication Name: Nifedipine ♦ Brand Names: Procardia (immediate-release - regional), Adalat (immediate-release/extended-release), Procardia XL (extended-release - regional), Adalat CC (extended-release), Nifedical XL (extended-release), Nifedipine (generic)
Pharmaceutical Forms & Appearance	Nifedipine is available as oral immediate-release capsules, and oral extended-release tablets. Immediate-release capsules typically contain a clear, yellowish liquid. Extended-release tablets are generally film-coated, often oblong, and may be yellow, orange, or reddish-brown, with specific imprints indicating strength or being part of an osmotic pump system (e.g., ghost tablet may be expelled in stool).
Dosage & Administration	Dosage varies by formulation and indication. For hypertension and chronic stable angina, extended-release formulations are generally preferred, with typical adult doses ranging from 30 mg to 90 mg once daily, adjusted based on patient response. Immediate-release capsules are rarely used for chronic conditions due to fluctuating blood pressure and increased side effects; they are sometimes used for acute hypertensive urgency but are not recommended for routine use. Extended-release tablets should be swallowed whole; do not chew, crush, or divide. It can be taken with or without food.
Supplied As	Nifedipine is supplied as: oral immediate-release capsules (e.g., 5 mg, 10 mg, 20 mg) and oral extended-release tablets (e.g., 30 mg, 60 mg, 90 mg).
Contraindications	Nifedipine is strictly contraindicated in patients with known hypersensitivity to nifedipine or any component of the formulation. It is also contraindicated in patients with cardiogenic shock, aortic stenosis (severe), unstable angina, and within the first few weeks after a myocardial infarction. Immediate-release nifedipine is particularly contraindicated for acute blood pressure reduction due to the risk of precipitous drops and reflex tachycardia, which can cause ischemic events. Concomitant use with rifampicin is contraindicated.
Storage & Expiry	Nifedipine capsules and tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Immediate-release capsules often come in light-protective containers. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are related to vasodilation and include peripheral edema (swelling of ankles/feet), headache, dizziness, flushing, and reflex tachycardia (increased heart rate, especially with immediate-release forms). Other common effects include nausea, fatigue, and gingival hyperplasia (gum overgrowth with long-term use). More serious but less common effects include symptomatic hypotension and, rarely, myocardial infarction or angina exacerbation (especially with immediate-release forms).
Warnings & Precautions	♦ Hypotension: Can cause symptomatic hypotension, especially at initiation or with dose increases. Use with caution in patients with low blood pressure or those susceptible to significant drops. ♦ Reflex Tachycardia: Immediate-release formulations, due to rapid and profound vasodilation, can cause reflex tachycardia, which may exacerbate angina or lead to myocardial infarction, especially in patients with existing CAD. Avoid immediate-release for acute hypertension or chronic management. ♦ Heart Failure: Use with caution in patients with heart failure or reduced left ventricular function as it can worsen cardiac output, although generally less problematic than non-dihydropyridines. ♦ Angina Exacerbation: Rarely, initiation or dose increase may lead to an increase in frequency, duration, or severity of angina, particularly in patients with severe obstructive CAD. ♦ Gastrointestinal Effects (Extended-Release): Extended-release tablets use a non-deformable osmotic pump system that may appear as a "ghost" tablet in the stool. This is normal. Caution in patients with severe GI narrowing. ♦ Hepatic Impairment: Nifedipine is extensively metabolized in the liver. Use with caution and consider dose reduction in patients with hepatic impairment. ♦ Concomitant Beta-Blockers: While often used together, careful monitoring is needed, as combined effects on blood pressure can be additive, though nifedipine has less direct cardiac depression than verapamil/diltiazem. ♦ Peripheral Edema: Common and dose-related. It is often due to arterial vasodilation rather than fluid overload and may not respond well to diuretics. ♦ Gingival Hyperplasia: Can occur with long-term use; good oral hygiene is essential. ♦ Diabetes Mellitus: Use with caution as it may occasionally affect glucose tolerance.
Missed Dose Instructions	For Nifedipine extended-release (ER) tablets: If a dose is missed, take it as soon as remembered on the same day. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For immediate-release (IR) capsules: If a dose is missed, take it as soon as remembered. If it is close to the next dose, skip the missed dose. Do not take a double dose. Consistency is important for blood pressure and angina control.
Overdose Instructions	Overdose symptoms are primarily severe hypotension, bradycardia (if cardiac depression is significant), reflex tachycardia, and potentially profound peripheral vasodilation with flushing. Other effects might include impaired consciousness, metabolic acidosis, and hyperglycemia. There is no specific antidote for nifedipine. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Maintain an open airway, ventilation, and cardiovascular support. Intravenous fluids and vasopressors (e.g., norepinephrine) may be needed for hypotension. Intravenous calcium gluconate or calcium chloride can help reverse some calcium channel blocker effects. Hemodialysis is not effective due to high protein binding. Seek immediate emergency medical help.
Medicine Interactions	♦ Strong CYP3A4 Inducers (e.g., rifampicin, phenytoin, carbamazepine, phenobarbital, St. John's Wort): Rifampicin is CONTRAINDICATED due to profound reduction in nifedipine levels, leading to loss of therapeutic effect. Other inducers may also significantly decrease nifedipine levels. ♦ Strong CYP3A4 Inhibitors (e.g., azole antifungals like ketoconazole, itraconazole; macrolide antibiotics like erythromycin, clarithromycin; protease inhibitors like ritonavir; fluoxetine; nefazodone; diltiazem; verapamil; grapefruit juice): Can significantly increase nifedipine levels, leading to enhanced effects (e.g., severe hypotension, edema). Dose adjustment or avoidance may be necessary. ♦ Beta-Blockers (e.g., metoprolol, propranolol): Can have additive hypotensive effects. While often co-administered, careful monitoring is needed to avoid excessive bradycardia (less common with nifedipine than verapamil/diltiazem) and hypotension. ♦ Magnesium Sulfate: Concurrent use with IV magnesium sulfate (e.g., in preeclampsia) can cause profound hypotension and neuromuscular blockade. ♦ Digoxin: May increase serum digoxin levels. Monitor digoxin levels. ♦ Theophylline: May increase theophylline levels. ♦ Warfarin: No significant interaction. ♦ Quinidine: Nifedipine may decrease quinidine levels. ♦ Cimetidine: May increase nifedipine levels. ♦ Cisapride: May increase nifedipine levels.

Nitazoxanide (Alinia)

Purpose/Indication	Nitazoxanide is an antiprotozoal medication primarily used to treat diarrhea caused by the protozoa Cryptosporidium parvum and Giardia lamblia in adults and children 1 year of age and older. It is particularly useful when protozoal infection is suspected, especially if diarrhea has lasted for more than 7 days.
Method of Action	Nitazoxanide's mechanism of action involves inhibiting the pyruvate:ferredoxin oxidoreductase (PFOR) enzyme-dependent electron transfer reactions within the anaerobic energy metabolism of certain protozoa and anaerobic bacteria. By disrupting this essential energy pathway, nitazoxanide effectively stops the growth and replication of the parasites, leading to their eradication.
Medication Name & Brand Names	♦ Medication Name: Nitazoxanide ♦ Brand Names: Alinia, Annita (regional), Daxon (regional), Nitamax (regional), Nitazoxanide (generic)
Pharmaceutical Forms & Appearance	Nitazoxanide is available as oral tablets and oral suspension. Tablets are typically yellow, film-coated, round, and may be debossed with specific markings. The oral suspension is a strawberry-flavored liquid, which needs to be shaken well before use.
Dosage & Administration	Dosage varies by age. For adults and children 12 years and older, the typical dose is 500 mg orally every 12 hours with food for 3 days. For children 4 to under 12 years, it's 200 mg every 12 hours with food for 3 days. For children 1 to under 4 years, it's 100 mg every 12 hours with food for 3 days. Always take with food to enhance absorption and minimize gastrointestinal upset.
Supplied As	Nitazoxanide is supplied as: oral tablets (e.g., 500 mg) and oral suspension (e.g., 100 mg/5 mL).
Contraindications	Nitazoxanide is contraindicated in patients with known hypersensitivity to nitazoxanide or any component of the formulation. Caution is advised in patients with hepatic or renal impairment, diabetes, HIV infection, or other immunodeficiencies, as it has not been extensively studied in these populations for its indicated uses.
Storage & Expiry	Nitazoxanide tablets and oral suspension should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. The oral suspension, once reconstituted by the pharmacist, typically needs to be used within 7 days and should not be frozen. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal disturbances such as abdominal pain, nausea, diarrhea, and vomiting. Other commonly reported side effects are headache and chromaturia (discolored urine, often yellow or greenish). Most side effects are mild and transient.
Warnings & Precautions	♦ Renal/Hepatic Impairment: Has not been studied in patients with significant renal or hepatic impairment; use with caution. ♦ Diabetes: The oral suspension contains sucrose; this should be considered for diabetic patients. ♦ Immunocompromised Patients: Effectiveness for C. parvum in HIV-infected or immunodeficient patients has not been established. ♦ Completing Course: It is important to complete the full prescribed course of treatment to ensure complete eradication of the infection and prevent recurrence. ♦ Hygiene: Advise patients on proper hygiene to prevent re-infection.
Missed Dose Instructions	If a dose of Nitazoxanide is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose to make up for a missed one. It is important to complete the full 3-day course of treatment.
Overdose Instructions	There is limited information on human overdose with nitazoxanide. Symptoms of overdose are likely to be an exaggeration of the known side effects, such as severe gastrointestinal distress (abdominal pain, nausea, vomiting, diarrhea) and headache. Treatment is supportive and symptomatic. Gastric lavage may be considered soon after acute overdose. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Warfarin: Nitazoxanide is highly bound to plasma proteins. Therefore, it may compete for binding sites with other highly plasma protein-bound drugs with narrow therapeutic indices, such as warfarin, potentially increasing the anticoagulant effect. Monitor INR closely if co-administered. ♦ Other highly protein-bound drugs: Theoretical potential for interaction with other highly protein-bound medications (e.g., phenytoin, lorazepam, valproic acid); monitor for altered effects of either drug. ♦ Food: Food enhances the absorption of nitazoxanide, and it should always be taken with food to ensure optimal absorption and minimize gastrointestinal upset.

Nitrofurantoin (Macrobid)

Purpose/Indication	Nitrofurantoin is an antibiotic specifically used for the treatment and prophylaxis of uncomplicated lower urinary tract infections (UTIs) caused by susceptible bacteria. It is effective against common uropathogens like E. coli and Enterococcus. It concentrates in the urine, making it highly effective for bladder infections without significant systemic antibacterial effects.
Method of Action	Nitrofurantoin is a nitrofuran antimicrobial. It works by being reduced by bacterial flavoproteins to highly reactive intermediates within the bacterial cell. These reactive intermediates then damage multiple bacterial macromolecules, including DNA, RNA, ribosomes, and other metabolic enzymes. This broad-spectrum damage inhibits bacterial growth and ultimately leads to bacterial cell death, primarily within the urinary tract. Its mechanism of action is unique, reducing the likelihood of cross-resistance with other antibiotics.
Medication Name & Brand Names	♦ Medication Name: Nitrofurantoin (macrocrystals), Nitrofurantoin monohydrate/macrocrystals ♦ Brand Names: Macrobid (macrocrystals/monohydrate - BID dosing), Macrodantin (macrocrystals - QID dosing), Furadantin (oral suspension - regional), Nitrofurantoin (generic)
Pharmaceutical Forms & Appearance	Nitrofurantoin is available as oral capsules and oral suspension. Macrocrystal capsules (Macrodantin) are typically yellow and white, or entirely yellow. Monohydrate/macrocrystal capsules (Macrobid) are typically yellow and white with specific imprints. The oral suspension is a yellow to orange, opaque liquid.
Dosage & Administration	Dosage varies by formulation and indication. For acute uncomplicated UTIs, Macrobid (monohydrate/macrocrystals) is typically 100 mg orally every 12 hours for 5 to 7 days. Macrodantin (macrocrystals) is typically 50-100 mg orally four times a day for 7 days. For prophylaxis, lower daily doses may be used. It should be taken with food to enhance absorption and minimize gastrointestinal upset.
Supplied As	Nitrofurantoin is supplied as: oral macrocrystal capsules (e.g., 25 mg, 50 mg, 100 mg), oral monohydrate/macrocrystal capsules (e.g., 100 mg), and oral suspension (e.g., 25 mg/5 mL).
Contraindications	Nitrofurantoin is contraindicated in patients with known hypersensitivity to nitrofurantoin or any component of the formulation. It is also contraindicated in patients with anuria, oliguria, or significant renal impairment (e.g., creatinine clearance < 60 mL/min or eGFR < 30-60 mL/min, depending on product and region) due to increased risk of toxicity and lack of efficacy. It is contraindicated in pregnant women at term (38-42 weeks gestation), during labor and delivery, or when the onset of labor is imminent due to the possibility of hemolytic anemia in the neonate. Also contraindicated in infants less than 1 month of age for the same reason.

Storage & Expiry	Nitrofurantoin capsules and oral suspension should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal disturbances (e.g., nausea, vomiting, abdominal pain, diarrhea), headache, and dizziness. The urine may turn a harmless brown or rust color. More serious but less common side effects include pulmonary reactions (acute, subacute, or chronic pneumonitis), peripheral neuropathy (potentially irreversible), hepatotoxicity (liver damage), hemolytic anemia (especially in G6PD deficiency), and Clostridioides difficile-associated diarrhea (CDAD).
Warnings & Precautions	♦ Pulmonary Reactions: Can cause acute, subacute, or chronic pulmonary reactions, ranging from mild reversible pneumonitis to severe, irreversible pulmonary fibrosis. Discontinue at first sign of lung injury. Risk increases with long-term use. ♦ Peripheral Neuropathy: Can cause severe and potentially irreversible peripheral neuropathy, particularly in patients with renal impairment, anemia, diabetes mellitus, electrolyte imbalance, or vitamin B deficiency. Discontinue if symptoms occur. ♦ Hepatotoxicity: Rare cases of hepatitis, cholestatic jaundice, and chronic active hepatitis have been reported. Monitor liver function in long-term therapy. ♦ Hemolytic Anemia: Can occur, particularly in patients with G6PD (glucose-6-phosphate dehydrogenase) deficiency. Avoid use in G6PD deficient patients. ♦ Renal Impairment: Use is contraindicated in patients with significant renal impairment due to accumulation and increased risk of toxicity, and lack of efficacy. ♦ Clostridioides difficile-associated diarrhea (CDAD): Can occur with nearly all antibacterial agents, including nitrofurantoin. ♦ Pregnancy (Term)/Infants: Contraindicated in pregnant women at term and in infants < 1 month of age due to risk of hemolytic anemia in the neonate. ♦ Urine Discoloration: May cause urine to turn a harmless brown or rust color. ♦ Hypersensitivity Reactions: Allergic reactions, including skin rashes and anaphylaxis, can occur.
Missed Dose Instructions	If a dose of Nitrofurantoin is missed, take it as soon as remembered with food. If it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. It is crucial to complete the full course of therapy to effectively treat the infection and prevent recurrence or development of resistance.
Overdose Instructions	Overdose of nitrofurantoin is rare. Symptoms are likely to be an exaggeration of the known side effects, particularly severe gastrointestinal disturbances (nausea, vomiting), and potentially more pronounced neurotoxic or pulmonary effects. Treatment is supportive and symptomatic. Increased fluid intake may promote urinary excretion. Hemodialysis is of limited value. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Antacids (magnesium trisilicate-containing): Can decrease the absorption of nitrofurantoin. Avoid co-administration or separate by several hours. ♦ Probenecid/Sulfinpyrazone: Can inhibit renal tubular secretion of nitrofurantoin, leading to increased plasma concentrations and reduced urinary concentrations. This decreases efficacy for UTIs and increases risk of toxicity. Avoid concurrent use. ♦ Quinolones: May reduce the antibacterial effect of quinolones in vitro (clinical significance uncertain). ♦ Live Bacterial Vaccines (e.g., typhoid vaccine): Antibiotics may reduce the therapeutic effect of live bacterial vaccines. Administer vaccine before starting nitrofurantoin, or defer antibiotic if possible. ♦ Food: Taking with food enhances absorption and improves tolerability, particularly for the macrocrystalline form.

Nystatin (Mycostatin)

Purpose/Indication	Nystatin is an antifungal medication primarily used to treat infections caused by Candida species (yeast), particularly candidiasis of the skin, mucous membranes (e.g., oral thrush, vaginal yeast infections), and the gastrointestinal tract. It is not absorbed systemically from these sites, making it effective for localized fungal infections.
Method of Action	Nystatin is a polyene antifungal. It works by binding to ergosterol, a vital sterol component of the fungal cell membrane. This binding creates pores or channels in the fungal cell membrane, leading to increased permeability, leakage of essential intracellular components (such as potassium and other cellular constituents), and ultimately, fungal cell death. Its mechanism is specific to fungi and does not significantly affect human cells, which contain cholesterol instead of ergosterol.
Medication Name & Brand Names	♦ Medication Name: Nystatin ♦ Brand Names: Mycostatin (oral suspension, tablets, topical, vaginal), Nystop (topical powder), Bio-Statin (oral tablets), Nystatin (generic)
Pharmaceutical Forms & Appearance	Nystatin is available in various topical, oral (non-systemic), and vaginal forms: oral suspension (for thrush), oral tablets/lozenges (for GI candidiasis), topical creams, ointments, and powders, and vaginal tablets/suppositories. Oral suspension is typically a yellow, viscous liquid. Oral tablets are usually yellow or brown. Topical creams/ointments are white to yellowish. Vaginal tablets are typically yellow.
Dosage & Administration	Dosage and administration vary significantly by the site of infection and formulation. For oral thrush, the oral suspension is typically 4-6 mL (400,000-600,000 units) swished in the mouth and swallowed, or held in the mouth and then spit out, 4 times daily. For topical infections, apply a thin layer to the affected area 2-3 times daily. For vaginal infections, one vaginal tablet or applicator-full of cream is typically inserted daily for 14 days or as directed. Administer oral suspension after meals for oral thrush.
Supplied As	Nystatin is supplied as: oral suspension (e.g., 100,000 units/mL), oral tablets (e.g., 500,000 units), oral lozenges (e.g., 200,000 units), topical cream (e.g., 100,000 units/g), topical ointment (e.g., 100,000 units/g), topical powder (e.g., 100,000 units/g), and vaginal tablets/suppositories (e.g., 100,000 units).
Contraindications	Nystatin is contraindicated in patients with known hypersensitivity to nystatin or any component of the formulation. It is intended for fungal infections sensitive to nystatin and should not be used for systemic fungal infections due to its negligible absorption from the GI tract and skin.
Storage & Expiry	Nystatin products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and excessive heat. Oral suspension should be kept tightly closed and shaken well before use. Do not freeze any formulations. Always check the specific expiry date on the packaging.
Side Effects	Side effects are generally mild and infrequent, given its poor systemic absorption. Common side effects include gastrointestinal upset (e.g., nausea, vomiting, diarrhea, abdominal pain) with oral forms, and local irritation, itching, or redness at the application site for topical or vaginal forms. Allergic reactions (e.g., rash, urticaria) are rare.
Warnings & Precautions	♦ Not for Systemic Infections: Nystatin is poorly absorbed from the gastrointestinal tract and skin; therefore, it is not effective for systemic fungal infections. ♦ Diagnosis: A definitive diagnosis of candidiasis should be made by appropriate laboratory methods (e.g., potassium hydroxide smears, cultures) before initiating treatment. ♦ Complete Full Course: Patients should complete the full prescribed course of treatment, even if symptoms improve, to ensure complete eradication of the infection and prevent recurrence. ♦ Oral Suspension Administration: For oral thrush, instruct patients to swish the suspension in the mouth for as long as possible before swallowing or spitting out, to maximize contact with the affected areas. ♦ Infants: For infants, apply to affected areas using a clean cloth or swab. ♦ Vaginal Use: Advise patients using vaginal preparations on proper hygiene and to continue use even during menstruation.
Missed Dose Instructions	If a dose of Nystatin is missed, take/apply it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not double a dose. Consistency is important for effective treatment of fungal infections.

Overdose Instructions	Overdose of nystatin is highly unlikely to cause systemic toxicity due to its minimal absorption from the gastrointestinal tract and skin. Symptoms of overdose are generally mild and limited to gastrointestinal upset (e.g., nausea, vomiting, diarrhea) if a large amount is ingested orally. Treatment is supportive and symptomatic. There is no specific antidote. Seek medical advice if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ No significant drug-drug interactions are commonly reported for nystatin due to its negligible systemic absorption. ♦ It does not typically interact with other medications, as it acts locally at the site of infection. However, local interactions with other topically applied medications are theoretically possible, although rare and not well-documented.

Olanzapine (Zyprexa)

Purpose/Indication	Olanzapine is an atypical antipsychotic medication used to treat schizophrenia and bipolar I disorder (manic or mixed episodes, and maintenance treatment). It is also used in combination with fluoxetine for treatment-resistant depression and depressive episodes associated with bipolar I disorder. Its purpose is to manage symptoms like hallucinations, delusions, mania, and severe mood disturbances.
Method of Action	Olanzapine is a thienobenzodiazepine atypical antipsychotic that acts on multiple neurotransmitter receptors in the brain. Its primary actions include antagonism of dopamine D2 and serotonin 5−HT2A receptors. It also has antagonistic effects on adrenergic (α1), histamine (H1), and muscarinic (M1,M2,M3,M4,M5) receptors. This multimodal receptor binding profile contributes to its antipsychotic, mood-stabilizing, and sedative effects, while minimizing the risk of extrapyramidal side effects compared to typical antipsychotics.
Medication Name & Brand Names	♦ Medication Name: Olanzapine ♦ Brand Names: Zyprexa (oral tablets, Zydis ODT, intramuscular injection), Zyprexa Relprevv (long-acting injection - historical, largely discontinued due to post-injection delirium/sedation syndrome risk), Olanzapine (generic)
Pharmaceutical Forms & Appearance	Olanzapine is available as oral tablets, orally disintegrating tablets (ODT), and powder for intramuscular (IM) injection (short-acting and long-acting forms). Oral tablets are typically white, round, or oblong, and may be scored, with various imprints. ODTs are white and dissolve rapidly on the tongue. The injectable powder is white to yellowish, reconstituted before use.
Dosage & Administration	Dosage is highly individualized. For schizophrenia, typical initial oral doses are 5-10 mg once daily, titrating to 10-15 mg/day. For bipolar disorder, initial oral doses are often 10-15 mg once daily. IM injection is used for acute agitation. Oral forms can be taken with or without food. Long-acting injectable forms are administered by healthcare professionals at specific intervals. Do not crush or chew ODTs; allow them to dissolve.
Supplied As	Olanzapine is supplied as: oral tablets (e.g., 2.5 mg, 5 mg, 7.5 mg, 10 mg, 15 mg, 20 mg), orally disintegrating tablets (e.g., 5 mg, 10 mg, 15 mg, 20 mg), and powder for injection for reconstitution (e.g., 10 mg/vial for acute IM, and long-acting forms in various strengths).
Contraindications	Olanzapine is contraindicated in patients with known hypersensitivity to olanzapine or any component of the formulation. It is also contraindicated in patients with narrow-angle glaucoma. The long-acting injectable form (Relprevv, if still available regionally) has additional contraindications due to the risk of post-injection delirium/sedation syndrome (PDSS).
Storage & Expiry	Olanzapine tablets and ODTs should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in tightly closed containers. Injectable forms (powder) should be stored protected from light and reconstituted immediately before use. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include drowsiness, weight gain, increased appetite, dizziness, dry mouth, constipation, and orthostatic hypotension. More serious side effects include metabolic changes (e.g., hyperglycemia, diabetes mellitus, dyslipidemia, weight gain), extrapyramidal symptoms (though less than typical antipsychotics), tardive dyskinesia, neuroleptic malignant syndrome (NMS), seizures, and increased mortality in elderly patients with dementia-related psychosis.
Warnings & Precautions	♦ BLACK BOX WARNINGS: Elderly Patients with Dementia-Related Psychosis: Increased risk of death compared to placebo, particularly due to cardiovascular (e.g., heart failure, sudden cardiac death) or infectious (e.g., pneumonia) causes. Not approved for this indication. ♦ Post-injection Delirium/Sedation Syndrome (PDSS): For long-acting injectable olanzapine (e.g., Zyprexa Relprevv), there is a risk of PDSS, a serious condition involving sedation, confusion, and delirium. Requires post-injection observation. (Note: This specific product has been largely discontinued in many regions due to this risk). ♦ Metabolic Changes: Significant risk of hyperglycemia and diabetes mellitus, dyslipidemia (high cholesterol/triglycerides), and substantial weight gain. Monitor blood glucose, lipids, and weight regularly. ♦ Neuroleptic Malignant Syndrome (NMS): A rare but potentially fatal syndrome characterized by fever, muscle rigidity, altered mental status, and autonomic instability. Discontinue immediately if NMS is suspected. ♦ Tardive Dyskinesia: A syndrome of potentially irreversible, involuntary dyskinetic movements. Risk increases with duration and total cumulative dose. Discontinue if symptoms occur. ♦ Orthostatic Hypotension/Syncope: Can cause dizziness and falls, especially during initial dose titration. Use with caution in patients with cardiovascular disease. ♦ Seizures: Use with caution in patients with a history of seizures or conditions that lower the seizure threshold. ♦ Dysphagia: Esophageal dysmotility and aspiration can occur. ♦ Leukopenia/Neutropenia/Agranulocytosis: Monitor complete blood counts during therapy. ♦ Body Temperature Regulation: May disrupt the body's ability to reduce core body temperature. ♦ Alcohol/Other CNS Depressants: Potentiation of sedation. ♦ Hepatic Impairment: Use with caution; dose adjustments may be needed.
Missed Dose Instructions	If a dose of Olanzapine (oral tablet or ODT) is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For long-acting injectable forms, follow the specific instructions from the healthcare provider for missed injections.
Overdose Instructions	Overdose symptoms are primarily related to CNS depression (drowsiness, slurred speech, coma), tachycardia, hypertension, miosis, and respiratory depression. Aspiration pneumonia and severe extrapyramidal symptoms can also occur. Treatment is supportive and symptomatic. There is no specific antidote. Maintain an open airway, ensure adequate oxygenation and ventilation. Monitor cardiovascular function. Activated charcoal may be considered if recent oral ingestion. Seek immediate emergency medical help.
Medicine Interactions	♦ CNS Depressants (e.g., alcohol, benzodiazepines, opioids, sedatives, hypnotics): Additive CNS depressant effects; increased sedation and respiratory depression. Avoid or use with extreme caution. ♦ Antihypertensives: Additive hypotensive effects. ♦ Drugs that Prolong QT Interval (e.g., certain antiarrhythmics, antipsychotics): Increased risk of QT prolongation and Torsades de Pointes. Use with caution. ♦ CYP1A2 Inducers (e.g., carbamazepine, omeprazole, rifampin, charcoal, smoking): Can significantly increase olanzapine clearance, reducing plasma concentrations and potentially efficacy. Increased doses of olanzapine may be needed. ♦ CYP1A2 Inhibitors (e.g., fluvoxamine, ciprofloxacin): Can significantly decrease olanzapine clearance, increasing plasma concentrations and potential for adverse effects. Reduced doses of olanzapine may be needed. ♦ Levodopa/Dopamine Agonists: Olanzapine may antagonize their effects. ♦ Anticholinergic Drugs (e.g., benztropine, oxybutynin): Additive anticholinergic effects (dry mouth, constipation, urinary retention). ♦ Metabolic Monitoring: Ensure regular monitoring for metabolic side effects, especially when co-prescribing drugs that might also affect glucose or lipid metabolism.

Omeprazole (Prilosec)

Purpose/Indication	Omeprazole is a proton pump inhibitor (PPI) primarily used to reduce stomach acid production. It is indicated for the treatment of gastroesophageal reflux disease (GERD), erosive esophagitis, duodenal and gastric ulcers, and Zollinger-Ellison syndrome. It is also used in combination with antibiotics to eradicate Helicobacter pylori infection, and for the prophylaxis of NSAID-associated ulcers.
Method of Action	Omeprazole is a prodrug that, after absorption, is converted to its active form in the acidic secretory canaliculi of the gastric parietal cells. The active form then irreversibly binds to and inhibits the H+/K+-ATPase enzyme system (the proton pump) on the secretory surface of the parietal cells. This action blocks the final step of acid secretion, significantly reducing both basal and stimulated gastric acid output, leading to potent and prolonged acid suppression.
Medication Name & Brand Names	♦ Medication Name: Omeprazole ♦ Brand Names: Prilosec (prescription), Prilosec OTC (over-the-counter), Zegerid (omeprazole/sodium bicarbonate - prescription & OTC), Omeprazole (generic)
Pharmaceutical Forms & Appearance	Omeprazole is available as delayed-release capsules, delayed-release tablets, and powder for oral suspension. Delayed-release capsules typically contain enteric-coated granules or pellets, often in a clear or colored capsule shell. Delayed-release tablets are film-coated and may vary in color. The powder for oral suspension is a white to off-white granular powder that is mixed with water before administration.
Dosage & Administration	Dosage varies widely depending on the indication. For GERD, common adult doses are 20 mg once daily for 4-8 weeks. For duodenal ulcers, 20 mg once daily for 4 weeks. For H. pylori eradication, it is usually 20 mg twice daily in combination with antibiotics for 7-14 days. Take capsules/tablets before a meal (preferably in the morning). Do not crush or chew delayed-release forms. Oral suspension should be mixed and administered immediately.
Supplied As	Omeprazole is supplied as: oral delayed-release capsules (e.g., 10 mg, 20 mg, 40 mg), oral delayed-release tablets (e.g., 20 mg), and powder for oral suspension (e.g., 2.5 mg/packet, 10 mg/packet, 20 mg/packet).
Contraindications	Omeprazole is contraindicated in patients with known hypersensitivity to omeprazole, substituted benzimidazoles (e.g., lansoprazole, pantoprazole), or any component of the formulation. It is also contraindicated for concomitant use with rilpivirine-containing products.
Storage & Expiry	Omeprazole capsules, tablets, and powder for suspension should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. The reconstituted oral suspension should be used within a specific timeframe (e.g., 30 minutes). Always check the specific expiry date on the packaging.
Side Effects	Common side effects include headache, abdominal pain, nausea, diarrhea, vomiting, and flatulence. More serious side effects, though less common, include Clostridioides difficile-associated diarrhea (CDAD), bone fractures (with long-term use), kidney problems (e.g., acute interstitial nephritis), magnesium deficiency (hypomagnesemia), vitamin B12 deficiency (with long-term use), and very rarely, severe skin reactions or systemic lupus erythematosus.
Warnings & Precautions	♦ CDAD: PPI therapy may increase the risk of Clostridioides difficile-associated diarrhea (CDAD). Use the lowest dose and shortest duration appropriate for the condition. ♦ Bone Fracture: Long-term and multiple daily dose PPI therapy may increase the risk for osteoporosis-related fractures of the hip, wrist, or spine. Use the lowest dose and shortest duration. ♦ Hypomagnesemia: Can occur with long-term therapy (at least 3 months, but usually a year or more). Consider monitoring magnesium levels in patients expected to be on prolonged treatment. ♦ Vitamin B12 Deficiency: Long-term daily treatment (e.g., >2-3 years) can lead to malabsorption of vitamin B12 due to acid suppression. ♦ Acute Interstitial Nephritis: Has been observed in patients taking PPIs, including omeprazole, and can occur at any point during therapy. ♦ Gastric Malignancy: Symptomatic response to therapy does not preclude the presence of gastric malignancy. ♦ Drug Interactions: Careful consideration of drug interactions, especially with clopidogrel (see Interactions). ♦ Atrophic Gastritis/Fundic Gland Polyps: Long-term PPI therapy may lead to atrophic gastritis or fundic gland polyps, especially with prolonged use. ♦ Pregnancy/Lactation: Use only if clearly needed. Minimal excretion into breast milk.
Missed Dose Instructions	If a dose of Omeprazole is missed, take it as soon as remembered before a meal. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for optimal acid suppression.
Overdose Instructions	Overdose symptoms are generally mild and self-limiting, including drowsiness, tachycardia, nausea, vomiting, abdominal pain, and headache. No specific antidote is known. Treatment is supportive and symptomatic. Hemodialysis is not effective for removing omeprazole. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Clopidogrel: Omeprazole reduces the antiplatelet effect of clopidogrel by inhibiting CYP2C19, an enzyme essential for clopidogrel activation. Concomitant use should generally be avoided, or an alternative antiplatelet or PPI with less CYP2C19 inhibition should be considered. ♦ Rilpivirine-containing products: Concomitant use is contraindicated as PPIs significantly reduce rilpivirine absorption. ♦ Warfarin: Increased INR and bleeding risk. Monitor INR closely. ♦ Digoxin: Increased digoxin absorption, leading to increased digoxin levels. Monitor digoxin levels. ♦ Methotrexate: May increase and prolong methotrexate serum levels and/or its active metabolite, potentially leading to toxicity. Consider temporary PPI withdrawal or lower doses of methotrexate. ♦ Tacrolimus: May increase tacrolimus levels. Monitor tacrolimus levels. ♦ Diazepam, Phenytoin, Cilostazol, Citalopram: Omeprazole can inhibit the metabolism of these drugs (CYP2C19/CYP3A4 substrates), increasing their concentrations. Dose adjustments may be needed. ♦ Erlotinib, Dasatinib, Nilotinib, Mycophenolate Mofetil: PPIs can significantly reduce the absorption of these drugs, reducing their efficacy. Avoid concurrent use where possible. ♦ St. John's Wort, Rifampin (CYP2C19/3A4 inducers): May decrease omeprazole plasma levels. ♦ Iron salts: PPIs can reduce the absorption of oral iron supplements.

Ondansetron (Zofran)

Purpose/Indication	Ondansetron is an antiemetic medication primarily used to prevent and treat nausea and vomiting, particularly those associated with chemotherapy, radiation therapy, and surgery (postoperative nausea and vomiting, PONV). It is also sometimes used off-label for severe nausea and vomiting in other conditions, such as hyperemesis gravidarum.
Method of Action	Ondansetron is a selective serotonin 5−HT3 receptor antagonist. It works by blocking serotonin's actions at the 5−HT3 receptors located in the chemoreceptor trigger zone (CTZ) in the brain and on vagal nerve terminals in the gastrointestinal tract. By blocking these receptors, ondansetron prevents the initiation of the vomiting reflex, which is often triggered by the release of serotonin from enterochromaffin cells in the gut in response to emetogenic stimuli (e.g., chemotherapy, radiation).
Medication Name & Brand Names	♦ Medication Name: Ondansetron Hydrochloride ♦ Brand Names: Zofran (oral tablets, ODT, oral solution, injection), Zofran ODT (orally disintegrating tablets), Ondansetron (generic)
Pharmaceutical Forms & Appearance	Ondansetron is available as oral tablets, orally disintegrating tablets (ODT), oral solution, and solution for intravenous (IV) or intramuscular (IM) injection. Oral tablets are typically white to yellow, round or oval, and may be scored, with various imprints. ODTs are white and dissolve rapidly on the tongue. The oral solution is a clear, colorless to pale yellow liquid. The injectable solution is clear and colorless.

Dosage & Administration	Dosage varies significantly by indication and route. For chemotherapy-induced nausea and vomiting (CINV), doses range from 8 mg to 24 mg orally or IV, often given 30 minutes prior to chemotherapy and then every 8-12 hours. For PONV, typical doses are 4 mg IV or orally, given before or after surgery. Oral forms can be taken with or without food. ODTs should be placed on the tongue to dissolve. IV administration should be given slowly (e.g., over 2-5 minutes).
Supplied As	Ondansetron is supplied as: oral tablets (e.g., 4 mg, 8 mg, 16 mg, 24 mg), orally disintegrating tablets (e.g., 4 mg, 8 mg), oral solution (e.g., 4 mg/5 mL), and solution for intravenous/intramuscular injection (e.g., 2 mg/mL in vials or pre-filled syringes).
Contraindications	Ondansetron is contraindicated in patients with known hypersensitivity to ondansetron or other 5−HT3 receptor antagonists (e.g., granisetron, palonosetron), or any component of the formulation. Concomitant use with apomorphine is strictly contraindicated due to reports of profound hypotension and loss of consciousness.
Storage & Expiry	Ondansetron tablets, ODTs, oral solution, and injectable solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Do not freeze the oral solution. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include headache, constipation, diarrhea, fatigue, and dizziness. More serious side effects, though less common, include QT prolongation and Torsades de Pointes (especially with high doses or in susceptible individuals), serotonin syndrome (with concomitant use of serotonergic drugs), and hypersensitivity reactions.
Warnings & Precautions	♦ QT Prolongation and Torsades de Pointes: Can cause dose-dependent QT interval prolongation, which may lead to Torsades de Pointes, a life-threatening arrhythmia. Avoid in patients with congenital long QT syndrome. Use with caution in patients with electrolyte abnormalities (e.g., hypokalemia, hypomagnesemia), congestive heart failure, bradyarrhythmias, or those taking other QT-prolonging drugs. Avoid single IV doses exceeding 16 mg. ♦ Serotonin Syndrome: Potentially life-threatening, can occur with concomitant use of other serotonergic drugs (e.g., SSRIs, SNRIs, MAOIs, tricyclic antidepressants, mirtazapine, fentanyl, tramadol). Symptoms include mental status changes, autonomic instability, neuromuscular abnormalities, and GI symptoms. ♦ Hypersensitivity Reactions: Anaphylaxis and bronchospasm have been reported. ♦ Masking Progressive Ileus: Ondansetron can mask a progressive ileus or gastric distension. Monitor patients with abdominal surgery or chemotherapy-induced nausea for decreased bowel motility. ♦ Hepatic Impairment: Dosage adjustment is recommended for severe hepatic impairment due to reduced clearance. ♦ Phenylketonuria: Orally disintegrating tablets may contain phenylalanine.
Missed Dose Instructions	Ondansetron is typically taken on an as-needed basis for nausea and vomiting, or on a specific schedule around chemotherapy/radiation. If a scheduled dose is missed, take it as soon as remembered if symptoms of nausea/vomiting are present or anticipated. If it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, including visual disturbances, severe constipation, hypotension, and potential for fatal arrhythmias (e.g., Torsades de Pointes, especially with massive overdose). Treatment is supportive and symptomatic. Monitor ECG for QT prolongation. There is no specific antidote. Seek immediate emergency medical help.
Medicine Interactions	♦ Apomorphine: Contraindicated: Concomitant use with apomorphine can cause profound hypotension and loss of consciousness. ♦ QT-Prolonging Drugs (e.g., Class IA and III antiarrhythmics, some antipsychotics, macrolides): Increased risk of QT prolongation and Torsades de Pointes. Avoid concurrent use where possible, or monitor ECG closely. ♦ Serotonergic Drugs (e.g., SSRIs, SNRIs, MAOIs, tricyclic antidepressants, lithium, tramadol, fentanyl): Increased risk of serotonin syndrome. Monitor patients for symptoms. ♦ Tramadol: May reduce the analgesic effect of tramadol. ♦ Carbamazepine, Phenytoin, Rifampin: These enzyme inducers can decrease ondansetron plasma concentrations, potentially reducing its efficacy. Increased ondansetron doses may be needed. ♦ Tamoxifen: Concurrent use may result in decreased tamoxifen levels due to CYP2D6 inhibition, potentially reducing its efficacy.

Oral Antacids (Calcium Carbonate) (Tums)

Purpose/Indication	Oral antacids containing calcium carbonate are used for the rapid, temporary relief of heartburn, indigestion, acid reflux, sour stomach, and upset stomach associated with excess stomach acid. They can also be used as a calcium supplement to prevent or treat calcium deficiency (e.g., in osteoporosis), although their primary role as an antacid is for acid neutralization.
Method of Action	Calcium carbonate acts as a direct-acting antacid by neutralizing gastric acid in the stomach. When ingested, it reacts with hydrochloric acid (HCl) in the stomach to form calcium chloride ($CaCl_2$), water (H_2O), and carbon dioxide (CO_2). This neutralization reaction directly raises the pH of the stomach contents, reducing acidity and providing quick relief from acid-related symptoms. The calcium is then partially absorbed.
Medication Name & Brand Names	♦ Medication Name: Calcium Carbonate (as an antacid) ♦ Brand Names: Tums, Rennie (regional), Titralac, Viactiv (as supplement with antacid properties), Caltrate (as supplement with antacid properties), Calcium Carbonate (generic)
Pharmaceutical Forms & Appearance	Oral antacids containing calcium carbonate are commonly available as chewable tablets, chewable gummies, and less commonly as oral suspensions or powders. Chewable tablets come in various flavors (e.g., fruit, mint) and colors, often chalky in texture. Gummies are softer and come in various fruit flavors.
Dosage & Administration	Dosage varies by product and individual need. For acid relief, chew 2-4 tablets as symptoms occur, not exceeding a maximum daily dose (e.g., 7500 mg calcium carbonate in 24 hours, or as per product label). Do not swallow whole. Administer after meals and at bedtime for sustained effect. For calcium supplementation, doses vary; often 500-600 mg elemental calcium per dose, taken with food.
Supplied As	Oral antacids (Calcium Carbonate) are supplied as: chewable tablets (e.g., 200 mg, 500 mg, 750 mg, 1000 mg elemental calcium per tablet), chewable gummies, oral suspensions, and powders.
Contraindications	Calcium carbonate antacids are contraindicated in patients with known hypersensitivity to calcium carbonate or any component of the formulation. They are also contraindicated in patients with hypercalcemia (high blood calcium levels), severe renal impairment (due to risk of hypercalcemia and metabolic alkalosis), and hypophosphatemia.
Storage & Expiry	Calcium carbonate antacid products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and include constipation, belching (due to CO_2 production), and flatulence. With excessive or prolonged use, more serious side effects can include hypercalcemia (e.g., nausea, vomiting, constipation, thirst, polyuria, muscle weakness), milk-alkali syndrome (hypercalcemia, metabolic alkalosis, renal impairment), and rebound acid secretion.

Warnings & Precautions	♦ Hypercalcemia: Excessive or prolonged use can lead to hypercalcemia, especially in patients with impaired renal function, or those taking high doses of vitamin D. Symptoms include nausea, vomiting, muscle weakness, and confusion. ♦ Renal Impairment: Use with caution in patients with mild to moderate renal impairment due to increased risk of hypercalcemia and metabolic alkalosis. Contraindicated in severe renal impairment. ♦ Milk-Alkali Syndrome: Rare but serious condition caused by excessive intake of calcium and absorbable alkali (like calcium carbonate), leading to hypercalcemia, metabolic alkalosis, and renal impairment. ♦ Constipation: Can cause or worsen constipation. ♦ Acid Rebound: Chronic high-dose use can sometimes lead to rebound acid secretion upon discontinuation. ♦ Other Medications: Can interact with numerous medications by altering gastric pH or binding to drugs (see Interactions). Separate administration times. ♦ Undiagnosed Symptoms: Not for prolonged use without medical advice, as chronic heartburn could indicate a more serious underlying condition. ♦ Cardiac Patients: Use with caution in patients with cardiac conditions, as high calcium levels can affect heart rhythm.
Missed Dose Instructions	Calcium carbonate antacids are typically used on an as-needed basis for symptom relief. If a dose is missed, it's not applicable in the same way as scheduled medications. Simply take the next dose when symptoms recur, adhering to the maximum daily dose and frequency limits stated on the product label.
Overdose Instructions	Overdose of calcium carbonate is usually due to excessive or chronic intake, leading to hypercalcemia and potentially milk-alkali syndrome. Symptoms of hypercalcemia include nausea, vomiting, constipation, polyuria, polydipsia, muscle weakness, confusion, and lethargy. Severe cases can lead to cardiac arrhythmias, renal failure, and coma. Treatment involves discontinuation of calcium carbonate and any other calcium/vitamin D supplements. Management includes hydration with IV fluids and, in severe cases, loop diuretics or calcitonin. Seek immediate medical attention for significant overdose or severe symptoms.
Medicine Interactions	♦ Tetracyclines & Quinolone Antibiotics (e.g., doxycycline, ciprofloxacin, levofloxacin): Calcium forms insoluble chelates with these antibiotics, significantly reducing their absorption. Separate administration by at least 2-6 hours. ♦ Bisphosphonates (e.g., alendronate): Reduced absorption of bisphosphonates. Separate administration by at least 30 minutes to 2 hours. ♦ Thyroid Hormones (e.g., levothyroxine): Reduced absorption of thyroid hormones. Separate administration by at least 4 hours. ♦ Iron Supplements: Reduced iron absorption. Separate administration by at least 2-4 hours. ♦ Digoxin: Hypercalcemia can predispose to digoxin toxicity. Monitor digoxin levels and calcium. ♦ Thiazide Diuretics: Can increase calcium reabsorption in the kidneys, increasing the risk of hypercalcemia. Monitor calcium levels. ♦ Phosphate Binders: Concomitant use can lead to higher calcium levels. ♦ Vitamin D: High doses of vitamin D increase calcium absorption, increasing risk of hypercalcemia. ♦ Other Antacids: Avoid concurrent use of multiple antacids unless advised by a healthcare professional.

Oral Rehydration Salts (ORS) (Pedialyte)

Purpose/Indication	Oral Rehydration Salts (ORS) are used for the prevention and treatment of dehydration, especially that caused by acute diarrhea (e.g., from cholera or rotavirus), vomiting, or other conditions leading to significant fluid and electrolyte loss. Their purpose is to restore lost fluids and essential electrolytes (sodium, potassium, chloride, bicarbonate/citrate) and provide some glucose for energy, thereby preventing or reversing dehydration and its complications.
Method of Action	ORS works based on the principle of co-transport of glucose and sodium in the small intestine. The glucose facilitates the absorption of sodium, and water passively follows the absorbed sodium, even in the presence of diarrhea. This mechanism allows for effective rehydration despite ongoing fluid losses. The other electrolytes (potassium, chloride, and bicarbonate/citrate) are included to replace losses from diarrhea and correct acid-base imbalances.
Medication Name & Brand Names	♦ Medication Name: Oral Rehydration Salts (ORS) ♦ Brand Names: ORS, Oralyte, Rehydralyte, Hydralyte (regional), Gastrolyte (regional), Pedialyte (regional), WHO ORS (World Health Organization ORS)
Pharmaceutical Forms & Appearance	ORS are typically supplied as a powder or granules that are dissolved in a specific volume of clean drinking water before administration. The powder is usually white and crystalline, and the resulting solution is clear and colorless, though some commercial preparations may have a slight color or flavor.
Dosage & Administration	Dosage depends on the age and severity of dehydration. For mild to moderate dehydration, adults and children should drink small, frequent sips of the prepared ORS solution. After each loose stool, infants under 2 years should be given 50-100 mL, children 2-10 years 100-200 mL, and older children/adults as much as they can drink comfortably. Continue administration until dehydration is corrected and diarrhea stops. Always use clean, safe water for preparation.
Supplied As	Oral Rehydration Salts are supplied as: powder sachets or packets (e.g., pre-measured for 1 liter of water), or as ready-to-use oral solutions (though less common for traditional ORS).
Contraindications	ORS are generally safe, but are contraindicated in conditions where oral fluid administration is not possible or safe, such as paralytic ileus, intestinal obstruction, severe persistent vomiting preventing oral intake, or unconsciousness (unless administered via nasogastric tube under medical supervision). They are also contraindicated in severe dehydration with shock, which requires intravenous fluids.
Storage & Expiry	Unprepared ORS powder sachets should be stored in a cool, dry place (typically room temperature) away from direct sunlight and moisture. Once prepared, the ORS solution should be used within 24 hours (if stored in a refrigerator) or within a shorter period (e.g., 12 hours) at room temperature, as per manufacturer guidelines, to prevent bacterial growth. Always check the specific expiry date on the packaging for the powder.
Side Effects	Side effects are rare when ORS are prepared and administered correctly. Occasionally, nausea or vomiting may occur if the solution is drunk too quickly or in large gulps. Over-hydration or electrolyte imbalances (e.g., hypernatremia) are very rare but possible if prepared incorrectly (too concentrated) or given in excessive amounts in specific situations.
Warnings & Precautions	♦ Proper Preparation: Crucial for efficacy and safety. Use the exact amount of clean drinking water specified on the packet; using too little water can lead to hypernatremia (excess sodium), and too much water can lead to insufficient electrolyte replacement. ♦ Severe Dehydration: ORS are for mild to moderate dehydration. Severe dehydration with shock or altered consciousness requires immediate intravenous fluid therapy. ♦ Persistent Vomiting: While ORS can often be given successfully even with vomiting (small, frequent sips), persistent severe vomiting that prevents adequate intake necessitates medical review and potentially IV fluids. ♦ Renal Impairment: Use with caution in patients with renal impairment, as electrolyte imbalances could worsen. ♦ Diabetic Patients: While ORS contain glucose, the amount is balanced with electrolytes; it generally does not significantly affect blood glucose in diabetics, but monitoring is advised. ♦ Do not add other substances: Do not add sugar, fruit juice, or other drinks to the prepared ORS solution, as this can alter the electrolyte balance and reduce effectiveness or worsen symptoms.
Missed Dose Instructions	ORS are given as needed to replace fluid and electrolyte losses. There isn't a "missed dose" in the traditional sense for scheduled medication. Continue to administer the solution in small, frequent amounts as long as fluid losses from diarrhea or vomiting persist, or until rehydration is achieved.

Overdose Instructions	Overdose of ORS is rare if prepared and administered correctly. If an overly concentrated solution is given or excessive amounts are consumed, it could potentially lead to hypernatremia (high sodium levels) and hypervolemia (fluid overload), especially in infants or those with compromised renal function. Symptoms might include lethargy, irritability, thirst, fever, or edema. Treatment involves discontinuing ORS and seeking immediate medical attention. Management includes careful monitoring of electrolytes and fluid status, and correction of imbalances.
Medicine Interactions	♦ Generally no significant drug-drug interactions with ORS. ♦ However, the effectiveness of ORS relies on its specific electrolyte and glucose balance. Therefore, it is important not to mix ORS with other beverages like fruit juice, soft drinks, or broth, as these can alter the electrolyte concentration and impair the solution's effectiveness or worsen dehydration. ♦ Certain medications that affect electrolyte balance or fluid status (e.g., diuretics) might require closer monitoring of fluid and electrolytes if ORS is being used, but this is usually managed clinically rather than being a direct interaction with ORS.

Oseltamivir (Tamiflu)

Purpose/Indication	Oseltamivir is an antiviral medication used for the treatment of acute, uncomplicated influenza (flu) in patients 2 weeks of age and older who have been symptomatic for no more than 48 hours. It is also used for the prophylaxis (prevention) of influenza in patients 1 year of age and older, either after exposure to an infected individual or during a community outbreak. It is effective against both influenza A and B viruses.
Method of Action	Oseltamivir is a prodrug that is rapidly converted in the body to its active metabolite, oseltamivir carboxylate. This active metabolite acts as a selective inhibitor of influenza virus neuraminidase, an enzyme found on the surface of the virus. Neuraminidase is crucial for the budding of new virions from infected host cells and for the release of virus particles from aggregated virions. By inhibiting neuraminidase, oseltamivir prevents the release of new viral particles, thereby limiting the spread of the virus within the respiratory tract.
Medication Name & Brand Names	♦ Medication Name: Oseltamivir Phosphate ♦ Brand Names: Tamiflu, Oseltamivir (generic)
Pharmaceutical Forms & Appearance	Oseltamivir is available as oral capsules and as a powder for oral suspension. The capsules are typically hard gelatin capsules with various colors (e.g., yellow and grey, yellow and blue) and imprints indicating strength. The powder for oral suspension is a white to off-white granular powder that is reconstituted with water before administration to form a white to off-white suspension with a fruity flavor.
Dosage & Administration	Dosage varies by age, weight, and whether it's for treatment or prophylaxis. For adults with influenza treatment, the typical dose is 75 mg orally twice daily for 5 days. For prophylaxis, it's 75 mg orally once daily for 10 days (after exposure) or up to 6 weeks (during outbreaks). Doses for children are weight-based. It can be taken with or without food, but taking it with food may improve tolerability and reduce gastrointestinal side effects. Begin treatment within 48 hours of symptom onset.
Supplied As	Oseltamivir is supplied as: oral capsules (e.g., 30 mg, 45 mg, 75 mg) and powder for oral suspension (e.g., 6 mg/mL, 12 mg/mL, 15 mg/mL after reconstitution).
Contraindications	Oseltamivir is contraindicated in patients with known hypersensitivity to oseltamivir phosphate or any component of the formulation.
Storage & Expiry	Oseltamivir capsules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. The powder for oral suspension should be stored dry at room temperature. Once reconstituted, the oral suspension must be stored in a refrigerator (2°C to 8°C or 36°F to 46°F) and typically used within 17 days. Do not freeze the suspension. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, vomiting, abdominal pain, diarrhea, and headache. In children, vomiting is frequently reported. More serious but rare side effects include severe skin reactions (e.g., Stevens-Johnson syndrome, toxic epidermal necrolysis), neuropsychiatric events (e.g., delirium, hallucinations, self-injury) particularly in pediatric patients, and allergic reactions.
Warnings & Precautions	♦ Neuropsychiatric Events: Rare reports of delirium and abnormal behavior leading to self-injury or fatal outcomes, primarily in pediatric patients with influenza who were taking oseltamivir. Monitor patients for signs of unusual behavior. These events have also been reported in patients with influenza not taking oseltamivir. ♦ Serious Skin Reactions: Cases of severe skin reactions (e.g., Stevens-Johnson syndrome, toxic epidermal necrolysis, erythema multiforme) have been reported. Discontinue if a severe allergic or skin reaction occurs. ♦ Bacterial Infections: Oseltamivir is only effective against influenza viruses. It does not treat bacterial infections; rule out bacterial infection as a cause of symptoms or treat concomitantly if present. ♦ Not a Substitute for Vaccination: Oseltamivir does not replace influenza vaccination. The use of oseltamivir should not affect the decision to be vaccinated annually. ♦ Renal Impairment: Dose adjustments are necessary for patients with moderate to severe renal impairment. ♦ Cardiac/Respiratory Disease: Efficacy has not been established in patients with chronic cardiac disease or respiratory disease. ♦ Severe Influenza: Not for severe influenza, which may require hospitalization.
Missed Dose Instructions	If a dose of Oseltamivir is missed, take it as soon as remembered. However, if it is within 2 hours of the next scheduled dose (for twice-daily dosing) or within 6 hours (for once-daily dosing), skip the missed dose and continue with the regular schedule. Do not take a double dose. It is crucial to complete the full prescribed course of therapy for effective treatment or prophylaxis.
Overdose Instructions	There are limited reports of overdose. Symptoms are generally consistent with known side effects, including nausea, vomiting, and dizziness. In some cases, accidental overdose in children has resulted in more severe gastrointestinal adverse events. Treatment is supportive and symptomatic. Hemodialysis is not effective for removing oseltamivir carboxylate. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Live Attenuated Influenza Vaccine (LAIV): Concomitant use with LAIV (nasal flu vaccine) is not recommended. Oseltamivir can inhibit the replication of the vaccine virus, reducing the vaccine's effectiveness. Avoid oseltamivir for 2 days before and 2 weeks after LAIV administration. ♦ Probenecid: Probenecid can increase the exposure to oseltamivir carboxylate by reducing its renal tubular secretion. This may require a dose adjustment of oseltamivir in patients with renal impairment or if high doses of probenecid are used. ♦ Other Antiviral Agents: No significant interactions are generally reported with other commonly used medications. However, caution is advised with other drugs primarily eliminated via renal tubular secretion.

Oxaprozin (Daypro)

Purpose/Indication	Oxaprozin is a nonsteroidal anti-inflammatory drug (NSAID) used for the symptomatic relief of pain and inflammation associated with osteoarthritis and rheumatoid arthritis. It is indicated to reduce joint pain, swelling, and stiffness, thereby improving physical function. Its long half-life allows for once-daily dosing.

Method of Action	Oxaprozin, like other NSAIDs, exerts its therapeutic effects primarily by inhibiting the enzyme cyclooxygenase (COX), specifically both COX-1 and COX-2. COX enzymes are responsible for the synthesis of prostaglandins, thromboxanes, and prostacyclins, which are potent mediators of pain, inflammation, and fever. By reducing prostaglandin synthesis, oxaprozin decreases inflammation, pain, and fever.
Medication Name & Brand Names	♦ Medication Name: Oxaprozin ♦ Brand Names: Daypro, Oxaprozin (generic)
Pharmaceutical Forms & Appearance	Oxaprozin is typically available as oral caplets or tablets. Caplets are generally white to off-white, oblong, and often scored, with specific imprints indicating strength or manufacturer.
Dosage & Administration	Dosage is individualized based on the patient's condition and response, with the lowest effective dose for the shortest duration. For osteoarthritis and rheumatoid arthritis, the typical adult oral dose is 1200 mg once daily. Some patients may start with 600 mg once daily. The maximum daily dose is generally 1800 mg or 26 mg/kg (whichever is less) for limited periods. It can be taken with food or milk to minimize gastrointestinal upset.
Supplied As	Oxaprozin is supplied as: oral caplets/tablets (e.g., 600 mg).
Contraindications	Oxaprozin is strictly contraindicated in patients with known hypersensitivity to oxaprozin, aspirin, or any other NSAID, due to the risk of allergic reactions (e.g., asthma, urticaria, rash). It is contraindicated in the setting of coronary artery bypass graft (CABG) surgery, due to increased risk of cardiovascular events. It is also contraindicated in severe uncontrolled heart failure, active gastrointestinal bleeding, or severe renal/hepatic impairment.
Storage & Expiry	Oxaprozin tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal disturbances (nausea, dyspepsia, abdominal pain, diarrhea, constipation), headache, dizziness, and rash. More serious side effects include gastrointestinal bleeding, ulceration, and perforation, cardiovascular thrombotic events (e.g., heart attack, stroke), renal impairment, liver injury, and hypersensitivity reactions.
Warnings & Precautions	♦ BLACK BOX WARNING: Cardiovascular Thrombotic Events: NSAIDs, including oxaprozin, increase the risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may occur early in treatment and may increase with duration of use. Contraindicated for the treatment of peri-operative pain in the setting of CABG surgery. ♦ BLACK BOX WARNING: Gastrointestinal Risk: NSAIDs, including oxaprozin, cause an increased risk of serious gastrointestinal adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. These events can occur at any time during use and without warning symptoms. Elderly patients and those with a history of peptic ulcer disease and/or GI bleeding are at greater risk. ♦ Renal Effects: Can cause dose-dependent renal toxicity (e.g., acute renal failure, interstitial nephritis) by inhibiting prostaglandin synthesis in the kidneys. Use with caution in patients with pre-existing renal impairment, heart failure, liver dysfunction, or those on diuretics/ACE inhibitors. Monitor renal function. ♦ Hepatic Effects: Can cause elevations in liver enzymes and, rarely, severe hepatic reactions (e.g., fulminant hepatitis). Monitor liver function tests. ♦ Hypertension: Can cause new-onset hypertension or worsen pre-existing hypertension. Monitor blood pressure closely. ♦ Heart Failure: Use with caution in patients with fluid retention or heart failure as it can cause edema. ♦ Anaphylactoid Reactions: Can occur in patients with no known prior exposure to NSAIDs. Seek emergency medical attention. ♦ Hematologic Effects: Can cause anemia and inhibit platelet aggregation. Monitor CBC and coagulation. ♦ Fluid Retention and Edema: Can cause fluid retention; use with caution in patients with cardiac decompensation or conditions predisposing to fluid retention. ♦ Photosensitivity: Rarely reported. ♦ Aseptic Meningitis: Rarely reported, especially in patients with systemic lupus erythematosus (SLE) or mixed connective tissue disease.
Missed Dose Instructions	If a dose of Oxaprozin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing helps maintain therapeutic levels for pain and inflammation control.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily gastrointestinal irritation (nausea, vomiting, abdominal pain), drowsiness, and lethargy. More severe symptoms in massive overdose can include acute renal failure, hepatic dysfunction, hypotension, respiratory depression, and coma. There is no specific antidote for oxaprozin. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Maintain an open airway, ventilation, and cardiovascular support. Monitor renal and hepatic function. Dialysis is generally not effective due to high protein binding. Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Other NSAIDs, Aspirin, Corticosteroids: Increased risk of gastrointestinal bleeding and ulceration. Avoid concomitant use of multiple NSAIDs. ♦ Anticoagulants (e.g., warfarin), Antiplatelet Agents (e.g., clopidogrel, aspirin), SSRIs/SNRIs: Increased risk of bleeding. Monitor for signs of bleeding and INR for warfarin. ♦ Diuretics (e.g., furosemide, hydrochlorothiazide): May reduce the natriuretic and antihypertensive effects of diuretics. Increased risk of renal impairment. ♦ ACE Inhibitors/ARBs (e.g., enalapril, valsartan): May diminish the antihypertensive effect and increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. ♦ Lithium: May increase serum lithium concentrations and toxicity by reducing renal clearance. Monitor lithium levels closely. ♦ Methotrexate: May increase methotrexate levels and toxicity. Avoid or use with extreme caution. ♦ Cyclosporine: Increased risk of nephrotoxicity. ♦ Digoxin: May increase digoxin levels. ♦ Pemetrexed: Avoid concomitant use with high-dose pemetrexed. ♦ CYP2C9 Inhibitors (e.g., fluconazole, amiodarone): May increase oxaprozin levels. ♦ CYP2C9 Inducers (e.g., rifampin, carbamazepine): May decrease oxaprozin levels.

Oxycodone (OxyContin)

Purpose/Indication	Oxycodone is a potent opioid analgesic used for the management of moderate to severe acute and chronic pain. It is often prescribed when other analgesics are insufficient or contraindicated. Extended-release formulations are specifically indicated for continuous, around-the-clock management of moderate to severe pain requiring a continuous, long-term opioid analgesic.
Method of Action	Oxycodone is a pure opioid agonist that primarily acts on mu (μ) opioid receptors in the central nervous system (CNS) and to a lesser extent on kappa (κ) and delta (δ) opioid receptors. By binding to these receptors, it mimics the effects of endogenous opioids (endorphins), leading to inhibition of pain signal transmission, altered perception of pain, and activation of descending inhibitory pain pathways. This action results in potent analgesia, sedation, euphoria, and respiratory depression, as well as effects on the gastrointestinal tract (constipation) and cough reflex.
Medication Name & Brand Names	♦ Medication Name: Oxycodone Hydrochloride ♦ Brand Names: OxyContin (controlled-release tablets), Roxicodone (immediate-release tablets, oral solution), Percocet (oxycodone/acetaminophen combination), Endocet (oxycodone/acetaminophen combination), OxyNorm (immediate-release capsules, oral solution - regional), Targin (oxycodone/naloxone combination - regional), Oxycodone (generic)

Oxycodone (OxyContin)	
Pharmaceutical Forms & Appearance	Oxycodone is available in various oral forms: immediate-release tablets, extended-release tablets, capsules, and oral solutions/concentrates. It is also available as solutions for injection (intravenous, intramuscular, subcutaneous) and occasionally as rectal suppositories. Tablets and capsules come in various colors, shapes, and imprints depending on strength and formulation. Injectable solutions are typically clear and colorless.
Dosage & Administration	Dosage is highly individualized and depends on the route, patient's pain severity, opioid tolerance, and renal/hepatic function. For acute pain, immediate-release oral doses typically range from 5-15 mg every 4-6 hours. Extended-release forms are usually given every 12 hours. Administer oral forms with food to reduce nausea. Long-term use requires careful titration and monitoring due to tolerance and dependence. Extended-release tablets must be swallowed whole and not crushed, chewed, or dissolved.
Supplied As	Oxycodone is supplied as: oral immediate-release tablets (e.g., 5 mg, 10 mg, 15 mg, 20 mg, 30 mg), oral extended-release tablets (e.g., 10 mg to 80 mg, some up to 160 mg), oral capsules (e.g., 5 mg, 10 mg, 20 mg), oral solutions/concentrates (e.g., 5 mg/5 mL, 100 mg/5 mL), and solutions for injection (e.g., 1 mg/mL, 10 mg/mL).
Contraindications	Oxycodone is contraindicated in patients with known hypersensitivity to oxycodone or other opioids. It is also contraindicated in patients with significant respiratory depression, acute or severe bronchial asthma (in an unmonitored setting or in the absence of resuscitative equipment), paralytic ileus (bowel obstruction), severe CNS depression, and acute alcohol intoxication. Use is also contraindicated in patients with suspected or known gastrointestinal obstruction, including paralytic ileus.
Storage & Expiry	Oxycodone products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed, child-resistant containers. Injectable solutions should be protected from freezing. Due to its status as a controlled substance, specific storage and handling regulations apply. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, vomiting, constipation, drowsiness, dizziness, sedation, itching, and dry mouth. More serious side effects include respiratory depression (potentially fatal), severe hypotension, bradycardia, CNS depression, addiction, dependence, and withdrawal symptoms upon abrupt discontinuation. Serotonin syndrome can occur with concomitant use of serotonergic drugs.
Warnings & Precautions	♦ BLACK BOX WARNINGS: Addiction, Abuse, Misuse: Oxycodone exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess risk before prescribing and monitor for signs of abuse and addiction. ♦ Respiratory Depression: BLACK BOX WARNING: Serious, life-threatening, or fatal respiratory depression may occur. Monitor closely, especially during initiation and dose escalation. Risk increased with concurrent CNS depressants. ♦ Concomitant Opioid Use with Benzodiazepines/Other CNS Depressants: BLACK BOX WARNING: Concomitant use with benzodiazepines or other CNS depressants (including alcohol) may result in profound sedation, respiratory depression, coma, and death. Reserve for use when alternative treatment options are inadequate. ♦ Neonatal Opioid Withdrawal Syndrome (NOWS): BLACK BOX WARNING (for prolonged use during pregnancy): Prolonged use during pregnancy can result in NOWS, which may be life-threatening if not recognized and treated. ♦ Cytochrome P450 3A4 and 2D6 Interaction: BLACK BOX WARNING (for oral forms): Concomitant use with CYP3A4 inhibitors (or discontinuation of CYP3A4 inducers) or CYP2D6 inhibitors (or discontinuation of CYP2D6 inducers) can result in increased or decreased oxycodone plasma concentrations and potentially fatal respiratory depression or reduced efficacy. ♦ Accidental Ingestion: Accidental ingestion of even one dose, especially by a child, can result in a fatal overdose. Keep out of reach of children. ♦ Adrenal Insufficiency: Can cause adrenal insufficiency. ♦ Severe Hypotension: Can cause severe hypotension, especially in patients whose ability to maintain blood pressure is compromised. ♦ GI Effects: Risk of severe constipation, paralytic ileus. Use with caution in patients with pre-existing GI conditions. ♦ Head Injury/Increased Intracranial Pressure: Can obscure the clinical course and elevate cerebrospinal fluid pressure. ♦ Drug Dependence: Physical dependence can develop with prolonged use. Abrupt discontinuation will lead to withdrawal symptoms. Taper gradually. ♦ Renal/Hepatic Impairment: Clearance is reduced. Use with caution and lower initial doses. ♦ Elderly/Debilitated Patients: More susceptible to respiratory depression and other adverse effects. Use lowest effective dose. ♦ Serotonin Syndrome: Potentially life-threatening, with concomitant use of serotonergic drugs.
Missed Dose Instructions	For scheduled pain management (e.g., extended-release oxycodone), if a dose is missed, take it as soon as remembered if it's not too close to the next scheduled dose (e.g., within 4-6 hours for a 12-hour regimen). Otherwise, skip the missed dose and continue with the regular schedule. Do not take a double dose. For immediate-release or as-needed dosing, take when pain recurs, but adhere to prescribed frequency limits. Consistent dosing is crucial for pain control and minimizing withdrawal symptoms.
Overdose Instructions	Overdose symptoms are characterized by respiratory depression (decreased respiratory rate and depth, Cheyne-Stokes respiration), extreme somnolence progressing to stupor or coma, constricted pupils (miosis), cold and clammy skin, skeletal muscle flaccidity, and sometimes bradycardia, hypotension, and pulmonary edema. Severe overdose can lead to circulatory collapse, cardiac arrest, and death. Treatment involves immediate medical attention, with primary focus on restoring respiration. Naloxone, an opioid antagonist, is the antidote and should be administered immediately. Repeated doses may be required due to oxycodone's longer duration of action. Supportive measures, including oxygen, IV fluids, and vasopressors, are essential. Seek immediate emergency medical help.
Medicine Interactions	♦ CNS Depressants (e.g., benzodiazepines, other opioids, alcohol, sedatives, hypnotics, general anesthetics, tricyclic antidepressants, phenothiazines): BLACK BOX WARNING: Potentiation of respiratory depression, profound sedation, coma, and death. Avoid concomitant use; if necessary, use lowest effective doses and shortest duration, monitoring closely. ♦ MAO Inhibitors: Can cause severe, unpredictable reactions (e.g., excitation, depression, rigidity, hyperpyrexia, convulsions). Avoid concomitant use and for 14 days after MAOI discontinuation. ♦ CYP3A4 Inhibitors (e.g., clarithromycin, ketoconazole, ritonavir, grapefruit juice): Can increase oxycodone plasma concentrations, leading to increased and prolonged opioid effects and potentially fatal respiratory depression. ♦ CYP3A4 Inducers (e.g., rifampin, carbamazepine, phenytoin, St. John's Wort): Can decrease oxycodone plasma concentrations, potentially leading to reduced efficacy and withdrawal symptoms. ♦ CYP2D6 Inhibitors (e.g., quinidine, fluoxetine, paroxetine, bupropion): Can reduce the conversion of oxycodone to its active metabolite oxymorphone, potentially altering the analgesic effect. ♦ Serotonergic Drugs (e.g., SSRIs, SNRIs, TCAs, triptans, tramadol, linezolid): Increased risk of serotonin syndrome. Monitor for symptoms. ♦ Muscle Relaxants: Enhanced neuromuscular blocking action; increased risk of respiratory depression. ♦ Anticholinergic Drugs (e.g., benztropine, oxybutynin): Additive anticholinergic effects (dry mouth, constipation, urinary retention), increasing risk of paralytic ileus. ♦ Mixed Agonist/Antagonist Opioid Analgesics (e.g., pentazocine, nalbuphine, butorphanol): Can precipitate withdrawal symptoms in

Pantoprazole (Protonix)

Pantoprazole (Protonix)	
Purpose/Indication	Pantoprazole is a proton pump inhibitor (PPI) used to decrease the amount of acid produced in the stomach. It is indicated for the treatment of gastroesophageal reflux disease (GERD), erosive esophagitis (including maintenance of healing), Zollinger-Ellison syndrome, and other hypersecretory conditions. It is also used in combination with antibiotics to eradicate Helicobacter pylori infection and for the prevention of rebleeding in patients with peptic ulcers following endoscopic therapy.
Method of Action	Pantoprazole is a prodrug that, after absorption, is converted to its active form in the acidic secretory canaliculi of the gastric parietal cells. The active form then irreversibly binds to and inhibits the H+/K+-ATPase enzyme system (the proton pump) on the secretory surface of the parietal cells. This action blocks the final step of acid secretion, significantly reducing both basal and stimulated gastric acid output, leading to potent and prolonged acid suppression.
Medication Name & Brand Names	♦ Medication Name: Pantoprazole Sodium ♦ Brand Names: Protonix (oral tablets, IV), Pantoloc (regional), Pantoprazole (generic)

Pharmaceutical Forms & Appearance	Pantoprazole is available as delayed-release tablets, delayed-release granules for oral suspension, and powder for intravenous (IV) injection. Delayed-release tablets are typically yellow, oval, and film-coated, with specific imprints. The delayed-release granules are for mixing with apple juice or applesauce. The IV powder is a white to off-white lyophilized powder for reconstitution.
Dosage & Administration	Dosage varies depending on the indication. For GERD/erosive esophagitis, the typical adult oral dose is 40 mg once daily for up to 8 weeks. For Zollinger-Ellison syndrome, doses can be much higher and individualized. For H. pylori eradication, it is typically 40 mg once or twice daily in combination with antibiotics for 7-14 days. Oral forms should be taken before a meal (preferably in the morning). Do not crush, chew, or split delayed-release tablets. IV administration is typically given over a short period (e.g., 2 minutes).
Supplied As	Pantoprazole is supplied as: oral delayed-release tablets (e.g., 20 mg, 40 mg), oral delayed-release granules for suspension (e.g., 10 mg, 20 mg, 40 mg packets), and powder for intravenous injection (e.g., 40 mg/vial).
Contraindications	Pantoprazole is contraindicated in patients with known hypersensitivity to pantoprazole, substituted benzimidazoles (e.g., omeprazole, lansoprazole), or any component of the formulation. Concomitant use with rilpivirine-containing products is also contraindicated.
Storage & Expiry	Pantoprazole tablets and granules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. The powder for IV injection should be stored protected from light and reconstituted immediately before use. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include headache, abdominal pain, diarrhea, nausea, flatulence, and dizziness. More serious side effects, though less common, include Clostridioides difficile-associated diarrhea (CDAD), bone fractures (with long-term use), kidney problems (e.g., acute interstitial nephritis), magnesium deficiency (hypomagnesemia), vitamin B12 deficiency (with long-term use), and very rarely, severe skin reactions or systemic lupus erythematosus.
Warnings & Precautions	♦ CDAD: PPI therapy may increase the risk of Clostridioides difficile-associated diarrhea (CDAD). Use the lowest dose and shortest duration appropriate for the condition. ♦ Bone Fracture: Long-term and multiple daily dose PPI therapy may increase the risk for osteoporosis-related fractures of the hip, wrist, or spine. Use the lowest dose and shortest duration. ♦ Hypomagnesemia: Can occur with long-term therapy (at least 3 months, but usually a year or more). Consider monitoring magnesium levels in patients expected to be on prolonged treatment. ♦ Vitamin B12 Deficiency: Long-term daily treatment (e.g., >2-3 years) can lead to malabsorption of vitamin B12 due to acid suppression. ♦ Acute Interstitial Nephritis: Has been observed in patients taking PPIs, including pantoprazole, and can occur at any point during therapy. ♦ Gastric Malignancy: Symptomatic response to therapy does not preclude the presence of gastric malignancy. ♦ Drug Interactions: Pantoprazole has relatively fewer significant drug interactions compared to some other PPIs (e.g., omeprazole) due to less extensive inhibition of certain CYP enzymes. ♦ Atrophic Gastritis/Fundic Gland Polyps: Long-term PPI therapy may lead to atrophic gastritis or fundic gland polyps. ♦ Pregnancy/Lactation: Use only if clearly needed. Minimal excretion into breast milk.
Missed Dose Instructions	If a dose of Pantoprazole is missed, take it as soon as remembered before a meal. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for optimal acid suppression.
Overdose Instructions	Overdose symptoms are generally mild and self-limiting, consistent with known side effects like drowsiness, tachycardia, nausea, vomiting, and abdominal pain. No specific antidote is known. Treatment is supportive and symptomatic. Hemodialysis is not effective for removing pantoprazole. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Rilpivirine-containing products: Concomitant use is contraindicated as PPIs significantly reduce rilpivirine absorption. ♦ Methotrexate: May increase and prolong methotrexate serum levels and/or its active metabolite, potentially leading to toxicity, especially with high-dose methotrexate. Consider temporary PPI withdrawal or lower doses of methotrexate. ♦ Drugs whose absorption is pH-dependent (e.g., ketoconazole, itraconazole, atazanavir, nelfinavir, erlotinib): Pantoprazole significantly reduces gastric acidity, which can impair the absorption and bioavailability of these drugs. Avoid concurrent use where possible, or use with caution and monitor. ♦ Warfarin: Isolated reports of increased INR and prothrombin time. Monitor INR closely, especially when initiating or discontinuing pantoprazole. ♦ Digoxin: May increase digoxin absorption, leading to increased digoxin levels, especially in elderly. Monitor digoxin levels. ♦ Tacrolimus: May increase tacrolimus levels. Monitor tacrolimus levels. ♦ Iron salts: PPIs can reduce the absorption of oral iron supplements.

Paracetamol (Tylenol)

Purpose/Indication	Paracetamol is a widely used analgesic and antipyretic, primarily indicated for the relief of mild to moderate pain (e.g., headache, muscle aches, backache, toothache, menstrual pain, pain from colds/flu, minor arthritis pain) and for the reduction of fever. It is often recommended as a first-line agent for pain and fever, especially when NSAIDs are contraindicated or not tolerated.
Method of Action	The exact mechanism of action of paracetamol is not fully understood, but it is believed to primarily act centrally within the brain and spinal cord, rather than peripherally. It selectively inhibits cyclooxygenase (COX) enzymes, particularly COX-2, in the central nervous system, which leads to a reduction in prostaglandin synthesis in these areas. Prostaglandins are key mediators of pain and fever. Unlike NSAIDs, it has weak anti-inflammatory effects and minimal peripheral COX inhibition.
Medication Name & Brand Names	♦ Medication Name: Paracetamol, Acetaminophen ♦ Brand Names: Panadol, Tylenol, Calpol (regional), Efferalgan (regional), Paracetamol (generic)
Pharmaceutical Forms & Appearance	Paracetamol is available in a wide range of oral forms: tablets (regular, caplets, extended-release, effervescent), chewable tablets, orally disintegrating tablets, oral suspensions/syrups, and granules. It is also available as rectal suppositories and solution for intravenous (IV) infusion. Tablets are typically white, round or oval, and may be scored. Suspensions are clear or slightly cloudy, often flavored.
Dosage & Administration	Dosage varies by age, weight, and formulation. For adults, typical oral doses are 500 mg to 1000 mg every 4-6 hours as needed, not exceeding 4000 mg (4g) in 24 hours. For children, doses are weight-based (e.g., 10-15 mg/kg per dose) every 4-6 hours, not exceeding 4-5 doses in 24 hours. Follow package instructions carefully. Oral forms can be taken with or without food. IV infusion is administered by healthcare professionals.
Supplied As	Paracetamol is supplied as: oral tablets/caplets (e.g., 325 mg, 500 mg, 650 mg), extended-release tablets (e.g., 650 mg), chewable tablets (e.g., 80 mg, 160 mg), oral suspensions/syrups (e.g., 160 mg/5 mL, 250 mg/5 mL), rectal suppositories (e.g., 120 mg, 325 mg, 650 mg), and solution for intravenous infusion (e.g., 10 mg/mL).
Contraindications	Paracetamol is contraindicated in patients with known hypersensitivity to paracetamol or any component of the formulation. It should be used with extreme caution or avoided in patients with severe active liver disease or severe hepatic impairment, due to the risk of hepatotoxicity.

Paracetamol (Tylenol)

Storage & Expiry	Paracetamol products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and excessive heat. Keep in tightly closed containers. Oral suspensions should be shaken well before use. Always check the specific expiry date on the packaging.
Side Effects	Side effects are generally rare and mild when used at recommended doses. The most significant concern is hepatotoxicity (liver damage), which can occur with overdose or excessive cumulative doses, especially in individuals with liver impairment or those who consume alcohol. Other rare side effects include severe skin reactions (e.g., Stevens-Johnson syndrome, toxic epidermal necrolysis), and allergic reactions.
Warnings & Precautions	♦ Hepatotoxicity: BLACK BOX WARNING (in some regions/products): The greatest risk of severe liver damage occurs with overdose. Advise patients not to exceed the maximum recommended daily dose and to avoid taking other products containing paracetamol. Risk is increased in chronic alcohol users, patients with liver disease, or those who are malnourished. ♦ Allergic Reactions/Serious Skin Reactions: Rare but potentially fatal skin reactions (e.g., Stevens-Johnson Syndrome, Toxic Epidermal Necrolysis, Acute Generalized Exanthematous Pustulosis) and anaphylaxis have been reported. Discontinue immediately at the first sign of rash or allergic reaction. ♦ Alcohol Use: Advise patients who consume 3 or more alcoholic drinks per day to consult a doctor before using paracetamol due to increased risk of liver damage. ♦ Undiagnosed Symptoms: For self-medication, advise patients not to use for prolonged periods for pain (>10 days for adults, >5 days for children) or fever (>3 days) without consulting a doctor, as symptoms may indicate a serious underlying condition. ♦ Children's Dosing: Emphasize the importance of accurate dosing for children, using appropriate measuring devices for liquid forms.
Missed Dose Instructions	Paracetamol is typically taken on an as-needed basis for pain or fever. If a scheduled dose is missed, take it as soon as remembered if still needed. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Adhere to the recommended dosing interval and maximum daily dose.
Overdose Instructions	Paracetamol overdose is a medical emergency and can cause severe, potentially fatal liver damage. Symptoms may not appear for 24-48 hours and can include nausea, vomiting, abdominal pain, loss of appetite, and general malaise. Later symptoms involve signs of liver failure (jaundice, confusion, bleeding). If an overdose is suspected, seek immediate emergency medical attention, even if there are no symptoms. N-acetylcysteine (NAC) is the antidote and is most effective when administered within 8 hours of ingestion.
Medicine Interactions	♦ Alcohol: Concomitant chronic alcohol use significantly increases the risk of paracetamol-induced hepatotoxicity, even at therapeutic doses. ♦ Warfarin: Regular daily use of paracetamol at higher doses may potentiate the anticoagulant effect of warfarin, increasing the risk of bleeding. Monitor INR more frequently. Intermittent use at lower doses is generally considered safe. ♦ Other Paracetamol-containing products: The most critical interaction is unintentional overdose due to taking multiple products that contain paracetamol (e.g., cold and flu remedies). Advise patients to check all labels. ♦ Carbamazepine, Phenytoin, Rifampin, Phenobarbital (Enzyme Inducers): May increase the metabolism of paracetamol to hepatotoxic metabolites, increasing the risk of liver injury, especially in overdose. ♦ Cholestyramine: May reduce the absorption of paracetamol. Administer paracetamol at least 1 hour before or 4 hours after cholestyramine.

Penicillin V (Veetids)

Purpose/Indication	Penicillin V (also known as phenoxymethylpenicillin) is a narrow-spectrum penicillin antibiotic primarily used to treat mild to moderate bacterial infections susceptible to penicillin. It is commonly indicated for respiratory tract infections (e.g., strep throat, otitis media), skin and soft tissue infections (e.g., erysipelas, cellulitis), and to prevent rheumatic fever recurrence. It is effective against many Gram-positive bacteria, especially Streptococcus pyogenes.
Method of Action	Penicillin V is a beta-lactam antibiotic that exerts its bactericidal effect by inhibiting bacterial cell wall synthesis. It binds to penicillin-binding proteins (PBPs), which are enzymes located in the bacterial cell membrane that are crucial for the cross-linking of peptidoglycan chains, a major component of the bacterial cell wall. By inhibiting PBPs, penicillin V prevents the formation of a rigid, stable cell wall, leading to weakened bacterial cell walls, increased osmotic pressure, and ultimately, bacterial cell lysis and death.
Medication Name & Brand Names	♦ Medication Name: Penicillin V Potassium, Phenoxymethylpenicillin ♦ Brand Names: Pen-Vee K, V-Cillin K (historical), Veetids (historical), Penicillin VK, Penicillin V (generic)
Pharmaceutical Forms & Appearance	Penicillin V is available as oral tablets and as a powder for oral solution or suspension. Oral tablets are typically white, round or oval, and may be scored. The powder for oral solution/suspension is white to off-white and, when reconstituted, forms a solution that is usually clear to slightly hazy, often with a fruit flavor for pediatric use.
Dosage & Administration	Dosage varies by age, weight, and infection severity. For adults, common doses range from 250 mg to 500 mg orally every 6 to 8 hours for 7 to 10 days. For children, doses are typically weight-based (e.g., 25-50 mg/kg/day in divided doses). It can be taken with or without food; however, absorption may be slightly better on an empty stomach. If stomach upset occurs, take with food. Complete the full prescribed course of treatment.
Supplied As	Penicillin V is supplied as: oral tablets (e.g., 250 mg, 500 mg), and powder for oral solution/suspension (e.g., 125 mg/5 mL, 250 mg/5 mL after reconstitution).
Contraindications	Penicillin V is strictly contraindicated in patients with a history of severe hypersensitivity reaction (e.g., anaphylaxis, Stevens-Johnson syndrome) to any penicillin or other beta-lactam antibiotics (e.g., cephalosporins) due to the risk of cross-reactivity.
Storage & Expiry	Unreconstituted penicillin V powder should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Oral tablets should be stored in a tightly closed container. Once reconstituted, the oral solution/suspension must be stored in a refrigerator (2°C to 8°C or 36°F to 46°F) and typically used within 14 days; discard any unused portion after this time. Do not freeze. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal disturbances (e.g., nausea, vomiting, diarrhea, abdominal pain), skin rash, and black hairy tongue. More serious but less common side effects include allergic reactions (ranging from mild rash to severe anaphylaxis), Clostridioides difficile-associated diarrhea (CDAD), and hemolytic anemia.
Warnings & Precautions	♦ Hypersensitivity Reactions: Crucial Warning: Serious and occasionally fatal hypersensitivity (anaphylactic) reactions have been reported, particularly with parenteral penicillin. Ask patients about any history of penicillin or other allergen sensitivities. If an allergic reaction occurs, discontinue immediately and initiate appropriate therapy. ♦ Cross-reactivity: Patients with a history of severe reactions to cephalosporins or other beta-lactams may be at higher risk for penicillin allergy. ♦ Clostridioides difficile-associated diarrhea (CDAD): Can occur with nearly all antibacterial agents, including penicillin V, and can range from mild diarrhea to fatal colitis. Consider in patients presenting with diarrhea after antibiotic use. ♦ Renal Impairment: Use with caution in patients with significant renal impairment, as accumulation may occur; dose adjustments may be necessary. ♦ Not for Severe Infections: Penicillin V is an oral antibiotic and is not suitable for severe infections requiring higher tissue concentrations or parenteral administration. ♦ Oral Contraceptives: May reduce the effectiveness of oral contraceptives (though evidence is weak). Advise patients to use alternative contraception.

Missed Dose Instructions	If a dose of Penicillin V is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular dosing schedule. Do not take a double dose. It is crucial to complete the full prescribed course of therapy, even if symptoms improve, to ensure eradication of the infection and prevent antibiotic resistance and recurrence.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily gastrointestinal upset (nausea, vomiting, diarrhea). High doses can also lead to neuromuscular excitability or seizures, particularly in patients with renal impairment. Treatment is supportive and symptomatic. Hemodialysis may be useful in removing penicillin V from the circulation, especially in severe renal impairment. Seek medical attention if a large amount is ingested or severe symptoms occur.
Medicine Interactions	♦ Oral Contraceptives: May reduce the effectiveness of oral contraceptives, potentially leading to breakthrough bleeding or unintended pregnancy. Advise alternative contraception. ♦ Tetracyclines: May antagonize the bactericidal effect of penicillin V; avoid concomitant use. ♦ Probenecid: Probenecid decreases the renal tubular secretion of penicillin V, leading to increased and prolonged blood levels of penicillin V. This interaction is sometimes used therapeutically to enhance penicillin's effect, but also increases the risk of toxicity. ♦ Methotrexate: Penicillins can reduce the renal clearance of methotrexate, potentially increasing methotrexate toxicity. Monitor for methotrexate toxicity. ♦ Live Bacterial Vaccines (e.g., typhoid vaccine): Antibiotics may reduce the therapeutic effect of live bacterial vaccines. Administer vaccine before starting antibiotic, or defer antibiotic if possible.

Perindopril (Aceon)

Purpose/Indication	Perindopril is an angiotensin-converting enzyme (ACE) inhibitor primarily used to treat essential hypertension (high blood pressure) and stable coronary artery disease. It is also indicated for the treatment of symptomatic heart failure and to reduce the risk of cardiovascular events (such as heart attack or stroke) in patients with stable coronary artery disease or other high-risk vascular conditions.
Method of Action	Perindopril is a prodrug that is converted in the liver to its active metabolite, perindoprilat. Perindoprilat works by inhibiting the angiotensin-converting enzyme (ACE), which is responsible for converting angiotensin I to angiotensin II. Angiotensin II is a powerful vasoconstrictor and also stimulates aldosterone secretion. By blocking its formation, perindoprilat causes vasodilation (widening of blood vessels), reduces aldosterone-mediated sodium and water retention, and decreases systemic vascular resistance, leading to lower blood pressure and reduced cardiac workload.
Medication Name & Brand Names	♦ Medication Name: Perindopril Arginine, Perindopril Erbumine ♦ Brand Names: Coversyl (perindopril arginine - regional), Aceon (perindopril erbumine), Perindopril (generic)
Pharmaceutical Forms & Appearance	Perindopril is available as oral tablets. Tablets are typically white, round or oval, and may be scored, with specific imprints indicating strength (e.g., 2 mg, 4 mg, 5 mg, 8 mg, 10 mg).
Dosage & Administration	Dosage is highly individualized based on the patient's condition, response, and renal function. For hypertension, typical initial doses are 4 mg or 5 mg orally once daily, adjusted based on blood pressure response, up to a maximum of 8 mg or 10 mg once daily. For heart failure, lower initial doses (e.g., 2 mg or 2.5 mg) are often used, titrating upwards. Take tablets before a meal (preferably in the morning) for better absorption.
Supplied As	Perindopril is supplied as: oral tablets (e.g., 2 mg, 4 mg, 5 mg, 8 mg, 10 mg).
Contraindications	Perindopril is contraindicated in patients with known hypersensitivity to perindopril or any other ACE inhibitor. It is also contraindicated in patients with a history of angioedema (swelling of the face, lips, tongue, throat) related to previous ACE inhibitor treatment, hereditary or idiopathic angioedema, or concomitant use with sacubitril/valsartan. Concomitant use with aliskiren is contraindicated in patients with diabetes mellitus or renal impairment.
Storage & Expiry	Perindopril tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include dry cough (persistent, non-productive), dizziness, headache, fatigue, and nausea. More serious but less common side effects include angioedema (swelling of the face, lips, tongue, throat, potentially life-threatening), hypotension (low blood pressure), hyperkalemia (high potassium levels), renal impairment, and hepatic dysfunction.
Warnings & Precautions	♦ BLACK BOX WARNING (in some regions/products): Fetal Toxicity: Use of ACE inhibitors during the second and third trimesters of pregnancy can cause injury and death to the developing fetus. Discontinue as soon as pregnancy is detected. ♦ Angioedema: Can cause angioedema, which may occur at any time during treatment, particularly early on. If laryngeal stridor or angioedema of the face, extremities, lips, tongue, glottis, or larynx occurs, discontinue perindopril immediately and provide appropriate medical therapy. Higher risk in Black patients. ♦ Hypotension: May cause symptomatic hypotension, especially in volume-depleted patients (e.g., those on diuretics, dialysis) or severe heart failure. Initiate with low doses and monitor. ♦ Hyperkalemia: Can cause hyperkalemia, especially in patients with renal impairment, diabetes, or those taking potassium-sparing diuretics, potassium supplements, or other drugs that increase potassium. Monitor serum potassium. ♦ Renal Impairment: Can cause acute renal failure, particularly in patients with pre-existing renal insufficiency, severe congestive heart failure, or bilateral renal artery stenosis. Monitor renal function regularly. ♦ Dual Blockade of RAAS: Dual blockade of the renin-angiotensin-aldosterone system (RAAS) with ACE inhibitors, ARBs, or aliskiren is associated with increased risks of hypotension, hyperkalemia, and renal function changes; generally avoid. ♦ Cough: Persistent, non-productive cough is common and resolves upon discontinuation. ♦ Hepatic Failure: Rarely associated with a syndrome of cholestatic jaundice progressing to fulminant hepatic necrosis, sometimes fatal. Discontinue if jaundice or marked elevations of hepatic enzymes occur. ♦ Surgery/Anesthesia: May cause hypotension during major surgery or anesthesia due to enhanced effects of hypotensive agents. ♦ Neutropenia/Agranulocytosis: Rare, but monitor white blood cell counts in high-risk patients.
Missed Dose Instructions	If a dose of Perindopril is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for blood pressure control and cardiovascular protection.
Overdose Instructions	Overdose symptoms are primarily severe hypotension, shock, bradycardia, electrolyte disturbances (hyperkalemia), and renal failure. Treatment is supportive and symptomatic. Maintain fluid and electrolyte balance. Lay the patient supine with legs elevated. IV fluid infusion and vasopressors may be needed for hypotension. Hemodialysis is effective in removing perindoprilat. Seek immediate emergency medical help.

Medicine Interactions	♦ Potassium-Sparing Diuretics (e.g., spironolactone, amiloride, triamterene) & Potassium Supplements: Significant risk of severe hyperkalemia. Avoid concomitant use or monitor potassium levels very closely. ♦ NSAIDs (Non-Steroidal Anti-inflammatory Drugs, including selective COX-2 inhibitors): May reduce the antihypertensive effect of ACE inhibitors and increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. Use with caution. ♦ Lithium: ACE inhibitors can reduce the renal clearance of lithium, leading to increased serum lithium levels and toxicity. Monitor lithium levels closely. ♦ Diuretics: Enhanced hypotensive effect, especially with the first dose. Consider withholding diuretics prior to initiating perindopril. ♦ Aliskiren: Contraindicated in patients with diabetes or renal impairment due to increased risk of hypotension, hyperkalemia, and renal impairment. ♦ Sacubitril/Valsartan (Neprilysin Inhibitor): Concomitant use is contraindicated due to increased risk of angioedema. A washout period (e.g., 36 hours) is required between stopping an ACE inhibitor and starting sacubitril/valsartan. ♦ mTOR Inhibitors (e.g., sirolimus, everolimus, temsirolimus) and Vildagliptin: Increased risk of angioedema. Use with caution. ♦ Racecadotril: Increased risk of angioedema. ♦ Gold (parenteral): Nitritoid reactions (facial flushing, nausea, vomiting, hypotension) have been reported rarely in patients on concurrent gold therapy and ACE inhibitors. ♦ Insulin/Oral Hypoglycemics: Increased risk of hypoglycemia, particularly at the initiation of ACE inhibitor therapy. Monitor blood glucose.

Permethrin (Nix)

Purpose/Indication	Permethrin is a topical antiparasitic agent used to treat infestations of scabies (caused by the mite Sarcoptes scabiei) and head lice (Pediculus humanus capitis). It is considered a first-line treatment due to its high efficacy and low toxicity when used as directed. Its purpose is to kill the mites, lice, and their eggs (nits).
Method of Action	Permethrin is a synthetic pyrethroid that acts as a neurotoxin to parasites. It works by disrupting the normal function of the neuron membrane in insects and mites. Specifically, it causes a prolonged state of depolarization of the neuronal membrane, leading to sustained hyperexcitation, paralysis, and ultimately death of the parasite. This effect is highly selective for invertebrates, which is why it has low toxicity to mammals.
Medication Name & Brand Names	♦ Medication Name: Permethrin ♦ Brand Names: Elimite (cream for scabies), Nix (cream rinse for lice), Acticin (cream for scabies), Permethrin (generic)
Pharmaceutical Forms & Appearance	Permethrin is primarily available as topical creams (typically 5% for scabies) and topical cream rinses or lotions (typically 1% for head lice). These are usually white to off-white, opaque, and creamy in texture.
Dosage & Administration	Dosage and administration vary significantly by indication. For scabies (5% cream): Apply a thin layer to all skin from the neck down to the soles of the feet, including between fingers and toes, under fingernails, wrists, armpits, and groin. Leave on for 8-14 hours, then wash off thoroughly. One application is usually sufficient, but a second application 7-14 days later may be needed. For head lice (1% cream rinse/lotion): Wash hair with a non-conditioning shampoo, rinse, and towel dry. Apply enough permethrin to saturate the hair and scalp. Leave on for 10 minutes, then rinse thoroughly. Remove nits with a fine-toothed comb. A second application after 7-10 days is often recommended to kill newly hatched lice.
Supplied As	Permethrin is supplied as: topical cream (e.g., 5% in tubes) and topical cream rinse/lotion (e.g., 1% in bottles).
Contraindications	Permethrin is contraindicated in patients with known hypersensitivity to permethrin, any synthetic pyrethroid, pyrethrin, or any component of the formulation (e.g., chrysanthemums for those with severe ragweed allergies).
Storage & Expiry	Permethrin topical cream and cream rinse/lotion should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from excessive heat and freezing. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and local, including transient itching, burning, stinging, redness, or tingling at the application site. These are often distinguishable from the persistent itching of the infestation. Persistent or worsening skin irritation may occur.
Warnings & Precautions	♦ External Use Only: Permethrin is for topical use only. Do not ingest. Avoid contact with eyes; if contact occurs, flush immediately with water. ♦ Skin Irritation: May cause mild skin irritation, especially in sensitive individuals or on broken skin. ♦ Allergic Reactions: Rare but serious allergic reactions are possible. Discontinue if signs of hypersensitivity occur. ♦ Pregnancy/Lactation: Generally considered safe for use in pregnancy and lactation under medical supervision, but use only if clearly needed. ♦ Infants: For infants, special instructions for application (e.g., entire body for scabies, not just neck down) may apply; consult product information or healthcare provider. ♦ Resistance: Though rare, resistance to permethrin has been reported in some areas, particularly for head lice. If treatment fails, re-evaluate diagnosis or consider alternative treatments. ♦ Residual Itching: Scabies itching may persist for up to 2-4 weeks after successful treatment due to residual dead mites or inflammatory reactions; this does not indicate treatment failure or re-infestation.
Missed Dose Instructions	Permethrin is typically a single-application treatment for scabies, or a two-application treatment for lice (7-10 days apart). If a scheduled second application for lice is missed, apply it as soon as remembered. If an initial application for scabies was somehow incomplete or washed off too soon, reapplication may be needed. Always follow the specific instructions on the product label or from a healthcare professional, as proper application is crucial for efficacy.
Overdose Instructions	Topical overdose of permethrin is unlikely to cause systemic toxicity due to minimal dermal absorption. Excessive application may lead to increased local skin irritation. If accidental oral ingestion occurs, symptoms would likely be mild gastrointestinal upset (e.g., nausea, vomiting). In rare cases of massive ingestion, systemic effects such as neurological symptoms (tremor, seizures) might occur, but this is highly uncommon. Treatment for accidental ingestion is supportive and symptomatic; gastric lavage may be considered if large quantities were recently swallowed. Seek medical attention if ingestion occurs or severe symptoms develop.
Medicine Interactions	♦ No significant drug-drug interactions are commonly reported for topical permethrin due to its minimal systemic absorption. ♦ There are no known specific drug interactions that would impact the efficacy or safety of systemically administered medications. ♦ However, avoid applying other creams, lotions, or moisturizers immediately before applying permethrin for scabies, as they might dilute or interfere with its absorption into the skin. Apply permethrin to clean, dry skin.

Piroxicam (Feldene)

Purpose/Indication	Piroxicam is a nonsteroidal anti-inflammatory drug (NSAID) used to relieve the signs and symptoms of osteoarthritis and rheumatoid arthritis. It helps to reduce pain, inflammation, swelling, and stiffness associated with these conditions, but it does not cure the underlying disease. Due to its long half-life and potential for serious gastrointestinal and cardiovascular side effects, it is often reserved for patients who have not responded adequately to other NSAIDs.
Method of Action	Piroxicam, like other NSAIDs, exerts its anti-inflammatory, analgesic, and antipyretic effects primarily by inhibiting the cyclooxygenase (COX) enzymes, specifically both COX-1 and COX-2. This inhibition leads to a decrease in the synthesis of prostaglandins, which are lipid compounds involved in mediating pain, inflammation, and fever. Piroxicam also inhibits the migration of leukocytes into inflammatory sites and prevents thromboxane A2 formation, further contributing to its anti-inflammatory actions.

MEDICATION | Medication List | N - Q | Piroxicam (Feldene)

Medication Name & Brand Names	♦ Medication Name: Piroxicam ♦ Brand Names: Feldene, Therafeldamine (regional), Piroxicam (generic)
Pharmaceutical Forms & Appearance	Piroxicam is available as oral capsules. Capsules are typically hard gelatin capsules, often with distinct colors (e.g., dark green and olive, or dark green) and imprints indicating strength (e.g., 10 mg or 20 mg). The powder inside is usually off-white to light tan or light yellow.
Dosage & Administration	The typical adult oral dosage for osteoarthritis and rheumatoid arthritis is 20 mg once daily, or 10 mg twice daily. Due to its long half-life, steady-state blood levels are not reached for 7 to 12 days, and the full therapeutic effect may take several weeks to become evident. It can be taken with or without food, but taking it with food, milk, or an antacid may help reduce stomach irritation. Do not chew, crush, or open the capsules.
Supplied As	Piroxicam is supplied as: oral capsules (e.g., 10 mg, 20 mg).
Contraindications	Piroxicam is contraindicated in patients with known hypersensitivity to piroxicam, aspirin, or other NSAIDs (e.g., those who have experienced asthma, urticaria, or allergic-type reactions). It is also contraindicated for the treatment of peri-operative pain in the setting of coronary artery bypass graft (CABG) surgery. Use is also contraindicated in patients with a history of recurrent gastrointestinal ulceration or bleeding, or severe heart failure.
Storage & Expiry	Piroxicam capsules should be stored at room temperature (typically 15°C to 30°C or 59°F to 86°F), protected from light and moisture. Keep in a tightly closed container. Always check the specific expiry date on the packaging and dispose of any unused or expired medication safely.
Side Effects	Common side effects include gastrointestinal issues such as stomach upset, nausea, vomiting, abdominal pain, diarrhea, or constipation. Other common effects include headache, dizziness, and tinnitus (ringing in the ears). More serious side effects can include gastrointestinal bleeding, ulceration, or perforation (potentially fatal), cardiovascular thrombotic events (heart attack, stroke), kidney problems, liver problems, and serious skin reactions.
Warnings & Precautions	♦ BLACK BOX WARNINGS: Cardiovascular Thrombotic Events: NSAIDs, including piroxicam, cause an increased risk of serious cardiovascular thrombotic events, including myocardial infarction and stroke, which can be fatal. This risk may occur early in treatment and may increase with duration of use. Piroxicam is contraindicated for peri-operative pain in CABG surgery. ♦ BLACK BOX WARNINGS: Gastrointestinal Bleeding, Ulceration, and Perforation: NSAIDs cause an increased risk of serious GI adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. These events can occur at any time without warning symptoms, especially in older adults. ♦ Hypertension: Can lead to new onset or worsening of pre-existing hypertension. Monitor blood pressure closely. ♦ Heart Failure & Edema: Fluid retention and edema have been observed; use with caution in patients with fluid retention, hypertension, or heart failure. Avoid in severe heart failure. ♦ Renal Toxicity: Long-term administration can result in renal papillary necrosis and other renal injury, especially in patients with impaired renal function, heart failure, or dehydration. Monitor renal function. ♦ Hepatotoxicity: Can cause liver injury; monitor liver function tests. ♦ Serious Skin Reactions: Rare but potentially fatal skin reactions (e.g., Stevens-Johnson syndrome, Toxic Epidermal Necrolysis) have been reported. Discontinue at first sign of rash. ♦ Fetal Toxicity: Use during the last trimester of pregnancy can cause premature closure of the fetal ductus arteriosus and fetal renal dysfunction. Avoid from 20 weeks gestation onwards. ♦ Masking of Inflammation and Fever: Can mask signs of infection.
Missed Dose Instructions	If a dose of Piroxicam is missed, take it as soon as you remember. However, if it is almost time for your next scheduled dose (e.g., if you take it once daily and it's close to the next day's dose), skip the missed dose and continue with your regular schedule. Do not take a double dose to make up for a missed one. Adhering to the prescribed dosing schedule is important for effective pain and inflammation management.
Overdose Instructions	Overdose symptoms are generally an exaggeration of common side effects, including severe stomach pain, nausea, vomiting, drowsiness, and headache. More severe signs of overdose can include gastrointestinal bleeding (black/tarry stools, coffee-ground vomit), kidney failure, hypertension, confusion, coma, and rarely, convulsions or respiratory depression. Treatment is supportive and symptomatic. There is no specific antidote. Gastric decontamination (e.g., activated charcoal) may be considered if recent ingestion. Seek immediate emergency medical attention for any suspected overdose.
Medicine Interactions	♦ Anticoagulants (e.g., warfarin, dabigatran) & Antiplatelet Agents (e.g., aspirin, clopidogrel) & SSRIs/SNRIs: Significantly increased risk of serious gastrointestinal bleeding. Avoid concomitant use or monitor closely with extreme caution. ♦ Other NSAIDs: Concomitant use with other NSAIDs (including low-dose aspirin for antiplatelet effect) increases the risk of GI adverse events; generally avoid. ♦ Diuretics (e.g., furosemide, hydrochlorothiazide): May reduce the natriuretic and antihypertensive effects of diuretics and increase the risk of renal dysfunction. ♦ ACE Inhibitors & Angiotensin Receptor Blockers (ARBs): May reduce the antihypertensive effect and increase the risk of renal impairment (including acute renal failure) and hyperkalemia, especially in elderly or volume-depleted patients. ♦ Lithium: May increase serum lithium levels and the risk of lithium toxicity by reducing its renal clearance. Monitor lithium levels. ♦ Methotrexate: May increase methotrexate levels and toxicity. ♦ Cyclosporine & Tacrolimus: Increased risk of nephrotoxicity. ♦ Corticosteroids: Increased risk of GI ulceration or bleeding. ♦ Alcohol: Increases the risk of GI irritation and bleeding. ♦ CYP2C9 Inhibitors/Inducers: Piroxicam is metabolized by CYP2C9; inhibitors (e.g., fluconazole) may increase piroxicam levels, and inducers (e.g., rifampin) may decrease levels. Monitor for altered effects.

Polyethylene Glycol (Miralax)

Purpose/Indication	Polyethylene Glycol (PEG), often referred to as macrogol, is an osmotic laxative used to treat occasional constipation and for bowel preparation before colonoscopies or other intestinal procedures. For constipation, it helps to soften stools and increase bowel movement frequency. For bowel prep, high-dose formulations are used to induce rapid and thorough bowel emptying.
Method of Action	Polyethylene Glycol is an inert, non-absorbable, and osmotically active polymer. When ingested, it passes through the gastrointestinal tract largely unabsorbed and retains water in the bowel lumen through osmotic action. This increases the water content of the stool, making it softer and increasing stool bulk. The increased bulk distends the colon, stimulating peristalsis and facilitating easier passage of stool. For bowel preparation, very large volumes of PEG solution are used to flush out the bowel.
Medication Name & Brand Names	♦ Medication Name: Polyethylene Glycol (PEG), Macrogol ♦ Brand Names: Miralax, GlycoLax, Movicol (regional, often with electrolytes), Osmolax (regional), PegLyte (for bowel prep, with electrolytes), GoLYTELY (for bowel prep, with electrolytes), PEG (generic)
Pharmaceutical Forms & Appearance	PEG is typically supplied as a white, free-flowing powder that is dissolved in water or other suitable liquids (e.g., juice) before ingestion. For bowel preparation, it often comes as a large container of powder along with electrolyte packets to be mixed into several liters of water. The resulting solution is usually clear and colorless.

Dosage & Administration	Dosage varies significantly between chronic constipation treatment and bowel preparation. For constipation, the typical adult dose is 17 grams (one level cap or scoop) of powder dissolved in 120-240 mL (4-8 ounces) of water or beverage once daily. It may take 1-3 days to produce a bowel movement. For bowel preparation, specific regimens are followed, involving large volumes (e.g., 2-4 liters) of solution consumed over several hours, usually the day before a procedure. Always follow product-specific instructions or healthcare provider's directions.
Supplied As	Polyethylene Glycol is supplied as: powder for oral solution (e.g., 17 g single dose packets, or larger containers with measuring caps/scoops), and as powder for oral solution with electrolytes (for bowel preparation, often in large jars or multiple sachets to be mixed into several liters of water).
Contraindications	Polyethylene Glycol is contraindicated in patients with known hypersensitivity to PEG. It should not be used in patients with known or suspected intestinal obstruction (e.g., paralytic ileus, bowel perforation, toxic megacolon) or acute abdominal conditions requiring surgery. Use with caution in patients with inflammatory bowel disease or impaired gag reflex.
Storage & Expiry	PEG powder should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep containers tightly closed. Once reconstituted, the solution for bowel preparation must be used within a specific timeframe (e.g., 24-48 hours when refrigerated), and usually discarded thereafter. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and include bloating, abdominal cramping, flatulence, and nausea. With bowel preparation doses, these symptoms are more pronounced and often include significant abdominal discomfort and diarrhea. Dehydration and electrolyte imbalances are rare with standard constipation doses but can occur with improper use or high doses, especially if not consumed with sufficient fluids or in patients with renal impairment.
Warnings & Precautions	♦ Electrolyte Imbalance: While PEG alone (without added electrolytes) causes minimal electrolyte shifts, high-dose bowel preparations (which usually contain electrolytes) and misuse of PEG can lead to significant fluid and electrolyte imbalances (e.g., hypokalemia, hyponatremia), especially in vulnerable patients (elderly, renal impairment, heart failure). Monitor electrolytes in high-risk patients. ♦ Renal Impairment: Use with caution in patients with renal impairment, particularly with large volumes. ♦ Cardiac/Renal Disease: Use with caution and monitor fluid/electrolytes in patients with heart failure or renal dysfunction due to the potential for fluid shifts. ♦ Aspiration Risk: Use with caution in patients with impaired gag reflex or at risk for aspiration, especially with large volumes of solution. ♦ Inflammatory Bowel Disease (IBD): Use with caution in patients with active IBD, as large volumes may exacerbate symptoms. ♦ Duration of Use: For chronic constipation, prolonged use is generally considered safe, but review chronic use with a healthcare provider. ♦ Not for Immediate Relief: PEG does not produce immediate bowel movements; it typically works within 1-3 days for constipation.
Missed Dose Instructions	For chronic constipation, if a daily dose of PEG is missed, take it as soon as remembered. However, if it's close to the time for the next day's dose, skip the missed dose and resume your regular schedule. Do not take a double dose. For bowel preparation, it's critical to follow the specific instructions and timing given by the healthcare provider; any missed or incomplete doses could compromise the procedure's success.
Overdose Instructions	Overdose of PEG alone is generally well-tolerated due to its low systemic absorption. Symptoms of an overdose might include severe diarrhea, abdominal distention, nausea, and vomiting. With very large amounts or in susceptible individuals (e.g., those with renal issues), electrolyte imbalances (especially hypernatremia or hypokalemia) could theoretically occur if not balanced by fluid intake. Treatment is supportive and symptomatic, focusing on maintaining fluid and electrolyte balance. Seek medical advice if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ No significant direct drug-drug interactions are commonly reported with PEG due to its inert and non-absorbed nature. ♦ However, PEG can decrease the absorption of other orally administered medications if taken concurrently, by rapidly moving them through the GI tract. Therefore, for bowel preparation uses, advise patients to avoid taking any other oral medications within 1 hour before, during, or 1 hour after taking the PEG solution. ♦ For constipation treatment, it's generally prudent to separate PEG administration from other medications by at least 1-2 hours to ensure optimal absorption of other drugs.

Polymyxin B / Colistin (Coly-Mycin S)

Purpose/Indication	Polymyxin B is an antibiotic primarily used to treat infections caused by susceptible Gram-negative bacteria, especially Pseudomonas aeruginosa, E. coli, Klebsiella pneumoniae, and Enterobacter aerogenes. Due to its potential for serious side effects (nephrotoxicity and neurotoxicity), its systemic use (intravenous, intramuscular, intrathecal) is typically reserved for severe, multi-drug resistant infections where less toxic agents are ineffective or contraindicated. It is more commonly found in topical preparations for localized infections of the eye, ear, and skin, often in combination with other antibiotics.
Method of Action	Polymyxin B is a cationic polypeptide antibiotic that acts as a detergent-like agent, disrupting the integrity of the bacterial cell membrane. It binds to the negatively charged lipopolysaccharide (LPS) components of the outer membrane of Gram-negative bacteria. This binding leads to increased permeability of the cell membrane, causing leakage of intracellular components and ultimately leading to bacterial cell lysis and death. It also binds to and neutralizes bacterial endotoxins.
Medication Name & Brand Names	♦ Medication Name: Polymyxin B Sulfate ♦ Brand Names: Polymyxin B (generic, injectable), often found in combination products like Polytrim (Polymyxin B/Trimethoprim ophthalmic), Neosporin (Neomycin/Polymyxin B/Bacitracin topical), Cortisporin (Neomycin/Polymyxin B/Hydrocortisone otic/ophthalmic), Polysporin (Polymyxin B/Bacitracin topical).
Pharmaceutical Forms & Appearance	Polymyxin B is available as a sterile powder for injection (for reconstitution for intravenous, intramuscular, or intrathecal use), and as various topical solutions, suspensions, and ointments, often in combination with other antibiotics or corticosteroids, for ophthalmic (eye), otic (ear), and dermatologic (skin) use. The powder for injection is typically white or off-white. Topical forms vary in appearance (e.g., clear solutions, white creams/ointments).
Dosage & Administration	Dosage and administration vary greatly by route and indication. For systemic infections, it is often given intravenously (e.g., 15,000 to 25,000 units/kg/day in divided doses) or intrathecally (e.g., 50,000 units daily or every other day for meningitis). Topical forms are applied directly to the affected area (e.g., eye drops: 1-2 drops every 3-4 hours; ear drops: 3-4 drops 3-4 times daily; skin ointment: 1-3 times daily). Careful dosing and monitoring are essential for systemic use due to toxicity.
Supplied As	Polymyxin B is supplied as: powder for injection (e.g., 500,000 units per vial), ophthalmic solutions/ointments (often in combination, e.g., Polymyxin B/Trimethoprim eye drops, Neomycin/Polymyxin B/Bacitracin ophthalmic ointment), otic solutions/suspensions (often in combination, e.g., Neomycin/Polymyxin B/Hydrocortisone ear drops), and topical ointments/creams (often in combination, e.g., Neomycin/Polymyxin B/Bacitracin ointment).
Contraindications	Polymyxin B is contraindicated in patients with known hypersensitivity to polymyxin B or any component of the formulation. Systemic use should be avoided in patients with severe renal impairment unless absolutely necessary, and close monitoring is required. For otic use, it is contraindicated if there is a perforated eardrum due to the risk of ototoxicity (hearing damage).

Storage & Expiry	Unreconstituted polymyxin B powder for injection should be stored at room temperature, protected from light. Reconstituted solutions should be used promptly or stored refrigerated for a limited time (e.g., 72 hours). Topical preparations should be stored at room temperature, protected from light and excessive heat, and kept in tightly closed containers. Always check specific product labeling for precise storage conditions and expiry dates.
Side Effects	Systemic (IV/IM/Intrathecal) use: Significant side effects include nephrotoxicity (kidney damage, e.g., albuminuria, azotemia, acute tubular necrosis) and neurotoxicity (e.g., paresthesia, dizziness, vertigo, blurred vision, ataxia, slurred speech, neuromuscular blockade leading to respiratory paralysis). Topical use: Generally well-tolerated with mild local irritation (e.g., transient stinging, burning, redness, itching). Rare systemic absorption with topical use can lead to systemic side effects. Allergic reactions (rash, hives) can occur with any form.
Warnings & Precautions	♦ Systemic Use is Restricted: Due to high risk of nephrotoxicity and neurotoxicity, systemic polymyxin B should only be used in hospitalized patients under constant supervision, for severe, multi-drug resistant Gram-negative infections. ♦ Renal Impairment: Careful monitoring of renal function (urine output, creatinine, BUN) is essential, especially with systemic use. Dose adjustments are required in renal impairment. ♦ Neurotoxicity: Monitor for signs of neurotoxicity, including paresthesias, dizziness, or respiratory depression, particularly when given systemically or concomitantly with neuromuscular blocking agents. ♦ Neuromuscular Blockade: Can cause neuromuscular blockade, leading to respiratory arrest, especially in patients with impaired renal function or concurrent use of muscle relaxants. ♦ Ototoxicity: (Rare but serious) risk of hearing loss or vestibular damage, particularly with ear formulations if eardrum is perforated, or with systemic use. ♦ Superinfection: Prolonged use of any antibiotic can lead to overgrowth of non-susceptible organisms, including fungi. ♦ Hypersensitivity: Monitor for allergic reactions. ♦ Not for Viral/Fungal Infections: Antibiotics only treat bacterial infections.
Missed Dose Instructions	For systemic (injectable) polymyxin B, doses are typically administered by a healthcare professional in a hospital setting, minimizing the chance of a missed dose. If a dose is missed, the healthcare team will adjust the schedule. For topical (eye/ear drops, ointments), if a dose is missed, apply it as soon as remembered. If it's almost time for the next dose, skip the missed one and continue the regular schedule. Do not double the dose. Completing the full course of therapy is important for infection eradication.
Overdose Instructions	Systemic (injectable) overdose can lead to severe nephrotoxicity (acute renal failure), neurotoxicity (e.g., ataxia, dizziness, paresthesia, respiratory paralysis due to neuromuscular blockade), and irreversible ototoxicity. Treatment is supportive and symptomatic; maintain respiration (may require mechanical ventilation), manage fluid and electrolyte balance, and provide renal support. Hemodialysis may remove some polymyxin B. Topical overdose is generally not associated with significant systemic toxicity due to poor absorption, but may cause increased local irritation. Accidental oral ingestion of topical forms would likely cause only gastrointestinal upset. Seek immediate medical attention for any suspected systemic overdose.
Medicine Interactions	♦ Nephrotoxic and Neurotoxic Drugs (e.g., aminoglycosides like gentamicin, amikacin; amphotericin B; cephalosporins; cisplatins; colistin; neuromuscular blocking agents; muscle relaxants): Concomitant use with systemic polymyxin B significantly increases the risk of nephrotoxicity and neurotoxicity. Avoid if possible, or monitor closely and adjust doses. ♦ Non-depolarizing Muscle Relaxants (e.g., atracurium, vecuronium, pancuronium): Polymyxin B can potentiate the neuromuscular blockade, leading to prolonged or enhanced muscle relaxation and respiratory depression. Use with extreme caution. ♦ Other Ototoxic Drugs: Increased risk of ototoxicity if used with other ototoxic medications. ♦ Other Topical Preparations: For topical forms, avoid applying other products simultaneously to prevent dilution or interference with absorption/action.

Prednisone (Deltasone)

Purpose/Indication	Prednisone is a synthetic corticosteroid widely used for its potent anti-inflammatory and immunosuppressive effects. It is indicated for a vast array of conditions, including allergic reactions (e.g., severe asthma, allergic rhinitis), inflammatory conditions (e.g., rheumatoid arthritis, lupus, inflammatory bowel disease, dermatological conditions like severe psoriasis), certain cancers (e.g., lymphomas, leukemias), organ transplant rejection prevention, and respiratory conditions (e.g., COPD exacerbations).
Method of Action	Prednisone is a prodrug that is converted by the liver to its active metabolite, prednisolone. Prednisolone acts by binding to intracellular glucocorticoid receptors, forming a complex that then translocates to the cell nucleus. This complex modulates gene expression, leading to a wide range of effects: it inhibits the synthesis of inflammatory mediators (prostaglandins, leukotrienes), suppresses immune cell function (e.g., lymphocytes, macrophages), stabilizes lysosomal membranes, and reduces capillary permeability. These actions result in profound anti-inflammatory, immunosuppressive, and antiallergic effects.
Medication Name & Brand Names	♦ Medication Name: Prednisone ♦ Brand Names: Deltasone, Prednisone Intensol (concentrated oral solution), Rayos (delayed-release tablets), Prednisone (generic)
Pharmaceutical Forms & Appearance	Prednisone is available as oral tablets, orally disintegrating tablets, and oral solutions/syrups. Oral tablets are typically white, round or oval, and may be scored, with various imprints indicating strength (e.g., 1 mg, 2.5 mg, 5 mg, 10 mg, 20 mg, 50 mg). Oral solutions are clear or slightly viscous liquids, often flavored.
Dosage & Administration	Dosage is highly variable and individualized depending on the specific condition, severity, and patient response. Doses can range from low physiological replacement doses (e.g., 2.5-5 mg daily) to very high immunosuppressive doses (e.g., 60 mg or more daily). It is generally taken orally, usually once daily in the morning or as divided doses. For short-term use, it may be taken with food to reduce stomach upset. Long-term therapy requires gradual tapering to avoid adrenal insufficiency.
Supplied As	Prednisone is supplied as: oral tablets (e.g., 1 mg, 2.5 mg, 5 mg, 10 mg, 20 mg, 50 mg), orally disintegrating tablets (e.g., 10 mg, 15 mg, 30 mg), and oral solution/syrup (e.g., 5 mg/5 mL, 15 mg/5 mL).
Contraindications	Prednisone is contraindicated in patients with known hypersensitivity to prednisone or any component of the formulation. It is generally contraindicated in patients with systemic fungal infections unless specific antifungal therapy is being administered. Live or live-attenuated vaccines should not be given to patients receiving immunosuppressive doses of corticosteroids.
Storage & Expiry	Prednisone tablets and oral solutions should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and light. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Side effects are numerous and dose/duration-dependent. Common short-term effects include increased appetite, weight gain, fluid retention, insomnia, mood changes (e.g., irritability, euphoria, anxiety), increased blood pressure, and hyperglycemia. Long-term effects include osteoporosis, muscle weakness, skin thinning/bruising, increased risk of infection, cataracts, glaucoma, Cushing's syndrome features, adrenal insufficiency (upon withdrawal), and impaired wound healing.

Warnings & Precautions	♦ Adrenal Suppression: Prolonged high-dose therapy can lead to adrenal cortical atrophy and suppression of the hypothalamic-pituitary-adrenal (HPA) axis. Abrupt discontinuation can cause life-threatening adrenal insufficiency (e.g., fatigue, weakness, nausea, vomiting, hypotension). Taper dose gradually. ♦ Increased Risk of Infection: Corticosteroids suppress the immune system, increasing susceptibility to, and masking symptoms of, infection (bacterial, viral, fungal, parasitic). Avoid exposure to chickenpox or measles if not immune. Avoid live vaccines. ♦ Cushing's Syndrome: Chronic use can lead to iatrogenic Cushing's syndrome with characteristic physical changes. ♦ Metabolic Effects: Can cause hyperglycemia, new-onset diabetes, worsening of pre-existing diabetes, dyslipidemia, and weight gain. Monitor blood glucose. ♦ Osteoporosis: Long-term use increases the risk of osteoporosis and fractures. Consider calcium and vitamin D supplementation. ♦ Ophthalmic Effects: Can cause cataracts (posterior subcapsular) and glaucoma (increased intraocular pressure). Regular eye exams are recommended for long-term users. ♦ Cardiovascular Effects: Can cause fluid retention, hypertension, and exacerbate heart failure. Use with caution in cardiovascular disease. ♦ GI Effects: Increased risk of peptic ulcers and GI bleeding/perforation, especially with concurrent NSAID use. ♦ Neuropsychiatric Disturbances: Wide range of effects including mood swings, insomnia, psychosis, depression, and euphoria. ♦ Growth Retardation: In children, chronic use can inhibit growth. ♦ Hypokalemia: Can cause potassium loss. ♦ Immunization: Patients on immunosuppressive doses should not receive live or live-attenuated vaccines. Killed vaccines may have a diminished response. ♦ Pregnancy/Lactation: Use only if potential benefit justifies risk. Excreted in breast milk; potential for adverse effects on infant.
Missed Dose Instructions	For once-daily dosing, if a dose of Prednisone is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For alternate-day or tapered dosing regimens, follow specific instructions provided by the healthcare professional, as consistency is critical. Never abruptly stop prednisone if you've been on it for more than a few days, due to the risk of adrenal insufficiency.
Overdose Instructions	Acute overdose of prednisone is generally not life-threatening. Symptoms are usually an exaggeration of typical side effects, including increased appetite, weight gain, fluid retention, high blood pressure, and agitation. However, chronic overdose can lead to more severe long-term complications such as Cushing's syndrome, severe metabolic disturbances, and immunosuppression. Treatment is supportive and symptomatic. There is no specific antidote. Gradual dose reduction is generally recommended for chronic overdose. Seek medical advice for significant acute overdose or if chronic overdose is suspected.
Medicine Interactions	♦ NSAIDs (Non-Steroidal Anti-inflammatory Drugs): Increased risk of gastrointestinal ulceration and bleeding. Use with caution. ♦ Diuretics (Potassium-depleting, e.g., thiazides, loop diuretics): Increased risk of hypokalemia. Monitor potassium levels. ♦ Anticoagulants (e.g., warfarin): Corticosteroids can either enhance or diminish the effect of anticoagulants; monitor INR closely. ♦ Insulin/Oral Hypoglycemics: Prednisone can increase blood glucose levels, requiring dose adjustments of antidiabetic medications. ♦ CYP3A4 Inducers (e.g., rifampin, carbamazepine, phenytoin, phenobarbital): Can increase the metabolism of prednisone, reducing its plasma levels and efficacy. Increased prednisone dose may be needed. ♦ CYP3A4 Inhibitors (e.g., ketoconazole, clarithromycin, ritonavir, grapefruit juice): Can decrease the metabolism of prednisone, increasing its plasma levels and risk of side effects. Reduced prednisone dose may be needed. ♦ Live Vaccines: Contraindicated for patients on immunosuppressive doses of corticosteroids. ♦ Immunosuppressants (e.g., cyclosporine, methotrexate): Increased risk of infection and adverse effects. ♦ Cholestyramine, Antacids: May decrease the absorption of prednisone; administer at separate times. ♦ Digitalis Glycosides: Hypokalemia induced by prednisone can increase the risk of digitalis toxicity.

Pregabalin (Lyrica)

Purpose/Indication	Pregabalin is an anticonvulsant and neuropathic pain agent used to treat various conditions. Its primary indications include neuropathic pain associated with diabetic peripheral neuropathy, postherpetic neuralgia (shingles pain), and spinal cord injury. It is also approved for the treatment of fibromyalgia and as adjunctive therapy for partial-onset seizures in adults.
Method of Action	Pregabalin's exact mechanism of action is not fully understood, but it is believed to exert its effects by binding with high affinity to the alpha2-delta (α2−δ) subunit of voltage-gated calcium channels in the central nervous system. This binding modulates the release of several neurotransmitters, including glutamate, norepinephrine, and substance P. By reducing the release of these excitatory neurotransmitters, pregabalin reduces neuronal excitability, thereby decreasing pain signals and stabilizing overactive nerve cells.
Medication Name & Brand Names	♦ Medication Name: Pregabalin ♦ Brand Names: Lyrica, Pregabalin (generic)
Pharmaceutical Forms & Appearance	Pregabalin is available as oral capsules, oral solution, and extended-release tablets. Capsules are typically hard gelatin capsules, varying in color and size depending on the strength, with specific imprints. The oral solution is a clear, colorless liquid. Extended-release tablets are generally white or off-white.
Dosage & Administration	Dosage is highly individualized and depends on the indication, patient's response, and renal function. For most indications, initial doses are typically 50 mg or 75 mg orally two or three times daily, gradually titrated upwards over a week to the effective dose (e.g., 150-300 mg/day or up to 600 mg/day). Extended-release tablets are taken once daily. Take with or without food. Avoid abrupt discontinuation to prevent withdrawal symptoms.
Supplied As	Pregabalin is supplied as: oral capsules (e.g., 25 mg, 50 mg, 75 mg, 100 mg, 150 mg, 200 mg, 225 mg, 300 mg), oral solution (e.g., 20 mg/mL), and extended-release tablets (e.g., 82.5 mg, 165 mg, 330 mg).
Contraindications	Pregabalin is contraindicated in patients with known hypersensitivity to pregabalin or any component of the formulation.
Storage & Expiry	Pregabalin capsules, oral solution, and extended-release tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include dizziness, somnolence (drowsiness), dry mouth, edema (swelling), blurred vision, weight gain, constipation, and difficulty concentrating. More serious side effects, though less common, include angioedema (swelling of face, lips, tongue), hypersensitivity reactions, suicidal thoughts or behavior, respiratory depression (especially with opioids or in patients with respiratory risk factors), and physical dependence leading to withdrawal symptoms upon abrupt discontinuation.

Warnings & Precautions	♦ Angioedema: Cases of angioedema (swelling of the face, limbs, lips, tongue, glottis, and larynx) have been reported, which may be life-threatening. Discontinue immediately if symptoms occur. ♦ Hypersensitivity Reactions: Discontinue at the first sign of hypersensitivity (e.g., rash, hives). ♦ Suicidal Thoughts and Behavior: Antiepileptic drugs, including pregabalin, may increase the risk of suicidal thoughts or behavior. Monitor patients for new or worsening depression, suicidal thoughts or behavior, or unusual changes in mood or behavior. ♦ Respiratory Depression: Serious, life-threatening, or fatal respiratory depression may occur, particularly in patients with pre-existing respiratory impairment, concomitant use of CNS depressants (e.g., opioids, benzodiazepines), or in the elderly. Use with caution and monitor. ♦ Peripheral Edema: May cause peripheral edema. Use with caution in patients with cardiovascular disease. ♦ Dizziness and Somnolence: Can impair physical and mental abilities. Advise patients not to drive or operate machinery until effects are known. ♦ Withdrawal Symptoms: Do not discontinue abruptly. Gradually taper the dose over at least 1 week to avoid withdrawal symptoms (e.g., insomnia, nausea, headache, anxiety, diarrhea, flu-like symptoms, seizures). ♦ Weight Gain: Common side effect. ♦ Creatine Kinase Elevation: Rare cases of elevated creatine kinase. ♦ Renal Impairment: Dose adjustments are necessary for patients with impaired renal function due to renal excretion. ♦ Drug Abuse and Dependence: Pregabalin has a potential for abuse and dependence, particularly in individuals with a history of substance abuse. It is a controlled substance in many regions.
Missed Dose Instructions	If a dose of Pregabalin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. It is important to avoid missing doses to maintain consistent blood levels and therapeutic effect, and to avoid potential withdrawal symptoms if you've been on it for a long time.
Overdose Instructions	Overdose symptoms are typically exaggerated side effects, including somnolence, confusion, agitation, and restlessness. Less common but more serious effects can include coma and seizures. There is no specific antidote for pregabalin overdose. Treatment is supportive and symptomatic. Maintain airway, breathing, and circulation. Hemodialysis can effectively remove pregabalin from the plasma. Seek immediate emergency medical help.
Medicine Interactions	♦ CNS Depressants (e.g., opioids, benzodiazepines, alcohol, sedatives, hypnotics): Additive CNS depressant effects leading to increased sedation, drowsiness, and potentially respiratory depression. Use with caution, and consider lower doses of one or both agents. ♦ Tramadol: May increase the risk of CNS depression and seizures. ♦ Antidiabetic Agents (e.g., thiazolidinediones like rosiglitazone, pioglitazone): Concomitant use with pregabalin may increase the risk of weight gain and peripheral edema. Monitor for fluid retention. ♦ No significant pharmacokinetic interactions with other commonly used drugs: Pregabalin is primarily excreted renally unchanged and is not significantly metabolized by the cytochrome P450 system, leading to a low potential for metabolic drug interactions.

Propranolol (Inderal)

Purpose/Indication	Propranolol is a non-selective beta-adrenergic receptor blocker used to treat a wide range of cardiovascular and other conditions. Its primary indications include hypertension (high blood pressure), angina pectoris (chest pain), cardiac arrhythmias, and hypertrophic subaortic stenosis. It is also used for the prophylaxis of migraine headaches, essential tremor, and to manage symptoms of anxiety (e.g., performance anxiety) and hyperthyroidism.
Method of Action	Propranolol is a non-selective beta-blocker, meaning it blocks both beta-1 (β1) and beta-2 (β2) adrenergic receptors. By blocking β1 receptors primarily in the heart, it reduces heart rate, myocardial contractility, and cardiac output, leading to decreased blood pressure and reduced oxygen demand. By blocking β2 receptors in the bronchial tree and peripheral blood vessels, it can cause bronchoconstriction and vasoconstriction. It also reduces renin release from the kidneys and has effects on the central nervous system, contributing to its diverse therapeutic actions.
Medication Name & Brand Names	♦ Medication Name: Propranolol Hydrochloride ♦ Brand Names: Inderal (immediate-release tablets, extended-release capsules, solution), Hemangeol (oral solution for infantile hemangioma), Propranolol (generic)
Pharmaceutical Forms & Appearance	Propranolol is available as oral tablets (immediate-release), oral extended-release capsules, oral solution, and solution for intravenous (IV) injection. Immediate-release tablets are typically white to off-white, round or heart-shaped, with various imprints and sometimes scored. Extended-release capsules contain beads and vary in color. The oral solution is a clear liquid.
Dosage & Administration	Dosage is highly individualized and depends on the indication, patient's response, and renal/hepatic function. For hypertension, typical initial adult oral doses are 40 mg twice daily (immediate-release) or 80 mg once daily (extended-release), titrated upwards. For migraine prophylaxis, doses are usually 80-240 mg daily in divided doses or once daily with extended-release. Take with or without food, but consistency is recommended. Do not crush or chew extended-release capsules. Abrupt discontinuation should be avoided.
Supplied As	Propranolol is supplied as: oral immediate-release tablets (e.g., 10 mg, 20 mg, 40 mg, 60 mg, 80 mg), oral extended-release capsules (e.g., 60 mg, 80 mg, 120 mg, 160 mg), oral solution (e.g., 4 mg/mL, 8 mg/mL, 20 mg/5 mL), and solution for intravenous injection (e.g., 1 mg/mL).
Contraindications	Propranolol is contraindicated in patients with known hypersensitivity to propranolol or any component of the formulation. It is strictly contraindicated in patients with bronchial asthma, acute severe exacerbation of COPD, cardiogenic shock, sinus bradycardia, second- or third-degree atrioventricular (AV) block (without a pacemaker), and overt cardiac failure.
Storage & Expiry	Propranolol tablets, capsules, and oral solutions should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. The oral solution for infantile hemangioma (Hemangeol) requires specific refrigeration after opening. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include bradycardia (slow heart rate), fatigue, dizziness, nausea, vomiting, diarrhea, constipation, and cold extremities. More serious side effects include bronchospasm (especially in patients with asthma/COPD), severe bradycardia, hypotension, heart failure exacerbation, masked hypoglycemia symptoms (in diabetics), and depression. Sexual dysfunction can also occur.
Warnings & Precautions	♦ Abrupt Cessation: BLACK BOX WARNING (in some regions/products): Abrupt discontinuation of beta-blockers, especially in patients with ischemic heart disease, can exacerbate angina, lead to myocardial infarction, or ventricular arrhythmias. When discontinuing, gradually taper the dose over 1-2 weeks. ♦ Bronchospastic Disease: Contraindicated in patients with asthma. Use with extreme caution, if at all, in patients with COPD or other bronchospastic diseases, as non-selective beta-blockade can worsen bronchoconstriction. ♦ Cardiac Failure: May depress myocardial contractility and precipitate or worsen cardiac failure. Use with caution in compensated heart failure, and avoid in overt cardiac failure. ♦ Bradycardia/Heart Block: Can cause severe bradycardia or heart block. Use with caution in patients with first-degree AV block or sick sinus syndrome. ♦ Diabetes Mellitus: Can mask symptoms of hypoglycemia (e.g., tremor, tachycardia) and prolong hypoglycemic episodes. Use with caution in diabetic patients, especially those on insulin or oral hypoglycemics. ♦ Thyrotoxicosis: Can mask clinical signs of hyperthyroidism (e.g., tachycardia). Abrupt withdrawal in patients with thyrotoxicosis may precipitate a thyroid storm. ♦ Peripheral Vascular Disease: May precipitate or aggravate symptoms of arterial insufficiency. ♦ Pheochromocytoma: If used in pheochromocytoma, always administer an alpha-blocker first to prevent unopposed alpha-adrenergic stimulation, which can lead to severe hypertension. ♦ Anaphylaxis: Patients taking beta-blockers may be less responsive to epinephrine for the treatment of severe allergic reactions. ♦ Hepatic/Renal Impairment: Metabolized in the liver and partially excreted by kidneys. Use with caution and consider dose adjustment in patients with significant hepatic or renal impairment.
Missed Dose Instructions	If a dose of Propranolol is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose (e.g., a few hours before the next immediate-release dose, or half-way through the interval for extended-release), skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining stable blood pressure and heart rate, and to prevent rebound effects from missed doses.

Overdose Instructions	Overdose symptoms are primarily severe bradycardia, severe hypotension, bronchospasm, acute cardiac failure, and hypoglycemia. Other symptoms may include convulsions, respiratory depression, and coma. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. For bradycardia, atropine or isoproterenol may be used. Glucagon may be effective for severe beta-blocker toxicity. Vasopressors may be needed for hypotension. Pacing may be required for severe bradycardia/heart block. Seek immediate emergency medical help.
Medicine Interactions	♦ Calcium Channel Blockers (e.g., verapamil, diltiazem): Concomitant use can cause severe bradycardia, AV block, and hypotension. Use with extreme caution; monitor ECG and blood pressure. ♦ Other Antihypertensives: Additive hypotensive effects. ♦ Alpha-blockers (e.g., prazosin): Can cause significant first-dose orthostatic hypotension. ♦ Clonidine: Concomitant use can cause rebound hypertension upon withdrawal of clonidine. If discontinuing both, taper propranolol first, then clonidine. ♦ Digoxin: Increased risk of bradycardia and AV block. ♦ Insulin & Oral Hypoglycemics: Can mask symptoms of hypoglycemia (tachycardia, tremor) and prolong hypoglycemic episodes. Monitor blood glucose closely. ♦ NSAIDs (Non-Steroidal Anti-inflammatory Drugs): May reduce the antihypertensive effect of beta-blockers. ♦ CYP2D6 Inhibitors (e.g., fluoxetine, paroxetine, quinidine): Can increase propranolol plasma levels due to inhibition of metabolism, potentially leading to increased beta-blockade and adverse effects. ♦ CYP1A2/CYP2C19/CYP3A4 Inhibitors/Inducers: Propranolol is metabolized by multiple CYP enzymes; concomitant use with inhibitors or inducers of these enzymes can alter propranolol levels. ♦ Theophylline: Beta-blockers can antagonize the bronchodilatory effects of theophylline. ♦ Ergot Alkaloids: Increased risk of peripheral vasoconstriction. ♦ Epinephrine: Beta-blockers can cause an exaggerated hypertensive and bradycardic response to epinephrine due to unopposed alpha-adrenergic stimulation.

Pseudoephedrine (Sudafed)

Purpose/Indication	Pseudoephedrine is a sympathomimetic amine used as a nasal decongestant. It is primarily indicated for the temporary relief of nasal congestion and sinus pressure caused by the common cold, hay fever, other upper respiratory allergies, or sinusitis. It works by shrinking swollen nasal passages, allowing for easier breathing.
Method of Action	Pseudoephedrine acts as a direct and indirect sympathomimetic, primarily by stimulating alpha-adrenergic receptors in the smooth muscle of nasal blood vessels and to a lesser extent, beta-adrenergic receptors. It causes vasoconstriction (narrowing) of the arterioles in the nasal mucosa, reducing blood flow to the area. This leads to a decrease in swelling and mucus formation, thereby opening up nasal passages and relieving congestion. It also causes indirect release of norepinephrine from adrenergic nerve endings.
Medication Name & Brand Names	♦ Medication Name: Pseudoephedrine Hydrochloride, Pseudoephedrine Sulfate ♦ Brand Names: Sudafed (original formulation), Claritin-D (loratadine/pseudoephedrine), Zyrtec-D (cetirizine/pseudoephedrine), Allegra-D (fexofenadine/pseudoephedrine), Pseudoephedrine (generic)
Pharmaceutical Forms & Appearance	Pseudoephedrine is available as oral tablets, extended-release tablets, chewable tablets, oral liquids/syrups, and oral drops. Tablets are typically white, round, or oval, and may be imprinted. Extended-release tablets vary in appearance. Oral liquids are clear, often flavored.
Dosage & Administration	Dosage varies by age, formulation, and product. For adults and children 12 years and older, typical immediate-release doses are 30 mg to 60 mg orally every 4-6 hours, not exceeding 240 mg in 24 hours. Extended-release forms are typically taken once or twice daily. For younger children, doses are weight-based and specific pediatric formulations (liquids, drops) should be used. Take with or without food. Do not crush or chew extended-release tablets.
Supplied As	Pseudoephedrine is supplied as: oral tablets (e.g., 30 mg, 60 mg), oral extended-release tablets (e.g., 120 mg, 240 mg), chewable tablets (e.g., 15 mg, 30 mg), oral liquids/syrups (e.g., 15 mg/5 mL, 30 mg/5 mL), and oral drops (e.g., 7.5 mg/0.8 mL).
Contraindications	Pseudoephedrine is contraindicated in patients with known hypersensitivity to pseudoephedrine or other sympathomimetics. It is also contraindicated in patients with severe hypertension, severe coronary artery disease, narrow-angle glaucoma, and urinary retention. Concomitant use or use within 14 days of discontinuing a monoamine oxidase inhibitor (MAOI) is strictly contraindicated due to the risk of hypertensive crisis.
Storage & Expiry	Pseudoephedrine products should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture and excessive heat. Keep in tightly closed, child-resistant containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nervousness, restlessness, insomnia (difficulty sleeping), headache, dizziness, and mild tremors. Cardiovascular effects such as increased heart rate (tachycardia) and elevated blood pressure can also occur. Less common but more serious side effects include hallucinations, arrhythmias, and seizures (especially with overdose).
Warnings & Precautions	♦ Cardiovascular Effects: Use with caution in patients with hypertension, heart disease (e.g., coronary artery disease, arrhythmias), hyperthyroidism, or diabetes, as pseudoephedrine can increase blood pressure and heart rate. ♦ CNS Stimulation: Can cause excitability, especially in children, nervousness, restlessness, and insomnia. Avoid taking close to bedtime. ♦ Urinary Retention: Use with caution in patients with prostatic enlargement or urinary retention, as it can worsen these conditions. ♦ Glaucoma: Use with caution in patients with glaucoma, particularly narrow-angle glaucoma. ♦ Seizures: Use with caution in patients with seizure disorders. ♦ Drug Abuse Potential: Pseudoephedrine is a precursor for illicit methamphetamine synthesis, leading to restrictions on its sale in many regions. ♦ Phenylketonuria (PKU): Some chewable tablets or liquids may contain phenylalanine. ♦ Not for Self-Treatment of Chronic Conditions: Not intended for prolonged use without medical advice. Consult a doctor if symptoms persist or worsen.
Missed Dose Instructions	Pseudoephedrine is typically used on an as-needed basis for symptom relief. If a scheduled dose is missed, take it as soon as remembered if symptoms are present. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Adhere to the recommended dosing interval and maximum daily dose.
Overdose Instructions	Overdose symptoms are an exaggeration of side effects and primarily involve central nervous system (CNS) stimulation and cardiovascular effects. These can include severe nervousness, restlessness, insomnia, tremors, hallucinations, seizures, severe headache, palpitations, tachycardia, hypertension, and arrhythmias. In severe cases, respiratory depression, circulatory collapse, and coma can occur. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral overdose. Control seizures with benzodiazepines. Manage hypertension and arrhythmias as needed. Seek immediate emergency medical help.
Medicine Interactions	♦ Monoamine Oxidase Inhibitors (MAOIs): Contraindicated: Concomitant use or use within 14 days of discontinuing an MAOI can lead to severe, potentially fatal hypertensive crisis (e.g., phenelzine, tranylcypromine, isocarboxazid, selegiline). ♦ Other Sympathomimetics (e.g., other decongestants, appetite suppressants, amphetamines): Additive stimulant and cardiovascular effects, increasing the risk of adverse reactions. Avoid concomitant use. ♦ Beta-blockers (e.g., propranolol): Pseudoephedrine may reduce the antihypertensive effect of beta-blockers. ♦ Tricyclic Antidepressants (TCAs): Can increase the pressor effect of pseudoephedrine. Use with caution. ♦ Digoxin: Increased risk of arrhythmias due to pseudoephedrine's cardiac effects. ♦ Methyldopa, Guanethidine, Reserpine: Pseudoephedrine may antagonize the antihypertensive effects of these medications. ♦ Caffeine and other CNS stimulants: Additive stimulant effects, increasing risk of nervousness, insomnia, and palpitations.

Pyrazinamide (Tebrazid)

Purpose/Indication	Pyrazinamide is an antitubercular agent used as a crucial component of multi-drug regimens for the treatment of active tuberculosis (TB), particularly during the initial intensive phase. Its purpose is to kill the Mycobacterium tuberculosis bacteria, especially those residing within macrophages and acidic environments, contributing to shortening the duration of TB treatment and preventing the emergence of drug resistance. It is not used as a single agent.
Method of Action	Pyrazinamide is a prodrug that is converted to its active form, pyrazinoic acid, by the mycobacterial enzyme pyrazinamidase, which is found in the susceptible Mycobacterium tuberculosis bacteria. Pyrazinoic acid is thought to act primarily in the acidic environment of lysosomes and macrophages, which is where M. tuberculosis often resides. Its exact mechanism is complex and not fully elucidated, but it is believed to inhibit mycobacterial fatty acid synthase I (FAS I), disrupt mycobacterial cell membrane energy metabolism, and lower intracellular pH, leading to bactericidal activity against slow-growing bacteria.
Medication Name & Brand Names	♦ Medication Name: Pyrazinamide ♦ Brand Names: Rifater (combination with rifampin and isoniazid - regional), Pyrazinamide (generic)
Pharmaceutical Forms & Appearance	Pyrazinamide is available as oral tablets. Tablets are typically white or off-white, round, and may be scored, with specific imprints indicating strength (e.g., 500 mg).
Dosage & Administration	Dosage is individualized based on the patient's body weight and is typically administered orally once daily. For adults, common doses range from 15-30 mg/kg per day, usually up to a maximum of 2 grams per day, as part of a multi-drug regimen (e.g., with isoniazid, rifampin, and ethambutol) for the initial 2 months of TB treatment. It can be taken with or without food. Adherence to the full prescribed regimen is critical for successful TB treatment.
Supplied As	Pyrazinamide is supplied as: oral tablets (e.g., 500 mg).
Contraindications	Pyrazinamide is contraindicated in patients with known hypersensitivity to pyrazinamide. It is also strictly contraindicated in patients with acute gout or severe liver damage, as it can exacerbate gout and cause hepatotoxicity.
Storage & Expiry	Pyrazinamide tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in a tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	The most significant and common serious side effect is hepatotoxicity (liver damage), which can range from asymptomatic elevations in liver enzymes to severe, potentially fatal hepatic necrosis. Other common side effects include arthralgia (joint pain) and hyperuricemia (increased uric acid levels, which can precipitate gout attacks). Less common effects include gastrointestinal upset (nausea, vomiting, loss of appetite), rash, and photosensitivity.
Warnings & Precautions	♦ Hepatotoxicity: Pyrazinamide can cause severe and potentially fatal hepatotoxicity. Liver function tests (ALT, AST, bilirubin) must be performed prior to and regularly throughout therapy, typically every 2-4 weeks. Discontinue if signs of liver damage appear. Alcohol consumption significantly increases the risk of hepatotoxicity. ♦ Hyperuricemia & Gout: Almost all patients treated with pyrazinamide develop hyperuricemia due to inhibition of uric acid excretion. This can precipitate acute gouty arthritis attacks. Monitor uric acid levels and manage symptoms if they occur. ♦ Renal Impairment: Use with caution and consider dose adjustment in patients with renal impairment, as accumulation may occur. ♦ Diabetes Mellitus: May make diabetes more difficult to control. Monitor blood glucose. ♦ Gastrointestinal Irritation: May cause nausea, vomiting, or loss of appetite. Taking with food may help. ♦ History of Gout: Contraindicated in patients with acute gout; use with extreme caution in those with a history of gout. ♦ Photosensitivity: May increase sensitivity to sunlight. Advise patients to use sun protection. ♦ Drug Resistance: Pyrazinamide should always be used in combination with other anti-TB drugs to prevent the development of drug resistance.
Missed Dose Instructions	Given that Pyrazinamide is a critical component of TB treatment, adherence is paramount. If a dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Any missed doses should be discussed with the healthcare provider, as consistent dosing is essential for treatment success and preventing drug resistance.
Overdose Instructions	Overdose symptoms are primarily related to hepatotoxicity (liver damage), which may manifest as nausea, vomiting, abdominal pain, jaundice, and elevated liver enzymes. Acute overdose can also lead to hyperuricemia and symptoms of gout. There is no specific antidote for pyrazinamide overdose. Treatment is supportive and symptomatic, focusing on liver protection. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Close monitoring of liver function and uric acid levels is essential. Seek immediate emergency medical help.
Medicine Interactions	♦ Drugs that cause Hepatotoxicity (e.g., alcohol, rifampin, isoniazid, acetaminophen at high doses): Concomitant use increases the risk of liver damage. Avoid or use with extreme caution and frequent liver function monitoring. ♦ Drugs for Gout (e.g., allopurinol, probenecid, colchicine): Pyrazinamide increases uric acid levels, which may necessitate dose adjustments of anti-gout medications or worsen gout symptoms. Probenecid may inhibit pyrazinamide excretion. ♦ Other Antitubercular Drugs: Pyrazinamide is always used in combination with other anti-TB drugs (e.g., isoniazid, rifampin, ethambutol). These combinations are often synergistic but also contribute to the overall risk of side effects. ♦ Diabetes Medications: May make blood glucose control more difficult. Monitor blood glucose and adjust antidiabetic medication as needed.

Quetiapine (Seroquel)

Purpose/Indication	Quetiapine is an atypical antipsychotic medication used to treat various mental health conditions. Its primary indications include schizophrenia, bipolar disorder (manic, depressive, or mixed episodes, and maintenance treatment), and as an adjunctive treatment for major depressive disorder (MDD). It helps to manage symptoms like hallucinations, delusions, mood swings, and severe depression.
Method of Action	Quetiapine is an atypical antipsychotic that acts as a potent antagonist at various neurotransmitter receptors in the brain. It has high affinity for serotonin 5-$HT2A anddopamine D2 receptors, with a higher affinity for HT2A receptors. It also antagonizes histamine H1$ and alpha-1 (a1) adrenergic receptors, which contribute to its sedative and orthostatic hypotensive effects, respectively. Its precise mechanism in treating psychosis and mood disorders is complex, but it is thought to involve a balance of dopamine and serotonin receptor blockade.
Medication Name & Brand Names	♦ Medication Name: Quetiapine Fumarate ♦ Brand Names: Seroquel (immediate-release tablets), Seroquel XR (extended-release tablets), Quetiapine (generic)
Pharmaceutical Forms & Appearance	Quetiapine is available as immediate-release (IR) tablets and extended-release (XR) tablets. IR tablets are typically round, biconvex, and film-coated, varying in color and imprint depending on strength (e.g., white, peach, yellow). XR tablets are often capsule-shaped or oval and also vary in color and imprint (e.g., white to yellowish-white).

Dosage & Administration	Dosage is highly individualized and titrated gradually based on the patient's condition, response, and tolerability. For schizophrenia, initial doses might be 25-50 mg daily, increasing to 300-800 mg/day in divided doses (IR) or once daily (XR). For bipolar disorder and MDD, doses vary significantly. IR tablets are typically taken twice or thrice daily. XR tablets are taken once daily, usually in the evening without food or with a light meal. Do not chew, crush, or split XR tablets.
Supplied As	Quetiapine is supplied as: oral immediate-release tablets (e.g., 25 mg, 50 mg, 100 mg, 200 mg, 300 mg, 400 mg) and oral extended-release tablets (e.g., 50 mg, 150 mg, 200 mg, 300 mg, 400 mg).
Contraindications	Quetiapine is contraindicated in patients with known hypersensitivity to quetiapine or any component of the formulation. Concomitant use with potent CYP3A4 inhibitors is generally contraindicated (see interactions).
Storage & Expiry	Quetiapine tablets (IR and XR) should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include drowsiness/sedation, dizziness, dry mouth, weight gain, constipation, orthostatic hypotension (drop in blood pressure upon standing), and increased appetite. More serious side effects can include metabolic changes (hyperglycemia, dyslipidemia), tardive dyskinesia (involuntary movements), neuroleptic malignant syndrome (NMS), seizures, QT prolongation, and falls.
Warnings & Precautions	♦ BLACK BOX WARNINGS: Elderly Patients with Dementia-Related Psychosis: Increased risk of death, primarily from cardiovascular events (e.g., heart failure, sudden death) or infections. Quetiapine is not approved for this use. ♦ BLACK BOX WARNINGS: Suicidality: Increased risk of suicidal thoughts and behavior in children, adolescents, and young adults (up to 24 years of age) with major depressive disorder and other psychiatric disorders. Monitor closely for clinical worsening and suicidality. ♦ Orthostatic Hypotension/Syncope: Can cause orthostatic hypotension, dizziness, and syncope, especially during initial dose titration. Use with caution in patients with cardiovascular disease, cerebrovascular disease, or conditions predisposing to hypotension. ♦ Neuroleptic Malignant Syndrome (NMS): Rare but potentially fatal idiosyncratic reaction. Discontinue immediately if NMS is suspected (fever, muscle rigidity, altered mental status, autonomic instability). ♦ Tardive Dyskinesia: Involuntary, repetitive movements, primarily of the face and tongue. May develop during treatment or after discontinuation. Discontinue if signs appear. ♦ Metabolic Changes: Risk of hyperglycemia/diabetes mellitus (sometimes severe and leading to ketoacidosis/coma/death), dyslipidemia (elevated cholesterol and triglycerides), and weight gain. Monitor regularly. ♦ QT Prolongation: Can prolong the QT interval, increasing risk of arrhythmias. Use with caution in patients with known cardiovascular disease, family history of QT prolongation, hypokalemia, or concomitant use of other QT-prolonging drugs. ♦ Seizures: Use with caution in patients with a history of seizures. ♦ Cataracts: Lens changes (cataracts) have been observed in animal studies. Routine eye examinations are recommended. ♦ Hypothyroidism: Can cause dose-related decreases in thyroid hormone levels. Monitor thyroid function. ♦ Leukopenia/Neutropenia/Agranulocytosis: Can occur. Monitor complete blood counts during the first few months of therapy in patients with pre-existing low WBC/ANC. ♦ Dysphagia: Esophageal dysmotility and aspiration risk. Use with caution in patients at risk for aspiration pneumonia. ♦ Withdrawal Symptoms: Abrupt discontinuation can cause withdrawal symptoms (e.g., insomnia, nausea, vomiting, headache, diarrhea, dizziness, irritability). Taper gradually. ♦ Controlled Substance: Potential for misuse or abuse, particularly for sedative effects.
Missed Dose Instructions	If a dose of Quetiapine (immediate-release) is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For extended-release tablets, if a dose is missed, take it as soon as remembered; if more than 6-12 hours late, skip and take the next dose as scheduled. Consult the prescriber about specific instructions for missed doses, as consistency is important. Do not abruptly stop taking quetiapine.
Overdose Instructions	Overdose symptoms are primarily an exaggeration of known pharmacological effects: severe sedation, somnolence, tachycardia, hypotension, dry mouth, and anticholinergic effects. More serious effects can include coma, seizures, QTc prolongation, and arrhythmias. There is no specific antidote. Treatment is supportive and symptomatic, maintaining airway, breathing, and circulation. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Continuous cardiovascular monitoring (including ECG) is essential. Seek immediate emergency medical help.
Medicine Interactions	♦ CNS Depressants (e.g., alcohol, benzodiazepines, opioids, sedatives, hypnotics): Additive CNS depressant effects leading to increased sedation, drowsiness, and respiratory depression. Avoid or use with extreme caution. ♦ Antihypertensives: Additive hypotensive effects; monitor blood pressure. ♦ CYP3A4 Inducers (e.g., carbamazepine, phenytoin, rifampin, phenobarbital, St. John's Wort): Significantly increase the metabolism of quetiapine, reducing its plasma levels and potentially leading to loss of efficacy. Increased quetiapine dose may be necessary. ♦ CYP3A4 Inhibitors (e.g., ketoconazole, itraconazole, erythromycin, clarithromycin, ritonavir, grapefruit juice): Significantly inhibit the metabolism of quetiapine, increasing its plasma levels and risk of side effects. Reduced quetiapine dose may be necessary or concomitant use may be contraindicated. ♦ Drugs that Prolong QT Interval (e.g., certain antiarrhythmics, tricyclic antidepressants, some antipsychotics, moxifloxacin): Increased risk of arrhythmias. Use with caution. ♦ Anticholinergic Agents: Additive anticholinergic effects (e.g., dry mouth, constipation, urinary retention, blurred vision). ♦ Thioridazine: Concomitant use is generally not recommended due to increased risk of QT prolongation and arrhythmias. ♦ Lithium: May alter lithium levels or effects, monitor.

Quinine (Qualaquin)

Purpose/Indication	Quinine is an antimalarial drug primarily used for the treatment of uncomplicated Plasmodium falciparum malaria, especially in regions where chloroquine resistance is high. Due to its significant side effects and the availability of newer, safer antimalarials, its use is typically reserved for cases where other agents are not effective or available. It may also be used in combination with other antimalarials. Historically, it was also used off-label for nocturnal leg cramps, but this use is generally discouraged due to safety concerns.
Method of Action	Quinine's antimalarial action is thought to occur by inhibiting the parasite's ability to detoxify heme, a byproduct of hemoglobin digestion within the red blood cells. Malaria parasites digest hemoglobin and convert toxic heme into non-toxic hemozoin. Quinine interferes with this process, allowing toxic heme to accumulate, which is lethal to the parasite. It also has schizonticidal activity, meaning it kills the asexual blood forms of the parasite. Additionally, quinine has muscle relaxant properties, affecting the excitability of muscle fibers, which may explain its historical use for leg cramps.
Medication Name & Brand Names	♦ Medication Name: Quinine Sulfate ♦ Brand Names: Qualaquin, Quinacrine (different drug), Quinine (generic)
Pharmaceutical Forms & Appearance	Quinine is primarily available as oral capsules or tablets. Capsules are typically hard gelatin capsules, varying in color and size depending on strength, often with specific imprints. Tablets are usually round or oval and white. It may also be found in some IV formulations for severe malaria in certain regions.
Dosage & Administration	Dosage and duration vary depending on the indication and severity of malaria. For uncomplicated P. falciparum malaria, a common adult oral dose is 648 mg (or 600 mg salt) every 8 hours for 3-7 days, typically in combination with a second antimalarial drug (e.g., doxycycline, clindamycin) to ensure radical cure and prevent resistance. It should be taken with food to minimize gastrointestinal upset.
Supplied As	Quinine is supplied as: oral capsules (e.g., 324 mg), oral tablets (e.g., 300 mg, 600 mg).

Contraindications	Quinine is contraindicated in patients with known hypersensitivity to quinine or mefloquine (due to cross-sensitivity). It is also contraindicated in patients with tinnitus, optic neuritis, glucose-6-phosphate dehydrogenase (G6PD) deficiency (risk of hemolytic anemia), myasthenia gravis (may worsen muscle weakness), and in patients with a history of blackwater fever associated with quinine use.
Storage & Expiry	Quinine tablets and capsules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	The most common side effects are collectively known as "cinchonism" and include tinnitus (ringing in ears), headache, nausea, vomiting, dizziness, blurred vision, and flushing. More serious side effects include hypersensitivity reactions (rash, angioedema), severe hypoglycemia (low blood sugar), hemolytic anemia (especially in G6PD deficiency), thrombocytopenia (low platelets), QT prolongation leading to arrhythmias (e.g., Torsades de Pointes), and rarely, acute renal failure.
Warnings & Precautions	♦ Cinchonism: A common syndrome of adverse effects (tinnitus, headache, nausea, visual disturbances, dizziness) that can occur even at therapeutic doses. Symptoms are usually reversible upon discontinuation. ♦ Hypoglycemia: Can cause severe hypoglycemia, especially in pregnant women and children, by stimulating insulin release. Monitor blood glucose closely. ♦ Hematologic Effects: Risk of hemolytic anemia (especially in G6PD deficiency), thrombocytopenia, and agranulocytosis. Test for G6PD deficiency before use if possible. ♦ Cardiac Effects: Can prolong the QT interval and increase the risk of serious ventricular arrhythmias (e.g., Torsades de Pointes). Avoid use in patients with known QT prolongation, uncorrected hypokalemia/hypomagnesemia, or concomitant use of other QT-prolonging drugs. Use with caution in patients with heart disease. ♦ Hypersensitivity Reactions: Severe and potentially fatal hypersensitivity reactions (e.g., rash, anaphylaxis, angioedema) can occur. ♦ Neuromuscular Blocking Agents: May potentiate the effects of neuromuscular blocking agents. ♦ Myasthenia Gravis: Can exacerbate muscle weakness. ♦ Renal/Hepatic Impairment: Use with caution and consider dose adjustment in patients with significant renal or hepatic impairment, as elimination may be reduced. ♦ Off-label Use (Leg Cramps): Due to risk of serious side effects, regulatory bodies in some regions (e.g., FDA) advise against its use for nocturnal leg cramps.
Missed Dose Instructions	If a dose of Quinine is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Adherence to the full prescribed course is crucial for effective malaria treatment and preventing the development of drug resistance.
Overdose Instructions	Overdose symptoms are typically severe cinchonism (pronounced tinnitus, severe headache, confusion, visual disturbances, deafness), profound hypotension, cardiac arrhythmias (especially QT prolongation and Torsades de Pointes), severe hypoglycemia, gastrointestinal distress, and CNS depression (coma, convulsions). Acute renal failure and respiratory depression can also occur. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Correct hypoglycemia immediately. Manage cardiac arrhythmias and hypotension. Hemodialysis is generally not effective. Seek immediate emergency medical help.
Medicine Interactions	♦ QT-Prolonging Drugs (e.g., amiodarone, sotalol, quinidine, some antipsychotics, macrolide antibiotics like erythromycin, fluoroquinolones like moxifloxacin): Concomitant use significantly increases the risk of serious ventricular arrhythmias, including Torsades de Pointes. Avoid concurrent use. ♦ Anticoagulants (e.g., warfarin): Quinine can potentiate the anticoagulant effect of warfarin, increasing bleeding risk. Monitor INR closely. ♦ Digoxin: Quinine can increase digoxin levels. Monitor digoxin levels. ♦ Mefloquine: Concomitant use increases the risk of seizures and cardiac arrhythmias; avoid or use with extreme caution. Avoid mefloquine for at least 12 hours after last quinine dose. ♦ CYP3A4 Inducers (e.g., rifampin, carbamazepine, phenytoin, phenobarbital): Can increase the metabolism of quinine, reducing its plasma levels and efficacy. ♦ CYP3A4 Inhibitors (e.g., ketoconazole, ritonavir, clarithromycin, grapefruit juice): Can decrease the metabolism of quinine, increasing its plasma levels and risk of toxicity. ♦ Antacids (containing aluminum or magnesium): Can decrease the absorption of quinine. Separate administration. ♦ Cimetidine: May increase quinine levels. ♦ Neuromuscular Blocking Agents: May enhance the effect of neuromuscular blockers. ♦ Grapefruit juice: May inhibit quinine metabolism and increase its levels.

R - Z

Any medications starting with R through to Z.

Raloxifene (Evista)

Purpose/Indication	Raloxifene is a selective estrogen receptor modulator (SERM) primarily used for the prevention and treatment of osteoporosis in postmenopausal women. It is also indicated to reduce the risk of invasive breast cancer in postmenopausal women at high risk for invasive breast cancer, and in postmenopausal women with osteoporosis. It offers bone-preserving benefits without stimulating breast or uterine tissue.
Method of Action	Raloxifene selectively binds to estrogen receptors, acting as an estrogen agonist in some tissues (like bone) and an estrogen antagonist in others (like breast and uterine tissue). In bone, it mimics estrogen's effects by decreasing bone resorption and increasing bone mineral density, thus reducing the risk of vertebral fractures. In breast tissue, it antagonizes estrogen's effects, which is thought to contribute to its breast cancer risk reduction. Its selective action differentiates it from traditional estrogen replacement therapy.
Medication Name & Brand Names	♦ Medication Name: Raloxifene Hydrochloride ♦ Brand Names: Evista, Raloxifene (generic)
Pharmaceutical Forms & Appearance	Raloxifene is available as oral tablets. Tablets are typically white, oval-shaped, and film-coated, with specific imprints indicating strength (e.g., "ELI LILLY 4165" or generic equivalent).
Dosage & Administration	The typical adult oral dosage for both osteoporosis and breast cancer risk reduction is 60 mg once daily. It can be taken with or without food. Patients should also receive adequate calcium and vitamin D supplementation, and consider weight-bearing exercise. It is important to discontinue raloxifene at least 72 hours (3 days) prior to and during prolonged immobilization (e.g., after surgery) due to the increased risk of thromboembolism.
Supplied As	Raloxifene is supplied as: oral tablets (e.g., 60 mg).
Contraindications	Raloxifene is contraindicated in women who are pregnant or may become pregnant (Pregnancy Category X). It is also contraindicated in women with active or a history of venous thromboembolic events, including deep vein thrombosis (DVT), pulmonary embolism (PE), and retinal vein thrombosis. Additionally, it is contraindicated in patients with known hypersensitivity to raloxifene or any component of the formulation.
Storage & Expiry	Raloxifene tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.

Side Effects	Common side effects include hot flashes/flushes, leg cramps, peripheral edema (swelling), flu-like syndrome, and arthralgia (joint pain). The most serious and significant side effect is an increased risk of venous thromboembolic events (DVT, PE, retinal vein thrombosis), especially during the first few months of therapy. Other rare but serious effects include stroke.
Warnings & Precautions	♦ BLACK BOX WARNING: Increased Risk of Venous Thromboembolism (VTE) and Stroke: Raloxifene increases the risk of VTE (DVT, PE, retinal vein thrombosis), particularly during the first 4 months of treatment. Risk is higher in women with a history of VTE. Discontinue at least 72 hours prior to and during prolonged immobilization. Increased risk of death due to stroke has also been observed in clinical trials. ♦ History of Stroke: Use with caution in women with a history of stroke or transient ischemic attack (TIA) due to increased risk of stroke. ♦ Immobilization: Discontinue raloxifene during prolonged periods of immobilization (e.g., after surgery or prolonged bed rest) due to increased VTE risk. Resume only after the patient is fully ambulatory. ♦ Hepatic Impairment: Not recommended for use in patients with hepatic impairment, as it is extensively metabolized by the liver. ♦ Estrogen Use: Should not be used with systemic estrogens. ♦ Hypertriglyceridemia: Use with caution in women with a history of estrogen-induced severe hypertriglyceridemia, as raloxifene may exacerbate this condition. ♦ Breast/Uterine Cancer: While it reduces the risk of invasive breast cancer, it does not prevent all types of breast cancer (e.g., non-invasive lobular or ductal carcinoma) and has no effect on endometrial cancer risk. ♦ Cholesterol: Can decrease total and LDL cholesterol but has no effect on HDL cholesterol or triglycerides.
Missed Dose Instructions	If a dose of Raloxifene is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining the bone and breast cancer risk reduction benefits.
Overdose Instructions	Limited experience with raloxifene overdose. Symptoms following large doses have included leg cramps and dizziness. There is no specific antidote for raloxifene overdose. Treatment should be supportive and symptomatic. Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Warfarin & other Coumarin Anticoagulants: Raloxifene can decrease prothrombin time, potentially enhancing the anticoagulant effect of warfarin. Monitor INR closely, especially when initiating or discontinuing raloxifene. ♦ Systemic Estrogens (e.g., hormone replacement therapy): Concomitant use with systemic estrogens is not recommended due to lack of evidence for added benefit and potential for increased adverse effects. ♦ Cholestyramine & other Bile Acid Sequestrants: Can significantly reduce the absorption and enterohepatic recirculation of raloxifene, leading to reduced plasma levels. Avoid concomitant use. ♦ Highly Protein-Bound Drugs (e.g., ibuprofen, diazepam, indomethacin, diclofenac): While in vitro studies suggest potential displacement, clinically significant interactions are generally not observed. However, use caution. ♦ Ampicillin: Oral ampicillin can decrease raloxifene concentrations, though the clinical significance is generally not considered major. ♦ Thyroid Hormones: No significant interaction; absorption and metabolism of thyroid hormones are not affected.

Ramipril (Altace)

Purpose/Indication	Ramipril is an angiotensin-converting enzyme (ACE) inhibitor primarily used to treat hypertension (high blood pressure) and to reduce the risk of cardiovascular events. It is indicated for reducing the risk of myocardial infarction, stroke, and cardiovascular death in patients aged 55 years or older at high risk (e.g., with coronary artery disease, history of stroke/MI, or diabetes with at least one cardiovascular risk factor). It is also used to treat symptomatic congestive heart failure and to reduce the risk of major cardiovascular events in patients with clinically evident cardiovascular disease.
Method of Action	Ramipril is a prodrug that is converted in the liver to its active metabolite, ramiprilat. Ramiprilat works by inhibiting the angiotensin-converting enzyme (ACE), which is responsible for converting angiotensin I to angiotensin II. Angiotensin II is a potent vasoconstrictor and also stimulates aldosterone secretion. By blocking its formation, ramiprilat causes vasodilation (widening of blood vessels), reduces aldosterone-mediated sodium and water retention, and decreases systemic vascular resistance, leading to lower blood pressure and reduced cardiac workload.
Medication Name & Brand Names	♦ Medication Name: Ramipril ♦ Brand Names: Altace, Ramipril (generic)
Pharmaceutical Forms & Appearance	Ramipril is available as oral capsules and oral solution. Capsules are typically hard gelatin capsules, varying in color depending on the strength, and may have specific imprints. The oral solution is usually a clear, colorless liquid.
Dosage & Administration	Dosage is highly individualized based on the patient's condition, response, and renal function. For hypertension, initial adult oral doses are typically 2.5 mg once daily, adjusted based on blood pressure response, up to a maximum of 20 mg once daily. For cardiovascular risk reduction, the typical target dose is 10 mg once daily. For heart failure, lower initial doses (e.g., 1.25 mg) are often used, titrating upwards. Take with or without food.
Supplied As	Ramipril is supplied as: oral capsules (e.g., 1.25 mg, 2.5 mg, 5 mg, 10 mg) and oral solution (e.g., 1 mg/mL).
Contraindications	Ramipril is contraindicated in patients with known hypersensitivity to ramipril or any other ACE inhibitor. It is also contraindicated in patients with a history of angioedema (swelling of the face, lips, tongue, throat) related to previous ACE inhibitor treatment, hereditary or idiopathic angioedema, or concomitant use with sacubitril/valsartan. Concomitant use with aliskiren is contraindicated in patients with diabetes mellitus or renal impairment.
Storage & Expiry	Ramipril capsules and oral solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include dry cough (persistent, non-productive), dizziness, fatigue, and headache. More serious but less common side effects include angioedema (swelling of the face, lips, tongue, throat, potentially life-threatening), hypotension (low blood pressure), hyperkalemia (high potassium levels), renal impairment, and hepatic dysfunction.
Warnings & Precautions	♦ BLACK BOX WARNING (in some regions/products): Fetal Toxicity: Use of ACE inhibitors during the second and third trimesters of pregnancy can cause injury and death to the developing fetus. Discontinue as soon as pregnancy is detected. ♦ Angioedema: Can cause angioedema, which may occur at any time during treatment, particularly early on. If laryngeal stridor or angioedema of the face, extremities, lips, tongue, glottis, or larynx occurs, discontinue ramipril immediately and provide appropriate medical therapy. Higher risk in Black patients. ♦ Hypotension: May cause symptomatic hypotension, especially in volume-depleted patients (e.g., those on diuretics, dialysis) or severe heart failure. Initiate with low doses and monitor. ♦ Hyperkalemia: Can cause hyperkalemia, especially in patients with renal impairment, diabetes, or those taking potassium-sparing diuretics, potassium supplements, or other drugs that increase potassium. Monitor serum potassium. ♦ Renal Impairment: Can cause acute renal failure, particularly in patients with pre-existing renal insufficiency, severe congestive heart failure, or bilateral renal artery stenosis. Monitor renal function regularly. ♦ Dual Blockade of RAAS: Dual blockade of the renin-angiotensin-aldosterone system (RAAS) with ACE inhibitors, ARBs, or aliskiren is associated with increased risks of hypotension, hyperkalemia, and renal function changes; generally avoid. ♦ Cough: Persistent, non-productive cough is common and resolves upon discontinuation.

	♦ Hepatic Failure: Rarely associated with a syndrome of cholestatic jaundice progressing to fulminant hepatic necrosis, sometimes fatal. Discontinue if jaundice or marked elevations of hepatic enzymes occur. ♦ Surgery/Anesthesia: May cause hypotension during major surgery or anesthesia due to enhanced effects of hypotensive agents. ♦ Neutropenia/Agranulocytosis: Rare, but monitor white blood cell counts in high-risk patients.
Missed Dose Instructions	If a dose of Ramipril is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for blood pressure control and cardiovascular protection.
Overdose Instructions	Overdose symptoms are primarily severe hypotension, shock, bradycardia, electrolyte disturbances (hyperkalemia), and renal failure. Treatment is supportive and symptomatic. Maintain fluid and electrolyte balance. Lay the patient supine with legs elevated. IV fluid infusion and vasopressors may be needed for hypotension. Hemodialysis is effective in removing ramiprilat. Seek immediate emergency medical help.
Medicine Interactions	♦ Potassium-Sparing Diuretics (e.g., spironolactone, amiloride, triamterene) & Potassium Supplements: Significant risk of severe hyperkalemia. Avoid concomitant use or monitor potassium levels very closely. ♦ NSAIDs (Non-Steroidal Anti-inflammatory Drugs, including selective COX-2 inhibitors): May reduce the antihypertensive effect of ACE inhibitors and increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. Use with caution. ♦ Lithium: ACE inhibitors can reduce the renal clearance of lithium, leading to increased serum lithium levels and toxicity. Monitor lithium levels closely. ♦ Diuretics: Enhanced hypotensive effect, especially with the first dose. Consider withholding diuretics prior to initiating ramipril. ♦ Aliskiren: Contraindicated in patients with diabetes or renal impairment due to increased risk of hypotension, hyperkalemia, and renal impairment. ♦ Sacubitril/Valsartan (Neprilysin Inhibitor): Concomitant use is contraindicated due to increased risk of angioedema. A washout period (e.g., 36 hours) is required between stopping an ACE inhibitor and starting sacubitril/valsartan. ♦ mTOR Inhibitors (e.g., sirolimus, everolimus, temsirolimus) and Vildagliptin: Increased risk of angioedema. Use with caution. ♦ Racecadotril: Increased risk of angioedema. ♦ Gold (parenteral): Nitritoid reactions (facial flushing, nausea, vomiting, hypotension) have been reported rarely in patients on concurrent gold therapy and ACE inhibitors. ♦ Insulin/Oral Hypoglycemics: Increased risk of hypoglycemia, particularly at the initiation of ACE inhibitor therapy. Monitor blood glucose.

Rifampin (Rifadin)

Purpose/Indication	Rifampin is a broad-spectrum antibiotic primarily used in combination with other drugs for the treatment of active tuberculosis (TB), including drug-resistant strains. It is also indicated for the treatment of latent TB infection (as monotherapy or in combination), and for the eradication of meningococcal carriers (to prevent meningococcal meningitis outbreaks). Less commonly, it's used for severe staphylococcal infections (e.g., endocarditis, osteomyelitis) when combined with other agents, due to its ability to penetrate biofilms.
Method of Action	Rifampin exerts its bactericidal effect by inhibiting bacterial RNA synthesis. It specifically binds to the beta-subunit of bacterial DNA-dependent RNA polymerase, thereby preventing the initiation of RNA transcription. This action selectively affects bacterial cells because mammalian RNA polymerase is not significantly inhibited by rifampin. Its unique mechanism allows it to kill rapidly growing and semi-dormant Mycobacterium tuberculosis bacilli.
Medication Name & Brand Names	♦ Medication Name: Rifampin, Rifampicin (international non-proprietary name) ♦ Brand Names: Rifadin, Rimactane, Rifamate (combination with isoniazid), Rifater (combination with isoniazid and pyrazinamide), Rifampin (generic)
Pharmaceutical Forms & Appearance	Rifampin is available as oral capsules and as a powder for oral suspension or intravenous (IV) injection. Oral capsules are typically opaque, reddish-brown, and may be imprinted. The powder for oral suspension is usually orange to red-brown. The powder for IV injection is a red-brown lyophilized powder for reconstitution. Due to its color, it can stain urine, sweat, tears, and other bodily fluids orange-red.
Dosage & Administration	Dosage varies significantly by indication and patient weight, and it is almost always used in combination with other anti-infective agents. For tuberculosis, typical adult oral doses are 10 mg/kg once daily (up to 600 mg daily), or 10 mg/kg two or three times weekly, depending on the regimen, for several months. For meningococcal carriers, the dose is typically 600 mg twice daily for 2 days. Take on an empty stomach (1 hour before or 2 hours after a meal) for optimal absorption. Oral suspension can be given via nasogastric tube.
Supplied As	Rifampin is supplied as: oral capsules (e.g., 150 mg, 300 mg), powder for oral suspension (e.g., 10 mg/mL after reconstitution), and powder for intravenous injection (e.g., 600 mg per vial).
Contraindications	Rifampin is contraindicated in patients with known hypersensitivity to rifampin or any rifamycin. It is also contraindicated in patients with severe liver disease or active hepatitis. Concomitant use with ritonavir-boosted saquinavir (and potentially other protease inhibitors) is contraindicated due to increased risk of hepatotoxicity.
Storage & Expiry	Rifampin capsules and powder for oral suspension (unreconstituted) should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Once reconstituted, the oral suspension should be stored at room temperature and typically used within a few weeks (check label). Reconstituted IV solution should be used promptly. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal upset (nausea, vomiting, diarrhea, abdominal pain), rash, and flu-like symptoms. The most significant and common serious side effect is hepatotoxicity (liver damage), which can range from asymptomatic elevations in liver enzymes to severe, potentially fatal hepatic necrosis. Other serious effects include thrombocytopenia (low platelets), hemolytic anemia, acute renal failure (rare), and discoloration of body fluids (orange-red urine, sweat, tears, saliva).
Warnings & Precautions	♦ Hepatotoxicity: Can cause severe and potentially fatal hepatotoxicity. Liver function tests (ALT, AST, bilirubin) must be performed prior to and regularly throughout therapy. Discontinue if signs of liver damage appear. The risk is increased with concomitant use of other hepatotoxic drugs (e.g., isoniazid, pyrazinamide), pre-existing liver disease, or chronic alcohol consumption. ♦ Drug Interactions: Rifampin is a potent inducer of many cytochrome P450 enzymes, leading to numerous significant drug interactions (see below). ♦ Discoloration of Body Fluids: Patients should be advised that rifampin will turn urine, sweat, tears, saliva, and contact lenses (soft) an orange-red color. This is harmless but permanent staining of soft contact lenses can occur. ♦ Hypersensitivity Reactions: Can cause various hypersensitivity reactions, including rash, fever, and flu-like syndrome. ♦ Hematologic Effects: Can cause thrombocytopenia, leukopenia, and hemolytic anemia, especially with intermittent dosing or if therapy is resumed after a break. Monitor blood counts. ♦ Renal Impairment: Rarely associated with acute renal failure. Monitor renal function. ♦ Intermittent Dosing: Risk of severe adverse reactions (flu-like syndrome, thrombocytopenia, hemolytic anemia) is increased with intermittent use (e.g., once or twice weekly) compared to daily dosing. ♦ Pseudomembranous Colitis: Can occur with nearly all antibacterial agents. ♦ Pregnancy: Use with caution; may interfere with vitamin K-dependent clotting factors in mother and infant. Administer vitamin K to mother before delivery and to infant.
Missed Dose Instructions	Given that Rifampin is a critical component of anti-tuberculosis therapy and prophylaxis, adherence is paramount to prevent drug resistance and treatment failure. If a dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Any missed doses should be discussed with the healthcare provider, as consistency is essential for treatment success.

Overdose Instructions	Overdose symptoms are typically related to hepatotoxicity (liver damage), which may manifest as nausea, vomiting, abdominal pain, jaundice, and elevated liver enzymes. Characteristic orange-red discoloration of skin, urine, sweat, and other bodily fluids is often pronounced. In severe cases, unconsciousness, convulsions, and cardiac arrhythmias may occur. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Close monitoring of liver function, renal function, and blood counts is essential. Seek immediate emergency medical help.
Medicine Interactions	♦ Potent CYP Enzyme Inducer: Rifampin is a strong inducer of numerous cytochrome P450 enzymes and transporter proteins. This leads to significantly reduced plasma concentrations and efficacy of many co-administered drugs. Numerous interactions require dose adjustments or alternative therapies. Key interactions include: ♦ Oral Contraceptives: Significantly reduces effectiveness, leading to unintended pregnancy. Advise alternative, reliable contraception. ♦ Warfarin & other Anticoagulants: Significantly reduces anticoagulant effect. Monitor INR very closely and adjust warfarin dose as needed. ♦ Anti-HIV Drugs (e.g., protease inhibitors, NNRTIs): Most anti-HIV drugs are significantly affected. Concomitant use often contraindicated or requires substantial dose adjustments or alternative anti-TB drugs. ♦ Corticosteroids: Reduces corticosteroid levels. Increased steroid dose may be needed. ♦ Oral Hypoglycemics (e.g., sulfonylureas): Reduces efficacy, potentially leading to hyperglycemia. Monitor blood glucose. ♦ Digoxin: Reduces digoxin levels. ♦ Cardiac Drugs (e.g., antiarrhythmics like quinidine, propafenone; calcium channel blockers like verapamil, diltiazem, nifedipine; beta-blockers like propranolol): Reduced efficacy of these drugs. Dose adjustments or alternative agents may be needed. ♦ Statins: Reduces levels of many statins. ♦ Immunosuppressants (e.g., cyclosporine, tacrolimus, sirolimus): Significantly reduces levels of immunosuppressants, leading to risk of transplant rejection. Monitor drug levels and adjust immunosuppressant dose significantly. ♦ Thyroid Hormones: Reduces levothyroxine levels. ♦ Methadone: Can cause withdrawal symptoms due to reduced

Risedronate (Actonel)

Purpose/Indication	Risedronate is a bisphosphonate medication primarily used for the treatment and prevention of osteoporosis in postmenopausal women, and for the treatment of osteoporosis in men. It is also indicated for the treatment of glucocorticoid-induced osteoporosis in men and women, and for the treatment of Paget's disease of bone. Its purpose is to increase bone mineral density and significantly reduce the risk of vertebral and non-vertebral fractures.
Method of Action	Risedronate is a nitrogen-containing bisphosphonate that specifically inhibits bone resorption by binding to hydroxyapatite crystals in bone and being taken up by osteoclasts (cells responsible for bone breakdown). Once internalized, risedronate interferes with the mevalonate pathway, an essential metabolic pathway in osteoclasts, leading to impaired osteoclast function, reduced osteoclast numbers, and ultimately, a decrease in bone turnover. This allows osteoblasts (bone-forming cells) to continue building new bone, leading to a net gain in bone mass and strength.
Medication Name & Brand Names	♦ Medication Name: Risedronate Sodium ♦ Brand Names: Actonel, Atelvia (delayed-release), Risedronate (generic)
Pharmaceutical Forms & Appearance	Risedronate is available as oral tablets (immediate-release and delayed-release). Immediate-release tablets are typically round or oval, white to off-white, and may be imprinted with strength and/or a company logo. Delayed-release tablets are often coated and may have a specific shape or color.
Dosage & Administration	Dosage varies by indication. For osteoporosis (treatment/prevention), common regimens are 5 mg daily, 35 mg once weekly, 75 mg on two consecutive days each month, or 150 mg once monthly. For Paget's disease, it's typically 30 mg once daily for 2 months. It is crucial to take risedronate on an empty stomach (at least 30-60 minutes before the first food, drink, or other medication of the day), with a full glass of plain water (not mineral water or juice), and remain upright for at least 30-60 minutes after taking the dose to prevent esophageal irritation. Do not chew or suck tablets.
Supplied As	Risedronate is supplied as: oral immediate-release tablets (e.g., 5 mg, 35 mg, 75 mg, 150 mg) and oral delayed-release tablets (e.g., 35 mg).
Contraindications	Risedronate is contraindicated in patients with known hypersensitivity to risedronate or any component of the formulation. It is strictly contraindicated in patients with hypocalcemia (low blood calcium levels), severe renal impairment (creatinine clearance less than 30 mL/min), or abnormalities of the esophagus that delay esophageal emptying (e.g., stricture or achalasia) due to the risk of esophageal adverse events. Patients unable to stand or sit upright for at least 30-60 minutes should also not take risedronate.
Storage & Expiry	Risedronate tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in the original tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal issues such as abdominal pain, dyspepsia (indigestion), nausea, diarrhea, and constipation. Esophageal adverse events (e.g., esophagitis, esophageal ulcers, erosions) are also a significant concern, especially if not taken correctly. Musculoskeletal pain is also reported. More serious but rare side effects include osteonecrosis of the jaw (ONJ), atypical femoral fractures, and severe bone, joint, and/or muscle pain.
Warnings & Precautions	♦ Esophageal Adverse Reactions: Can cause severe esophageal irritation, including esophagitis, ulcers, and erosions, which can be severe and require hospitalization. Strict adherence to administration instructions is crucial. Do not chew or suck tablets; take with plain water; remain upright for 30-60 min; avoid taking with food, drinks (other than plain water), or other medications. Discontinue if new or worsening dysphagia, painful swallowing, or retrosternal pain occurs. ♦ Osteonecrosis of the Jaw (ONJ): Rare but serious adverse event, particularly in cancer patients receiving IV bisphosphonates, but also reported with oral bisphosphonates (including risedronate). Risk factors include cancer, concomitant therapies (chemotherapy, corticosteroids, anti-angiogenic agents), poor oral hygiene, pre-existing dental disease, and invasive dental procedures. A dental exam should be considered prior to initiation, especially for patients with risk factors. ♦ Atypical Femoral Fractures: Low-trauma subtrochanteric and diaphyseal femoral fractures have been reported with bisphosphonate use. Evaluate new thigh, hip, or groin pain. ♦ Musculoskeletal Pain: Severe and occasionally incapacitating bone, joint, and/or muscle pain has been reported. Discontinue if pain develops. ♦ Hypocalcemia: Must be corrected before initiating risedronate. Monitor calcium and vitamin D levels. Ensure adequate calcium and vitamin D intake. ♦ Renal Impairment: Use with caution and contraindicated in severe renal impairment. ♦ Hypersensitivity Reactions: Allergic reactions, including angioedema and severe skin reactions, have been reported. ♦ Existing GI Disorders: Use with caution in patients with active upper GI problems (e.g., dysphagia, peptic ulcer, active GI bleeding).
Missed Dose Instructions	For once-weekly dosing (35 mg): If a dose is missed, take one tablet on the morning after it is remembered, then return to taking one tablet once a week on your chosen day. Do not take two tablets on the same day. For monthly dosing (150 mg, or 75 mg x 2): If a dose is missed and the next scheduled monthly dose is more than 7 days away, take the missed dose the next morning. If the next scheduled monthly dose is within 7 days, skip the missed dose and resume your regular schedule. Do not take more than one risedronate tablet in a single week. For daily dosing (5 mg): If a dose is missed, skip the missed dose and take the next dose at the regular time. Do not take two doses on the same day. Always adhere strictly to administration instructions to minimize esophageal risk.

Overdose Instructions	Overdose of risedronate can lead to hypocalcemia, hypophosphatemia, and upper gastrointestinal adverse events (e.g., stomach upset, heartburn, esophagitis). Management includes administering milk or antacids containing calcium to bind the risedronate and relieve GI irritation. Do not induce vomiting. Patients should remain upright. Monitor serum calcium and phosphorus levels. Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Calcium-Containing Products (e.g., antacids, calcium supplements, dairy products): Significantly interfere with the absorption of risedronate. Must be administered at least 30-60 minutes after risedronate. ♦ Multivitamins, Iron, Magnesium, Aluminum-containing preparations: These can also interfere with absorption. Administer at least 30-60 minutes after risedronate. ♦ Proton Pump Inhibitors (PPIs) and H2-blockers: Prolonged use of these acid-suppressing medications may potentially reduce the efficacy of bisphosphonates by affecting gastric pH, though clinical significance with risedronate is debated. Consider delayed-release formulations of risedronate (e.g., Atelvia) which are designed to be less affected by gastric pH. ♦ Aspirin/NSAIDs: Concomitant use with bisphosphonates may increase the risk of upper GI adverse events. Use with caution.

Rivaroxaban (Xarelto)

Purpose/Indication	Rivaroxaban is an oral anticoagulant used to prevent and treat various thromboembolic conditions. It is indicated for the prevention of stroke and systemic embolism in patients with non-valvular atrial fibrillation, for the treatment of deep vein thrombosis (DVT) and pulmonary embolism (PE), and for the prevention of recurrent DVT and PE. It is also used for prophylaxis of DVT and PE in patients undergoing hip or knee replacement surgery.
Method of Action	Rivaroxaban is a highly selective direct factor Xa (FXa) inhibitor. Factor Xa is a crucial enzyme in the coagulation cascade that converts prothrombin to thrombin. By directly and reversibly inhibiting both free and clot-bound FXa, rivaroxaban effectively blocks the formation of thrombin, thereby inhibiting both the intrinsic and extrinsic pathways of the coagulation cascade. This action prevents the formation of blood clots, without requiring a cofactor like antithrombin.
Medication Name & Brand Names	♦ Medication Name: Rivaroxaban ♦ Brand Names: Xarelto, Rivaroxaban (generic)
Pharmaceutical Forms & Appearance	Rivaroxaban is available as oral film-coated tablets. Tablets are typically round, biconvex, and may vary in color and imprint depending on strength (e.g., light yellow, red-brown, yellow). They often have a triangle with the strength embossed on one side.
Dosage & Administration	Dosage varies significantly by indication. For non-valvular atrial fibrillation, doses range from 15 mg or 20 mg once daily with the evening meal. For DVT/PE treatment, an initial higher dose (e.g., 15 mg twice daily for 21 days) is followed by a maintenance dose (e.g., 20 mg once daily). For DVT/PE prophylaxis after hip/knee surgery, it's typically 10 mg once daily. Tablets should be taken with food, especially for doses of 15 mg or 20 mg, as food enhances absorption. Patients unable to swallow whole tablets may crush them and mix with water or applesauce immediately before administration.
Supplied As	Rivaroxaban is supplied as: oral film-coated tablets (e.g., 2.5 mg, 10 mg, 15 mg, 20 mg).
Contraindications	Rivaroxaban is strictly contraindicated in patients with active pathological bleeding (e.g., gastrointestinal bleeding, intracranial hemorrhage). It is also contraindicated in patients with known hypersensitivity to rivaroxaban or any component of the formulation. Not recommended in patients with prosthetic heart valves or severe hepatic disease associated with coagulopathy. Concomitant use of other anticoagulants is generally contraindicated.
Storage & Expiry	Rivaroxaban tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in the original packaging or a tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	The most significant side effect is bleeding, which can range from minor (e.g., nosebleeds, bruising, gum bleeding) to serious or even fatal (e.g., gastrointestinal bleeding, intracranial hemorrhage). Other common side effects include nausea, abdominal pain, dyspepsia, and elevated liver enzymes. Less common effects include allergic reactions and skin rash.
Warnings & Precautions	♦ BLACK BOX WARNINGS: Premature Discontinuation: Discontinuation of rivaroxaban, in the absence of adequate alternative anticoagulation, increases the risk of thrombotic events. ♦ BLACK BOX WARNINGS: Spinal/Epidural Hematoma: Patients treated with rivaroxaban who are receiving neuraxial anesthesia (epidural/spinal anesthesia) or undergoing spinal puncture are at risk of developing an epidural or spinal hematoma, which can result in long-term or permanent paralysis. Factors increasing risk include traumatic or repeated punctures, concomitant use of drugs affecting hemostasis (e.g., NSAIDs, antiplatelet agents), and history of spinal deformity or surgery. ♦ Bleeding Risk: Increased risk of bleeding, which can be severe and life-threatening. Monitor for signs of bleeding. No routine monitoring of INR is required, but specific coagulation tests (anti-Factor Xa activity) may be used if needed. ♦ Reversal Agent: An antidote (andexanet alfa) is available to reverse the anti-Factor Xa activity of rivaroxaban in situations of life-threatening or uncontrolled bleeding. ♦ Renal Impairment: Dose adjustments are necessary for patients with moderate to severe renal impairment. Avoid in severe renal impairment (CrCl < 15 mL/min) or end-stage renal disease (ESRD). ♦ Hepatic Impairment: Avoid in patients with moderate to severe hepatic impairment or liver disease associated with coagulopathy due to increased bleeding risk. ♦ Prosthetic Heart Valves: Not recommended for use in patients with prosthetic heart valves due to increased risk of thrombotic events. ♦ Acute PE with Hemodynamic Instability: Not recommended for patients with PE who are hemodynamically unstable or who may
Missed Dose Instructions	For doses of 15 mg twice daily: If a dose is missed during the day, the patient may take two 15 mg tablets at the next scheduled time to ensure 30 mg is taken over 24 hours. For doses of 2.5 mg, 10 mg, or 20 mg once daily: If a dose is missed, the patient should take the next dose at the regularly scheduled time. Do not take a double dose to make up for a missed one. Consistency is crucial for maintaining effective anticoagulation.
Overdose Instructions	Overdose of rivaroxaban increases the risk of bleeding. Symptoms may include visible bleeding (e.g., nosebleeds, bruising, blood in urine or stools) or internal bleeding (e.g., severe abdominal pain, signs of stroke from intracranial hemorrhage). Treatment includes discontinuing rivaroxaban and managing bleeding. An antidote, andexanet alfa, is available for reversal of anti-Factor Xa activity in cases of severe, uncontrolled bleeding. Supportive care, including pressure on bleeding sites, surgical intervention, and administration of blood products, may be necessary. Activated charcoal may be considered if ingestion was very recent. Hemodialysis is not expected to be effective. Seek immediate emergency medical help.
Medicine Interactions	♦ Strong CYP3A4 and P-glycoprotein (P-gp) Inhibitors (e.g., ketoconazole, itraconazole, posaconazole, voriconazole, ritonavir, lopinavir/ritonavir, cobicistat): Significantly increase rivaroxaban exposure, leading to a greatly increased bleeding risk. Concomitant use should generally be avoided. ♦ Strong CYP3A4 and P-gp Inducers (e.g., rifampin, phenytoin, carbamazepine, phenobarbital, St. John's Wort): Significantly decrease rivaroxaban exposure, leading to a reduced anticoagulant effect and increased risk of thrombotic events. Avoid concomitant use. ♦ Other Anticoagulants (e.g., warfarin, heparin, other direct oral anticoagulants): Concomitant use is generally contraindicated due to a significantly increased risk of bleeding. ♦ Antiplatelet Agents (e.g., aspirin, clopidogrel, prasugrel, ticagrelor): Concomitant use increases the risk of bleeding. Use with caution; benefits should outweigh risks. ♦ NSAIDs (Non-Steroidal Anti-inflammatory Drugs): Concomitant use increases the risk of bleeding. Use with caution. ♦ SSRIs/SNRIs: Concomitant use may increase the risk of bleeding, particularly GI bleeding.

Rosuvastatin (Crestor)

Purpose/Indication	Rosuvastatin is an HMG-CoA reductase inhibitor, commonly known as a statin, used to lower elevated cholesterol levels and reduce the risk of cardiovascular disease. It is indicated for treating primary hypercholesterolemia (including heterozygous familial hypercholesterolemia), mixed dyslipidemia, homozygous familial hypercholesterolemia, and for slowing the progression of atherosclerosis. It also reduces the risk of major cardiovascular events (myocardial infarction, stroke, arterial revascularization) in patients at increased risk.
Method of Action	Rosuvastatin works by competitively inhibiting 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase, an enzyme crucial for the synthesis of cholesterol in the liver. By blocking this rate-limiting step, rosuvastatin reduces the production of cholesterol. This leads to an upregulation of LDL receptors on the surface of liver cells, which increases the uptake and catabolism of LDL (low-density lipoprotein) cholesterol from the bloodstream, thereby lowering total cholesterol, LDL-C, and triglycerides, and increasing HDL-C (high-density lipoprotein cholesterol).
Medication Name & Brand Names	♦ Medication Name: Rosuvastatin Calcium ♦ Brand Names: Crestor, Rosuvastatin (generic)
Pharmaceutical Forms & Appearance	Rosuvastatin is available as oral film-coated tablets. Tablets are typically round, biconvex, and may vary in color and imprint depending on strength (e.g., white, pink, yellow). They often have imprints like "ZD" followed by the strength (e.g., ZD40) or other identifying marks.
Dosage & Administration	Dosage is highly individualized and depends on the patient's cholesterol levels, cardiovascular risk, and response to therapy. Initial adult doses range from 5 mg to 20 mg orally once daily, typically in the evening, as cholesterol synthesis is highest at night. Doses can be adjusted after 2-4 weeks, up to a maximum of 40 mg once daily. It can be taken with or without food. Continue a cholesterol-lowering diet throughout treatment.
Supplied As	Rosuvastatin is supplied as: oral film-coated tablets (e.g., 5 mg, 10 mg, 20 mg, 40 mg).
Contraindications	Rosuvastatin is contraindicated in patients with known hypersensitivity to rosuvastatin or any component of the formulation. It is also contraindicated in patients with active liver disease, including unexplained persistent elevations of serum transaminases. Concomitant use with cyclosporine is contraindicated. It is contraindicated in pregnancy and lactation due to the potential for fetal harm.
Storage & Expiry	Rosuvastatin tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in the original tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and include headache, muscle pain (myalgia), abdominal pain, nausea, asthenia (weakness), and constipation. More serious but rare side effects include myopathy (muscle disease) and rhabdomyolysis (severe muscle breakdown, potentially leading to kidney failure), liver dysfunction (elevated liver enzymes), and new-onset diabetes mellitus. Allergic reactions and peripheral neuropathy can also occur.
Warnings & Precautions	♦ Myopathy/Rhabdomyolysis: Statins, including rosuvastatin, can cause myopathy and rhabdomyolysis, which can be severe and lead to acute renal failure. Risk factors include higher doses (especially 40 mg), advanced age, renal impairment, hypothyroidism, and concomitant use of certain interacting drugs. Advise patients to report unexplained muscle pain, tenderness, or weakness, especially if accompanied by malaise or fever. Creatine kinase (CK) levels should be monitored if muscle symptoms occur. Discontinue if CK levels are markedly elevated or rhabdomyolysis is diagnosed. ♦ Liver Dysfunction: Can cause elevations in serum transaminases. Liver function tests (LFTs) should be performed before initiating therapy and as clinically indicated thereafter. Discontinue if persistent elevations occur. Use with caution in patients who consume substantial quantities of alcohol or have a history of liver disease. ♦ Diabetes Mellitus: Statins may increase HbA1c and fasting serum glucose levels. Monitor blood glucose in patients at risk for diabetes. ♦ Renal Impairment: Increased risk of myopathy/rhabdomyolysis, particularly at higher doses. Dose adjustments are necessary; avoid 40 mg dose in patients with moderate to severe renal impairment. ♦ Hypothyroidism: Must be adequately treated before initiating rosuvastatin, as untreated hypothyroidism increases the risk of myopathy. ♦ Asian Patients: Increased systemic exposure to rosuvastatin has been observed in Asian individuals. A lower starting dose (e.g., 5 mg) should be considered, and the 40 mg dose is generally not recommended unless the patient has not achieved desired lipid levels with lower doses. ♦ Pregnancy & Lactation: Contraindicated in pregnancy and lactation due to potential harm to the fetus/infant. ♦ Neurocognitive Effects: Rare reports of cognitive impairment (e.g., memory loss, confusion) have been associated with statin use. Symptoms are generally reversible upon discontinuation.
Missed Dose Instructions	If a dose of Rosuvastatin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for effective cholesterol management and cardiovascular risk reduction.
Overdose Instructions	There is no specific treatment for rosuvastatin overdose. Overdose symptoms are generally an exaggeration of known side effects, particularly muscle pain, gastrointestinal upset, and liver enzyme elevations. In severe cases, rhabdomyolysis with acute renal failure could occur. Treatment is supportive and symptomatic. Hemodialysis is not expected to be beneficial due to extensive protein binding. Monitor liver function and CK levels. Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Cyclosporine: Concomitant use with rosuvastatin is contraindicated due to significantly increased rosuvastatin exposure and greatly increased risk of myopathy/rhabdomyolysis. ♦ Gemfibrozil & other Fibrates (e.g., fenofibrate): Increased risk of myopathy/rhabdomyolysis. Avoid concomitant use with gemfibrozil. Use with caution and monitor with other fibrates. ♦ Niacin (Lipid-lowering doses, ≥1 g/day): Increased risk of muscle adverse events (myopathy/rhabdomyolysis). Use with caution. ♦ Colchicine: Cases of myopathy/rhabdomyolysis have been reported with co-administration. Use with caution. ♦ Strong CYP3A4 Inhibitors (e.g., clarithromycin, erythromycin, azole antifungals like itraconazole, protease inhibitors like ritonavir/lopinavir): Rosuvastatin is a substrate of CYP2C9 and CYP2C19, but also marginally CYP3A4. Strong inhibitors of CYP3A4 can increase rosuvastatin levels. Refer to specific drug-drug interaction guidelines, as some combinations are contraindicated or require dose adjustment. ♦ Coumarin Anticoagulants (e.g., warfarin): Rosuvastatin can potentiate the anticoagulant effect of warfarin, increasing bleeding risk. Monitor INR closely, especially when initiating or discontinuing rosuvastatin. ♦ Antacids (containing aluminum or magnesium hydroxide): Can decrease the plasma concentration of rosuvastatin. Administer antacids at least 2 hours after rosuvastatin. ♦ Ezetimibe: Concomitant use may increase the risk of muscle adverse events. ♦ Regorafenib: Significantly increases rosuvastatin exposure, increasing risk of myopathy. Avoid concomitant use.

Sertraline (Zoloft)

Purpose/Indication	Sertraline is a selective serotonin reuptake inhibitor (SSRI) antidepressant used to treat a range of mental health conditions. Its primary indications include major depressive disorder (MDD), obsessive-compulsive disorder (OCD), panic disorder, post-traumatic stress disorder (PTSD), social anxiety disorder (social phobia), and premenstrual dysphoric disorder (PMDD). It helps to improve mood, reduce anxiety, and alleviate symptoms associated with these conditions.

Method of Action	Sertraline works by selectively inhibiting the reuptake of serotonin (5-HT) into presynaptic neurons in the central nervous system. By blocking the reabsorption of serotonin, it increases the concentration of serotonin in the synaptic cleft, leading to enhanced serotonergic neurotransmission. This prolonged availability of serotonin is thought to be responsible for its antidepressant, anxiolytic, and anti-obsessive effects, although the full therapeutic effects typically take several weeks to manifest.
Medication Name & Brand Names	♦ Medication Name: Sertraline Hydrochloride ♦ Brand Names: Zoloft, Lustral (regional), Sertraline (generic)
Pharmaceutical Forms & Appearance	Sertraline is available as oral tablets and oral concentrated solution. Tablets are typically film-coated, often oval or capsule-shaped, and may vary in color and imprint depending on strength (e.g., white, blue, green). The oral concentrated solution is a clear, colorless liquid.
Dosage & Administration	Dosage is highly individualized and titrated gradually to minimize side effects, starting with lower doses. For MDD and OCD, typical initial adult oral doses are 25 mg or 50 mg once daily, usually in the morning or evening. Doses can be gradually increased, generally up to a maximum of 200 mg daily. For panic disorder, PTSD, and social anxiety disorder, a lower initial dose (e.g., 25 mg once daily) is often used due to increased sensitivity to activating side effects. The oral concentrated solution must be diluted before use. Take with or without food. Avoid abrupt discontinuation.
Supplied As	Sertraline is supplied as: oral tablets (e.g., 25 mg, 50 mg, 100 mg) and oral concentrated solution (e.g., 20 mg/mL).
Contraindications	Sertraline is contraindicated in patients with known hypersensitivity to sertraline or any component of the formulation. It is strictly contraindicated in patients taking or within 14 days of discontinuing a monoamine oxidase inhibitor (MAOI) due to the risk of serotonin syndrome. Concomitant use with pimozide is also contraindicated. Disulfiram is contraindicated with sertraline oral solution due to its alcohol content.
Storage & Expiry	Sertraline tablets and oral concentrated solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging. Once the oral solution is diluted, it typically needs to be used within a short period (e.g., 24 hours).
Side Effects	Common side effects include nausea, diarrhea, dry mouth, insomnia, somnolence (drowsiness), dizziness, tremor, sweating, and sexual dysfunction (e.g., ejaculatory delay, decreased libido). More serious but less common side effects include serotonin syndrome, suicidal thoughts or behavior, activation of mania/hypomania, hyponatremia, and abnormal bleeding.
Warnings & Precautions	♦ BLACK BOX WARNING: Suicidality: Antidepressants increase the risk of suicidal thoughts and behavior in children, adolescents, and young adults (up to 24 years of age) with major depressive disorder and other psychiatric disorders. Closely monitor patients for clinical worsening and suicidality, especially at the beginning of treatment or during dose changes. ♦ Serotonin Syndrome: Potentially life-threatening condition that can occur with SSRIs, particularly with concomitant use of other serotonergic drugs (e.g., MAOIs, triptans, fentanyl, lithium, tramadol, St. John's Wort). Symptoms include mental status changes (agitation, hallucinations, coma), autonomic instability (tachycardia, labile blood pressure, hyperthermia), neuromuscular aberrations (hyperreflexia, incoordination), and GI symptoms. Discontinue immediately if suspected. ♦ Activation of Mania/Hypomania: Can precipitate manic or hypomanic episodes in patients with bipolar disorder. Screen for bipolar disorder before initiating therapy. ♦ Hyponatremia: Clinically significant hyponatremia (low sodium) can occur, especially in elderly patients, those on diuretics, or volume-depleted patients. ♦ Abnormal Bleeding: SSRIs may increase the risk of bleeding events, especially gastrointestinal bleeding, in patients taking antiplatelet agents, anticoagulants, or NSAIDs. ♦ Seizures: Use with caution in patients with a history of seizure disorder. ♦ Sexual Dysfunction: Common side effect, including decreased libido, delayed ejaculation, and anorgasmia. ♦ Discontinuation Syndrome: Abrupt discontinuation can lead to withdrawal symptoms (e.g., dizziness, sensory disturbances like paresthesias, anxiety, agitation, tremor, nausea, sweating). Taper dose gradually over weeks to months. ♦ Glaucoma: May cause mydriasis (pupil dilation), potentially triggering an acute angle-closure attack in predisposed individuals. Use with caution. ♦ Renal/Hepatic Impairment: Use with caution and consider dose adjustment in patients with significant hepatic or renal impairment. ♦ Oral Solution: Contains alcohol; avoid in patients taking disulfiram or who are sensitive to alcohol.
Missed Dose Instructions	If a dose of Sertraline is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining therapeutic effect and preventing withdrawal symptoms.
Overdose Instructions	Overdose symptoms are typically mild to moderate and include somnolence, vomiting, tachycardia, nausea, dizziness, agitation, tremor, and mydriasis. More serious effects can occur, especially with co-ingestion of other drugs or alcohol, including altered mental status, seizures, and prolonged QT interval leading to arrhythmias. There is no specific antidote. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Monitor cardiac and vital signs. Seek immediate emergency medical help.
Medicine Interactions	♦ Monoamine Oxidase Inhibitors (MAOIs, e.g., selegiline, phenelzine, tranylcypromine, linezolid, methylene blue): Contraindicated. Concomitant use or use within 14 days of stopping an MAOI can lead to life-threatening serotonin syndrome. ♦ Pimozide: Contraindicated due to increased pimozide levels and risk of QT prolongation and arrhythmias. ♦ Other Serotonergic Drugs (e.g., triptans, tramadol, fentanyl, lithium, St. John's Wort, dextromethorphan, buspirone, other SSRIs/SNRIs, TCAs): Increased risk of serotonin syndrome. Use with caution, monitor symptoms. ♦ Warfarin & other Anticoagulants: Increased risk of bleeding due to sertraline's effect on platelet aggregation. Monitor INR closely. ♦ NSAIDs & Antiplatelet Agents (e.g., aspirin, clopidogrel): Increased risk of gastrointestinal bleeding. ♦ Diuretics: Increased risk of hyponatremia. ♦ CYP2D6 Substrates (e.g., tricyclic antidepressants like imipramine, desipramine; antipsychotics like risperidone; antiarrhythmics like propafenone, flecainide): Sertraline is a moderate inhibitor of CYP2D6; may increase levels of drugs metabolized by CYP2D6. Monitor and adjust doses. ♦ Cimetidine: May increase sertraline levels due to inhibition of metabolism. ♦ Digoxin & Atenolol: No significant interaction. ♦ Oral Solution: Contains alcohol; avoid with disulfiram.

Sildenafil (Viagra)

Purpose/Indication	Sildenafil is a phosphodiesterase-5 (PDE5) inhibitor primarily used for the treatment of erectile dysfunction (ED) in men. It helps to achieve and maintain an erection sufficient for sexual activity. It is also indicated for the treatment of pulmonary arterial hypertension (PAH) to improve exercise capacity and delay clinical worsening, marketed under a different brand name and typically at a lower dose.
Method of Action	Sildenafil works by inhibiting phosphodiesterase type 5 (PDE5), an enzyme that is abundant in the corpus cavernosum of the penis and in the pulmonary vasculature. In erectile dysfunction, sexual stimulation leads to the local release of nitric oxide (NO), which activates guanylate cyclase, increasing levels of cyclic guanosine monophosphate (cGMP). cGMP causes smooth muscle relaxation, leading to increased blood flow into the penis. Sildenafil enhances this effect by preventing the breakdown of cGMP by PDE5, thus facilitating an erection. In PAH, it similarly causes vasodilation in the pulmonary arteries, reducing pulmonary arterial pressure.
Medication Name & Brand Names	♦ Medication Name: Sildenafil Citrate ♦ Brand Names: Viagra (for ED), Revatio (for PAH), Sildenafil (generic)

Pharmaceutical Forms & Appearance	Sildenafil is available as oral tablets, oral suspension, and solution for intravenous (IV) injection. Viagra tablets are typically blue, film-coated, diamond-shaped, and imprinted with "Pfizer" on one side and "VGR" followed by the strength (e.g., VGR 50) on the other. Revatio tablets are white, round, and film-coated, often with "REV" and strength imprinted. The oral suspension is a white to off-white suspension after reconstitution.
Dosage & Administration	Dosage varies significantly by indication. For erectile dysfunction (ED), the typical adult oral dose is 50 mg taken approximately 30 minutes to 4 hours before sexual activity (usually 1 hour before). Doses can range from 25 mg to 100 mg per day. It should not be taken more than once daily. For pulmonary arterial hypertension (PAH), the typical adult oral dose is 20 mg three times daily, taken approximately 4-6 hours apart. It can be taken with or without food.
Supplied As	Sildenafil is supplied as: oral tablets (e.g., 20 mg, 25 mg, 50 mg, 100 mg), powder for oral suspension (e.g., 10 mg/mL after reconstitution), and solution for intravenous injection (e.g., 10 mg/12.5 mL).
Contraindications	Sildenafil is strictly contraindicated in patients taking nitrates (e.g., nitroglycerin, isosorbide dinitrate) in any form, as this can lead to a dangerous and potentially fatal drop in blood pressure. It is also contraindicated in patients with known hypersensitivity to sildenafil or any component of the formulation. Concomitant use with guanylate cyclase stimulators (e.g., riociguat) is also contraindicated.
Storage & Expiry	Sildenafil tablets and powder for oral suspension (unreconstituted) should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Once reconstituted, the oral suspension should be stored refrigerated and used within a specific timeframe (e.g., 60 days). Always check the specific expiry date on the packaging.
Side Effects	Common side effects include headache, flushing (redness of face), dyspepsia (indigestion), nasal congestion, visual disturbances (e.g., blurred vision, bluish tinge to vision), and dizziness. More serious but rare side effects include priapism (prolonged erection lasting >4 hours), sudden decrease or loss of vision (NAION), sudden hearing loss, and cardiovascular events (MI, stroke, arrhythmias) in patients with pre-existing heart conditions.
Warnings & Precautions	♦ Nitrate Co-administration: STRICTLY CONTRAINDICATED with nitrates in any form (oral, sublingual, transdermal, spray, IV) due to potentiation of hypotensive effects, leading to a profound and potentially fatal drop in blood pressure. ♦ Alpha-Blockers: Use with caution, as concomitant use can lead to symptomatic hypotension. Start sildenafil at the lowest dose and ensure patient is stable on alpha-blocker therapy. ♦ Cardiovascular Risk: Patients should have their cardiovascular status assessed before initiating sildenafil for ED, as there is a degree of cardiac risk associated with sexual activity. Use with caution in patients with pre-existing cardiovascular disease. ♦ Priapism: Rare but serious adverse effect; prolonged erection (more than 4 hours) or painful erection (more than 6 hours) requires immediate medical attention to avoid permanent damage. ♦ Non-Arteritic Anterior Ischemic Optic Neuropathy (NAION): Rare but serious eye condition leading to sudden decrease or loss of vision. Risk factors include underlying cardiovascular disease, diabetes, hypertension, and smoking. Advise patients to seek immediate medical attention if sudden vision loss occurs. ♦ Sudden Hearing Loss: Rare reports of sudden decrease or loss of hearing, sometimes with tinnitus and dizziness. Seek immediate medical attention. ♦ Renal/Hepatic Impairment: Use with caution and consider dose adjustment in patients with severe renal or hepatic impairment. ♦ Concomitant use with other PDE5 Inhibitors or ED treatments: Not recommended. ♦ Bleeding Disorders/Active Peptic Ulceration: Use with caution due to antiplatelet effects. ♦ Anatomical Deformation of the Penis: Use with caution in patients with Peyronie's disease or other anatomical deformities, or conditions predisposing to priapism (e.g., sickle cell anemia, multiple myeloma, leukemia).
Missed Dose Instructions	For erectile dysfunction: Sildenafil is taken on an as-needed basis before sexual activity. If a planned dose is missed, simply take it when ready for sexual activity, ensuring not to exceed one dose per 24 hours. For pulmonary arterial hypertension (PAH): If a dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent dosing is important for PAH management.
Overdose Instructions	Overdose symptoms are typically an exaggeration of common side effects, including severe headache, flushing, dizziness, dyspepsia, and nasal congestion. Hypotension may be more pronounced. There is no specific antidote for sildenafil overdose. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Monitor blood pressure and cardiac status. Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Nitrates (e.g., nitroglycerin, isosorbide dinitrate, amyl nitrite/poppers): STRICTLY CONTRAINDICATED due to dangerous potentiation of hypotensive effects. ♦ Guanylate Cyclase Stimulators (e.g., riociguat): Contraindicated due to risk of severe hypotension. ♦ Alpha-Blockers (e.g., doxazosin, tamsulosin, alfuzosin): Concomitant use can cause symptomatic hypotension. Initiate sildenafil at the lowest dose and only in hemodynamically stable patients on alpha-blocker. ♦ CYP3A4 Inhibitors (e.g., ketoconazole, itraconazole, erythromycin, clarithromycin, cimetidine, ritonavir, other protease inhibitors, grapefruit juice): Significantly increase sildenafil plasma levels, leading to increased side effects. Lower starting doses of sildenafil may be required. ♦ CYP3A4 Inducers (e.g., rifampin, carbamazepine, phenytoin, phenobarbital, St. John's Wort): Can decrease sildenafil plasma levels, reducing efficacy. ♦ Other PDE5 Inhibitors (e.g., tadalafil, vardenafil, avanafil): Concomitant use is generally not recommended due to increased risk of adverse effects. ♦ Alcohol: Excessive alcohol consumption can impair erectile function and potentially increase the risk of orthostatic hypotension with sildenafil.

Silver Sulfadiazine (Silvadene)

Purpose/Indication	Silver sulfadiazine is a topical antimicrobial agent primarily used for the prevention and treatment of wound infections in patients with second- and third-degree burns. Its purpose is to reduce the bacterial load in burn wounds, thereby preventing sepsis and facilitating wound healing. It is effective against a broad spectrum of Gram-positive and Gram-negative bacteria, as well as some fungi, commonly found in burn wounds.
Method of Action	Silver sulfadiazine exerts its antimicrobial action through a dual mechanism involving both the silver ion (Ag^+) and the sulfadiazine component. The silver component is released slowly from the cream and acts on the bacterial cell wall and membrane, disrupting its integrity, impairing cellular respiration, and interfering with bacterial DNA and RNA. The sulfadiazine component, a sulfonamide antibiotic, inhibits bacterial dihydrofolate reductase, an enzyme essential for bacterial folic acid synthesis, thereby inhibiting bacterial growth. This dual action provides broad-spectrum coverage and helps prevent resistance.
Medication Name & Brand Names	♦ Medication Name: Silver Sulfadiazine ♦ Brand Names: Silvadene, SSD Cream, Thermazene, Silver Sulfadiazine (generic)
Pharmaceutical Forms & Appearance	Silver sulfadiazine is available as a topical cream. It is typically a white, smooth, hydrophilic cream.
Dosage & Administration	Silver sulfadiazine cream is typically applied topically to the affected areas once or twice daily, to a thickness of approximately 1-2 mm. The burn wound should be cleaned and debrided prior to application. The cream should be applied with a sterile gloved hand. The burned area should be continuously covered with cream; if removed by activity, reapply. Dressings are generally not required but may be used. Treatment is continued until satisfactory healing occurs or the burn site is ready for grafting.

Supplied As	Silver sulfadiazine is supplied as: topical cream (e.g., 1% silver sulfadiazine, in various tube or jar sizes like 20 g, 50 g, 400 g).
Contraindications	Silver sulfadiazine is contraindicated in patients with known hypersensitivity to silver sulfadiazine, other sulfonamides, or any component of the formulation. It is also contraindicated in premature and full-term infants less than 2 months of age due to the risk of kernicterus (a form of brain damage). Use is generally not recommended in pregnant women near term, or breastfeeding mothers of infants less than 2 months old, due to the risk of kernicterus in the infant.
Storage & Expiry	Silver sulfadiazine cream should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and excessive heat. Keep the tube or jar tightly closed. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally local and include transient pain or burning sensation upon application, itching, and rash. Discoloration of the skin (argyria, a permanent grayish-blue discoloration) can occur with prolonged or extensive use. Systemic absorption can lead to sulfonamide-related systemic side effects, though less common with topical use, such as leukopenia (low white blood cell count), allergic reactions (e.g., rash, fever), methemoglobinemia, and rarely, renal dysfunction or hepatic dysfunction.
Warnings & Precautions	♦ Systemic Absorption & Sulfonamide-Related Effects: Although topical, significant systemic absorption of sulfadiazine can occur, especially with extensive burn areas or prolonged use. This can lead to sulfonamide-related systemic adverse reactions, including: ♦ Hematologic Reactions: Leukopenia (neutropenia) is the most common, usually self-limiting. Agranulocytosis, aplastic anemia, and hemolytic anemia (especially in G6PD deficiency) can occur. Monitor blood counts, particularly in large burns or prolonged use. ♦ Renal Impairment: Use with caution in patients with renal impairment, as sulfadiazine is primarily excreted renally. Crystalluria or renal tubular necrosis may occur. ♦ Hepatic Impairment: Use with caution in patients with hepatic impairment. ♦ Hypersensitivity Reactions: Allergic reactions, including severe dermatologic reactions (e.g., Stevens-Johnson Syndrome, toxic epidermal necrolysis), can occur. Discontinue at first sign of rash. ♦ G6PD Deficiency: Use with extreme caution in patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency due to the risk of hemolytic anemia. ♦ Kernicterus: Contraindicated in infants less than 2 months of age due to the risk of kernicterus from displacement of bilirubin. ♦ Porphyria: Sulfonamides may precipitate an acute attack of porphyria. ♦ Discoloration (Argyria): Prolonged or extensive use may lead to a permanent grayish-blue discoloration of the skin due to silver deposition. ♦ Not for Eye Use: Do not apply to the eyes.
Missed Dose Instructions	Silver sulfadiazine is typically applied on a continuous basis for burn wounds. If a scheduled application is missed, apply it as soon as remembered. Then, resume the regular application schedule (e.g., once or twice daily). It is important to maintain continuous coverage of the burn wound to prevent bacterial proliferation. Do not apply a double amount to make up for a missed dose.
Overdose Instructions	Overdose with topical silver sulfadiazine is primarily associated with excessive systemic absorption of the sulfadiazine component, particularly with large burn areas or prolonged use. Symptoms of systemic toxicity may include nausea, vomiting, diarrhea, crystalluria, renal dysfunction, hepatic dysfunction, and hematologic abnormalities (e.g., leukopenia, thrombocytopenia). Permanent skin discoloration (argyria) can result from prolonged, extensive use. Treatment is supportive and symptomatic. Discontinue the cream. Maintain hydration to prevent crystalluria. Monitor renal function, liver function, and blood counts. Forced diuresis may be considered. There is no specific antidote. Seek medical attention if systemic signs of overdose occur.
Medicine Interactions	♦ Enzymatic Debriding Agents (e.g., collagenase, papain-urea): Silver can inactivate some enzymatic debriding agents. Avoid concomitant use, or ensure adequate removal of silver sulfadiazine before applying enzymatic debridement. ♦ Cimetidine: Concomitant systemic cimetidine may increase the risk of leukopenia/neutropenia when used with silver sulfadiazine. Monitor white blood cell count. ♦ Systemic Sulfonamides: Additive risk of sulfonamide-related systemic adverse effects (e.g., hematologic, renal, allergic reactions) if significant systemic absorption occurs from silver sulfadiazine. ♦ Oral Hypoglycemics (sulfonylureas) and Anticoagulants (warfarin): Theoretically, absorbed sulfadiazine could potentiate the effects of these agents, similar to systemic sulfonamides. Monitor blood glucose and INR if extensive application is used in patients on these medications.

Simvastatin (Zocor)

Purpose/Indication	Simvastatin is an HMG-CoA reductase inhibitor, commonly known as a statin, used to lower elevated cholesterol levels and reduce the risk of cardiovascular disease. It is indicated for treating primary hypercholesterolemia, mixed dyslipidemia, homozygous familial hypercholesterolemia (as an adjunct to other lipid-lowering treatments), and for slowing the progression of atherosclerosis. It also significantly reduces the risk of major cardiovascular events (coronary death, nonfatal myocardial infarction, stroke, revascularization procedures) in patients with coronary heart disease or at high risk for it.
Method of Action	Simvastatin is a prodrug that is converted in the liver to its active beta-hydroxyacid form. This active metabolite competitively inhibits 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase, an enzyme essential for cholesterol synthesis in the liver. By blocking this rate-limiting step, simvastatin reduces the production of cholesterol. This leads to an upregulation of LDL receptors on the surface of liver cells, which increases the uptake and catabolism of LDL (low-density lipoprotein) cholesterol from the bloodstream, thereby lowering total cholesterol, LDL-C, and triglycerides, and increasing HDL-C (high-density lipoprotein cholesterol).
Medication Name & Brand Names	♦ Medication Name: Simvastatin ♦ Brand Names: Zocor, Lipex (regional), Simvastatin (generic)
Pharmaceutical Forms & Appearance	Simvastatin is available as oral film-coated tablets. Tablets are typically round or oval, film-coated, and may vary in color and imprint depending on strength (e.g., peach, light brown, tan). They often have specific imprints indicating strength and/or a company logo.
Dosage & Administration	Dosage is highly individualized and depends on the patient's cholesterol levels, cardiovascular risk, and response to therapy. Initial adult doses typically range from 10 mg to 20 mg orally once daily, usually in the evening, as cholesterol synthesis is highest at night. Doses can be adjusted after 4 weeks, up to a maximum of 40 mg once daily. For certain high-risk patients, the 40 mg dose may be used. The 80 mg dose is generally reserved for patients who have been on 80 mg for a year or more without myopathy, or where benefits outweigh risks. Take with or without food. Continue a cholesterol-lowering diet throughout treatment.
Supplied As	Simvastatin is supplied as: oral film-coated tablets (e.g., 5 mg, 10 mg, 20 mg, 40 mg, 80 mg).
Contraindications	Simvastatin is contraindicated in patients with known hypersensitivity to simvastatin or any component of the formulation. It is strictly contraindicated in patients with active liver disease, including unexplained persistent elevations of serum transaminases. It is also contraindicated in pregnancy and lactation due to the potential for fetal harm. Concomitant use with strong CYP3A4 inhibitors (e.g., azole antifungals, macrolide antibiotics, HIV protease inhibitors) and grapefruit juice is contraindicated due to increased risk of myopathy.
Storage & Expiry	Simvastatin tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in the original tightly closed container. Always check the specific expiry date on the packaging.

Side Effects	Common side effects are generally mild and include headache, muscle pain (myalgia), abdominal pain, constipation, and nausea. More serious but rare side effects include myopathy (muscle disease) and rhabdomyolysis (severe muscle breakdown, potentially leading to kidney failure), liver dysfunction (elevated liver enzymes), and new-onset diabetes mellitus. Allergic reactions, peripheral neuropathy, and memory impairment can also occur.
Warnings & Precautions	♦ BLACK BOX WARNING (in some regions/products): Myopathy/Rhabdomyolysis: Statins, including simvastatin, can cause myopathy and rhabdomyolysis, which can be severe and lead to acute renal failure. Risk factors include higher doses (especially 80 mg), advanced age, renal impairment, hypothyroidism, and concomitant use of certain interacting drugs (see interactions). Advise patients to report unexplained muscle pain, tenderness, or weakness, especially if accompanied by malaise or fever. Creatine kinase (CK) levels should be monitored if muscle symptoms occur. Discontinue if CK levels are markedly elevated or rhabdomyolysis is diagnosed. ♦ Liver Dysfunction: Can cause elevations in serum transaminases. Liver function tests (LFTs) should be performed before initiating therapy and as clinically indicated thereafter. Discontinue if persistent elevations occur. Use with caution in patients who consume substantial quantities of alcohol or have a history of liver disease. ♦ Diabetes Mellitus: Statins may increase HbA1c and fasting serum glucose levels. Monitor blood glucose in patients at risk for diabetes. ♦ Renal Impairment: Use with caution, as accumulation may occur. The 80 mg dose is generally not recommended in patients with renal impairment. ♦ Hypothyroidism: Must be adequately treated before initiating simvastatin, as untreated hypothyroidism increases the risk of myopathy. ♦ Pregnancy & Lactation: Contraindicated in pregnancy and lactation due to potential harm to the fetus/infant. ♦ Neurocognitive Effects: Rare reports of cognitive impairment (e.g., memory loss, confusion) have been associated with statin use. Symptoms are generally reversible upon discontinuation. ♦ Interactions with strong CYP3A4 inhibitors (e.g., grapefruit juice, certain antibiotics/antifungals/HIV drugs): Concomitant use is contraindicated due to a significantly increased risk of myopathy/rhabdomyolysis.
Missed Dose Instructions	If a dose of Simvastatin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for effective cholesterol management and cardiovascular risk reduction.
Overdose Instructions	There is no specific treatment for simvastatin overdose. Overdose symptoms are generally an exaggeration of known side effects, particularly muscle pain, gastrointestinal upset, and liver enzyme elevations. In severe cases, rhabdomyolysis with acute renal failure could occur. Treatment is supportive and symptomatic. Hemodialysis is not expected to be beneficial due to extensive protein binding. Monitor liver function and CK levels. Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Strong CYP3A4 inhibitors (e.g., itraconazole, ketoconazole, posaconazole, voriconazole, erythromycin, clarithromycin, telithromycin, HIV protease inhibitors like nelfinavir, ritonavir, boceprevir, telaprevir, cobicistat-containing products): STRICTLY CONTRAINDICATED due to significantly increased simvastatin exposure and greatly increased risk of myopathy/rhabdomyolysis. ♦ Gemfibrozil & other Fibrates (e.g., fenofibrate): Increased risk of myopathy/rhabdomyolysis. Avoid concomitant use with gemfibrozil. Use with caution and monitor with other fibrates. ♦ Niacin (Lipid-lowering doses, ≥1 g/day): Increased risk of muscle adverse events (myopathy/rhabdomyolysis). Avoid doses of simvastatin >10 mg daily with lipid-modifying doses of niacin. ♦ Colchicine: Cases of myopathy/rhabdomyolysis have been reported with co-administration. Use with caution. ♦ Amiodarone, Amlodipine, Ranolazine, Diltiazem, Verapamil: These drugs can increase simvastatin exposure, increasing the risk of myopathy. Dose limitations for simvastatin may apply (e.g., not exceeding 20 mg or 40 mg daily with these drugs). Consult specific guidelines. ♦ Grapefruit Juice: Contraindicated with simvastatin, as it is a strong CYP3A4 inhibitor and significantly increases simvastatin exposure, raising the risk of myopathy/rhabdomyolysis. ♦ Coumarin Anticoagulants (e.g., warfarin): Simvastatin can potentiate the anticoagulant effect of warfarin, increasing bleeding risk. Monitor INR closely, especially when initiating or discontinuing simvastatin. ♦ Cyclosporine: Concomitant use greatly increases simvastatin exposure and risk of myopathy/rhabdomyolysis. Avoid simvastatin with cyclosporine. ♦ Daptomycin: Cases of myopathy/rhabdomyolysis

Sitagliptin (Januvia)

Purpose/Indication	Sitagliptin is an oral antihyperglycemic agent from the dipeptidyl peptidase-4 (DPP-4) inhibitor class, used to improve glycemic control in adults with type 2 diabetes mellitus. It is used as an adjunct to diet and exercise, either as monotherapy or in combination with other antidiabetic medications (e.g., metformin, sulfonylureas, thiazolidinediones, insulin) when those agents alone do not provide adequate blood glucose control.
Method of Action	Sitagliptin works by selectively inhibiting the enzyme dipeptidyl peptidase-4 (DPP-4). DPP-4 is responsible for the rapid degradation of incretin hormones, primarily glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP). By inhibiting DPP-4, sitagliptin increases the levels of active incretin hormones in the body. These elevated incretin levels enhance glucose-dependent insulin release from pancreatic beta cells and decrease glucagon secretion from pancreatic alpha cells, especially during hyperglycemia, leading to improved blood glucose control.
Medication Name & Brand Names	♦ Medication Name: Sitagliptin ♦ Brand Names: Januvia, Tesavel (regional), Sitagliptin (generic) ♦ Combination Products: Janumet (sitagliptin/metformin), Janumet XR (sitagliptin/metformin extended-release), Eucreas (sitagliptin/vildagliptin - regional), Combinational products (e.g., with pioglitazone or dapagliflozin - regional)
Pharmaceutical Forms & Appearance	Sitagliptin is available as oral film-coated tablets. Tablets are typically round, film-coated, and may vary in color depending on the strength, with specific imprints indicating the dose or manufacturer (e.g., 100 mg tablets are typically beige-orange, 50 mg light beige, 25 mg light pink).
Dosage & Administration	The typical adult oral dosage for type 2 diabetes mellitus is 100 mg once daily. It can be taken with or without food. For patients with moderate or severe renal impairment, or end-stage renal disease (ESRD) requiring hemodialysis or peritoneal dialysis, the dose must be adjusted (e.g., 50 mg daily for moderate impairment, 25 mg daily for severe impairment/ESRD).
Supplied As	Sitagliptin is supplied as: oral film-coated tablets (e.g., 25 mg, 50 mg, 100 mg).
Contraindications	Sitagliptin is contraindicated in patients with known hypersensitivity to sitagliptin or any component of the formulation. It should not be used in patients with type 1 diabetes mellitus or for the treatment of diabetic ketoacidosis.
Storage & Expiry	Sitagliptin tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in the original tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and include upper respiratory tract infection, nasopharyngitis, headache, and rarely, hypoglycemia (especially when used with sulfonylureas or insulin). More serious but rare side effects include pancreatitis (sometimes fatal), severe hypersensitivity reactions (anaphylaxis, angioedema, Stevens-Johnson Syndrome), bullous pemphigoid, and joint pain.

Warnings & Precautions	♦ Pancreatitis: Postmarketing reports of acute pancreatitis, including fatal and non-fatal hemorrhagic or necrotizing pancreatitis. If pancreatitis is suspected (e.g., persistent severe abdominal pain, radiating to the back, with or without vomiting), discontinue sitagliptin and other potentially causative agents. ♦ Hypersensitivity Reactions: Serious hypersensitivity reactions, including anaphylaxis, angioedema, and exfoliative skin conditions (e.g., Stevens-Johnson Syndrome), have been reported. If such reactions occur, discontinue sitagliptin and initiate appropriate treatment. ♦ Joint Pain (Arthralgia): Severe and disabling arthralgia has been reported. Consider sitagliptin as a possible cause and discontinue if appropriate. ♦ Bullous Pemphigoid: Postmarketing cases of bullous pemphigoid requiring hospitalization have been reported. If bullous pemphigoid is suspected, discontinue sitagliptin. ♦ Renal Impairment: Dose adjustments are necessary for patients with moderate to severe renal impairment and end-stage renal disease. Renal function should be assessed prior to initiation and periodically thereafter. ♦ Heart Failure: Some post-marketing reports suggest an increased risk of heart failure hospitalization with other DPP-4 inhibitors in certain patient populations; however, sitagliptin's cardiovascular safety data has generally been favorable. Use with caution in patients with a history of heart failure. ♦ Hypoglycemia: When used in combination with a sulfonylurea or insulin, the risk of hypoglycemia is increased. A lower dose of the sulfonylurea or insulin may be required. ♦ Type 1 Diabetes/Diabetic Ketoacidosis: Not effective in these conditions; do not use.
Missed Dose Instructions	If a dose of Sitagliptin is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for maintaining glycemic control.
Overdose Instructions	In clinical trials, single doses of up to 800 mg and multiple doses of up to 600 mg/day for 10 days were well-tolerated. The most common adverse event in overdose was mild gastrointestinal discomfort. There is no specific antidote for sitagliptin overdose. Treatment is supportive and symptomatic. Sitagliptin is modestly dialyzable (approximately 13.5% removed over 3-4 hours of dialysis). Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Digoxin: Sitagliptin can cause a slight increase in digoxin levels, but this is generally not considered clinically significant and dose adjustment of digoxin is usually not required. However, monitor digoxin levels if co-administered. ♦ Cyclosporine: Concomitant use with cyclosporine (a potent P-glycoprotein inhibitor) slightly increases sitagliptin exposure, but this is not considered clinically significant and no dose adjustment for sitagliptin is needed. ♦ Metformin, Sulfonylureas, Thiazolidinediones, Insulin: Sitagliptin is often used in combination with these agents, and while it generally does not cause hypoglycemia as monotherapy, the risk of hypoglycemia increases when combined with sulfonylureas or insulin. Dose adjustments of the sulfonylurea or insulin may be necessary. ♦ Other Antidiabetic Agents: No significant pharmacokinetic interactions with most other commonly used antidiabetic medications. ♦ No significant interaction with strong CYP3A4 inhibitors or inducers. Sitagliptin is primarily eliminated renally with minimal metabolism.

Spinosad (Natroba)

Purpose/Indication	Spinosad is a topical pediculicide used for the treatment of head lice infestations in individuals 6 months of age and older. It is an effective treatment for eliminating both lice and nits (lice eggs). Its unique mechanism of action makes it a valuable option, particularly in cases of resistance to other common pediculicides.
Method of Action	Spinosad is a naturally derived insecticidal agent that works by causing hyperexcitation of the insect's nervous system. It achieves this by activating nicotinic acetylcholine receptors and affecting gamma-aminobutyric acid (GABA) gated chloride channels in the insect, leading to involuntary muscle contractions, tremors, and ultimately paralysis and death of the lice. It is ovicidal (kills nits) as well as lousicidal (kills lice).
Medication Name & Brand Names	♦ Medication Name: Spinosad ♦ Brand Names: Natroba, Spinosad (generic)
Pharmaceutical Forms & Appearance	Spinosad is available as a topical suspension for external use. It is typically a white to off-white, slightly viscous liquid.
Dosage & Administration	For the treatment of head lice, apply enough spinosad topical suspension to cover dry scalp and hair. Typically, this means applying to scalp first, then working it through the hair to ensure all hair is saturated. Leave on for 10 minutes, then rinse thoroughly with warm water. Repeat treatment may be needed if live lice are seen 7 days after the first application; however, a second treatment is generally not required for most individuals. Only for topical use.
Supplied As	Spinosad is supplied as: topical suspension (e.g., 0.9% spinosad, in bottles containing 118 mL).
Contraindications	Spinosad is contraindicated in infants younger than 6 months of age. This is due to its benzyl alcohol content, which has been associated with serious adverse reactions, including "gasping syndrome," in neonates and low birth weight infants. It is also contraindicated in patients with known hypersensitivity to spinosad or any component of the formulation.
Storage & Expiry	Spinosad topical suspension should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and excessive heat. Do not freeze. Keep the bottle tightly closed. Always check the specific expiry date on the packaging.
Side Effects	Common side effects are generally mild and local, including application site irritation, redness, dryness, or itching of the scalp. Eye irritation can occur if the product gets into the eyes.
Warnings & Precautions	♦ Not for Oral, Ophthalmic, or Intravaginal Use: Spinosad topical suspension is for external use on hair and scalp only. Avoid contact with eyes, mouth, nose, and other mucous membranes. Rinse thoroughly with water if contact occurs. ♦ Benzyl Alcohol Content: Contains benzyl alcohol. While systemic absorption is minimal with typical use, it is contraindicated in infants less than 6 months of age due to the risk of "gasping syndrome." Use with caution in older children and adults with impaired skin barrier or extensive application. ♦ Skin Irritation: May cause local irritation. If irritation persists or worsens, discontinue use and consult a healthcare professional. ♦ Flammability: Spinosad is flammable. Keep away from heat and open flame. ♦ Resistance: As with all pediculicides, resistance can develop over time. If the infestation persists after a second treatment, consider alternative therapies. ♦ Allergic Reactions: Rare hypersensitivity reactions may occur.
Missed Dose Instructions	Spinosad is typically a single-application treatment. If a second application is deemed necessary (e.g., if live lice are still observed 7 days after the first treatment), ensure it is applied as instructed. There isn't a "missed dose" concept as it's not a regularly scheduled medication.
Overdose Instructions	Overdose with topical spinosad is unlikely with normal use due to minimal systemic absorption. Ingesting the product could lead to gastrointestinal upset. There is no specific antidote. Treatment would be supportive and symptomatic. If swallowed, contact a poison control center or seek medical attention. If excessive topical application leads to significant skin irritation, wash the area thoroughly.

Medicine Interactions	♦ No significant drug interactions are known or expected with topical spinosad due to its minimal systemic absorption. Systemic interactions are unlikely.

Streptomycin (Streptomycin Sulfate)

Purpose/Indication	Streptomycin is an aminoglycoside antibiotic primarily used in multi-drug regimens for the treatment of severe bacterial infections, particularly tuberculosis (TB), especially in cases of multidrug-resistant TB (MDR-TB) or severe forms of the disease. It is also indicated for certain non-tubercular infections such as plague, tularemia, brucellosis, and bacterial endocarditis (in combination with penicillin or vancomycin), when other less toxic agents are ineffective or contraindicated. Its use is generally limited due to its toxicity profile.
Method of Action	Streptomycin exerts its bactericidal effect by irreversibly binding to the 30S ribosomal subunit of susceptible bacteria. This binding interferes with the initiation complex of protein synthesis, causes misreading of the mRNA template during translation, and prematurely terminates polypeptide chain elongation. This disruption of protein synthesis leads to the production of non-functional proteins and ultimately bacterial cell death. Its action is concentration-dependent.
Medication Name & Brand Names	♦ Medication Name: Streptomycin Sulfate ♦ Brand Names: Streptomycin (generic)
Pharmaceutical Forms & Appearance	Streptomycin is primarily available as a powder for injection, which is reconstituted to form a solution for intramuscular (IM) or intravenous (IV) administration. The powder is typically white to off-white, and the reconstituted solution is clear and colorless to pale yellow. It is not available in oral form as it is poorly absorbed from the gastrointestinal tract.
Dosage & Administration	Dosage is individualized based on the patient's weight, renal function, severity of infection, and specific indication. For tuberculosis, typical adult doses are 15 mg/kg (up to 1 gram) administered intramuscularly or intravenously once daily or 2-3 times weekly, as part of a multi-drug regimen. Dosing frequency and duration are adjusted for renal impairment. It must be administered by a healthcare professional.
Supplied As	Streptomycin is supplied as: sterile powder for injection (e.g., 1 gram or 5 grams per vial).
Contraindications	Streptomycin is strictly contraindicated in patients with known hypersensitivity to streptomycin or any other aminoglycoside antibiotic. It is also contraindicated in patients with myasthenia gravis or other conditions that impair neuromuscular transmission due to the risk of exacerbating muscle weakness and respiratory depression. Use in pregnant women is contraindicated due to the risk of fetal ototoxicity.
Storage & Expiry	Streptomycin powder for injection should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light. Once reconstituted, the solution should be used promptly (e.g., within 24 hours), or stored refrigerated for a short period (check specific product information). Always check the specific expiry date on the packaging.
Side Effects	The most significant and common serious side effects are ototoxicity (damage to hearing and/or balance, which can be irreversible) and nephrotoxicity (kidney damage). Ototoxicity manifests as tinnitus, vertigo, dizziness, and hearing loss. Other side effects include local pain at the injection site, rash, fever, and neuromuscular blockade leading to respiratory depression.
Warnings & Precautions	♦ BLACK BOX WARNINGS: Neurotoxicity (Ototoxicity & Vestibulotoxicity): Streptomycin can cause irreversible vestibular damage (dizziness, vertigo, ataxia) and auditory damage (hearing loss). The risk is dose-related and increased with prolonged use, higher doses, concomitant ototoxic drugs, and renal impairment. Audiometric and vestibular function tests should be performed before and periodically during therapy. ♦ BLACK BOX WARNINGS: Nephrotoxicity: Can cause acute tubular necrosis, leading to renal impairment. The risk is increased with pre-existing renal dysfunction, higher doses, prolonged therapy, and concomitant nephrotoxic drugs. Monitor renal function (serum creatinine, BUN) frequently. ♦ Neuromuscular Blockade & Respiratory Depression: Can cause neuromuscular blockade and respiratory paralysis, especially in patients with pre-existing neuromuscular disorders (e.g., myasthenia gravis, Parkinsonism), those receiving neuromuscular blocking agents, or those receiving large, rapid intravenous doses. Have calcium salts (e.g., calcium gluconate) available for emergency reversal. ♦ Fetal Harm: Contraindicated in pregnancy due to risk of congenital deafness in the fetus. ♦ Hypersensitivity Reactions: Allergic reactions can occur, ranging from rash to anaphylaxis. ♦ Renal Impairment: Dose adjustment is mandatory for patients with impaired renal function to prevent accumulation and increased toxicity. ♦ Concurrent Use with other Aminoglycosides or Nephrotoxic/Ototoxic Drugs: Avoid or use with extreme caution due to additive toxicity. ♦ Optic Nerve Toxicity: Rare reports of optic nerve damage
Missed Dose Instructions	Streptomycin is administered by a healthcare professional, typically in a hospital or clinic setting, due to its administration route and toxicity profile. Strict adherence to the prescribed dosing schedule is critical for efficacy and to minimize the development of drug resistance, particularly in TB treatment. If a dose is missed, it should be reported immediately to the prescribing healthcare professional, who will determine the appropriate course of action, possibly rescheduling the dose or adjusting the regimen.
Overdose Instructions	Overdose symptoms are primarily severe neurotoxicity (profound ototoxicity, vestibular dysfunction, neuromuscular blockade leading to respiratory paralysis) and severe nephrotoxicity (acute renal failure). Other symptoms may include nausea, vomiting, rash, and paresthesias. There is no specific antidote for streptomycin. Treatment is supportive and symptomatic. Hemodialysis or peritoneal dialysis can aid in the removal of streptomycin from the blood. Calcium salts (e.g., calcium gluconate) may be administered for neuromuscular blockade. Mechanical ventilation may be required for respiratory depression. Seek immediate emergency medical help.
Medicine Interactions	♦ Other Ototoxic Drugs (e.g., loop diuretics like furosemide, ethacrynic acid; cisplatin; vancomycin): Concomitant use significantly increases the risk of ototoxicity. Avoid or use with extreme caution. ♦ Other Nephrotoxic Drugs (e.g., cyclosporine, amphotericin B, NSAIDs, platinum compounds like cisplatin, other aminoglycosides): Concomitant use significantly increases the risk of nephrotoxicity. Avoid or use with extreme caution. ♦ Neuromuscular Blocking Agents (e.g., succinylcholine, rocuronium, vecuronium): Streptomycin can potentiate and prolong the neuromuscular blocking effects, leading to profound respiratory depression or paralysis. Use with extreme caution. ♦ Polymyxins (e.g., polymyxin B, colistin): Increased risk of neuromuscular blockade and nephrotoxicity. ♦ Bisphosphonates (e.g., zoledronic acid): May increase the risk of hypocalcemia. ♦ Myasthenia Gravis Medications: Streptomycin can exacerbate muscle weakness in myasthenia gravis, potentially leading to respiratory crisis. ♦ Digoxin: Some anecdotal reports of reduced digoxin absorption, though generally not considered clinically significant.

Sumatriptan (Imitrex)

Purpose/Indication	Sumatriptan is a selective serotonin (5-HT1B/1D) receptor agonist, commonly known as a triptan, used for the acute treatment of migraine attacks with or without aura, and for the acute treatment of cluster headache. It is not indicated for the prophylactic (preventive) treatment of migraine or for the management of hemiplegic or basilar migraine. Its purpose is to relieve the pain and associated symptoms of migraine and cluster headache once they have started.

Method of Action	Sumatriptan's therapeutic effect is primarily attributed to its agonistic action on 5-HT1B and 5-HT1D serotonin receptors. This leads to three main actions: 1) Cranial Vasoconstriction: Selective constriction of intracranial blood vessels that are dilated during a migraine attack. 2) Inhibition of Neuropeptide Release: Reduces the release of pro-inflammatory neuropeptides (e.g., substance P, CGRP) from trigeminal nerve endings. 3) Inhibition of Pain Signal Transmission: Modulates pain signals transmitted through the trigeminal pathway. These combined actions help to reverse the physiological changes associated with migraine and cluster headache.
Medication Name & Brand Names	♦ Medication Name: Sumatriptan Succinate ♦ Brand Names: Imitrex, Imigran (regional), Sumatriptan (generic), Onzetra Xsail (nasal powder), Tosymra (nasal spray), Zembrace SymTouch (injection)
Pharmaceutical Forms & Appearance	Sumatriptan is available in various forms for acute administration: oral tablets, nasal spray, subcutaneous (SC) injection, and a nasal powder. Oral tablets are typically film-coated, often oblong, and vary in color and imprint. The nasal spray is a clear solution. The subcutaneous injection is a clear solution in prefilled syringes or auto-injectors. Nasal powder is a fine white to off-white powder.
Dosage & Administration	Dosage varies by form and individual response. For oral tablets, typical adult doses are 25 mg, 50 mg, or 100 mg taken at the first sign of migraine pain. A second dose can be taken after 2 hours if needed, not exceeding 200 mg in 24 hours. For subcutaneous injection, 6 mg is a common dose, which can be repeated once after 1 hour, not exceeding 12 mg in 24 hours. For nasal spray, 5 mg, 10 mg, or 20 mg in one nostril, which can be repeated after 2 hours, not exceeding 40 mg in 24 hours. Administer at the onset of headache, but not during the aura phase.
Supplied As	Sumatriptan is supplied as: oral tablets (e.g., 25 mg, 50 mg, 100 mg), nasal spray (e.g., 5 mg, 10 mg, 20 mg per spray device), subcutaneous injection (e.g., 6 mg/0.5 mL in vials, prefilled syringes, or auto-injectors), and nasal powder (e.g., 11 mg per single-dose device).
Contraindications	Sumatriptan is strictly contraindicated in patients with known hypersensitivity to sumatriptan or any component. It is contraindicated in patients with a history of ischemic heart disease (e.g., angina pectoris, myocardial infarction), Prinzmetal's angina, uncontrolled hypertension, or other significant cardiovascular disease. It is also contraindicated in patients with a history of stroke or transient ischemic attack (TIA), peripheral vascular disease, severe hepatic impairment, and in concurrent use with MAOIs (or within 2 weeks of stopping MAOIs), ergotamine-containing medications, or other 5-HT1 agonists (triptans).
Storage & Expiry	Sumatriptan tablets, nasal spray, and injections should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light. Keep in the original packaging. Do not freeze injections. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include sensations of tingling, warmth, flushing, dizziness, drowsiness, weakness, and pain/pressure/tightness in the chest, throat, or jaw (often non-cardiac). Injection site reactions are common with SC forms. Nausea and vomiting may also occur. More serious but less common side effects include coronary artery vasospasm (leading to angina or MI), stroke, serotonin syndrome, and severe hypersensitivity reactions.
Warnings & Precautions	♦ Cardiovascular Risk: Can cause coronary artery vasospasm, leading to myocardial ischemia and infarction, even in patients with no history of coronary artery disease (CAD). Contraindicated in patients with known or suspected CAD or uncontrolled hypertension. Perform cardiovascular evaluation prior to use in patients with risk factors for CAD. ♦ Cerebrovascular Events: Rare but serious cerebrovascular events (e.g., stroke, TIA) have been reported. ♦ Serotonin Syndrome: Potentially life-threatening condition that can occur with concomitant use of other serotonergic drugs (e.g., SSRIs, SNRIs, MAOIs - contraindicated, TCAs, tramadol, lithium). Symptoms include mental status changes, autonomic instability, neuromuscular aberrations, and GI symptoms. Seek immediate medical attention if suspected. ♦ Hypertension: Can cause significant increases in blood pressure, including hypertensive crisis. Monitor blood pressure. ♦ Drug Overuse Headache (MOH): Prolonged or frequent use of triptans for acute treatment can lead to medication overuse headache. Limit use to no more than 10 days per month. ♦ Vasospasm Risk: Caution in patients with Raynaud's phenomenon or other peripheral vascular diseases. ♦ Seizures: Use with caution in patients with a history of seizures or conditions that lower the seizure threshold. ♦ Hepatic Impairment: Use with caution and consider lower doses in patients with mild to moderate hepatic impairment. Contraindicated in severe hepatic impairment. ♦ Renal Impairment: No specific dose adjustment generally needed. ♦ Anaphylaxis: Rare but severe hypersensitivity reactions can occur. ♦ Driving/Operating Machinery: May cause drowsiness or dizziness; advise caution. ♦ Specific Formulations: Nasal spray/powder for unilateral nostril use. SC injection has fastest onset but higher incidence of injection site reactions and chest sensations.
Missed Dose Instructions	Sumatriptan is an acute treatment for migraine or cluster headache and is taken only when an attack occurs. There is no concept of a "missed dose" in a regular dosing schedule. If a dose was taken and the headache returns or symptoms are not fully relieved, a second dose may be taken after the recommended interval (e.g., 2 hours for oral, 1 hour for SC), provided the maximum daily dose is not exceeded. Do not take if symptoms are mild or if it is for prevention.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, including severe drowsiness, vomiting, dizziness, flushing, hypotension or hypertension, tachycardia, and potentially seizures or more severe cardiovascular events (e.g., vasospasm, MI). There is no specific antidote for sumatriptan. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Monitor cardiac and respiratory function closely. Provide oxygen if needed. Seek immediate emergency medical help.
Medicine Interactions	♦ MAOIs (Monoamine Oxidase Inhibitors, e.g., phenelzine, tranylcypromine, selegiline, linezolid, methylene blue): STRICTLY CONTRAINDICATED. Concomitant use or use within 14 days of stopping an MAOI can lead to severe serotonin syndrome and increased sumatriptan exposure. ♦ Ergot-containing Medications (e.g., ergotamine, dihydroergotamine): Concomitant use is CONTRAINDICATED due to additive vasoconstrictive effects, increasing the risk of vasospastic reactions. Do not use within 24 hours of each other. ♦ Other 5-HT1 Agonists/Triptans (e.g., zolmitriptan, rizatriptan): Concomitant use is CONTRAINDICATED due to additive vasoconstrictive effects and increased risk of adverse events. Do not use within 24 hours of each other. ♦ SSRIs (Selective Serotonin Reuptake Inhibitors, e.g., fluoxetine, sertraline) & SNRIs (Serotonin-Norepinephrine Reuptake Inhibitors, e.g., venlafaxine, duloxetine): Increased risk of serotonin syndrome. Use with caution; monitor for symptoms. ♦ Alcohol: May exacerbate CNS depressant effects. ♦ St. John's Wort: May increase the risk of serotonin syndrome. ♦ Cimetidine: May increase sumatriptan levels. ♦ Propoxyphene: May decrease sumatriptan clearance. ♦ Tobacco Smoking: May reduce overall exposure to sumatriptan.

Tadalafil (Cialis)

Purpose/Indication	Tadalafil is a phosphodiesterase-5 (PDE5) inhibitor primarily used for the treatment of erectile dysfunction (ED) in men, distinguished by its longer duration of action allowing for more spontaneity. It is also indicated for the treatment of benign prostatic hyperplasia (BPH) signs and symptoms, and for pulmonary arterial hypertension (PAH) to improve exercise capacity, marketed under different brand names and dosing.

MEDICATION | Medication | List | R - Z | Tadalafil (Cialis)

Method of Action	Tadalafil works by selectively inhibiting phosphodiesterase type 5 (PDE5), an enzyme concentrated in the corpus cavernosum of the penis, prostate, bladder, and pulmonary vasculature. In erectile dysfunction, sexual stimulation triggers nitric oxide (NO) release, activating guanylate cyclase and increasing cyclic guanosine monophosphate (cGMP) levels. cGMP leads to smooth muscle relaxation and increased blood flow for an erection. Tadalafil enhances this effect by preventing cGMP breakdown. In BPH, it relaxes smooth muscle in the prostate and bladder, improving urinary flow. In PAH, it causes vasodilation in the pulmonary arteries.
Medication Name & Brand Names	♦ Medication Name: Tadalafil ♦ Brand Names: Cialis (for ED/BPH), Adcirca (for PAH), Tadalafil (generic)
Pharmaceutical Forms & Appearance	Tadalafil is available as oral film-coated tablets. Cialis tablets are typically yellow, almond-shaped, and film-coated, with specific imprints indicating strength (e.g., "C" followed by the strength). Adcirca tablets are typically orange, oval, and film-coated.
Dosage & Administration	Dosage varies significantly by indication. For erectile dysfunction (ED), it can be taken as needed (e.g., 10 mg or 20 mg before sexual activity, effective for up to 36 hours), or as a daily dose (2.5 mg or 5 mg). For benign prostatic hyperplasia (BPH) or ED with BPH, the daily dose is typically 5 mg. For pulmonary arterial hypertension (PAH), the typical adult oral dose is 40 mg once daily. It can be taken with or without food. Do not take more than once daily for ED/BPH.
Supplied As	Tadalafil is supplied as: oral film-coated tablets (e.g., 2.5 mg, 5 mg, 10 mg, 20 mg, 40 mg).
Contraindications	Tadalafil is strictly contraindicated in patients taking nitrates (e.g., nitroglycerin, isosorbide dinitrate) in any form due to the risk of dangerous and potentially fatal hypotension. It is also contraindicated in patients with known hypersensitivity to tadalafil or any component of the formulation. Concomitant use with guanylate cyclase stimulators (e.g., riociguat) is also contraindicated.
Storage & Expiry	Tadalafil tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in the original tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include headache, dyspepsia (indigestion), back pain, muscle aches (myalgia), flushing, and nasal congestion. Back pain and myalgia are more common with tadalafil due to its longer half-life. More serious but rare side effects include priapism (prolonged erection lasting >4 hours), sudden decrease or loss of vision (NAION), sudden hearing loss, and cardiovascular events (MI, stroke, arrhythmias) in patients with pre-existing heart conditions.
Warnings & Precautions	♦ Nitrate Co-administration: STRICTLY CONTRAINDICATED with nitrates in any form (oral, sublingual, transdermal, spray, IV) due to potentiation of hypotensive effects, leading to a profound and potentially fatal drop in blood pressure. ♦ Alpha-Blockers: Use with caution, as concomitant use can lead to symptomatic hypotension. Start tadalafil at the lowest dose and ensure patient is stable on alpha-blocker therapy. ♦ Cardiovascular Risk: Patients should have their cardiovascular status assessed before initiating tadalafil, especially for ED, as there is a degree of cardiac risk associated with sexual activity. Use with caution in patients with pre-existing cardiovascular disease. ♦ Priapism: Rare but serious adverse effect; prolonged erection (more than 4 hours) or painful erection (more than 6 hours) requires immediate medical attention to avoid permanent damage. ♦ Non-Arteritic Anterior Ischemic Optic Neuropathy (NAION): Rare but serious eye condition leading to sudden decrease or loss of vision. Risk factors include underlying cardiovascular disease, diabetes, hypertension, and smoking. Advise patients to seek immediate medical attention if sudden vision loss occurs. ♦ Sudden Hearing Loss: Rare reports of sudden decrease or loss of hearing, sometimes with tinnitus and dizziness. Seek immediate medical attention. ♦ Renal/Hepatic Impairment: Use with caution and consider dose adjustment in patients with moderate to severe renal or hepatic impairment. Avoid in severe renal impairment if taking for PAH. ♦ Concomitant use with other PDE5 Inhibitors or ED treatments: Not recommended. ♦ Bleeding Disorders/Active Peptic Ulceration: Use with caution due to antiplatelet effects. ♦ Anatomical Deformation of the Penis: Use with caution in patients with Peyronie's disease or other anatomical deformities, or conditions predisposing to priapism (e.g., sickle cell anemia, multiple myeloma, leukemia).
Missed Dose Instructions	For as-needed ED dosing: Tadalafil is taken before anticipated sexual activity. If a planned dose is missed, simply take it when ready, ensuring not to exceed one dose within 24-36 hours depending on the prescribed frequency. For daily ED/BPH dosing: If a dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For PAH dosing: If a dose is missed, take it as soon as remembered, and then take the next dose at the regular time. Do not take a double dose.
Overdose Instructions	Overdose symptoms are typically an exaggeration of common side effects, including severe headache, dyspepsia, back pain, muscle aches, flushing, and nasal congestion. Hypotension may be more pronounced. There is no specific antidote for tadalafil overdose. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Monitor blood pressure and cardiac status. Hemodialysis is not expected to be effective. Seek immediate emergency medical help.
Medicine Interactions	♦ Nitrates (e.g., nitroglycerin, isosorbide dinitrate, amyl nitrite/poppers): STRICTLY CONTRAINDICATED due to dangerous potentiation of hypotensive effects. ♦ Guanylate Cyclase Stimulators (e.g., riociguat): Contraindicated due to risk of severe hypotension. ♦ Alpha-Blockers (e.g., doxazosin, tamsulosin, alfuzosin): Concomitant use can cause symptomatic hypotension. Initiate tadalafil at the lowest dose and only in hemodynamically stable patients on alpha-blocker. ♦ Strong CYP3A4 Inhibitors (e.g., ketoconazole, itraconazole, clarithromycin, erythromycin, saquinavir, ritonavir, other protease inhibitors, grapefruit juice): Significantly increase tadalafil plasma levels, leading to increased side effects. Lower starting doses or reduced frequency of tadalafil may be required. ♦ Strong CYP3A4 Inducers (e.g., rifampin, carbamazepine, phenytoin, phenobarbital): Can decrease tadalafil plasma levels, reducing efficacy. Avoid concomitant use. ♦ Antacids (containing magnesium hydroxide/aluminum hydroxide): May reduce the absorption rate of tadalafil. ♦ Other PDE5 Inhibitors (e.g., sildenafil, vardenafil, avanafil): Concomitant use is generally not recommended due to increased risk of adverse effects. ♦ Alcohol: Excessive alcohol consumption can increase the risk of orthostatic hypotension with tadalafil.

Telmisartan (Micardis)

Purpose/Indication	Telmisartan is an angiotensin II receptor blocker (ARB) primarily used for the treatment of hypertension (high blood pressure). It is also indicated to reduce the risk of myocardial infarction, stroke, or death from cardiovascular causes in patients 55 years of age or older at high risk (e.g., with coronary artery disease, peripheral arterial disease, history of stroke, or diabetes with end-organ damage). Its purpose is to lower blood pressure and provide cardiovascular protection.
Method of Action	Telmisartan works by selectively blocking the binding of angiotensin II to the angiotensin II type 1 (AT1) receptor in various tissues, including vascular smooth muscle and the adrenal gland. Angiotensin II is a potent vasoconstrictor and also stimulates aldosterone secretion, leading to sodium and water retention. By blocking AT1 receptors, telmisartan causes vasodilation, reduces aldosterone-mediated effects, and ultimately lowers blood pressure. It does not inhibit ACE, so it does not cause the dry cough associated with ACE inhibitors.
Medication Name & Brand Names	♦ Medication Name: Telmisartan ♦ Brand Names: Micardis, Telmisartan (generic) ♦ Combination Products: Micardis Plus (telmisartan/hydrochlorothiazide), Twynsta (telmisartan/amlodipine)

Pharmaceutical Forms & Appearance	Telmisartan is available as oral tablets. Tablets are typically oblong, biconvex, and may vary in color and imprint depending on strength (e.g., white, off-white, yellowish). They often have specific imprints indicating strength and/or a company logo.
Dosage & Administration	Dosage is individualized based on the patient's blood pressure response and renal function. For hypertension, the typical adult oral dose is 40 mg once daily. The dosage can be adjusted from 20 mg to 80 mg once daily. For cardiovascular risk reduction, the typical dose is 80 mg once daily. It can be taken with or without food. Maximum antihypertensive effect is generally achieved after 4-8 weeks of therapy.
Supplied As	Telmisartan is supplied as: oral tablets (e.g., 20 mg, 40 mg, 80 mg).
Contraindications	Telmisartan is contraindicated in patients with known hypersensitivity to telmisartan or any component of the formulation. It is strictly contraindicated in pregnancy due to the risk of fetal injury or death. Concomitant use with aliskiren is contraindicated in patients with diabetes mellitus or renal impairment (eGFR < 60 mL/min/1.73m2). It is also contraindicated in patients with biliary obstructive disorders or severe hepatic impairment.
Storage & Expiry	Telmisartan tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in the original tightly sealed blister packaging or container, as the tablets are sensitive to humidity. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include back pain, sinusitis, dizziness, and diarrhea. More serious but less common side effects include hypotension (low blood pressure), hyperkalemia (high potassium levels), renal impairment, and rarely, angioedema (swelling of the face, lips, tongue, throat), although less frequent than with ACE inhibitors.
Warnings & Precautions	♦ BLACK BOX WARNING: Fetal Toxicity: Use of drugs that act on the renin-angiotensin system during the second and third trimesters of pregnancy can cause injury and death to the developing fetus. Discontinue as soon as pregnancy is detected. ♦ Hypotension: May cause symptomatic hypotension, especially in volume-depleted patients (e.g., those on high-dose diuretics, dialysis) or severe heart failure. Initiate with low doses and monitor. ♦ Hyperkalemia: Can cause hyperkalemia, especially in patients with renal impairment, diabetes, or those taking potassium-sparing diuretics, potassium supplements, or other drugs that increase potassium. Monitor serum potassium closely. ♦ Renal Impairment: Can cause acute renal failure, particularly in patients with pre-existing renal insufficiency, severe congestive heart failure, or bilateral renal artery stenosis. Monitor renal function regularly. ♦ Dual Blockade of RAAS: Dual blockade of the renin-angiotensin-aldosterone system (RAAS) with ARBs, ACE inhibitors, or aliskiren is associated with increased risks of hypotension, hyperkalemia, and renal function changes; generally avoid. ♦ Hepatic Impairment: Use with caution in patients with mild to moderate hepatic impairment, as telmisartan is eliminated primarily by biliary excretion. Contraindicated in severe hepatic impairment or biliary obstructive disorders. ♦ Angioedema: Rare cases of angioedema have been reported. If laryngeal stridor or angioedema of the face, extremities, lips, tongue, glottis, or larynx occurs, discontinue telmisartan immediately. ♦ Aortic/Mitral Valve Stenosis or Hypertrophic Obstructive Cardiomyopathy: Use with caution.
Missed Dose Instructions	If a dose of Telmisartan is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for effective blood pressure control and cardiovascular protection.
Overdose Instructions	Overdose symptoms are primarily severe hypotension, dizziness, and tachycardia (rapid heart rate). Bradycardia (slow heart rate) may also occur. There is no specific antidote for telmisartan overdose. Treatment is supportive and symptomatic. Maintain fluid and electrolyte balance. If ingestion was recent, gastric lavage and activated charcoal may be considered. Lay the patient supine with legs elevated. IV fluid infusion and vasopressors may be needed for hypotension. Telmisartan is not removed by hemodialysis. Seek immediate emergency medical help.
Medicine Interactions	♦ Aliskiren: Contraindicated in patients with diabetes mellitus or renal impairment due to increased risk of hypotension, hyperkalemia, and renal impairment. ♦ Potassium-Sparing Diuretics (e.g., spironolactone, amiloride, triamterene) & Potassium Supplements: Significant risk of severe hyperkalemia. Avoid concomitant use or monitor potassium levels very closely. ♦ NSAIDs (Non-Steroidal Anti-inflammatory Drugs, including selective COX-2 inhibitors): May reduce the antihypertensive effect of ARBs and increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. Use with caution. ♦ Lithium: ARBs can reduce the renal clearance of lithium, leading to increased serum lithium levels and toxicity. Monitor lithium levels closely. ♦ Digoxin: Telmisartan can increase mean trough digoxin plasma concentrations. Monitor digoxin levels. ♦ Diuretics: Enhanced hypotensive effect, especially with the first dose. Consider withholding diuretics prior to initiating telmisartan. ♦ Ramipril (or other ACE inhibitors): Dual blockade of RAAS with an ARB and an ACE inhibitor is generally not recommended due to increased risk of adverse events. ♦ Metformin: No clinically significant interaction with telmisartan. ♦ Warfarin: No clinically significant interaction with telmisartan.

Temazepam (Restoril)

Purpose/Indication	Temazepam is a benzodiazepine medication primarily indicated for the short-term treatment of insomnia. It is used to help patients fall asleep and stay asleep for a sufficient duration, especially when insomnia is severe, debilitating, or causing extreme distress. Due to the risk of dependence and withdrawal, its use is generally limited to 7-10 consecutive nights.
Method of Action	Temazepam, like other benzodiazepines, works by enhancing the activity of gamma-aminobutyric acid (GABA), the primary inhibitory neurotransmitter in the brain. It binds specifically to benzodiazepine receptors on the GABA-A receptor complex, leading to an increased frequency of chloride channel opening. This influx of chloride ions hyperpolarizes the neuron, making it less excitable and resulting in central nervous system depression, which manifests as sedative, hypnotic, anxiolytic, anticonvulsant, and muscle relaxant effects.
Medication Name & Brand Names	♦ Medication Name: Temazepam ♦ Brand Names: Restoril, Temaze (regional), Normison (regional), Temazepam (generic)
Pharmaceutical Forms & Appearance	Temazepam is primarily available as oral capsules or tablets. Capsules are typically hard gelatin capsules, varying in color depending on the strength, and may have specific imprints. Tablets are usually round or oval and may also be imprinted.
Dosage & Administration	The typical adult oral dosage for insomnia is 7.5 mg to 30 mg, taken once daily at bedtime. The lowest effective dose should be used, especially in elderly or debilitated patients, to minimize the risk of oversedation and adverse effects. It should be taken immediately before going to bed, and only when the patient has sufficient time for a full night's sleep (7-8 hours) to minimize residual drowsiness the next morning. Its use should be short-term.
Supplied As	Temazepam is supplied as: oral capsules (e.g., 7.5 mg, 15 mg, 30 mg) or oral tablets (e.g., 10 mg, 20 mg - regional variations).
Contraindications	Temazepam is contraindicated in patients with known hypersensitivity to temazepam or any other benzodiazepine. It is also contraindicated in patients with severe respiratory insufficiency (e.g., severe COPD, sleep apnea) due to the risk of respiratory depression, or in patients with severe hepatic insufficiency. Concomitant use with opioids is a strong caution (see warnings).
Storage & Expiry	Temazepam capsules/tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers and keep out of reach of children. Always check the specific expiry date on the packaging.

Side Effects	Common side effects include drowsiness, dizziness, fatigue, headache, and impaired coordination. Residual sedation ("hangover" effect) can occur the next day. More serious but less common side effects include paradoxical reactions (e.g., agitation, hallucinations, aggression, disinhibition), anterograde amnesia, respiratory depression, and dependence/withdrawal symptoms upon discontinuation.
Warnings & Precautions	♦ CNS Depression & Impaired Alertness: Can cause profound sedation, dizziness, and impaired motor coordination, affecting ability to drive or operate machinery. Avoid activities requiring mental alertness. ♦ Concomitant Opioid Use: BLACK BOX WARNING (in some regions/products): Concomitant use of benzodiazepines and opioids may result in profound sedation, respiratory depression, coma, and death. Reserve concomitant prescribing for patients for whom alternative treatment options are inadequate. Limit dosages and durations. ♦ Abuse, Misuse, Addiction: Benzodiazepines carry a risk of abuse, misuse, and addiction, which can lead to overdose or death. The risk is increased with higher doses, longer duration of use, and in patients with a history of substance abuse. ♦ Dependence & Withdrawal: Can cause physical dependence. Abrupt discontinuation or rapid dose reduction, especially after prolonged use, can lead to severe withdrawal symptoms (e.g., seizures, tremors, anxiety, insomnia, delirium, hallucinations). Taper dose gradually when discontinuing. ♦ Respiratory Depression: Use with extreme caution in patients with respiratory compromise (e.g., COPD, sleep apnea) due to the risk of exacerbating respiratory depression. ♦ Anterograde Amnesia: Can cause dose-related anterograde amnesia (difficulty remembering events after drug administration). Patients should ensure they have 7-8 hours of uninterrupted sleep. ♦ Paradoxical Reactions: Rarely, benzodiazepines can cause paradoxical excitement, aggression, agitation, or hallucinations, particularly in elderly or psychiatric patients. Discontinue if these occur. ♦ Hepatic/Renal Impairment: Use with caution and consider dose reduction in patients with hepatic or severe renal impairment. ♦ Elderly Patients: Highly susceptible to CNS depressant effects; use lower starting doses and monitor closely to avoid falls and cognitive impairment. ♦ Depression/Suicidality: Use with caution in patients with depression; may be associated with increased risk of suicidal ideation. ♦ Complex Sleep Behaviors: Rarely reported, including "sleep-driving" or preparing food and eating while not fully awake, with no memory of the event.
Missed Dose Instructions	Temazepam is an as-needed medication for insomnia, taken right before bedtime. If a dose is missed (e.g., you forget to take it before going to sleep and wake up later), do not take it in the middle of the night or if you do not have a full 7-8 hours available for sleep before you need to be awake. Taking it too late can lead to next-day drowsiness and impaired function. Do not take a double dose.
Overdose Instructions	Overdose symptoms are typically central nervous system depression, ranging from somnolence to coma, with respiratory depression. Other symptoms may include confusion, impaired coordination, diminished reflexes, slurred speech, and hypotension. Severe consequences (coma, death) are more likely with co-ingestion of other CNS depressants, especially alcohol or opioids. There is a specific benzodiazepine receptor antagonist, flumazenil, which can reverse the sedative effects, but it should be used with caution due to the risk of seizures in patients dependent on benzodiazepines or those with mixed overdoses. Treatment is supportive and symptomatic, focusing on maintaining an open airway, ventilation, and cardiovascular support. Seek immediate emergency medical help.
Medicine Interactions	♦ Opioids (e.g., morphine, oxycodone, hydrocodone): BLACK BOX WARNING: Concomitant use significantly increases the risk of profound sedation, respiratory depression, coma, and death. Avoid concomitant use or limit dosages and durations if absolutely necessary. ♦ Other CNS Depressants (e.g., alcohol, other hypnotics, sedatives, antidepressants, antipsychotics, antihistamines, muscle relaxants, general anesthetics): Additive CNS depressant effects. Avoid or use with extreme caution. ♦ CYP450 Inhibitors (e.g., azole antifungals, macrolide antibiotics, HIV protease inhibitors, cimetidine, grapefruit juice): May inhibit the metabolism of temazepam (though temazepam is less prone to significant CYP interactions than some other benzodiazepines, primarily undergoing glucuronidation), potentially increasing its levels and effects. ♦ Phenytoin: May alter phenytoin levels. ♦ Theophylline/Aminophylline: May reduce the sedative effects of benzodiazepines. ♦ Disulfiram: May inhibit temazepam metabolism, leading to increased levels. ♦ Smoking: May decrease temazepam levels.

Tenofovir (Viread)

Purpose/Indication	Tenofovir is a nucleotide reverse transcriptase inhibitor (NtRTI) primarily used in combination with other antiretroviral agents for the treatment of human immunodeficiency virus type 1 (HIV-1) infection in adults and pediatric patients. It is also indicated for the treatment of chronic hepatitis B virus (HBV) infection in adults and, for some formulations, in pediatric patients, including those with compensated and decompensated liver disease. It helps to suppress viral replication, improve immune function, and reduce disease progression in both HIV and HBV.
Method of Action	Tenofovir disoproxil fumarate (TDF) is a prodrug that is converted intracellularly to tenofovir diphosphate, the active metabolite. Tenofovir diphosphate then competitively inhibits reverse transcriptase, an enzyme essential for HIV replication, and DNA polymerase, an enzyme essential for HBV replication. By acting as a chain terminator during viral DNA synthesis, tenofovir diphosphate prevents the transcription of viral RNA into DNA, thereby blocking viral replication. Tenofovir alafenamide (TAF) is also a prodrug, more efficiently delivering tenofovir to target cells.
Medication Name & Brand Names	♦ Medication Name: Tenofovir (available as Tenofovir Disoproxil Fumarate - TDF, and Tenofovir Alafenamide - TAF) ♦ Brand Names: Viread (TDF), Vemlidy (TAF for HBV only), Descovy (TAF/emtricitabine for HIV/PrEP), Genvoya (elvitegravir/cobicistat/emtricitabine/TAF), Odefsey (emtricitabine/rilpivirine/TAF), Biktarvy (bictegravir/emtricitabine/TAF), Symtuza (darunavir/cobicistat/emtricitabine/TAF), Tenofovir (generic TDF)
Pharmaceutical Forms & Appearance	Tenofovir is available as oral tablets. TDF tablets (Viread) are typically almond-shaped and light blue, often with strength imprints. TAF tablets (Vemlidy, or in combination products) are generally smaller, often round or oval, and may vary in color depending on strength or combination.
Dosage & Administration	Dosage varies by formulation, indication, and patient renal function. For HIV-1 (TDF), the typical adult oral dose is 300 mg once daily, usually in combination with other antiretrovirals. For chronic HBV (TDF), 300 mg once daily. For chronic HBV (TAF), 25 mg once daily. TDF can be taken with or without food. TAF should be taken with food. Dose adjustments for TDF are necessary for patients with renal impairment; TAF generally requires less frequent adjustment for moderate renal impairment.
Supplied As	Tenofovir is supplied as: oral tablets (TDF: 150 mg, 200 mg, 250 mg, 300 mg; TAF: 25 mg in combination products or 25 mg as Vemlidy).
Contraindications	Tenofovir is contraindicated in patients with known hypersensitivity to tenofovir or any component of the formulation. It is not approved for use as monotherapy for HIV, as this can lead to the development of drug resistance.
Storage & Expiry	Tenofovir tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in the original tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects for TDF include nausea, vomiting, diarrhea, abdominal pain, headache, and dizziness. More significant side effects unique to TDF include renal impairment (nephrotoxicity) and decreased bone mineral density (bone loss). Common side effects for TAF (which generally has better renal and bone safety) include nausea, abdominal pain, and headache. Both can rarely cause lactic acidosis with severe hepatomegaly with steatosis.

Warnings & Precautions	♦ BLACK BOX WARNING (for TDF): Lactic Acidosis/Severe Hepatomegaly with Steatosis. Fatal cases have been reported with nucleoside analogs, including TDF. Use with caution in patients with risk factors for liver disease. ♦ BLACK BOX WARNING (for TDF): Post-Treatment Exacerbation of HBV: Severe acute exacerbations of hepatitis B have been reported in HBV-infected patients discontinuing TDF or TAF. Monitor liver function closely for several months after stopping. ♦ Renal Impairment (TDF): TDF can cause or worsen renal impairment, including acute renal failure and Fanconi syndrome. Monitor serum creatinine, phosphorus, and urinalysis (proteinuria, glycosuria) before and during therapy. Dose adjustment is required for renal impairment. ♦ Bone Mineral Density (TDF): TDF is associated with decreases in bone mineral density (BMD), particularly in younger patients. Consider calcium and vitamin D supplementation. Monitor BMD in patients with a history of fracture or osteoporosis risk. ♦ TAF generally has improved renal and bone safety profiles compared to TDF. ♦ HIV/HBV Co-infection: Patients with HIV/HBV co-infection must receive TDF or TAF as part of an appropriate anti-HIV regimen to prevent HIV resistance. Monotherapy for HBV in co-infected patients is not recommended. ♦ Immune Reconstitution Inflammatory Syndrome (IRIS): Can occur in HIV-infected patients during initial phases of antiretroviral treatment, leading to inflammation or worsening of opportunistic infections. ♦ Drug Interactions: Numerous drug interactions due to metabolism or renal excretion (see below). ♦ Lipids: TAF-containing regimens may lead to greater increases in total cholesterol and LDL-C compared
Missed Dose Instructions	If a dose of Tenofovir is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is crucial for suppressing viral replication and preventing the development of drug resistance in both HIV and HBV. If more than one dose is missed, consult a healthcare professional.
Overdose Instructions	Limited data on overdose of tenofovir. Overdose symptoms are generally not well-established, but exaggerated side effects such as gastrointestinal upset or renal impairment could occur. There is no specific antidote for tenofovir. Treatment is supportive and symptomatic. Hemodialysis can remove tenofovir, but its utility in overdose is unknown. Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Drugs Affecting Renal Function (e.g., NSAIDs, aminoglycosides, high-dose vancomycin, cisplatin, cidofovir, adefovir): Concomitant use with TDF can increase serum concentrations of tenofovir and/or increase the risk of renal toxicity. Monitor renal function closely. ♦ Ledipasvir/Sofosbuvir, Sofosbuvir/Velpatasvir, Sofosbuvir/Velpatasvir/Voxilaprevir: Can increase tenofovir (TAF) levels, especially in combination with other antivirals that include cobicistat. Monitor for tenofovir-related adverse effects. ♦ Atazanavir/Ritonavir and Lopinavir/Ritonavir: These ritonavir-boosted protease inhibitors can significantly increase tenofovir (TDF) exposure, requiring careful renal monitoring or consideration of alternative regimens. With TAF, the interaction is less pronounced. ♦ Didanosine (ddI): Concomitant use with TDF can increase ddI concentrations, leading to ddI-related adverse events (e.g., pancreatitis, neuropathy). Co-administration is generally not recommended or requires ddI dose reduction. ♦ Drugs Highly Protein-Bound: Tenofovir is not highly protein-bound, so significant interactions related to protein binding displacement are unlikely. ♦ Statins (e.g., atorvastatin): No significant interaction.

Terbinafine (Lamisil)

Purpose/Indication	Terbinafine is an antifungal medication used to treat various fungal infections. Oral terbinafine is primarily indicated for the treatment of onychomycosis (fungal infections of the fingernails and toenails) due to dermatophytes, and severe tinea capitis (ringworm of the scalp). Topical formulations are used for superficial fungal skin infections like tinea pedis (athlete's foot), tinea corporis (ringworm of the body), and tinea cruris (jock itch), and sometimes for cutaneous candidiasis.
Method of Action	Terbinafine is an allylamine antifungal that selectively inhibits squalene epoxidase, a key enzyme in the fungal ergosterol biosynthesis pathway. By blocking squalene epoxidase, terbinafine causes an accumulation of squalene within the fungal cell and a deficiency of ergosterol, which is a vital component of the fungal cell membrane. The accumulation of squalene is toxic to the fungal cell, leading to increased cell membrane permeability and ultimately fungal cell death (fungicidal action).
Medication Name & Brand Names	♦ Medication Name: Terbinafine Hydrochloride ♦ Brand Names: Lamisil (oral tablets, topical cream/gel/spray), Lamisil AT (topical), Terbinafine (generic)
Pharmaceutical Forms & Appearance	Terbinafine is available as oral tablets, and various topical formulations including creams, gels, and sprays. Oral tablets are typically white to off-white, round, biconvex, and may be scored. Topical creams are white, smooth, and homogeneous. Gels and sprays are clear or translucent.
Dosage & Administration	Dosage varies significantly by formulation and indication. For oral onychomycosis, the typical adult oral dose is 250 mg once daily for 6 weeks for fingernail infections and 12 weeks for toenail infections. For tinea capitis (in children), doses are weight-based. For topical skin infections, the cream/gel/spray is applied once or twice daily to the affected area and surrounding skin for 1-4 weeks, depending on the infection type. Oral tablets can be taken with or without food. Complete the full course of treatment to prevent recurrence.
Supplied As	Terbinafine is supplied as: oral tablets (e.g., 250 mg), topical cream (e.g., 1%), topical gel (e.g., 1%), and topical solution/spray (e.g., 1%).
Contraindications	Terbinafine is contraindicated in patients with known hypersensitivity to terbinafine or any component of the formulation. Oral terbinafine is also contraindicated in patients with chronic or active liver disease, as it can cause significant hepatic dysfunction.
Storage & Expiry	Terbinafine oral tablets and topical formulations should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects for oral terbinafine include gastrointestinal disturbances (diarrhea, dyspepsia, abdominal pain, nausea), headache, rash, and taste disturbance (dysgeusia), which can be severe and prolonged. Serious but less common side effects include hepatotoxicity (liver damage), neutropenia (low white blood cell count), Stevens-Johnson Syndrome, and toxic epidermal necrolysis. Common side effects for topical terbinafine are usually mild and local, such as irritation, burning, stinging, or redness at the application site.
Warnings & Precautions	♦ Hepatotoxicity (Oral): Oral terbinafine can cause liver dysfunction, including cholestasis, hepatitis, and liver failure (rarely fatal). Liver function tests (ALT, AST) should be performed prior to initiating treatment and periodically during therapy (e.g., at 4-6 weeks) or if signs/symptoms of liver dysfunction occur. Discontinue if liver enzymes are significantly elevated or if clinical signs of liver disease develop. Contraindicated in active or chronic liver disease. ♦ Taste Disturbance/Loss of Taste (Oral): Can cause persistent or severe taste disturbance, including taste loss, which may sometimes be irreversible. This can lead to decreased appetite and weight loss. ♦ Hematologic Effects (Oral): Rare cases of neutropenia, agranulocytosis, thrombocytopenia, and pancytopenia have been reported. Monitor blood counts if signs of blood dyscrasias occur. ♦ Skin Reactions (Oral): Rare but severe skin reactions (e.g., Stevens-Johnson Syndrome, toxic epidermal necrolysis) have been reported. Discontinue at the first sign of progressive skin rash. ♦ Lupus Erythematosus: May exacerbate or precipitate cutaneous and systemic lupus erythematosus. ♦ Renal Impairment (Oral): Use with caution and consider dose reduction in patients with renal impairment (CrCl < 50 mL/min). ♦ Pregnancy & Lactation: Use during pregnancy and lactation is generally not recommended unless benefits outweigh risks, as it is excreted in breast milk. ♦ Depression: Rare reports of depression with oral terbinafine.

Missed Dose Instructions	For oral terbinafine: If a dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Completing the full prescribed course is crucial for successful treatment and preventing relapse of fungal infections. For topical terbinafine: If a dose is missed, apply it as soon as remembered, then resume the regular application schedule.
Overdose Instructions	Overdose with oral terbinafine is uncommon. Symptoms are generally an exaggeration of known side effects, including severe gastrointestinal upset (nausea, vomiting, abdominal pain), headache, and dizziness. There is no specific antidote for terbinafine overdose. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Monitor liver function. Seek medical attention if a large amount is ingested or severe symptoms develop. Topical overdose is unlikely to cause systemic toxicity but may lead to increased local irritation.
Medicine Interactions	♦ CYP2D6 Inhibitors (e.g., cimetidine, fluconazole, amiodarone, selective serotonin reuptake inhibitors - SSRIs like fluoxetine, paroxetine): Can significantly increase plasma concentrations of oral terbinafine, leading to increased side effects. Dose adjustment of terbinafine may be necessary. ♦ CYP2D6 Substrates (e.g., tricyclic antidepressants - TCAs like desipramine, clomipramine; beta-blockers like metoprolol; selective serotonin reuptake inhibitors - SSRIs like fluoxetine, paroxetine): Terbinafine is a strong inhibitor of CYP2D6, potentially increasing the levels and toxicity of drugs metabolized by this enzyme. Monitor and adjust doses of co-administered CYP2D6 substrates. ♦ Caffeine: Terbinafine may reduce caffeine clearance, potentially leading to increased caffeine effects. ♦ Rifampin (a CYP inducer): Can decrease terbinafine levels, potentially reducing its efficacy. ♦ Warfarin: Rare reports of altered INR/PT with concomitant use. Monitor INR closely. ♦ Oral Contraceptives: Rare reports of menstrual irregularities, though causality is not firmly established.

Tetracycline (Sumycin)

Purpose/Indication	Tetracycline is a broad-spectrum antibiotic used to treat a wide range of bacterial infections, including respiratory tract infections, urinary tract infections, skin infections, and certain sexually transmitted infections like chlamydia and gonorrhea (when penicillin is contraindicated). It is also effective against atypical organisms such as Mycoplasma pneumoniae, Chlamydia psittaci (psittacosis), Rickettsiae (Rocky Mountain spotted fever, typhus), and in conditions like acne vulgaris, cholera, and Lyme disease.
Method of Action	Tetracycline acts by reversibly binding to the 30S ribosomal subunit of susceptible bacteria, thereby inhibiting bacterial protein synthesis. This prevents the attachment of aminoacyl transfer RNA (tRNA) to the ribosomal A site, effectively blocking the elongation of the polypeptide chain and ultimately inhibiting bacterial growth (bacteriostatic action). This mechanism allows it to exert its antimicrobial effects against a wide variety of Gram-positive and Gram-negative bacteria, as well as some other microorganisms.
Medication Name & Brand Names	♦ Medication Name: Tetracycline Hydrochloride ♦ Brand Names: Sumycin, Achromycin V, Tetracyn (regional), Tetracycline (generic)
Pharmaceutical Forms & Appearance	Tetracycline is available as oral capsules or tablets, and also as a topical ointment/solution for skin infections and an ophthalmic ointment for eye infections. Oral capsules are typically hard gelatin capsules, often yellow, with specific imprints. Tablets are usually film-coated. The topical and ophthalmic preparations are typically yellow.
Dosage & Administration	Dosage varies by indication and patient age. For adults, typical oral doses are 250 mg to 500 mg every 6 hours (four times daily). For acne, lower doses (e.g., 250 mg once or twice daily) may be used long-term. It is crucial to take oral tetracycline on an empty stomach, at least 1 hour before or 2 hours after meals, and with a full glass of water. Avoid taking it with milk, dairy products, antacids, or iron supplements due to significant absorption interference. Complete the full prescribed course of treatment.
Supplied As	Tetracycline is supplied as: oral capsules (e.g., 250 mg, 500 mg), oral tablets (e.g., 250 mg, 500 mg), topical ointment/solution, and ophthalmic ointment.
Contraindications	Tetracycline is strictly contraindicated in pregnancy and in children under 8 years of age due to the risk of permanent tooth discoloration (yellow-gray-brown) and inhibition of bone growth. It is also contraindicated in patients with known hypersensitivity to tetracycline or any other tetracycline antibiotic. Use in severe renal impairment may also be a contraindication or require extreme caution.
Storage & Expiry	Tetracycline capsules/tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging. Degradation products of tetracycline can be nephrotoxic, so expired tetracycline should not be used.
Side Effects	Common side effects include gastrointestinal disturbances (nausea, vomiting, diarrhea, abdominal pain), photosensitivity (increased sensitivity to sunlight, leading to severe sunburn), and tooth discoloration (in children under 8). More serious but less common side effects include esophageal irritation/ulceration (if taken without sufficient water or lying down), liver toxicity, renal dysfunction, benign intracranial hypertension (pseudotumor cerebri), and superinfections (e.g., Clostridioides difficile-associated diarrhea).
Warnings & Precautions	♦ Tooth Discoloration & Bone Effects: Contraindicated in children under 8 years of age and during pregnancy/lactation due to irreversible tooth discoloration and potential inhibition of bone growth. ♦ Photosensitivity: Can cause severe sunburn-like reactions. Advise patients to avoid prolonged sun exposure, use sunscreen, and wear protective clothing. Discontinue at the first sign of erythema. ♦ Esophageal Irritation/Ulceration: Can cause severe esophageal irritation, especially if taken without sufficient water or lying down immediately after ingestion. Advise patients to take with a full glass of water and remain upright for at least 30 minutes to 1 hour. ♦ Renal Impairment: Use with caution in patients with renal impairment; higher doses may lead to excessive systemic accumulation and liver toxicity. Some formulations (e.g., doxycycline) are preferred. ♦ Hepatic Impairment: Use with caution; can cause liver toxicity, especially in high doses or in patients with pre-existing liver disease. ♦ Benign Intracranial Hypertension (Pseudotumor Cerebri): Can cause increased intracranial pressure with symptoms like headache, blurred vision, or papilledema. Discontinue if symptoms occur. ♦ Superinfection: Prolonged use can lead to overgrowth of non-susceptible organisms, including fungi and Clostridioides difficile (leading to C. diff-associated diarrhea). ♦ Myasthenia Gravis: Use with caution as it may exacerbate muscle weakness. ♦ Drug Resistance: Use responsibly to prevent the development of antibiotic resistance. ♦ Oral Absorption: Very susceptible to chelation; must be taken on an empty stomach and separated from interacting substances.
Missed Dose Instructions	If a dose of Tetracycline is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Completing the full prescribed course is crucial for successful bacterial eradication and preventing the development of antibiotic resistance.
Overdose Instructions	Overdose symptoms are primarily an exaggeration of known side effects, including severe gastrointestinal upset (nausea, vomiting, diarrhea), potential liver toxicity, and renal impairment. There is no specific antidote for tetracycline overdose. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion to reduce absorption. Hemodialysis is generally not effective for removing tetracycline. Monitor liver and kidney function. Seek medical attention if a large amount is ingested or severe symptoms develop.

Medicine Interactions	♦ Antacids (containing aluminum, calcium, magnesium), Iron Supplements, Zinc, Bismuth Subsalicylate: Significantly chelate tetracycline, forming insoluble complexes and reducing its absorption. Administer tetracycline at least 2 hours before or 4-6 hours after these agents. ♦ Dairy Products (Milk, Cheese, Yogurt): Contain calcium, which also chelates tetracycline and reduces absorption. Avoid taking tetracycline with dairy products. ♦ Oral Contraceptives: Tetracyclines may reduce the effectiveness of oral contraceptives, increasing the risk of unintended pregnancy. Advise alternative birth control methods. ♦ Warfarin & other Anticoagulants: May potentiate the anticoagulant effect, increasing bleeding risk by altering gut flora and vitamin K synthesis. Monitor INR closely. ♦ Penicillins: Tetracycline is bacteriostatic, and can interfere with the bactericidal action of penicillins. Avoid concomitant use when the bactericidal effect of penicillin is crucial. ♦ Methoxyflurane: Concomitant use with tetracyclines has been associated with fatal renal toxicity. Avoid. ♦ Ergot Alkaloids: Increased risk of ergotism. ♦ Retinoids (e.g., isotretinoin, acitretin): Concomitant use increases the risk of benign intracranial hypertension (pseudotumor cerebri). Avoid concomitant use. ♦ Digoxin: May increase digoxin absorption due to altered gut flora. Monitor digoxin levels.

Tinidazole (Tindamax)

Purpose/Indication	Tinidazole is an antimicrobial agent primarily used to treat various anaerobic bacterial and protozoal infections. It is indicated for trichomoniasis (a sexually transmitted infection), giardiasis, amebiasis (intestinal and hepatic), and bacterial vaginosis. It is also used in combination regimens for the eradication of Helicobacter pylori (associated with peptic ulcers).
Method of Action	Tinidazole is a nitroimidazole antimicrobial that works by being selectively activated within anaerobic bacteria and protozoa. Once inside the organism, its nitro group is reduced by microbial enzymes, forming reactive nitro radicals. These highly reactive intermediates damage the organism's DNA, causing strand breaks and inhibiting nucleic acid synthesis, which leads to cell death. This selective activation mechanism is crucial for its efficacy against anaerobic pathogens while having less effect on aerobic host cells.
Medication Name & Brand Names	♦ Medication Name: Tinidazole ♦ Brand Names: Tindamax, Fasigyn (regional), Tinidazole (generic)
Pharmaceutical Forms & Appearance	Tinidazole is available as oral tablets. Tablets are typically film-coated, round or oval, and may vary in color (e.g., white to off-white). They often have specific imprints indicating strength or manufacturer.
Dosage & Administration	Dosage varies significantly by indication and can often involve single doses or short courses. For trichomoniasis and bacterial vaginosis, a common adult dose is a single 2 gram oral dose. For giardiasis and amebiasis, doses vary from a single 2 gram dose to 2 grams daily for 2-3 days. For H. pylori eradication, it's usually 500 mg twice daily for 7-14 days as part of a multi-drug regimen. Tablets should be taken with food to minimize gastrointestinal upset.
Supplied As	Tinidazole is supplied as: oral tablets (e.g., 250 mg, 500 mg).
Contraindications	Tinidazole is contraindicated in patients with known hypersensitivity to tinidazole or any other nitroimidazole derivative (e.g., metronidazole). It is also contraindicated during the first trimester of pregnancy due to potential fetal harm, and in breastfeeding mothers during and for 3 days after treatment. It should not be used in patients with active neurological disorders or a history of blood dyscrasias.
Storage & Expiry	Tinidazole tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal disturbances (nausea, metallic taste, vomiting, diarrhea, abdominal pain), dizziness, and headache. More serious but less common side effects include seizures, peripheral neuropathy (numbness, tingling), transient leukopenia (low white blood cell count), and allergic reactions (rash, itching). A disulfiram-like reaction (flushing, palpitations, nausea, vomiting) can occur with alcohol consumption.
Warnings & Precautions	♦ Alcohol Interaction: Can cause a disulfiram-like reaction (e.g., abdominal cramps, nausea, vomiting, headaches, flushing) if alcohol is consumed during therapy and for at least 3 days after stopping tinidazole. Advise patients to avoid all alcohol-containing products. ♦ Neurological Effects: Rare but serious adverse neurological reactions, including seizures and peripheral neuropathy (e.g., numbness, paresthesia, weakness), have been reported. Discontinue if abnormal neurological symptoms develop. ♦ Blood Dyscrasias: Transient leukopenia and neutropenia have been observed. Use with caution in patients with a history of blood dyscrasias. ♦ Vaginal Candidiasis: Treatment for trichomoniasis can lead to the development of candidiasis, requiring antifungal treatment. ♦ Hepatic Impairment: Use with caution in patients with severe hepatic impairment as tinidazole is metabolized in the liver. ♦ Pregnancy & Lactation: Contraindicated in the first trimester of pregnancy due to potential genotoxicity. Avoid during breastfeeding and for 3 days after the last dose due to excretion into breast milk. ♦ Drug Resistance: Use responsibly to prevent the development of drug resistance.
Missed Dose Instructions	Tinidazole regimens often involve single doses or short courses. If a scheduled dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose (for multi-dose regimens), skip the missed dose and continue with the regular schedule. Do not take a double dose. Completing the full prescribed course is crucial for effective eradication of the infection.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily gastrointestinal upset (nausea, vomiting, abdominal pain) and potential neurological effects (dizziness, headache, peripheral neuropathy, seizures). There is no specific antidote for tinidazole overdose. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Hemodialysis can remove tinidazole from the blood and may be beneficial in severe overdose. Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Alcohol: STRICTLY AVOID during therapy and for at least 3 days after stopping tinidazole due to the risk of disulfiram-like reaction. ♦ Oral Anticoagulants (e.g., warfarin): Tinidazole may potentiate the anticoagulant effect of warfarin, increasing the risk of bleeding. Monitor INR closely, especially when initiating or discontinuing tinidazole. ♦ Lithium: May increase serum lithium concentrations and the risk of lithium toxicity. Monitor lithium levels closely. ♦ Phenytoin/Fosphenytoin: May increase phenytoin levels. ♦ Cyclosporine: May increase cyclosporine levels. ♦ Cimetidine: May prolong the half-life of tinidazole, increasing its exposure. ♦ Phenobarbital & Rifampin (CYP Inducers): May decrease tinidazole levels, potentially reducing its efficacy. ♦ Fluorouracil: May increase the toxicity of fluorouracil.

Tramadol (Ultram)

Purpose/Indication	Tramadol is an opioid analgesic indicated for the management of moderate to moderately severe pain in adults. It can be used for acute pain, chronic pain, and sometimes for neuropathic pain. It is often considered a weaker opioid but still carries risks associated with opioid use.

Method of Action	Tramadol has a dual mechanism of action. It acts as a weak opioid agonist, binding to mu-opioid receptors in the central nervous system, thereby inhibiting pain transmission. Additionally, it inhibits the reuptake of norepinephrine and serotonin, which enhances descending inhibitory pain pathways and contributes to its analgesic effects. This dual action provides a synergistic effect in pain relief.
Medication Name & Brand Names	♦ Medication Name: Tramadol Hydrochloride ♦ Brand Names: Ultram, Conzip (extended-release), Ryzolt (extended-release), Tramal (regional), Tramacet (tramadol/paracetamol combination - regional), Tramadol (generic)
Pharmaceutical Forms & Appearance	Tramadol is available as oral tablets (immediate-release and extended-release), oral capsules (immediate-release and extended-release), and oral drops/solution. Tablets and capsules vary in color, shape, and imprint depending on strength and manufacturer. Extended-release formulations are designed for once-daily dosing.
Dosage & Administration	Dosage is individualized based on pain severity, patient response, and tolerance. For immediate-release tablets/capsules, typical adult oral doses start at 50 mg every 4-6 hours as needed, with a maximum generally not exceeding 400 mg per day. For extended-release formulations, doses usually range from 100 mg to 300 mg once daily. It can be taken with or without food. Dosage should be tapered gradually upon discontinuation to avoid withdrawal symptoms.
Supplied As	Tramadol is supplied as: oral immediate-release tablets (e.g., 50 mg), oral extended-release tablets/capsules (e.g., 100 mg, 150 mg, 200 mg, 300 mg), and oral drops/solution (e.g., 100 mg/mL - regional).
Contraindications	Tramadol is strictly contraindicated in patients with known hypersensitivity to tramadol, opioids, or any component of the formulation. It is contraindicated in situations where opioids are contraindicated, such as acute or severe bronchial asthma in an unmonitored setting, significant respiratory depression, or paralytic ileus. It is also contraindicated in patients who have consumed significant amounts of alcohol, hypnotics, analgesics, or psychotropic drugs. Concomitant use with MAOIs is strictly contraindicated.
Storage & Expiry	Tramadol tablets, capsules, and oral solutions should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed, child-resistant containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, constipation, dizziness, headache, drowsiness, vomiting, and sweating. More serious but less common side effects include seizures, serotonin syndrome, respiratory depression, opioid dependence/addiction, withdrawal symptoms, and anaphylactoid reactions.
Warnings & Precautions	♦ BLACK BOX WARNING: Addiction, Abuse, and Misuse: Tramadol exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient's risk prior to prescribing and monitor regularly. ♦ BLACK BOX WARNING: Respiratory Depression: Serious, life-threatening, or fatal respiratory depression may occur. Monitor closely, especially during initiation or after a dose increase. ♦ BLACK BOX WARNING: Accidental Ingestion: Accidental ingestion of even one dose, especially by children, can result in a fatal overdose. ♦ BLACK BOX WARNING: Neonatal Opioid Withdrawal Syndrome: Prolonged use during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life-threatening if not recognized and treated. ♦ BLACK BOX WARNING: CYP2D6 Ultrarapid Metabolizers: Life-threatening respiratory depression or death can occur in children who are ultrarapid metabolizers of codeine into morphine. Tramadol is not recommended for pediatric patients younger than 12 years of age. Avoid in adolescents 12 to 18 years of age who are obese or have sleep apnea or severe lung disease. ♦ Seizures: Can lower the seizure threshold. The risk is increased with higher doses, concomitant use of SSRIs/SNRIs, tricyclic antidepressants, antipsychotics, and other drugs that lower the seizure threshold. Use with caution in patients with epilepsy or a history of seizures. ♦ Serotonin Syndrome: Potentially life-threatening condition that can occur with concomitant use of other serotonergic drugs (e.g., SSRIs, SNRIs, MAOIs, tricyclic antidepressants, lithium, triptans, St. John's Wort). Symptoms include mental status changes, autonomic instability, neuromuscular aberrations, and GI symptoms. Discontinue immediately if suspected. ♦ Suicidal Risk: Increased risk of suicidal thoughts and behavior, particularly in patients with depression or a history of suicidal ideation. ♦ Adrenal Insufficiency: May occur with opioid use. ♦ Androgen Deficiency: Long-term opioid use may result in decreased fertility and sexual dysfunction. ♦ Concomitant CNS Depressants (e.g., alcohol, benzodiazepines): Potentiates CNS depression and respiratory depression. Use with extreme caution. ♦ Renal/Hepatic Impairment: Use with caution and reduce dose due to decreased clearance. ♦ Driving/Operating Machinery: Impairs mental and physical abilities; avoid dangerous activities. ♦ Withdrawal Symptoms: Avoid abrupt discontinuation; taper dose gradually.
Missed Dose Instructions	If a dose of Tramadol is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For extended-release formulations, do not take a missed dose if it's close to the next scheduled dose; maintain the once-daily rhythm. Consistency is important for chronic pain management.
Overdose Instructions	Overdose symptoms are similar to other opioids and include severe respiratory depression, somnolence progressing to stupor or coma, skeletal muscle flaccidity, cold and clammy skin, constricted pupils, bradycardia, and hypotension. In severe cases, circulatory collapse, cardiac arrest, and death can occur. Seizures may also occur. There is a specific opioid antagonist, naloxone, which can reverse respiratory depression, but it may not fully reverse the non-opioid components of tramadol's toxicity (e.g., serotonin reuptake inhibition) and may precipitate withdrawal. Treatment is supportive and symptomatic, focusing on maintaining an open airway, ventilation, and cardiovascular support. Seek immediate emergency medical help.
Medicine Interactions	♦ MAOIs (Monoamine Oxidase Inhibitors, e.g., phenelzine, tranylcypromine, selegiline, linezolid, methylene blue): STRICTLY CONTRAINDICATED. Concomitant use or use within 14 days of stopping an MAOI can lead to severe adverse reactions, including serotonin syndrome and hypertensive crisis. ♦ Other CNS Depressants (e.g., alcohol, benzodiazepines, other opioids, sedatives, hypnotics, anxiolytics, general anesthetics, phenothiazines, skeletal muscle relaxants): Additive CNS and respiratory depressant effects. Concomitant use of benzodiazepines and opioids may result in profound sedation, respiratory depression, coma, and death (BLACK BOX WARNING for many opioids). Avoid or limit dosages and durations. ♦ Serotonergic Drugs (e.g., SSRIs, SNRIs, TCAs, triptans, lithium, St. John's Wort, buspirone, fentanyl, dextromethorphan): Increased risk of serotonin syndrome. Use with caution; monitor for symptoms. ♦ CYP2D6 Inhibitors (e.g., quinidine, fluoxetine, paroxetine, cimetidine, amiodarone): Can inhibit the metabolism of tramadol to its active O-desmethyltramadol metabolite, potentially reducing analgesic efficacy. ♦ CYP3A4 Inducers (e.g., carbamazepine, rifampin, phenytoin, St. John's Wort): Can decrease tramadol levels, potentially reducing efficacy. Carbamazepine also increases tramadol metabolism, which can reduce its analgesic effect and increase the risk of seizures. Concomitant use with carbamazepine is generally not recommended. ♦ Warfarin: Rare reports of increased INR and bleeding. Monitor INR closely. ♦ Digoxin: Rare reports of digoxin toxicity. ♦ Naloxone: Will reverse opioid effects but may not fully reverse serotonin reuptake inhibition effects, and may precipitate

Tretinoin (Retin-A)

Purpose/Indication	Tretinoin is a retinoid medication primarily used topically for the treatment of acne vulgaris and to reduce the appearance of fine wrinkles, mottled hyperpigmentation, and tactile roughness associated with photodamage. Oral tretinoin is specifically indicated for the induction of remission in acute promyelocytic leukemia (APL). Its various formulations target different conditions by influencing cellular growth and differentiation.

Method of Action	Tretinoin (all-trans retinoic acid) works by binding to specific retinoic acid receptors (RARs) found in the nucleus of cells, which then bind to DNA and regulate gene expression. For acne, this leads to increased cell turnover in the follicular epithelium, preventing the formation of new comedones (blackheads and whiteheads), and promoting the expulsion of existing ones. It also has anti-inflammatory properties. For photodamage, it influences epidermal cell differentiation and proliferation, and promotes collagen synthesis in the dermis. For APL, it induces terminal differentiation of promyelocytes, leading to their maturation and preventing uncontrolled proliferation.
Medication Name & Brand Names	♦ Medication Name: Tretinoin ♦ Brand Names: Retin-A, Renova, Tretinoin (generic), Atralin, Altreno, Refissa, Vesanoid (oral for APL)
Pharmaceutical Forms & Appearance	Tretinoin is available in various topical forms including creams, gels, and solutions, and as oral capsules for specific systemic indications. Topical creams are typically white to yellowish, gels are translucent or yellowish, and solutions are clear. Oral capsules (for APL) are usually soft gelatin capsules, brown-orange.
Dosage & Administration	Dosage and administration vary significantly by formulation and indication. For topical acne/photodamage, a thin layer of cream, gel, or solution is applied to the affected areas once daily, usually in the evening, after washing and drying the skin. Start with lower concentrations (e.g., 0.025%) and gradually increase as tolerated. For oral APL, the typical adult dose is 45 mg/m2/day divided into two equally daily doses, taken with food, until complete remission or for a maximum of 90 days. Topical use should be gradual to avoid irritation; oral use requires specialized medical supervision.
Supplied As	Tretinoin is supplied as: topical creams (e.g., 0.025%, 0.05%, 0.1%), topical gels (e.g., 0.01%, 0.025%, 0.05%), topical solutions (e.g., 0.05%), and oral capsules (e.g., 10 mg for APL).
Contraindications	Topical tretinoin is generally contraindicated in patients with known hypersensitivity to tretinoin or any component of the formulation. Oral tretinoin for APL has fewer absolute contraindications due to the severity of the disease, but caution is used. Both topical and oral forms are contraindicated in pregnancy due to significant teratogenic risk. Oral tretinoin is also contraindicated in breastfeeding mothers.
Storage & Expiry	Topical tretinoin creams/gels/solutions should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and excessive heat. Keep tubes/bottles tightly closed. Oral tretinoin capsules should be stored refrigerated (2°C to 8°C or 36°F to 46°F) and protected from light. Always check the specific expiry date on the packaging.
Side Effects	Common side effects for topical tretinoin include local skin irritation (redness, dryness, peeling, stinging, burning), increased sensitivity to sunlight, and initial worsening of acne ("purging"). Common side effects for oral tretinoin (for APL) are more severe and include "retinoic acid syndrome" (fever, dyspnea, weight gain, pleural/pericardial effusion), headache, dry skin/mucous membranes, cheilitis, rash, bone pain, and elevated liver enzymes.
Warnings & Precautions	♦ Teratogenicity (Pregnancy Risk): STRICT BLACK BOX WARNING (for oral tretinoin, and strong warning for topical). Tretinoin is a potent teratogen and can cause severe birth defects. It is absolutely contraindicated in pregnancy. Females of reproductive potential must use two reliable forms of contraception and have negative pregnancy tests before, during, and after treatment (for oral). Topical absorption is minimal but still carries a theoretical risk, so avoid in pregnancy. ♦ Photosensitivity: Both topical and oral forms increase sensitivity to sunlight and artificial UV light. Advise patients to use sunscreen, wear protective clothing, and avoid excessive sun exposure. ♦ Skin Irritation (Topical): Initial irritation (redness, peeling, burning) is common. Reduce frequency or concentration if severe. Avoid contact with eyes, mouth, nose, and mucous membranes. ♦ Retinoic Acid Syndrome (Oral APL): A potentially life-threatening complication characterized by fever, dyspnea, acute respiratory distress, weight gain, pleural/pericardial effusions, and hypotension. Requires immediate medical attention and often treatment with corticosteroids. ♦ Leukocytosis (Oral APL): Rapid increase in white blood cell count. ♦ Pseudotumor Cerebri/Benign Intracranial Hypertension (Oral): Can occur, especially in children. Monitor for symptoms (headache, visual disturbances). ♦ Lipid Abnormalities (Oral): Can cause hypertriglyceridemia and hypercholesterolemia. Monitor lipid profiles. ♦ Liver Dysfunction (Oral): Can cause elevated liver enzymes. Monitor LFTs. ♦ Special Populations (Oral APL): Use with caution in patients with hepatic or renal impairment.
Missed Dose Instructions	For topical tretinoin: If a dose is missed, apply it as soon as remembered. However, if it's nearly time for the next scheduled application, skip the missed dose and apply the next one at the regular time. Do not apply a double amount. Consistency is important, but excessive application can increase irritation. For oral tretinoin (APL): This is a critical medication for a serious condition, administered under strict medical supervision. If a dose is missed, contact the treating physician or healthcare team immediately for instructions, as adherence is paramount for treatment success.
Overdose Instructions	Topical Overdose: Excessive application of topical tretinoin will not yield faster or better results but will significantly increase local irritation (redness, peeling, discomfort). Systemic absorption from topical overdose is unlikely to cause systemic toxicity. Wash off excess product. Treat irritation symptomatically. Oral Overdose (APL): Overdose symptoms are generally an exaggeration of common side effects, including severe headache, nausea, vomiting, skin and mucosal dryness, cheilitis, and abdominal discomfort. More severe effects like pseudotumor cerebri, hyperlipidemia, and liver enzyme elevations could occur. There is no specific antidote. Treatment is supportive and symptomatic. Gastric lavage may be considered if recent. Monitor for signs of retinoic acid syndrome and manage accordingly. Seek immediate emergency medical help.
Medicine Interactions	♦ Topical Preparations: ♦ Abrasive Soaps/Cleansers, Astringents, Alcohol-containing Products: May cause additive irritation, dryness, or peeling when used concurrently with topical tretinoin. ♦ Medicated Soaps/Cleansers/Cosmetics: Use with caution. ♦ Photosensitizing Drugs (e.g., thiazides, tetracyclines, sulfonamides, phenothiazines): May increase photosensitivity risk when used with topical tretinoin. ♦ Oral Preparations (for APL): ♦ CYP3A4 Inducers (e.g., rifampin, phenytoin, carbamazepine, phenobarbital): Can decrease plasma concentrations of oral tretinoin, potentially reducing its efficacy. Dose adjustment of tretinoin may be needed. ♦ CYP3A4 Inhibitors (e.g., ketoconazole, itraconazole, clarithromycin, erythromycin, diltiazem, verapamil): May increase plasma concentrations of oral tretinoin, potentially increasing toxicity. ♦ Fibrates/Statins: Increased risk of myalgia or rhabdomyolysis when used with oral tretinoin, possibly due to exacerbation of hypertriglyceridemia. ♦ Vitamin A Supplements: Avoid high doses due to potential additive toxicity (hypervitaminosis A syndrome). ♦ Other Retinoids: Avoid concomitant use due to additive toxicity.

Trimethoprim (Primsol)

Purpose/Indication	Trimethoprim is an antibiotic primarily used for the treatment of uncomplicated urinary tract infections (UTIs) caused by susceptible organisms. It is also used in combination with sulfamethoxazole (as co-trimoxazole or trimethoprim/sulfamethoxazole) for a broader range of infections, including respiratory tract infections, otitis media, gastrointestinal infections, and Pneumocystis jirovecii pneumonia (PJP). When used alone, its indication is generally limited to UTIs.
Method of Action	Trimethoprim exerts its antibacterial effect by selectively inhibiting bacterial dihydrofolate reductase (DHFR). This enzyme is crucial for the synthesis of tetrahydrofolic acid, a necessary cofactor in the bacterial synthesis of purines, thymidine, and ultimately DNA and RNA. By inhibiting DHFR, trimethoprim blocks bacterial nucleic acid and protein synthesis, leading to bacteriostatic action. When combined with sulfamethoxazole, a synergistic bactericidal effect is achieved as sulfamethoxazole inhibits an earlier step in the folate synthesis pathway.
Medication Name & Brand Names	♦ Medication Name: Trimethoprim ♦ Brand Names: Primsol (oral solution - regional), Trimpex (regional), Monoprim (regional), Trimethoprim (generic) ♦ Combination Products: Bactrim, Septra, Co-trimoxazole (trimethoprim/sulfamethoxazole)

Pharmaceutical Forms & Appearance	Trimethoprim is available as oral tablets and an oral solution. Tablets are typically white, round or oval, and may be scored with specific imprints. The oral solution is usually clear and colorless to pale yellow, often with a fruity flavor.
Dosage & Administration	Dosage varies by indication and patient factors. For uncomplicated urinary tract infections, the typical adult oral dose is 100 mg twice daily for 3-10 days, or 200 mg once daily for 3-5 days. It can be taken with or without food. Ensure adequate fluid intake during treatment. Dose adjustments are necessary for patients with renal impairment.
Supplied As	Trimethoprim is supplied as: oral tablets (e.g., 100 mg, 200 mg) and oral solution (e.g., 50 mg/5 mL).
Contraindications	Trimethoprim is contraindicated in patients with known hypersensitivity to trimethoprim or any component of the formulation. It is also contraindicated in patients with documented megaloblastic anemia due to folate deficiency, or in patients with severe renal impairment (CrCl < 15 mL/min) if unable to be monitored closely. Its use in infants less than 2 months of age is generally not recommended due to theoretical risk of kernicterus.
Storage & Expiry	Trimethoprim tablets and oral solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include gastrointestinal disturbances (nausea, vomiting, diarrhea, abdominal pain), rash, pruritus (itching), and headache. More serious but less common side effects include hyperkalemia (high potassium levels), bone marrow suppression (e.g., megaloblastic anemia, leukopenia, thrombocytopenia), kidney dysfunction, and severe skin reactions (e.g., Stevens-Johnson Syndrome).
Warnings & Precautions	♦ Hematologic Effects/Bone Marrow Suppression: Trimethoprim can interfere with folate metabolism, leading to megaloblastic anemia, leukopenia, or thrombocytopenia, especially in patients with pre-existing folate deficiency (e.g., elderly, chronic alcoholics, malnourished, or those on anticonvulsants), or long-term high-dose therapy. Monitor complete blood counts (CBC) periodically, especially with prolonged use or in at-risk patients. Administering folinic acid (leucovorin) can mitigate these effects. ♦ Hyperkalemia: Can cause hyperkalemia, particularly in elderly patients, those with renal impairment, or those receiving high doses or concomitant potassium-sparing diuretics. Monitor serum potassium levels. ♦ Renal Impairment: Use with caution and dose adjust in patients with renal impairment. Can cause transient increases in serum creatinine without affecting glomerular filtration rate. ♦ Allergic Reactions/Skin Reactions: Rash is common. Severe cutaneous adverse reactions (e.g., Stevens-Johnson Syndrome, toxic epidermal necrolysis) are rare but serious. Discontinue at first sign of rash. ♦ Folice Deficiency: Use with caution in patients with potential folate deficiency. ♦ Pregnancy & Lactation: Should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus, as it is a folate antagonist. It is excreted in breast milk. ♦ Liver Dysfunction: Use with caution in patients with severe hepatic impairment. ♦ Driving/Operating Machinery: May cause dizziness; advise caution.
Missed Dose Instructions	If a dose of Trimethoprim is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Completing the full prescribed course of antibiotics is crucial for effective bacterial eradication and preventing the development of drug resistance.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, including acute (nausea, vomiting, diarrhea, headache, dizziness) and chronic (bone marrow depression leading to megaloblastic anemia, leukopenia, thrombocytopenia). There is no specific antidote for trimethoprim. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Folinic acid (leucovorin) can be administered to counteract bone marrow depression. Forced diuresis may increase excretion. Hemodialysis is modestly effective. Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Potassium-Sparing Diuretics (e.g., spironolactone, amiloride, triamterene): Increased risk of severe hyperkalemia. Monitor serum potassium closely. ♦ Digoxin: Trimethoprim can increase serum digoxin concentrations, especially in elderly patients, increasing the risk of digoxin toxicity. Monitor digoxin levels. ♦ Warfarin: May potentiate the anticoagulant effect of warfarin, increasing the risk of bleeding. Monitor INR closely. ♦ Phenytoin: May increase phenytoin levels. ♦ Methotrexate: Concomitant use can lead to increased bone marrow suppression due to additive folate antagonism. Avoid or use with extreme caution, and consider folinic acid supplementation. ♦ Pyrimethamine: Increased risk of megaloblastic anemia. ♦ ACE Inhibitors/ARBs: Increased risk of hyperkalemia. ♦ Procainamide: May increase procainamide levels. ♦ Lamivudine, Zidovudine: Potential for interaction with their renal elimination. ♦ Rifampin: Can affect trimethoprim levels.

Trimethoprim/Sulfamethoxazole (TMP/SMX) (Bactrim)

Purpose/Indication	Trimethoprim/Sulfamethoxazole (TMP/SMX), also known as co-trimoxazole, is a synergistic antibacterial combination used to treat a wide range of infections. It is commonly indicated for urinary tract infections, respiratory tract infections (including exacerbations of chronic bronchitis), otitis media, traveler's diarrhea, and specific serious infections like Pneumocystis jirovecii pneumonia (PJP), nocardiosis, and toxoplasmosis. Its broad spectrum and dual mechanism make it effective against many Gram-positive and Gram-negative bacteria.
Method of Action	This combination works by sequentially blocking two different steps in the bacterial folic acid synthesis pathway, leading to a synergistic bactericidal effect. Sulfamethoxazole, a sulfonamide, inhibits the incorporation of para-aminobenzoic acid (PABA) into dihydrofolic acid. Trimethoprim then inhibits bacterial dihydrofolate reductase, an enzyme responsible for converting dihydrofolic acid to tetrahydrofolic acid. By disrupting two essential steps in bacterial folate metabolism, both DNA and protein synthesis are halted, leading to effective bacterial eradication.
Medication Name & Brand Names	♦ Medication Name: Trimethoprim/Sulfamethoxazole (Co-trimoxazole) ♦ Brand Names: Bactrim, Septra, Resprim (regional), Co-trimoxazole (generic)
Pharmaceutical Forms & Appearance	Trimethoprim/Sulfamethoxazole is available as oral tablets (both regular and double strength), an oral suspension, and an intravenous (IV) infusion. Oral tablets are typically white, round or oval, and may be scored. The oral suspension is usually white to off-white. The IV solution is clear and colorless to yellowish.
Dosage & Administration	Dosage varies widely depending on the indication, patient's age, weight, and renal function. For uncomplicated urinary tract infections, a common adult oral dose is 160 mg TMP/800 mg SMX (double strength tablet) every 12 hours for 3-10 days. For PJP treatment, much higher doses (e.g., 15-20 mg/kg/day TMP and 75-100 mg/kg/day SMX, divided into 3-4 doses) are used. IV infusion must be diluted before administration. It can be taken with or without food, but taking it with food may reduce gastrointestinal upset. Adequate hydration is important to prevent crystalluria.
Supplied As	Trimethoprim/Sulfamethoxazole is supplied as: oral tablets (e.g., 80 mg TMP/400 mg SMX; 160 mg TMP/800 mg SMX), oral suspension (e.g., 40 mg TMP/200 mg SMX per 5 mL), and concentrate for intravenous infusion (e.g., 80 mg TMP/400 mg SMX per 5 mL vial).
Contraindications	Trimethoprim/Sulfamethoxazole is strictly contraindicated in patients with known hypersensitivity to trimethoprim or sulfonamides, or any component of the formulation. It is also contraindicated in infants less than 2 months of age (due to risk of kernicterus), during pregnancy (especially near term), in breastfeeding mothers of infants less than 2 months old, and in patients with documented megaloblastic anemia due to folate deficiency. Severe hepatic impairment or marked renal impairment (CrCl < 15 mL/min) without close monitoring are also contraindications.

Storage & Expiry	Trimethoprim/Sulfamethoxazole tablets and oral suspension should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light. Oral suspension should not be refrigerated. IV concentrate should be stored at room temperature. Always check the specific expiry date on the packaging. Once reconstituted or diluted (for IV), use promptly according to specific product instructions.
Side Effects	Common side effects include gastrointestinal disturbances (nausea, vomiting, diarrhea, abdominal pain), rash, pruritus (itching), and headache. More serious side effects can include severe skin reactions (e.g., Stevens-Johnson Syndrome, toxic epidermal necrolysis), hyperkalemia (high potassium), bone marrow suppression (e.g., megaloblastic anemia, leukopenia, thrombocytopenia), liver injury, acute kidney injury, and crystalluria.
Warnings & Precautions	♦ Severe Hypersensitivity Reactions/Skin Reactions: Can cause severe, life-threatening, or fatal cutaneous adverse reactions (e.g., Stevens-Johnson Syndrome, toxic epidermal necrolysis, DRESS syndrome). Discontinue at the first appearance of skin rash. ♦ Hematologic Effects/Bone Marrow Suppression: Can cause bone marrow depression (e.g., megaloblastic anemia, leukopenia, neutropenia, thrombocytopenia) by interfering with folate metabolism. Risk is increased with high doses, prolonged therapy, elderly patients, or pre-existing folate deficiency. Monitor complete blood counts (CBC) regularly. Folinic acid (leucovorin) may be given to counteract this. ♦ Hyperkalemia: Can cause hyperkalemia, especially in elderly patients, those with renal impairment, or those receiving high doses or concomitant potassium-sparing diuretics. Monitor serum potassium levels. ♦ Renal Impairment & Crystalluria: Can cause acute kidney injury or crystalluria. Maintain adequate hydration during treatment to prevent crystalluria. Dose adjustment is mandatory for patients with renal impairment. ♦ Hepatic Impairment: Cases of liver injury, including fatal hepatic necrosis, have been reported. Use with caution in patients with hepatic impairment. ♦ Fetal Toxicity: Contraindicated in pregnancy, especially near term, due to risk of kernicterus in the infant and folate antagonism. ♦ G6PD Deficiency: Can cause hemolytic anemia in glucose-6-phosphate dehydrogenase (G6PD) deficient patients. Avoid or use with extreme caution. ♦ Hypoglycemia: Rare cases of hypoglycemia, especially in patients with impaired renal function, liver disease, or malnutrition. ♦ Clostridioides difficile-associated Diarrhea (CDAD): Can occur with nearly all antibacterial agents, including TMP/SMX. ♦ Photosensitivity: Can cause photosensitivity reactions. Advise patients to avoid prolonged sun exposure. ♦ Porphyria: May exacerbate acute intermittent porphyria.
Missed Dose Instructions	If a dose of Trimethoprim/Sulfamethoxazole is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Completing the full prescribed course of antibiotics is crucial for effective bacterial eradication and preventing the development of drug resistance and relapse of infection.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, including acute (nausea, vomiting, diarrhea, headache, dizziness) and chronic (bone marrow depression leading to megaloblastic anemia, leukopenia, thrombocytopenia; severe skin reactions; hyperkalemia; kidney dysfunction). There is no specific antidote for TMP/SMX overdose. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Administer folinic acid (leucovorin) to counteract bone marrow depression. Maintain hydration to prevent crystalluria. Acidification of urine can enhance sulfamethoxazole excretion, but alkalinization is sometimes preferred to prevent crystalluria. Hemodialysis is modestly effective. Seek immediate emergency medical help.
Medicine Interactions	♦ Warfarin: Potentiates the anticoagulant effect of warfarin significantly, increasing the risk of bleeding. Monitor INR closely, especially when initiating or discontinuing TMP/SMX. ♦ Methotrexate: Concomitant use can lead to increased bone marrow suppression due to additive folate antagonism. Avoid or use with extreme caution, and consider folinic acid supplementation. ♦ Potassium-Sparing Diuretics (e.g., spironolactone, amiloride, triamterene), ACE Inhibitors, ARBs, Eplerenone: Increased risk of severe hyperkalemia. Monitor serum potassium closely. ♦ Phenytoin: May increase phenytoin levels, increasing the risk of toxicity. Monitor phenytoin levels. ♦ Digoxin: May increase serum digoxin concentrations, especially in elderly patients, increasing the risk of digoxin toxicity. Monitor digoxin levels. ♦ Cyclosporine: May lead to increased risk of nephrotoxicity and decreased cyclosporine levels. ♦ Oral Hypoglycemics (sulfonylureas, e.g., glipizide, glyburide): May potentiate hypoglycemic effect. Monitor blood glucose. ♦ Lamivudine, Zidovudine: Potential for interaction with their renal elimination. ♦ Amiodarone: Increased risk of QT prolongation and torsades de pointes. ♦ Antacids (containing aluminum, magnesium): May decrease absorption of sulfamethoxazole.

Valacyclovir (Valtrex)

Purpose/Indication	Valacyclovir is an antiviral medication used to treat various herpes virus infections. It is indicated for the treatment of herpes zoster (shingles), genital herpes (initial and recurrent episodes, and for suppression of recurrent episodes), and herpes labialis (cold sores). It is also used to reduce the risk of transmission of genital herpes to uninfected partners when used as suppressive therapy.
Method of Action	Valacyclovir is a prodrug of acyclovir. After oral administration, it is rapidly and extensively converted to acyclovir by first-pass intestinal and hepatic metabolism. Acyclovir then enters herpesvirus-infected cells, where it is selectively phosphorylated by viral thymidine kinase to acyclovir monophosphate, which is then further phosphorylated by cellular kinases to acyclovir triphosphate. Acyclovir triphosphate competitively inhibits viral DNA polymerase and is incorporated into viral DNA, leading to chain termination and inhibition of viral DNA replication. This selective activation mechanism ensures its antiviral activity is primarily directed at virus-infected cells.
Medication Name & Brand Names	♦ Medication Name: Valacyclovir Hydrochloride ♦ Brand Names: Valtrex, Valacyclovir (generic)
Pharmaceutical Forms & Appearance	Valacyclovir is available as oral film-coated tablets. Tablets are typically white, caplet-shaped, and film-coated, with specific imprints indicating strength and/or manufacturer.
Dosage & Administration	Dosage varies significantly by indication and patient renal function. For herpes zoster (shingles), the typical adult oral dose is 1 gram three times daily for 7 days. For genital herpes (initial episode), 1 gram twice daily for 7-10 days. For recurrent genital herpes, 500 mg twice daily for 3 days. For suppression of recurrent genital herpes, 1 gram once daily (or 500 mg once daily for some patients). For herpes labialis (cold sores), 2 grams twice daily for 1 day. Dosage adjustments are necessary for patients with renal impairment. Can be taken with or without food. Start treatment at the first sign or symptom of infection.
Supplied As	Valacyclovir is supplied as: oral film-coated tablets (e.g., 500 mg, 1 gram).
Contraindications	Valacyclovir is contraindicated in patients with known hypersensitivity to valacyclovir, acyclovir, or any component of the formulation.
Storage & Expiry	Valacyclovir tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.

Side Effects	Common side effects include headache, nausea, abdominal pain, and fatigue. More serious but less common side effects, particularly with high doses or in patients with renal impairment, include central nervous system effects (e.g., confusion, hallucinations, agitation, dizziness, seizures), and acute kidney injury. Thrombotic thrombocytopenic purpura/hemolytic uremic syndrome (TTP/HUS) is a rare but life-threatening complication reported in immunocompromised patients, especially those with severe HIV or post-renal transplant.
Warnings & Precautions	♦ Renal Impairment: Dose adjustment is necessary for patients with renal impairment to prevent acyclovir accumulation and increased risk of adverse effects, especially CNS effects and nephrotoxicity. Maintain adequate hydration during treatment. ♦ CNS Effects: Can cause neurological symptoms, including confusion, agitation, dizziness, hallucinations, and seizures, especially in elderly patients or those with renal impairment. Monitor for these symptoms. ♦ Immunocompromised Patients: Patients with advanced HIV disease or those who have undergone bone marrow or renal transplantation may be at increased risk of TTP/HUS (Thrombotic Thrombocytopenic Purpura/Hemolytic Uremic Syndrome), a rare but potentially fatal complication. Use with caution in these populations. ♦ Hydration: Ensure adequate hydration during therapy, particularly when taking high doses or in patients with renal impairment, to prevent renal tubular crystallization. ♦ Transmission of Genital Herpes: Valacyclovir suppressive therapy reduces but does not eliminate the risk of genital herpes transmission. Patients should still be advised to practice safe sex. ♦ Elderly Patients: More likely to have impaired renal function; dose adjustment and close monitoring for adverse effects are crucial. ♦ Driving/Operating Machinery: May cause dizziness or CNS effects; advise caution.
Missed Dose Instructions	If a dose of Valacyclovir is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For optimal antiviral effect, especially in acute infections, adhering to the prescribed dosing schedule is important.
Overdose Instructions	Overdose symptoms are generally an exaggeration of known side effects, primarily gastrointestinal upset (nausea, vomiting), headache, and neurological symptoms (dizziness, confusion, hallucinations). Acute renal failure is a potential serious complication, especially with large doses. Hemodialysis can significantly remove acyclovir from the blood and may be beneficial in cases of severe overdose or acute renal failure. Treatment is supportive and symptomatic. Maintain hydration. Seek medical attention if a large amount is ingested or severe symptoms develop.
Medicine Interactions	♦ Nephrotoxic Drugs (e.g., NSAIDs, aminoglycosides, cyclosporine, tacrolimus, cisplatin): Concomitant use with valacyclovir may increase the risk of renal dysfunction due to additive nephrotoxicity. Monitor renal function closely. ♦ Cimetidine & Probenecid: Both drugs can increase acyclovir plasma concentrations by reducing its renal clearance, potentially increasing the risk of acyclovir-related toxicity. Co-administration should be with caution, and dose reduction of valacyclovir may be necessary, especially in patients with renal impairment. ♦ Mycophenolate Mofetil (MMF): Concomitant use with valacyclovir may increase plasma concentrations of both drugs due to competition for renal tubular secretion. Monitor patients closely. ♦ No significant interactions with most other commonly used medications are expected due to valacyclovir's rapid conversion to acyclovir and acyclovir's primary renal excretion with minimal hepatic metabolism.

Valsartan (Diovan)

Purpose/Indication	Valsartan is an angiotensin II receptor blocker (ARB) primarily used for the treatment of hypertension (high blood pressure). It is also indicated for heart failure to reduce cardiovascular mortality and morbidity, and to reduce cardiovascular mortality in clinically stable patients with left ventricular failure or left ventricular dysfunction following myocardial infarction. Its purpose is to lower blood pressure, improve cardiac function, and provide cardiovascular protection.
Method of Action	Valsartan works by selectively blocking the binding of angiotensin II to the angiotensin II type 1 (AT1) receptor in various tissues, including vascular smooth muscle, the adrenal gland, and the heart. Angiotensin II is a potent vasoconstrictor and also stimulates aldosterone secretion, leading to sodium and water retention, and promotes cardiac remodeling. By blocking AT1 receptors, valsartan causes vasodilation, reduces aldosterone-mediated effects, and ultimately lowers blood pressure and reduces cardiac workload without affecting ACE.
Medication Name & Brand Names	♦ Medication Name: Valsartan ♦ Brand Names: Diovan, Valsartan (generic) ♦ Combination Products: Diovan HCT (valsartan/hydrochlorothiazide), Entresto (valsartan/sacubitril), Exforge (valsartan/amlodipine), Exforge HCT (valsartan/amlodipine/hydrochlorothiazide)
Pharmaceutical Forms & Appearance	Valsartan is available as oral film-coated tablets. Tablets are typically round or oval, film-coated, and may vary in color and imprint depending on strength (e.g., yellowish-white to red-brown, with specific imprints indicating dose).
Dosage & Administration	Dosage is individualized based on the patient's condition, blood pressure response, and renal function. For hypertension, the typical adult oral dose is 80 mg to 160 mg once daily. The dose can be adjusted from 40 mg to 320 mg once daily. For heart failure and post-MI, the typical starting dose is 20 mg or 40 mg twice daily, titrated up to a target dose of 160 mg twice daily as tolerated. It can be taken with or without food.
Supplied As	Valsartan is supplied as: oral film-coated tablets (e.g., 40 mg, 80 mg, 160 mg, 320 mg).
Contraindications	Valsartan is strictly contraindicated in patients with known hypersensitivity to valsartan or any component of the formulation. It is strictly contraindicated in pregnancy due to the risk of fetal injury or death. Concomitant use with aliskiren is contraindicated in patients with diabetes mellitus or renal impairment (eGFR < 60 mL/min/1.73m2).
Storage & Expiry	Valsartan tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from moisture. Keep in the original tightly closed container. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include dizziness, headache, fatigue, and orthostatic hypotension. More serious but less common side effects include hyperkalemia (high potassium levels), renal impairment, hypotension, and rarely, angioedema (swelling of the face, lips, tongue, throat), though less frequent than with ACE inhibitors.
Warnings & Precautions	♦ BLACK BOX WARNING: Fetal Toxicity: Use of drugs that act on the renin-angiotensin system during the second and third trimesters of pregnancy can cause injury and death to the developing fetus. Discontinue as soon as pregnancy is detected. ♦ Hypotension: May cause symptomatic hypotension, especially in volume-depleted patients (e.g., those on high-dose diuretics), or in severe heart failure. Initiate with low doses and monitor. ♦ Hyperkalemia: Can cause hyperkalemia, especially in patients with renal impairment, diabetes, or those taking potassium-sparing diuretics, potassium supplements, or other drugs that increase potassium. Monitor serum potassium closely. ♦ Renal Impairment: Can cause acute renal failure, particularly in patients with pre-existing renal insufficiency, severe congestive heart failure, or bilateral renal artery stenosis. Monitor renal function regularly. ♦ Dual Blockade of RAAS: Dual blockade of the renin-angiotensin-aldosterone system (RAAS) with ARBs, ACE inhibitors, or aliskiren is associated with increased risks of hypotension, hyperkalemia, and renal function changes; generally avoid. (Contraindicated with aliskiren in diabetes/renal impairment). ♦ Angioedema: Rare cases of angioedema have been reported. If laryngeal stridor or angioedema of the face, extremities, lips, tongue, glottis, or larynx occurs, discontinue valsartan immediately. ♦ Aortic/Mitral Valve Stenosis or Hypertrophic Obstructive Cardiomyopathy: Use with caution.

MEDICATION

Medication

R - Z

Missed Dose Instructions	If a dose of Valsartan is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. Consistent daily dosing is important for effective blood pressure control and cardiovascular protection, especially in conditions like heart failure.
Overdose Instructions	Overdose symptoms are primarily severe hypotension, dizziness, and tachycardia (rapid heart rate). Bradycardia (slow heart rate) may also occur. There is no specific antidote for valsartan. Treatment is supportive and symptomatic. Maintain fluid and electrolyte balance. If ingestion was recent, gastric lavage and activated charcoal may be considered. Lay the patient supine with legs elevated. IV fluid infusion and vasopressors may be needed for hypotension. Valsartan is not removed by hemodialysis. Seek immediate emergency medical help.
Medicine Interactions	♦ Aliskiren: Contraindicated in patients with diabetes mellitus or renal impairment due to increased risk of hypotension, hyperkalemia, and renal impairment. ♦ Potassium-Sparing Diuretics (e.g., spironolactone, amiloride, triamterene) & Potassium Supplements: Significant risk of severe hyperkalemia. Avoid concomitant use or monitor potassium levels very closely. ♦ NSAIDs (Non-Steroidal Anti-inflammatory Drugs, including selective COX-2 inhibitors): May reduce the antihypertensive effect of ARBs and increase the risk of renal impairment, especially in elderly, volume-depleted, or renally impaired patients. Use with caution. ♦ Lithium: ARBs can reduce the renal clearance of lithium, leading to increased serum lithium levels and toxicity. Monitor lithium levels closely. ♦ Diuretics: Enhanced hypotensive effect, especially with the first dose. Consider withholding diuretics prior to initiating valsartan. ♦ ACE Inhibitors (e.g., enalapril, lisinopril): Dual blockade of RAAS with an ARB and an ACE inhibitor is generally not recommended due to increased risk of adverse events. ♦ Sacubitril (in Entresto): Used in combination to enhance effects in heart failure; specific contraindications and warnings apply for this combination. ♦ No significant interactions with cytochrome P450 enzymes.

Vancomycin (Vancocin)

Purpose/Indication	Vancomycin is a glycopeptide antibiotic primarily used to treat serious and life-threatening infections caused by Gram-positive bacteria, especially methicillin-resistant Staphylococcus aureus (MRSA) and Clostridioides difficile infection (CDI) in its oral form. Intravenous vancomycin is indicated for conditions like complicated skin and soft tissue infections, bloodstream infections, endocarditis, osteomyelitis, and pneumonia, particularly when caused by multidrug-resistant Gram-positive pathogens. Oral vancomycin is used exclusively for CDI.
Method of Action	Vancomycin exerts its bactericidal effect by inhibiting bacterial cell wall synthesis. It binds to the D-Ala-D-Ala terminus of peptidoglycan precursors, preventing the incorporation of these building blocks into the growing cell wall. This action weakens the bacterial cell wall, leading to increased permeability, osmotic lysis, and ultimately bacterial cell death. Its unique mechanism of action makes it effective against many Gram-positive bacteria, including those resistant to beta-lactam antibiotics.
Medication Name & Brand Names	♦ Medication Name: Vancomycin Hydrochloride ♦ Brand Names: Vancocin (oral capsules), Firvanq (oral solution), Vanco (generic for IV and oral)
Pharmaceutical Forms & Appearance	Vancomycin is available as a powder for injection (for intravenous or oral reconstitution), and oral capsules or an oral solution. The powder for injection is typically white to off-white, and the reconstituted solution is clear and colorless to pale yellow. Oral capsules are typically white to off-white, and the oral solution is generally clear.
Dosage & Administration	Dosage varies significantly by indication, patient weight, renal function, and therapeutic drug monitoring. For intravenous systemic infections, typical adult doses are 15-20 mg/kg (up to 1-2 grams) every 8-12 hours, adjusted to achieve target trough levels (e.g., 10-20 mcg/mL). For oral Clostridioides difficile infection, typical adult doses are 125 mg to 500 mg orally four times daily for 10-14 days. IV vancomycin must be infused slowly over at least 60 minutes to avoid "red man syndrome." Oral vancomycin is not absorbed systemically and is used only for gut infections.
Supplied As	Vancomycin is supplied as: sterile powder for injection (e.g., 500 mg, 1 gram, 10 grams per vial), oral capsules (e.g., 125 mg, 250 mg), and powder for oral solution.
Contraindications	Vancomycin is contraindicated in patients with known hypersensitivity to vancomycin. Intravenous vancomycin is generally not indicated for mild infections or as a first-line agent where less toxic antibiotics are effective. Oral vancomycin is not for systemic infections.
Storage & Expiry	Vancomycin powder for injection should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F). Once reconstituted, the solution stability varies by concentration and diluent (check specific product information, often stable for 24 hours at room temperature or longer refrigerated). Oral capsules should be stored at room temperature. Oral solution, once prepared, typically requires refrigeration and has a limited shelf life (e.g., 14 days). Always check the specific expiry date on the packaging.
Side Effects	The most significant side effects are nephrotoxicity (kidney damage) and ototoxicity (hearing loss, tinnitus, vertigo). Other common side effects include "red man syndrome" (a non-IgE mediated infusion-related reaction with flushing, rash, itching, and hypotension due to rapid IV infusion), phlebitis at the infusion site, and gastrointestinal upset with oral use.
Warnings & Precautions	♦ BLACK BOX WARNING (in some regions/products): Nephrotoxicity & Ototoxicity: Vancomycin can cause both nephrotoxicity and ototoxicity, which may be irreversible. The risk is increased with higher doses, prolonged therapy, pre-existing renal impairment, and concomitant use of other nephrotoxic or ototoxic drugs. Monitor serum creatinine and vancomycin trough levels frequently. Perform audiometric testing for high-risk patients or those on prolonged therapy. ♦ Red Man Syndrome (Infusion-Related Reactions): Occurs with rapid intravenous infusion. Characterized by flushing, rash (erythematous or urticarial), pruritus, hypotension, and sometimes angioedema or chest pain. Prevent by infusing over at least 60 minutes (or longer for larger doses) and by premedicating with antihistamines. ♦ Oral Use for CDI: Oral vancomycin is not absorbed systemically and is not effective for systemic infections; it is only for Clostridioides difficile infection. ♦ Superinfection: Prolonged use can lead to overgrowth of non-susceptible organisms. ♦ Neutropenia/Thrombocytopenia: Rare reports of transient neutropenia or thrombocytopenia, especially with high doses or prolonged use. Monitor blood counts. ♦ Pseudomembranous Colitis: Although used to treat CDI, it can rarely cause or exacerbate it if a different pathogen causes the colitis. ♦ Allergic Reactions: Rare severe hypersensitivity reactions (e.g., anaphylaxis).
Missed Dose Instructions	Vancomycin is typically administered by healthcare professionals in a controlled setting (e.g., hospital) for IV use, or strict adherence for oral CDI treatment. For IV vancomycin, adherence to the prescribed dosing schedule and therapeutic drug monitoring (trough levels) is crucial for efficacy and safety. If a dose is missed, it should be reported immediately to the prescribing healthcare professional, who will determine the appropriate course of action based on the patient's condition, renal function, and upcoming trough level measurements. For oral vancomycin (CDI), take the missed dose as soon as remembered. If it is almost time for the next dose, skip the missed dose and continue with the regular schedule. Do not take a double dose.

Vancomycin (Vancocin)	
Overdose Instructions	Overdose symptoms are primarily severe nephrotoxicity (acute renal failure) and ototoxicity (hearing loss, tinnitus, vertigo). Other symptoms may include hypotension, profound "red man syndrome" if IV infused, and potential for more generalized toxicity. There is no specific antidote for vancomycin. Treatment is supportive and symptomatic. Hemodialysis or hemofiltration can significantly remove vancomycin from the blood and may be beneficial in severe overdose or acute renal failure. Maintain hydration and monitor renal function, hearing, and vital signs closely. Seek immediate emergency medical help.
Medicine Interactions	♦ Other Nephrotoxic Drugs (e.g., aminoglycosides like gentamicin, amikacin; amphotericin B; cisplatin; cyclosporine; NSAIDs): Concomitant use significantly increases the risk of nephrotoxicity. Avoid or use with extreme caution and monitor renal function very closely. ♦ Other Ototoxic Drugs (e.g., aminoglycosides like gentamicin, amikacin; loop diuretics like furosemide; cisplatin): Concomitant use significantly increases the risk of ototoxicity. Avoid or use with extreme caution. ♦ Anesthetic Agents: Concomitant use of IV vancomycin with anesthetic agents has been associated with increased incidence of infusion-related reactions (e.g., hypotension, flushing, erythema, urticaria, bronchospasm) when administered prior to anesthesia. Infuse vancomycin slowly. ♦ Neuromuscular Blocking Agents (e.g., succinylcholine, rocuronium): Vancomycin can prolong the neuromuscular blocking effects. Monitor for prolonged respiratory depression. ♦ Cholestyramine (for oral vancomycin): May bind to oral vancomycin and reduce its efficacy. Administer several hours apart. ♦ No significant interactions with cytochrome P450 enzymes.

Venlafaxine (Effexor)

Venlafaxine (Effexor)	
Purpose/Indication	Venlafaxine is a serotonin-norepinephrine reuptake inhibitor (SNRI) antidepressant primarily used for the treatment of major depressive disorder (MDD). It is also indicated for generalized anxiety disorder (GAD), social anxiety disorder (SAD), and panic disorder (PD). Its purpose is to alleviate symptoms of depression and anxiety by restoring the balance of certain neurotransmitters in the brain.
Method of Action	Venlafaxine and its active metabolite, O-desmethylvenlafaxine (desvenlafaxine), work by potently inhibiting the reuptake of both serotonin and norepinephrine in the central nervous system. At lower doses, it primarily affects serotonin reuptake, while at higher doses, it also significantly inhibits norepinephrine reuptake. This dual reuptake inhibition leads to increased concentrations of these neurotransmitters in the synaptic cleft, enhancing their activity and thereby exerting antidepressant and anxiolytic effects. It has a weak inhibitory effect on dopamine reuptake.
Medication Name & Brand Names	♦ Medication Name: Venlafaxine Hydrochloride ♦ Brand Names: Effexor (immediate-release), Effexor XR (extended-release), Venlafaxine (generic)
Pharmaceutical Forms & Appearance	Venlafaxine is available as oral tablets (immediate-release) and extended-release capsules or tablets. Immediate-release tablets are typically round or oval, and may vary in color. Extended-release capsules often contain beads, and can vary in color and size. Extended-release tablets are often film-coated and may be oblong.
Dosage & Administration	Dosage is individualized based on the patient's condition and response, starting with a low dose and gradually titrating upwards. For MDD, typical adult oral starting doses are 75 mg/day (for extended-release) or 37.5 mg twice daily (for immediate-release), often increasing to 75-225 mg/day. Doses can be up to 375 mg/day for severe depression in hospitalized patients. Extended-release forms are taken once daily. It should be taken with food. Dosage should be tapered gradually upon discontinuation to avoid withdrawal symptoms.
Supplied As	Venlafaxine is supplied as: oral immediate-release tablets (e.g., 25 mg, 37.5 mg, 50 mg, 75 mg, 100 mg), and oral extended-release capsules (e.g., 37.5 mg, 75 mg, 150 mg, 225 mg) or tablets.
Contraindications	Venlafaxine is strictly contraindicated in patients with known hypersensitivity to venlafaxine or any component of the formulation. It is absolutely contraindicated in patients taking monoamine oxidase inhibitors (MAOIs) or within 14 days of stopping an MAOI, due to the significant risk of serotonin syndrome. Conversely, an MAOI should not be started within at least 7 days of stopping venlafaxine.
Storage & Expiry	Venlafaxine tablets and capsules should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include nausea, headache, insomnia, dizziness, sweating, dry mouth, constipation, nervousness, and sexual dysfunction. More serious but less common side effects include elevated blood pressure, serotonin syndrome, seizures, increased risk of suicidal thoughts and behavior (especially in young adults), hyponatremia, and withdrawal symptoms upon abrupt discontinuation.
Warnings & Precautions	♦ BLACK BOX WARNING: Suicidality: Antidepressants increase the risk of suicidal thoughts and behavior in children, adolescents, and young adults (up to age 24) with major depressive disorder and other psychiatric disorders. Monitor patients closely for clinical worsening, suicidality, or unusual changes in behavior. ♦ Serotonin Syndrome: Potentially life-threatening condition that can occur with concomitant use of other serotonergic drugs (e.g., MAOIs - contraindicated, SSRIs, triptans, lithium, tramadol, St. John's Wort). Symptoms include mental status changes, autonomic instability, neuromuscular aberrations, and GI symptoms. Discontinue immediately if suspected. ♦ Elevated Blood Pressure: Can cause sustained dose-related increases in blood pressure. Monitor blood pressure regularly, especially with dose increases. Pre-existing hypertension should be controlled before starting venlafaxine. ♦ Withdrawal Symptoms: Abrupt discontinuation or rapid dose reduction, especially after prolonged use, can lead to severe withdrawal symptoms (e.g., dizziness, headache, nausea, paresthesia, anxiety, dysphoria, insomnia). Taper dose gradually over weeks to months. ♦ Seizures: Can lower the seizure threshold. Use with caution in patients with a history of seizures. ♦ Mania/Hypomania Activation: Can precipitate a manic or hypomanic episode in patients with bipolar disorder. Screen for bipolar disorder before initiating. ♦ Hyponatremia: Can cause hyponatremia (low sodium levels), especially in elderly or volume-depleted patients. ♦ Abnormal Bleeding: May increase the risk of bleeding, especially with concomitant use of antiplatelet agents or anticoagulants. ♦ Angle-Closure Glaucoma: Can cause mydriasis (pupil dilation), potentially triggering an acute angle-closure glaucoma attack. Use with caution in patients with a history of glaucoma. ♦ Renal/Hepatic Impairment: Use with caution and reduce dose in patients with renal or hepatic impairment. ♦ Sexual Dysfunction: Common side effect. ♦ Driving/Operating Machinery: May impair judgment, thinking, or motor skills.
Missed Dose Instructions	If a dose of Venlafaxine (immediate-release) is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For extended-release (XR) formulations, if a dose is missed, take it as soon as remembered if it's within the same day. If it's the next day, skip the missed dose and resume your regular once-daily schedule. Do not take two doses at once. Consistent daily dosing is important for maintaining stable drug levels and therapeutic effect.

Overdose Instructions	Overdose symptoms range from mild (somnolence, nausea, vomiting, dizziness, tachycardia) to severe (seizures, serotonin syndrome, QTc prolongation, ventricular arrhythmias, respiratory depression, coma). Fatal outcomes have been reported, especially in mixed overdoses. There is no specific antidote for venlafaxine overdose. Treatment is supportive and symptomatic. Focus on maintaining an open airway, ventilation, and cardiovascular support. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Continuous monitoring of cardiac rhythm and vital signs is essential. Dialysis is generally not effective due to the high volume of distribution. Seek immediate emergency medical help.
Medicine Interactions	♦ MAOIs (Monoamine Oxidase Inhibitors, e.g., phenelzine, tranylcypromine, selegiline, linezolid, methylene blue): STRICTLY CONTRAINDICATED. Concomitant use or use within 14 days of stopping an MAOI (or MAOI within 7 days of stopping venlafaxine) can lead to severe, potentially fatal serotonin syndrome. ♦ Other Serotonergic Drugs (e.g., SSRIs, SNRIs, triptans, tramadol, lithium, buspirone, fentanyl, St. John's Wort, dextromethorphan): Increased risk of serotonin syndrome. Use with caution; monitor for symptoms. ♦ Drugs that Affect Blood Pressure (e.g., alpha-blockers, beta-blockers): Venlafaxine can increase blood pressure; monitor concomitant use. ♦ Drugs that Lower Seizure Threshold (e.g., TCAs, other antidepressants, antipsychotics, bupropion, tramadol): Increased risk of seizures. Use with caution. ♦ Anticoagulants (e.g., warfarin) & Antiplatelet Agents (e.g., aspirin, NSAIDs): Increased risk of bleeding. Monitor INR closely for warfarin. ♦ Cimetidine: Can inhibit venlafaxine metabolism, increasing its levels. ♦ Haloperidol, Risperidone, Metoprolol: Venlafaxine can increase plasma levels of these drugs due to CYP2D6 inhibition. Monitor and adjust doses. ♦ Alcohol: Potentiates CNS depressant effects; avoid. ♦ CYP2D6 Inhibitors (e.g., fluoxetine, paroxetine, quinidine): May increase levels of venlafaxine, but decrease levels of its active metabolite, O-desmethylvenlafaxine. Overall, the ratio of active compounds remains similar, but caution is still advised. ♦ CYP3A4 Inhibitors (e.g., ketoconazole, erythromycin, clarithromycin, indinavir): Can increase venlafaxine and O-desmethylvenlafaxine levels. Use with caution.

Verapamil (Calan)

Purpose/Indication	Verapamil is a non-dihydropyridine calcium channel blocker primarily used for the management of hypertension (high blood pressure), angina pectoris (chest pain due to reduced blood flow to the heart), and certain supraventricular tachyarrhythmias (abnormally fast heart rhythms originating above the ventricles, such as atrial fibrillation, atrial flutter, and paroxysmal supraventricular tachycardia - PSVT). It helps to relax blood vessels, reduce heart rate, and decrease the heart's workload.
Method of Action	Verapamil works by inhibiting the influx of extracellular calcium ions across the cell membranes of cardiac and vascular smooth muscle cells. This action leads to several physiological effects: 1) Vasodilation: Decreases peripheral vascular resistance, lowering blood pressure. 2) Negative Chronotropic Effect: Slows the heart rate by depressing sinus node automaticity and slowing conduction through the atrioventricular (AV) node. 3) Negative Inotropic Effect: Reduces myocardial contractility, decreasing the heart's workload. These combined effects contribute to its anti-hypertensive, anti-anginal, and anti-arrhythmic properties.
Medication Name & Brand Names	♦ Medication Name: Verapamil Hydrochloride ♦ Brand Names: Calan, Isoptin, Verelan (extended-release), Verelan PM (extended-release), Covera-HS (extended-release), Verapamil (generic)
Pharmaceutical Forms & Appearance	Verapamil is available as oral immediate-release tablets, oral extended-release tablets/capsules, and as an intravenous (IV) injection. Oral tablets are typically round or oval, and may be film-coated or sugar-coated, varying in color and imprint. Extended-release formulations are designed to be taken once or twice daily. The IV solution is clear and colorless.
Dosage & Administration	Dosage varies significantly by indication, patient response, and formulation. For oral hypertension, typical adult immediate-release doses are 80-120 mg three times daily, or extended-release 180-480 mg once daily. For angina, immediate-release doses typically range from 80-120 mg three times daily. For arrhythmias, doses are often individualized, starting with smaller oral doses (e.g., 40-80 mg 3-4 times daily) or IV bolus (e.g., 2.5-10 mg over 2 minutes). Oral forms can be taken with food. IV administration requires careful monitoring.
Supplied As	Verapamil is supplied as: oral immediate-release tablets (e.g., 40 mg, 80 mg, 120 mg), oral extended-release tablets/capsules (e.g., 120 mg, 180 mg, 240 mg, 360 mg), and solution for intravenous injection (e.g., 2.5 mg/mL).
Contraindications	Verapamil is strictly contraindicated in patients with known hypersensitivity to verapamil. It is also contraindicated in severe left ventricular dysfunction, hypotension (systolic BP < 90 mmHg), cardiogenic shock, sick sinus syndrome (unless a functional pacemaker is in place), second- or third-degree AV block (unless a functional pacemaker is in place), and in patients with atrial flutter or atrial fibrillation and an accessory bypass tract (e.g., Wolff-Parkinson-White or Lown-Ganong-Levine syndromes) due to risk of dangerously fast ventricular rates. Concomitant IV beta-blocker use is also a contraindication due to risk of severe bradycardia and asystole.
Storage & Expiry	Verapamil tablets, capsules, and IV solution should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers. Do not freeze the IV solution. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include constipation (very common with oral forms), headache, dizziness, fatigue, nausea, and peripheral edema (swelling of ankles/feet). More serious but less common side effects include bradycardia (slow heart rate), AV block, hypotension, worsening of heart failure, and elevated liver enzymes.
Warnings & Precautions	♦ Cardiac Effects: Can cause bradycardia, AV block (potentially leading to asystole), and hypotension, especially with IV administration or in patients with pre-existing conduction abnormalities. Use with extreme caution in patients with heart failure or reduced left ventricular function as it can worsen cardiac output. ♦ Concomitant Beta-Blockers: Concomitant use (especially IV) with beta-blockers is generally contraindicated due to the additive effects on heart rate, AV conduction, and cardiac contractility, which can lead to severe bradycardia, AV block, and hypotension. Oral combination should be with caution. ♦ Hypotension: May cause symptomatic hypotension. Monitor blood pressure closely. ♦ Liver Dysfunction: Verapamil is extensively metabolized in the liver. Use with caution and consider dose reduction in patients with hepatic impairment, as drug levels can increase significantly. ♦ Kidney Dysfunction: Use with caution in patients with renal impairment; however, dose adjustment is usually not necessary unless severe. ♦ Geriatric Use: Elderly patients are more likely to experience adverse effects, especially bradycardia, constipation, and hypotension. Use lower starting doses. ♦ Grapefruit Juice: Can increase verapamil levels, potentially increasing side effects. Advise patients to avoid grapefruit juice. ♦ Neuromuscular Transmission: Has been reported to potentiate the effects of neuromuscular blocking agents. ♦ Digoxin: Can increase serum digoxin levels. Monitor digoxin levels and reduce digoxin dose if necessary. ♦ Constipation: A very common and often troublesome side effect; advise on dietary measures or laxatives.
Missed Dose Instructions	For oral immediate-release Verapamil: If a dose is missed, take it as soon as remembered. However, if it is almost time for the next scheduled dose, skip the missed dose and continue with the regular schedule. Do not take a double dose. For oral extended-release Verapamil: If a dose is missed, take it as soon as remembered if it's within several hours of the usual time. Otherwise, skip the missed dose and take the next one at the regular time. Do not take a double dose. Consistency is important for blood pressure and heart rate control.
Overdose Instructions	Overdose symptoms are typically profound hypotension, severe bradycardia, AV block (including complete heart block), asystole, reduced cardiac contractility, and metabolic acidosis. Non-cardiac effects may include hyperglycemia and confusion. There is no specific antidote for verapamil. Treatment is supportive and symptomatic. Gastric lavage and activated charcoal may be considered for recent oral ingestion. Intravenous calcium gluconate or calcium chloride can help reverse some cardiac depression. Other treatments include vasopressors (e.g., norepinephrine), atropine, glucagon, and inotropic agents (e.g., dopamine, dobutamine). Pacemaker insertion may be required for severe bradycardia/heart block. Hemodialysis is not effective. Seek immediate emergency medical help.

Medicine Interactions	♦ Beta-Blockers (e.g., metoprolol, propranolol): IV concomitant use is CONTRAINDICATED. Oral co-administration requires extreme caution due to additive negative effects on heart rate, AV conduction, and myocardial contractility, leading to severe bradycardia, heart block, and hypotension. ♦ Digoxin: Verapamil can increase serum digoxin levels by inhibiting its renal and biliary clearance. Monitor digoxin levels and reduce digoxin dose as needed. ♦ Antiarrhythmics (e.g., flecainide, disopyramide, quinidine, amiodarone): Increased risk of adverse cardiac effects due to additive effects on contractility, conduction, and heart rate. Avoid or use with extreme caution. ♦ Statins (especially simvastatin, lovastatin, atorvastatin): Verapamil inhibits CYP3A4, which metabolizes many statins, leading to increased statin levels and increased risk of myopathy/rhabdomyolysis. Consider lower statin doses or use statins not metabolized by CYP3A4 (e.g., pravastatin, rosuvastatin). ♦ Grapefruit Juice: Inhibits CYP3A4, increasing oral verapamil bioavailability and plasma levels, potentially increasing side effects. Advise patients to avoid. ♦ CYP3A4 Inducers (e.g., rifampin, carbamazepine, phenobarbital, phenytoin, St. John's Wort): Can decrease verapamil levels, reducing efficacy. ♦ CYP3A4 Inhibitors (e.g., ketoconazole, itraconazole, clarithromycin, erythromycin, ritonavir): Can increase verapamil levels, increasing toxicity. ♦ Alpha-Blockers (e.g., prazosin, doxazosin): Increased risk of hypotension. ♦ Lithium: May alter lithium levels. ♦ Neuromuscular Blocking Agents: May potentiate their effects. ♦ Aspirin: No significant interaction

Warfarin (Coumadin)

Purpose/Indication	Warfarin is an oral anticoagulant used to prevent and treat various thromboembolic conditions. It is indicated for the prophylaxis and treatment of venous thrombosis and its extension (e.g., deep vein thrombosis - DVT, pulmonary embolism - PE), prophylaxis and treatment of thromboembolic complications associated with atrial fibrillation and/or cardiac valve replacement, and to reduce the risk of death, recurrent myocardial infarction, and thromboembolic events after myocardial infarction. Its purpose is to thin the blood and prevent harmful blood clots.
Method of Action	Warfarin acts as a vitamin K antagonist. It inhibits the synthesis of vitamin K-dependent clotting factors (Factors II, VII, IX, X) and anticoagulant proteins C and S, which are produced in the liver. It does this by inhibiting vitamin K epoxide reductase (VKORC1), an enzyme essential for the recycling of oxidized vitamin K back to its reduced form, which is required for the carboxylation (activation) of these clotting factors. This leads to a dose-dependent decrease in the synthesis of functional clotting factors, resulting in an anticoagulant effect.
Medication Name & Brand Names	♦ Medication Name: Warfarin Sodium ♦ Brand Names: Coumadin, Jantoven, Marevan (regional), Warfarin (generic)
Pharmaceutical Forms & Appearance	Warfarin is available as oral tablets, and also as a powder for injection (for intravenous use, though less common than oral). Oral tablets are typically round, scored, and come in various colors to denote different strengths (e.g., pink-2.5mg, peach-3mg, yellow-5mg, lavender-6mg, green-7.5mg, white-10mg).
Dosage & Administration	Dosage is highly individualized and is guided by regular monitoring of the International Normalized Ratio (INR), a measure of blood clotting time. Initial adult oral doses often range from 2 mg to 5 mg once daily, adjusted based on INR response. The therapeutic INR target range typically falls between 2.0 and 3.0 for most indications, but higher for mechanical heart valves (e.g., 2.5-3.5). It should be taken once daily at the same time each day, with or without food. Compliance is crucial, and dose adjustments should only be made by a healthcare professional.
Supplied As	Warfarin is supplied as: oral tablets (e.g., 1 mg, 2 mg, 2.5 mg, 3 mg, 4 mg, 5 mg, 6 mg, 7.5 mg, 10 mg) and powder for intravenous injection (e.g., 5 mg per vial).
Contraindications	Warfarin is strictly contraindicated in pregnancy (except for women with mechanical heart valves at high risk for thromboembolism for whom the benefits may outweigh the risks), as it is a potent teratogen causing fetal bleeding and malformations (warfarin embryopathy). It is also contraindicated in patients with active bleeding, hemorrhagic tendencies (e.g., hemophilia, thrombocytopenia), recent or anticipated surgery with a high risk of bleeding, severe uncontrolled hypertension, recent hemorrhagic stroke, and conditions with high risk of hemorrhage (e.g., aortic aneurysm, severe liver disease, infectious endocarditis, active peptic ulcer disease).
Storage & Expiry	Warfarin tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed, original containers. Always check the specific expiry date on the packaging.
Side Effects	The most significant side effect is bleeding, which can range from minor (bruising, nosebleeds) to severe and life-threatening (e.g., gastrointestinal bleeding, intracranial hemorrhage). Other side effects include skin necrosis (rare, early in therapy), purple toe syndrome (rare), nausea, diarrhea, and abdominal pain.
Warnings & Precautions	♦ BLACK BOX WARNING: Fatal Bleeding: Warfarin can cause major or fatal bleeding. Regular monitoring of INR is essential to optimize therapy. Factors increasing bleeding risk include high intensity of anticoagulation (INR > 4.0), age 65 or older, history of GI bleeding, uncontrolled hypertension, history of stroke/TIA, serious heart disease, anemia, trauma, renal insufficiency, concomitant drugs. ♦ Pregnancy (Teratogenicity): STRICTLY CONTRAINDICATED in pregnancy (except for mechanical heart valves where benefit outweighs risk) due to severe birth defects (warfarin embryopathy) and fetal hemorrhage. Discuss risks and benefits with reproductive-aged women. ♦ INR Monitoring: Regular and frequent INR monitoring is crucial to ensure therapeutic anticoagulation and minimize bleeding risk. INR should be checked more frequently when starting or stopping medications, or with dietary changes. ♦ Dietary Vitamin K: Consistent daily intake of vitamin K (found in leafy green vegetables, certain oils) is important, as large fluctuations can affect INR. Avoid drastic changes in diet. ♦ Drug Interactions: Warfarin has numerous significant drug and herbal interactions (see below) that can dramatically alter its anticoagulant effect. Always inform healthcare providers about all medications, supplements, and herbal products. ♦ Liver Disease: Impaired liver function can reduce clotting factor synthesis, increasing warfarin's effect. Use with extreme caution and monitor INR closely. ♦ Renal Disease: May increase bleeding risk. ♦ Skin Necrosis/Gangrene: Rare but serious complication (usually within days of starting), typically in patients with protein C or S deficiency. ♦ Purple Toe Syndrome: Rare cholesterol microemboli. ♦ Falls: Increased risk of serious bleeding with falls, especially in elderly. ♦ Alcohol: Acute binge drinking may increase INR, chronic heavy drinking may decrease INR. Advise moderation or avoidance. ♦ Dental Procedures/Surgery: Patients must inform their dentist/surgeon they are on warfarin. Management (e.g., temporary discontinuation) should be guided by INR and procedural bleeding risk.
Missed Dose Instructions	If a dose of Warfarin is missed, take it as soon as remembered on the same day. However, if it's the next day, do not take a double dose to make up for a missed dose. Instead, take the regular dose and inform your healthcare provider that a dose was missed, as your INR may need to be checked sooner. Never adjust your dose without consulting your doctor.
Overdose Instructions	Overdose symptoms are primarily related to bleeding, ranging from minor bruising, nosebleeds, and blood in urine/stool to severe, life-threatening hemorrhage (e.g., intracranial, GI bleeding, retroperitoneal). The INR will be significantly elevated. Treatment involves stopping warfarin and administering vitamin K (oral or IV) to reverse its effects. In severe bleeding or dangerously high INR, fresh frozen plasma (FFP) or prothrombin complex concentrate (PCC) may be given to rapidly replenish clotting factors. Seek immediate emergency medical help.

Medicine Interactions	♦ NSAIDS (Non-Steroidal Anti-Inflammatory Drugs, e.g., ibuprofen, naproxen), Aspirin, Antiplatelet Agents (e.g., clopidogrel, ticagrelor), other Anticoagulants (e.g., heparin, DOACs): Significantly increase the risk of bleeding due to additive antiplatelet/anticoagulant effects or GI irritation. Concomitant use should be with extreme caution and frequent INR monitoring. ♦ CYP2C9 Inhibitors (e.g., amiodarone, fluconazole, metronidazole, fluoxetine, cimetidine, trimethoprim/sulfamethoxazole): Inhibit the metabolism of warfarin, leading to increased warfarin levels and greatly enhanced anticoagulant effect (increased INR). Dose reduction of warfarin often necessary; monitor INR very closely. ♦ CYP2C9 Inducers (e.g., rifampin, carbamazepine, phenobarbital, phenytoin, St. John's Wort): Increase the metabolism of warfarin, leading to decreased warfarin levels and reduced anticoagulant effect (decreased INR). Dose increase of warfarin often necessary; monitor INR very closely. ♦ Vitamin K Supplements/Foods High in Vitamin K (e.g., leafy green vegetables like spinach, kale, broccoli): Can reduce warfarin's anticoagulant effect. Maintain consistent dietary intake; avoid large fluctuations. ♦ Thyroid Hormones: Can increase warfarin's effect. ♦ Antibiotics (broad-spectrum): Can enhance warfarin's effect by altering gut flora (reducing vitamin K-producing bacteria). Monitor INR. ♦ Alcohol: Acute binge drinking can increase INR; chronic heavy drinking can decrease INR. ♦ Herbal Products (e.g., Ginkgo biloba, Garlic, Ginseng, Dong Quai, Feverfew): Many herbal products can interact with warfarin, either increasing bleeding risk or altering INR. Advise patients to avoid or consult a healthcare

Zolpidem (Ambien)

Purpose/Indication	Zolpidem is a sedative-hypnotic medication primarily indicated for the short-term treatment of insomnia, characterized by difficulties with sleep initiation. It helps patients fall asleep more quickly and maintain sleep, but its use is generally limited to short durations (e.g., 7-10 days) due to the risk of dependence and other adverse effects. Specific formulations (e.g., extended-release) also help with sleep maintenance.
Method of Action	Zolpidem is a non-benzodiazepine hypnotic that acts as a selective agonist at the benzodiazepine 1 (BZ1) receptor subtype of the gamma-aminobutyric acid (GABA)-A receptor complex in the brain. This selective binding enhances the inhibitory effects of GABA, leading to chloride ion influx, hyperpolarization of neurons, and resulting in sedative, hypnotic, and to a lesser extent, anxiolytic, muscle relaxant, and anticonvulsant effects. Its selective action on BZ1 receptors contributes to its more specific hypnotic profile compared to classic benzodiazepines.
Medication Name & Brand Names	♦ Medication Name: Zolpidem Tartrate ♦ Brand Names: Ambien (immediate-release), Ambien CR (extended-release), Edluar (sublingual), Intermezzo (sublingual for middle-of-the-night awakening), Stilnox (regional), Zolpidem (generic)
Pharmaceutical Forms & Appearance	Zolpidem is available as oral tablets (immediate-release and extended-release), and sublingual tablets. Immediate-release tablets are typically oval, film-coated, and vary in color depending on strength (e.g., white, pink). Extended-release tablets are often bilayered for immediate and sustained release. Sublingual tablets are designed to dissolve under the tongue.
Dosage & Administration	Dosage is individualized, with the lowest effective dose for the shortest duration. For immediate-release oral tablets, the typical adult dose is 5 mg or 10 mg taken once immediately before bedtime. For extended-release oral tablets, the typical adult dose is 6.25 mg or 12.5 mg once immediately before bedtime. The lowest dose should be used in elderly or debilitated patients. It should be taken on an empty stomach for faster onset, but for extended-release or if stomach upset occurs, it can be taken with a light meal. It should only be taken when the patient can get a full night's sleep (7-8 hours) to minimize next-day impairment.
Supplied As	Zolpidem is supplied as: oral immediate-release tablets (e.g., 5 mg, 10 mg), oral extended-release tablets (e.g., 6.25 mg, 12.5 mg), and sublingual tablets (e.g., 1.75 mg, 3.5 mg, 5 mg, 10 mg).
Contraindications	Zolpidem is contraindicated in patients with known hypersensitivity to zolpidem or any component of the formulation. It is also contraindicated in patients with known complex sleep behaviors after zolpidem use. Due to the risk of respiratory depression, it should be used with extreme caution or avoided in patients with severe respiratory insufficiency (e.g., severe COPD, sleep apnea).
Storage & Expiry	Zolpidem tablets should be stored at room temperature (typically 20°C to 25°C or 68°F to 77°F), protected from light and moisture. Keep in tightly closed containers and keep out of reach of children. Always check the specific expiry date on the packaging.
Side Effects	Common side effects include drowsiness, dizziness, headache, fatigue, nausea, and diarrhea. More serious but less common side effects include complex sleep behaviors (e.g., sleep-driving, making phone calls, preparing and eating food while not fully awake with no memory of the event), anterograde amnesia, hallucinations, agitation, dependence, and withdrawal symptoms upon abrupt discontinuation.
Warnings & Precautions	♦ Complex Sleep Behaviors: Can cause potentially dangerous complex sleep behaviors, including "sleep-driving" (driving while not fully awake with no memory of the event), making phone calls, or preparing and eating food. These events can occur after the first dose. Discontinue if a patient experiences such an episode. ♦ CNS Depression & Impaired Alertness: Can cause profound sedation, dizziness, and impaired motor coordination, affecting ability to drive or operate machinery the next day. The risk is dose-dependent and higher with inadequate sleep duration. ♦ Concomitant Opioid Use: BLACK BOX WARNING (in some regions/products): Concomitant use of sedative-hypnotics like zolpidem and opioids may result in profound sedation, respiratory depression, coma, and death. Reserve concomitant prescribing for patients for whom alternative treatment options are inadequate. Limit dosages and durations. ♦ Abuse, Misuse, Addiction: Zolpidem carries a risk of abuse, misuse, and addiction, which can lead to overdose or death. The risk is increased with higher doses, longer duration of use, and in patients with a history of substance abuse. ♦ Dependence & Withdrawal: Can cause physical dependence. Abrupt discontinuation or rapid dose reduction after prolonged use can lead to severe withdrawal symptoms (e.g., insomnia, anxiety, dysphoria, seizures, tremors, abdominal cramps). Taper dose gradually when discontinuing. ♦ Respiratory Depression: Use with caution in patients with compromised respiratory function (e.g., COPD, sleep apnea) due to the risk of exacerbating respiratory depression. ♦ Anterograde Amnesia: Can cause dose-related anterograde amnesia (difficulty remembering events after drug administration). Patients should ensure they have 7-8 hours of uninterrupted sleep. ♦ Paradoxical Reactions: Rarely, can cause paradoxical excitement, aggression, or hallucinations, particularly in elderly or psychiatric patients. Discontinue if these occur. ♦ Hepatic Impairment: Use with caution and consider dose reduction in patients with hepatic impairment, as zolpidem is extensively metabolized in the liver. ♦ Elderly Patients: Highly susceptible to CNS depressant effects; use lower starting doses (e.g., 5 mg for immediate-release) to minimize risk of falls and cognitive impairment. ♦ Depression/Suicidality: Use with caution in patients with depression; may be associated with increased risk of suicidal ideation. ♦ Tolerance: Develops with prolonged use, requiring higher doses to achieve the same effect. ♦ Duration of Use: Limit to short-term (7-10 nights) as efficacy beyond this period has not been established and risks increase.
Missed Dose Instructions	Zolpidem is an as-needed medication for sleep, taken right before bedtime. If a dose is missed (e.g., you forget to take it before going to sleep and wake up later), do not take it in the middle of the night or if you do not have a full 7-8 hours available for sleep before you need to be awake. Taking it too late can lead to next-day drowsiness and impaired function. Do not take a double dose.
Overdose Instructions	Overdose symptoms are typically central nervous system depression, ranging from somnolence to coma, with respiratory depression. Other symptoms may include confusion, impaired coordination, diminished reflexes, slurred speech, and hypotension. Severe consequences (coma, death) are more likely with co-ingestion of other CNS depressants, especially alcohol or opioids. There is a specific benzodiazepine receptor antagonist, flumazenil, which can reverse the sedative effects, but it should be used with caution due to the risk of seizures in patients dependent on zolpidem or those with mixed overdoses. Treatment is supportive and symptomatic, focusing on maintaining an open airway, ventilation, and cardiovascular support. Seek immediate emergency medical help.

R	Zolpidem (Ambien)	**Medicine Interactions**	♦ Alcohol: STRICTLY AVOID concomitant use due to additive CNS depressant effects, leading to profound sedation, respiratory depression, coma, and potentially death. ♦ Opioids (e.g., morphine, oxycodone, hydrocodone): BLACK BOX WARNING: Concomitant use significantly increases the risk of profound sedation, respiratory depression, coma, and death. Avoid concomitant use or limit dosages and durations if absolutely necessary. ♦ Other CNS Depressants (e.g., other hypnotics, sedatives, anxiolytics, antidepressants, antipsychotics, antihistamines, muscle relaxants, general anesthetics): Additive CNS depressant effects. Avoid or use with extreme caution. ♦ CYP3A4 Inhibitors (e.g., ketoconazole, itraconazole, clarithromycin, erythromycin, ritonavir, grapefruit juice): Can significantly inhibit zolpidem metabolism, leading to increased zolpidem levels and enhanced CNS depressant effects. Dose reduction of zolpidem may be necessary. ♦ CYP3A4 Inducers (e.g., rifampin, carbamazepine, phenytoin, phenobarbital, St. John's Wort): Can increase zolpidem metabolism, leading to decreased zolpidem levels and reduced efficacy. Avoid concomitant use if possible. ♦ Imipramine/Chlorpromazine: May decrease zolpidem's plasma levels. ♦ Sertraline: No significant interaction.

Illness

Common illnesses and how to treat them

"Never let the things you cannot do
prevent you from doing the things you can."
John Wooden

Introduction

A category listing the symptoms, identification methods, prevention methods and the treatment of common illnesses.

Purpose	The aim of ILLNESS is to inform the reader on the causes, symptoms, prevention techniques and treatments of the most common illnesses you're likely to pick up in a disaster.
Lost?	***** **QUICK TRIAGE (If you're injured or sick and looking for the correct section)** ***** ● **Sections under ILLNESS:** Radiation Sickness, Parasitic Infections, Bacterial Infections, Viral Infections, Fungal Infections, Altitude Sickness, Poisoning, Chemical Agents, Biological Agents. ● **Sections under INJURY:** Surface Wound & Bruises, Internal Injuries (Back Pain, Cerebral Hemorrhage, Bone Fractures, Dislocation, Concussion) Open Wounds, Avulsion, Burns, Environmental (Anaphylaxis, Heat Stroke, Hypothermia, Hyperthermia, Motion Sickness, Aero-otitis Media), Atmosphere (Asphyxiation, Drowning, Choking, Hypoxia, Carbon Monoxide Poisoning), Animal & Plant (Bites and Stings), Childbirth, Toothaches. ● **Sections under EMOTIONAL:** Depression, Anxiety, Stress, Confidence, Relaxation, Memory & Dementia, Grief & Loss, Postnatal Depression, New Parents, Body Image, Family & Friends and Healthy Living.

● For medications and recommended doses, see the MEDICATION section.
● For curing ailments naturally and herbal remedies, see the NATURAL REMEDIES section.
● For eating disorders, see the HEALTH > Nutrients section.

Contents

1 Parasitic

In evolutionary biology, parasitism is a relationship between species, where one organism, the parasite, lives on or in another organism, the host, causing it some harm, and is adapted structurally to this way of life. The entomologist E. O. Wilson has characterised parasites as "predators that eat prey in units of less than one". Parasites include protozoans such as the agents of malaria, sleeping sickness, and amoebic dysentery; animals such as hookworms, lice, mosquitoes, and vampire bats; fungi such as honey fungus and the agents of ringworm; and plants such as mistletoe, dodder, and the broomrapes.

ILLNESS

Parasitic

Parasites Overview	**Parasites** ● Ticks ● Fleas ● Louse ● Tapeworms ● Pinworms ● Roundworms	**Symptoms** Intestinal pain, alternating bouts of diarrhoea and constipation, bloating, excessive flatulence, irritable bowel syndrome, constant tiredness and fatigue, increasing allergies and a general decrease in immunity.	**Contamination** May enter body through contaminated water or food (particularly under cooked pork, beef and fish), mosquito bites, touching pets and other animals or any infected surface and then touching your nose or mouth.	**Treatment** Fresh Green Black Walnut Wormwood Complex - Take in the morning before any food and don't eat for an hour.

Incubation Period
The delay between consumption of a contaminated food and appearance of the first symptoms of illness is called the incubation period. This ranges from hours to days depending on the agent, and on how much was consumed. If symptoms occur within 1-6 hours after eating the food, it suggests that it is caused by a bacterial toxin or a chemical rather than live bacteria.

The long incubation period of many foodborne illnesses tends to cause sufferers to attribute their symptoms to gastroenteritis. During the incubation period, microbes pass through the stomach into the intestine, attach to the cells lining the intestinal walls, and begin to multiply there. Some types of microbes stay in the intestine, some produce a toxin that is absorbed into the bloodstream, and some can directly invade the deeper body tissues. The symptoms produced depend on the type of microbe.

Infectious Dose
The infectious dose is the amount of agent that must be consumed to give rise to symptoms of foodborne illness, and varies according to the agent and the consumer's age and overall health. Pathogens vary in minimum infectious dose; for example, Shigella sonnei has a low estimated minimum dose of < 500 colony-forming units (CFU) while Staphylococcus aureus has a relatively high estimate.

In the case of Salmonella a relatively large inoculum of 1 million to 1 billion organisms is necessary to produce symptoms in healthy human volunteers, as Salmonellae are very sensitive to acid. An unusually high stomach pH level (low acidity) greatly reduces the number of bacteria required to cause symptoms by a factor of between 10 and 100.

Most Common Foodborne Illnesses	**Highest Death Causes**		
Novovirus - 5.46m cases Salmonella - 1.02m cases Clostridium Perfringes - 965k cases Campylobacter - 845k cases	Salmonella - 0.126% Toxoplasma Gondii - 0.109% Listeria - 0.085% Norovirus - 0.050%

1 Tick

ILLNESS Parasitic Tick

Ticks are small arachnids, typically 3 to 5 mm long, part of the order Parasitiformes. Along with mites, they constitute the subclass Acari. Ticks are ectoparasites (external parasites), living by feeding on the blood of mammals, birds, and sometimes reptiles and amphibians. Ticks are widely distributed around the world, especially in warm, humid climates. Almost all ticks belong to one of two major families, the Ixodidae or hard ticks, and the Argasidae or soft ticks. Adults have ovoid or pear-shaped bodies which become engorged with blood when they feed, and eight legs. As well as having a hard shield on their dorsal surfaces, hard ticks have a beak-like structure at the front containing the mouthparts whereas soft ticks have their mouthparts on the underside of the body. Both families locate a potential host by odour or from changes in the environment. Ticks have four stages to their lifecycle, namely egg, larva, nymph, and adult. Ixodid ticks have three hosts, taking at least a year to complete their lifecycle. Argasid ticks have up to seven nymphal stages (instars), each one requiring a blood meal. Because of their habit of ingesting blood, ticks are vectors of at least twelve diseases that affect humans and other animals.

Tick

There are four stages in the life cycle of a tick; the egg, larvae (around 1mm and light brown in colour when not full of blood), nymph (around 2mm and pale brown) and the adults (4–5mm in length, without blood). ^The Paralysis Tick needs to feed on blood to develop through its lifecycle from the larvae stage to a nymph and to an adult. The adult female takes blood to obtain protein for the laying of eggs. When fully engorged it is grey-blue in colour up to around 1cm in length. Paralysis Ticks are not particularly mobile, and rely on passing animals for a blood meal.

The Paralysis Tick will crawl up the stems of grasses or along branches and 'perch' ready to latch on to a passing animal, including humans. They rarely climb higher than 50cm in their habitat, so do not drop out of trees, despite this common belief. However, after landing on a person or animal they can walk up the body and attach to the head area. A tick attaches itself by piercing its sharp mouthparts into skin. It then injects an anticoagulant (a substance that prevents blood from forming clots) saliva which allows it to feed without the blood clotting. In the case of the Paralysis Tick, the saliva may be highly toxic to some animals and, potentially, humans.

Life Cycle
- Eggs - Summer
- Larvae - Autumn (Fall)
- Nymph - Winter
- Adult - Spring

ILLNESS Tick

Most tick bites pose no medical problems apart from some localised swelling and redness at the bite site if the tick is removed promptly. However, in some cases people can experience more severe conditions such as tick paralysis or allergic reactions including anaphylactic shock. Early symptoms of tick paralysis may include rashes, headache, fever, influenza like symptoms, tenderness of lymph nodes, unsteady gait, intolerance to bright light, increased weakness of the limbs and partial facial paralysis. Tick paralysis, while rare, is usually seen in children rather than adults.

Parasitic Tick

Allergic reactions can result in swelling of the throat, and may lead to breathing difficulties or collapse. It is important to seek medical attention quickly if such symptoms occur. If you have had similar symptoms in the past after being bitten by a tick, then it is a good idea to always be prepared. Some serious tick-borne diseases also occur in Australia including, Queensland tick typhus and Flinders Island spotted fever. There are concerns that other serious illnesses, such as a Lyme disease-like syndrome, may be caused by exposure to Australian ticks, however there is no evidence yet this is the case (Lyme Disease).

ILLNESS Parasitic Tick

Tick (Australia Specific)
Ticks are parasites that feed on animal and human blood. There are more than 800 species of ticks around the world, with 70 found in Australia and 16 species have been reported as feeding on humans. The most important tick in Australia is the Paralysis Tick, Ixodes holocyclus, and over 95% of tick bites in Eastern Australia are due to this species. Most tick-borne illnesses are due to this species. The Paralysis Tick, Ixodes holocyclus, is found along the eastern seaboard of Australia east of the Great Dividing Range, and possibly into Tasmania.

It is commonly referred to as the grass tick, seed tick and bush tick depending upon its stage of development. It is not known to occur in South Australia, Western Australia or the Northern Territory. While I. holocyclus is the most common, there are two other Ixodes species in Australia which cause paralysis: I. hirsti, which occurs in South Australia and also has been documented in NSW and Tasmania, and I. cornuatus, which occurs in Tasmania and Victoria.

Range / Habitat
Tick species are widely distributed around the world, but they tend to flourish more in countries with warm, humid climates, because they require a certain amount of moisture in the air to undergo metamorphosis, and because low temperatures inhibit their development from egg to larva. Ticks are also widely distributed among host taxa, which include marsupial and placental mammals, birds, reptiles such as snakes, iguanas and lizards, and amphibians. Ticks of domestic animals cause considerable harm to livestock by transmission of many species of pathogen, as well as causing anaemia and damaging wool and hides.

Some of the most debilitating species occur in tropical countries. Tropical bont ticks affect most domestic animals and occur in Africa and the Caribbean. The spinose ear tick has a worldwide distribution, the young feeding inside the ears of cattle and wild animals. In general, ticks are to be found wherever their host species occur. Migrating birds carry ticks with them on their journeys; a study of migratory birds passing through Egypt found more than half the bird species examined were carrying ticks.

The species of tick often differed between the autumn and spring migrations, probably because of the seasonal periodicities of the different species. For an ecosystem to support ticks, it must satisfy two requirements: the population density of host species in the area must be high enough, and humidity must be high enough for ticks to remain hydrated.

Due to their role in transmitting Lyme disease, ixodid ticks, particularly the North American I. scapularis, have been studied using geographic information systems to develop predictive models for ideal tick habitats. According to these studies, certain features of a given microclimate – such as sandy soil, hardwood trees, rivers, and the presence of deer – were determined to be good predictors of dense tick populations.

Diet / Feeding
Ticks satisfy all of their nutritional requirements as ectoparasites, feeding on a diet of blood. They are obligate hematophages, needing blood to survive and move from one stage of life to another. Ticks can fast for long periods but eventually die if unable to find a host. This behaviour evolved approximately 120 million years ago through adaptation to blood-feeding. The behaviour evolved independently in the separate tick families, with differing host-tick interactions driving the evolutionary change.

Some ticks attach quickly while others wander around looking for thinner skin such as is found on the ears of mammals. Depending on the species and the life stage, preparing to feed can take from ten minutes to two hours. On locating a suitable feeding spot, the tick grasps the host's skin and cuts into the surface. They extract blood by cutting a hole in the host's epidermis, into which they insert their hypostome, and keep the blood from clotting by excreting an anticoagulant or platelet aggregation inhibitor.

Ticks find their hosts by detecting animals' breath and body odours, or by sensing body heat, moisture and vibrations. They are incapable of flying or jumping, but many tick species, particularly Ixodidae, lie in wait in a position known as "questing". While questing, ticks cling to leaves and grasses by their third and fourth pairs of legs. They hold the first pair of legs outstretched, waiting to grasp and climb on to any passing host. Tick questing heights tend to be correlated with the size of the desired host; nymphs and small species tend to quest close to the ground where they may encounter small mammalian or bird hosts; adults climb higher into the vegetation where larger hosts may be encountered. Some species are hunters and lurk near places where hosts may rest. On receiving an olfactory or other stimulus, they crawl or run across the intervening surface.

Hypostome
The hypostome is a calcified harpoon-like structure near the mouth area of certain parasitic arthropods including ticks, that allows them to anchor themselves firmly in place on a host mammal while sucking blood. This mechanism is normally so strong that removal of a lodged tick requires two actions: One to remove the tick, and one to remove the remaining head section of the tick.

Diet / Feeding
Other ticks, mainly the Argasidae, are "nidicolous", finding hosts in their nests or burrows, and in caves in the case of bats. They use the same stimuli as non-nidicolous species to identify hosts, with body heat and odours often being the main factors. Many of them feed primarily on birds, though some Ornithodoros, for example, feed on mammals. Both groups feed rapidly, typically biting painfully and drinking their fill within minutes. None of the species stick to the host in the way that hard ticks do. Unlike the Ixodidae that have no fixed dwelling place except on the host, they live in sand or in crevices near animal dens or nests, or in human dwellings where they come out nightly to attack roosting birds, or emerge when they detect carbon dioxide in the breath of their hosts. In the Ixodidae, the tick stays in place until it is completely engorged.

Its weight may increase by 200 to 600 times as compared to its weight before it started feeding. To accommodate this large expansion, cell division takes place and its cuticle grows larger; the tick may remain attached for days or weeks, depending on species, life stage and host. In the Argasidae, the tick's cuticle stretches to accommodate the fluid ingested but does not grow new cells, the weight of the tick increasing five to tenfold over the unfed state. The tick then drops off the host and typically remains in the nest or burrow until its host returns to provide its next meal.

Population Control
With the possible exception of widespread DDT use in the Soviet Union, attempts to limit the population or distribution of disease-causing ticks have been quite unsuccessful. The parasitoid chalcid wasp Ixodiphagus hookeri has been investigated for its potential to control tick populations. It lays its eggs into ticks; the hatching wasps kill their hosts. Another natural form of control for ticks is the guineafowl, a bird species which consumes mass quantities of ticks. Topical tick medicines may be toxic to animals and humans. The synthetic pyrethroid insecticide Phenothrin in combination with the hormone analogue methoprene was a popular topical flea and tick therapy for felines. Phenothrin kills adult ticks, while methoprene kills eggs. However, some products have been withdrawn, while others are known to cause adverse reactions.

Identification

There are two major groups of ticks: hard ticks and soft ticks.	**Hard Ticks (family: Ixodidae)** Have a hard flat body and elongated mouthparts with rows of backward pointing teeth. This group includes the most important species that bite humans.	**Soft Ticks (family: Argasidae)** Have a wrinkled leathery appearance. Only a few species of this type are found in Australia and they rarely come into contact with people.

Below are pictures and descriptions of the different types of ticks you can find.

Ixodes Scapularis (Blacklegged ticks / Deer Ticks)		**Ixodes Scapularis** **(Blacklegged ticks / Deer Ticks)** Blacklegged ticks (a.k.a Deer ticks) take 2 years to complete their life cycle and are found predominately in deciduous forest. Their distribution relies greatly on the distribution of its reproductive host, white-tailed deer. Both nymph and adult stages transmit diseases such as Lyme disease, Babesiosis, and Anaplasmosis.
Dermacentor Variabilis (American Dog Ticks)		**Dermacentor Variabilis** **(American Dog Ticks)** American Dog ticks are found predominantly in areas with little or no tree cover, such as grassy fields and scrubland, as well as along walkways and trails. They feed on a variety of hosts, ranging in size from mice to deer, and nymphs and adults can transmit diseases such as Rocky Mountain Spotted Fever and Tularemia. American dog ticks can survive for up to 2 years at any given stage if no host is found. Females can be identified by their large off-white scutum against a dark brown body.
Amblyomma Americanum (Lone Star Ticks)		**Amblyomma Americanum** **(Lone Star Ticks)** Lone Star ticks are found mostly in woodlands with dense undergrowth and around animal resting areas. The larvae do not carry disease, but the nymphal and adult stages can transmit the pathogens causing Monocytic Ehrlichiosis, Rocky Mountain Spotted Fever and 'Stari' borreliosis. Lone Star ticks are notorious pests, and all stages are aggressive human biters.
Rhipicephalus Sanguineus (Brown Dog Tick)		**Rhipicephalus Sanguineus** **(Brown Dog Tick)** Brown Dog Ticks have a world-wide distribution, and can be found throughout the United States, although they are encountered more frequently in the southern tier of states. All life stages of this tick can transmit Rocky Mountain Spotted Fever rickettsia (Rickettsia rickettsia) to dogs, and rarely to humans. Both nymphal and adult stages can transmit the agents of canine ehrlichiosis (Ehrlichia canis) and canine babesiosis (Babesia canis vogeli and Babesia gibsoni-like) to dogs.
Dermacentor Andersoni (Rocky Mountain Wood Ticks)		**Dermacentor Andersoni** **(Rocky Mountain Wood Ticks)** Rocky Mountain Wood ticks are found predominantly in shrublands, lightly wooded areas, open grasslands, and along trails, mainly at lower elevations. All life stages of this tick can transmit Colorado tick fever virus (CTFV) to humans, and Rocky Mountain spotted fever (RMSF) rickettsia (Rickettsia rickettsii) to humans, cats, and dogs. Rocky Mountain wood tick saliva contains a neurotoxin that can occasionally cause tick paralysis in humans and pets; usually a bite from an adult female induces an ascending paralysis that dissipates within 24-72 hrs after tick removal.
Amblyomma Maculatum (Gulf Coast Tick)		**Amblyomma Maculatum** **(Gulf Coast Tick)** o
Dermacentor Occidentalis (Pacific Coast Tick)		**Dermacentor Occidentalis** **(Pacific Coast Tick)** o
Ixodes Pacificus (Western-Blacklegged Tick)		**Ixodes Pacificus** **(Western-Blacklegged Tick)** o
Amblyomma Cajennense (Cayenne Tick)		**Amblyomma Cajennense** **(Cayenne Tick)** o

Treatment

Removal
1. Use fine-tipped tweezers to grasp the tick as close to the skin's surface as possible.
2. Pull upward with steady, even pressure. Don't twist or jerk the tick; this can cause the mouth-parts to break off and remain in the skin. If this happens, remove the mouth-parts with tweezers. If you are unable to remove the mouth easily with clean tweezers, leave it alone and let the skin heal.
3. After removing the tick, thoroughly clean the bite area and your hands with rubbing alcohol or soap and water.
4. Never crush a tick with your fingers. Dispose of a live tick by putting it in alcohol, placing it in a sealed bag/container, wrapping it tightly in tape, or flushing it down the toilet.

Avoid folklore remedies such as "painting" the tick with nail polish or petroleum jelly, or using heat to make the tick detach from the skin. Your goal is to remove the tick as quickly as possible–not waiting for it to detach. If you suspect an infection, keep the tick in a small jar or vial for testing.

Mouthparts
It is not uncommon for the tick's mouthparts to break off, with some part of them being left behind in the skin. However, the saliva glands that hold the tick's toxin and potential allergens (substances that can cause an allergic reaction) are actually located in the body of the tick, so the mouthparts on their own are not dangerous. The mouthparts usually come out on their own with natural skin shedding.

Do Not
● Avoid applying methylated spirits, kerosene, petroleum jelly, nail polish, oil or alcohol to the tick. These chemicals are generally ineffective in getting the tick to detach from the skin, and may even cause the tick to burrow deeper into the skin and inject more toxins.
● Don't use a lighted match or other hot object to try and kill the tick or detach it. Aside from the risk of burning yourself, this method does not effectively remove ticks.
● Don't use blunt-nosed household tweezers to remove a tick as they are more likely to squeeze the body of the tick.
Do Not
● Don't handle a tick with bare hands as infective agents or allergens can enter your body through breaks in your skin or by rubbing your eyes. Wash your hands with soap and water if you have touched or handled a tick.

Prevention

Ticks tend to be more active during warmer months, though this varies by geographic region and climate. Areas with woods, bushes, high grass, or leaf litter are likely to have more ticks. Those bitten commonly experience symptoms such as body aches, fever, fatigue, joint pain, or rashes. People can limit their exposure to tick bites by wearing light-coloured clothing (including pants and long sleeves), using insect repellent with 20%–30% DEET, tucking their pants legs into their socks, checking for ticks frequently, and washing and drying their clothing (in a hot dryer).

Avoiding Areas	Avoid known tick-infested areas and areas of tall grass. Try not to let much foliage brush against you.
Avoid Bushland	Avoid bushland areas and long grass, especially after rain. Keeping your lawns mowed short can help to reduce risk of ticks.
Covering Clothes	Wear clothes that fully cover your arms and legs. Choose light-coloured clothes so that you can spot any ticks more easily.
Tuck Clothes In	Tuck your trousers into your socks, and your shirt into your trousers to reduce the amount of skin that is exposed.
Wide Hat	Wear a wide-brimmed hat.
Wear Repellent	Apply insect repellent that contains DEET (e.g. RID, Heavy Duty Aerogard, Tropical Aerogard or Bushman) or picaridin (e.g. Aerogard) to your skin, clothes and hats. Make sure you follow the instructions on the product.
Wear Insecticides	Apply an insecticide containing permethrin to your clothes (e.g. Equip Debugger). These are available from outdoor and camping shops.
Brush Off Clothes	When returning from the outdoors, brush off your clothes to remove any ticks before going inside.
Shower	Shower and check for ticks (including adult ticks and ticks in the larval and nymphal stages) soon after being outdoors in areas known to have ticks.
Heat Clothes	Clothes that have been worn outside in tick-infested areas can be placed in a hot dryer for at least 20 minutes to kill any ticks that may be on the clothes.
Check Thoroughly	The entire body should be then checked for ticks of all sizes and stages, paying particular attention to areas behind the ears and the back of the head or neck, especially on children.
Regular Checks	Check yourself regularly when hiking through tick prone areas or have a friend to check each other every 15 minutes.

Tick-Borne Diseases

Ticks are implicated in the transmission of a number of infections caused by pathogens such as bacteria, viruses and protozoa. Sometimes the tick harbours more than one type of pathogen, making diagnosis of the infection more difficult. Species of the bacterium Rickettsia are responsible for typhus, rickettsialpox, Boutonneuse fever, African tick bite fever, Rocky Mountain spotted fever, Flinders Island spotted fever and Queensland tick typhus (Australian tick typhus). Some species, notably the Australian paralysis tick, are also intrinsically venomous and can cause tick paralysis. Eggs can become infected with pathogens inside a female tick's ovaries, in which case the larval ticks are infectious immediately at hatching, before feeding on their first host. Tropical bont ticks transmit the rickettsial disease heartwater which can be particularly devastating in cattle. The ticks carried by migratory birds may act as reservoirs and vectors of infectious diseases. Over twenty strains of pathogenic virus were found in the autumn in the Egyptian migratory bird study.

Not all ticks in an infective area are infected with pathogens, and both attachment of the tick and a long-feeding session seem to be necessary for transmission of these diseases to take place. Thus tick bites often do not lead to infection, especially if the ticks are removed within 36 hours. Adult ticks can be removed with fine-tipped tweezers or proprietary tick removal tools, disinfecting the wound. It is also possible to freeze them off with a medical wart remover. If the tick's head and mouthparts break off during removal, they can be removed with tweezers like a splinter. Tick-borne diseases, which afflict humans and other animals, are caused by infectious agents transmitted by tick bites. Tick-borne illnesses are caused by infection with a variety of pathogens, including rickettsia and other types of bacteria, viruses, and protozoa. Because individual ticks can harbor more than one disease-causing agent, patients can be infected with more than one pathogen at the same time, compounding the difficulty in diagnosis and treatment.

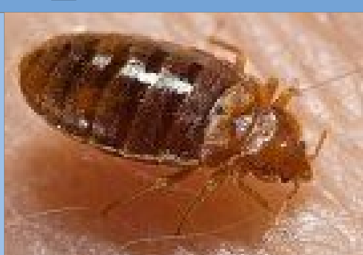
Bacterial Illnesses

Lyme Disease / Borreliosis	Lyme disease, also known as Lyme borreliosis, is an infectious disease caused by a bacteria named Borrelia spread by ticks. The most common sign of infection is an expanding area of redness on the skin, known as erythema migrans, that appears at the site of the tick bite about a week after it occurred.
Relapsing Fever	Relapsing fever is a vector-born disease caused by infection with certain bacteria in the genus Borrelia, which are transmitted through the bites of lice or soft-bodied ticks (genus Ornithodoros).
Typhus	Typhus, also known as typhus fever, is a group of infectious diseases that include epidemic typhus, scrub typhus and murine typhus. Common symptoms include fever, headache, and a rash. Typically these begin one to two weeks after exposure.
Rocky Mountain Spotted Fever	Rocky Mountain spotted fever (RMSF) is the most lethal and most frequently reported rickettsial illness in the United States. Initial signs and symptoms of the disease include sudden onset of fever, headache, and muscle pain, followed by development of rash.
Helvetica Spotted Fever	Rickettsia helvetica, previously known as the Swiss Agent, is a bacterium found in Dermacentor reticulatus and other ticks which has been implicated as a suspected but unconfirmed human pathogen.
Ehrlichiosis Anaplasmosis	Ehrlichiosis is a tickborne bacterial infection, caused by bacteria of the family Anaplasmataceae, genera Ehrlichia and Anaplasma. These obligate intracellular bacteria infect and kill white blood cells.

Bartonella	Bartonella is a genus of Gram-negative bacteria. It is the only genus in the family Bartonellaceae. Facultative intracellular parasites, Bartonella species can infect healthy people, but are considered especially important as opportunistic pathogens.
Tularemia	Tularemia, also known as rabbit fever, is an infectious disease caused by the bacterium Francisella tularensis. Symptoms may include fever, skin ulcer, and enlarged lymph nodes. Occasionally, a form that results in pneumonia or a throat infection may occur.
Viral Illnesses	
Tick-Borne Meningoencephalitis	Tick-borne encephalitis (TBE) is a viral infectious disease involving the central nervous system. The disease most often manifests as meningitis, encephalitis, or meningoencephalitis. Although TBE is most commonly recognized as a neurological disorder, mild fever can also occur.
Powassan Virus/Deer Tick Virus	Powassan virus is a flavivirus transmitted by ticks, found in North America and in the Russian Far East. It is named after the town of Powassan, Ontario, where it was identified in a young boy who eventually died from it. It can cause encephalitis, an infection of the brain. No vaccine or antiviral drug exists. Prevention of tick bites is the best precaution.
Colorado Tick Fever	Colorado tick fever (CTF) (also called mountain tick fever, American tick fever, and American mountain tick fever) is a viral infection (Coltivirus) transmitted from the bite of an infected Rocky Mountain wood tick (Dermacentor andersoni). It should not be confused with the bacterial tick-borne infection, Rocky Mountain spotted fever.
Crimean-Congo Hemorrhagic Fever	Crimean–Congo hemorrhagic fever (CCHF) is a viral disease. Symptoms of CCHF may include fever, muscle pains, headache, vomiting, diarrhoea, and bleeding into the skin. Onset of symptoms is less than two weeks following exposure. Complications may include liver failure. In those who survive, recovery generally occurs around two weeks after onset.
Severe Febrile Illness	Organism: Heartland virus, a phlebovirus, from the Bunyaviridae Vector: Lone star tick (Amblyomma americanum) Region: Missouri and Tennessee, United States
Protozoan Illnesses	
Babesiosis	Babesiosis is a malaria-like parasitic disease caused by infection with Babesia, a type of Apicomplexa. Human babesiosis transmission via tick bite is most common in the North-eastern and Midwestern United States and parts of Europe, and sporadic throughout the rest of the world.
Cytauxzoonosis	Cytauxzoon felis is a protozoal organism transmitted to domestic cats by tick bites, and whose natural reservoir host is the bobcat. C. felis has been found in other wild felid species such as Florida bobcat, eastern bobcat, Texas cougar, and a white tiger in captivity.

Tick Paralysis
Tick paralysis is the only tick-borne disease that is not caused by an infectious organism. The illness is caused by a neurotoxin produced in the tick's salivary gland. After prolonged attachment, the engorged tick transmits the toxin to its host. The incidence of tick paralysis is unknown. Patients can experience severe respiratory distress (similar to anaphylaxis).

2 Bedbug



Bed bugs are a type of insect that feed on human blood, usually at night. Their bites can result in a number of health effects including skin rashes, psychological effects and allergic symptoms. Bed bug bites may lead to skin changes ranging from invisible to prominent blisters. Symptoms may take between minutes to days to appear. Itchiness is common, while some may feel tired or have a fever. Typically, uncovered areas of the body are affected and three bites occur in a row.

Bed bugs bites are not known to transmit any infectious disease. Bed bug bites are caused primarily by two species of the insect Cimex: Cimex lectularius (the common bed bug) and Cimex hemipterus. Their size ranges between 1 and 7 mm. They spread by crawling between nearby locations or by being carried within personal items. Infestation is rarely due to a lack of hygiene but is more common in high-density areas. Diagnosis involves both finding the bugs and the occurrence of compatible symptoms. Bed bugs spend much of their time in dark, hidden locations like mattress seams or cracks in the wall.

Signs & Symptoms
On the skin, individual responses to bites vary, ranging from no visible effect (in about 20–70%), to small macular spots, to prominent wheals and bullae formations along with intense itching that may last several days. The bites often occur in a line. A central spot of bleeding may also occur due to the release of anticoagulants in the bug's saliva. Symptoms may not appear until some days after the bites have occurred. Reactions often become more brisk after multiple bites due to possible sensitization to the salivary proteins of the bed bug. The skin reaction usually occurs in the area of the bite which is most commonly the arms, shoulders and legs as they are more frequently exposed at night. Numerous bites may lead to an erythematous rash or urticaria.

Treatment
Treatment is symptomatic. Eliminating bed bugs from the home is often difficult, partly because bed bugs can survive up to a year without feeding. Repeated treatments of a home may be required. These treatments may include heating the room to 50 °C (122 °F) for more than 90 minutes, frequent vacuuming, washing clothing at high temperatures, and the use of various pesticides.

3 Flea

Fleas are small flightless insects that form the order Siphonaptera. As external parasites of mammals and birds, they live by consuming the blood of their hosts. Adults are up to about 3 mm (0.12 in) long and usually brown. Bodies flattened sideways enable them to move through their host's fur or feathers; strong claws prevent them from being dislodged.

They lack wings, and have mouthparts adapted for piercing skin and sucking blood and hind legs adapted for jumping. The latter enable them to leap a distance of some 50 times their body length, a feat second only to jumps made by froghoppers. Larvae are worm-like with no limbs; they have chewing mouthparts and feed on organic debris.

ILLNESS Parasitic Flea

Morphology

Fleas are wingless insects, 1/16 to 1/8-inch (1.5 to 3.3 mm) long, that are agile, usually dark collared (for example, the reddish-brown of the cat flea), with a proboscis, or stylet, adapted to feeding by piercing the skin and sucking their host's blood through their epipharynx. Flea legs end in strong claws that are adapted to grasp a host. Unlike other insects, fleas do not possess compound eyes but instead only have simple eyespots with a single biconvex lens; some species lack eyes altogether. Their bodies are laterally compressed, permitting easy movement through the hairs or feathers on the host's body (or in the case of humans, under clothing).

The flea body is covered with hard plates called sclerites. These sclerites are covered with many hairs and short spines directed backward, which also assist its movements on the host. The tough body is able to withstand great pressure, likely an adaptation to survive attempts to eliminate them by scratching. Fleas lay tiny, white, oval eggs. The larvae are small and pale, have bristles covering their worm-like bodies, lack eyes, and have mouth parts adapted to chewing. The larvae feed on organic matter, especially the faeces of mature fleas, which contain dried blood. Adults feed only on fresh blood.

Their legs are long, the hind pair well adapted for jumping; a flea can jump vertically up to 7 in (18 cm) and horizontally up to 13 in (33 cm), making the flea one of the best jumpers of all known animals (relative to body size), second only to the froghopper. The flea jump is so rapid and forceful that it exceeds the capabilities of muscle, and instead of relying on direct muscle power, fleas store muscle energy in a pad of the elastic protein named resilin before releasing it rapidly (like a human using a bow and arrow). Immediately before the jump, muscles contract and deform the resilin pad, slowly storing energy which can then be released extremely rapidly to power leg extension for propulsion.

To prevent premature release of energy or motions of the leg, the flea employs a "catch mechanism". Early in the jump, the tendon of the primary jumping muscle passes slightly behind the coxa-trochanter joint, generating a torque which holds the joint closed with the leg close to the body. To trigger jumping, another muscle pulls the tendon forward until it passes the joint axis, generating the opposite torque to extend the leg and power the jump by release of stored energy. The actual take off has been shown by high-speed video to be from the tibiae and tarsi rather than from the trochantera (knees).

Life Cycle

Fleas are holometabolous insects, going through the four lifecycle stages of egg, larva, pupa, and imago (adult). In most species, neither female nor male fleas are fully mature when they first emerge but must feed on blood before they become capable of reproduction. The first blood meal triggers the maturation of the ovaries in females and the dissolution of the testicular plug in males, and copulation soon follows. Some species breed all year round while others synchronise their activities with their hosts' life cycles or with local environmental factors and climatic conditions. Flea populations consist of roughly 50% eggs, 35% larvae, 10% pupae, and 5% adults.

Egg	The number of eggs laid depends on species, with batch sizes ranging from two to several dozen. The total number of eggs produced in a female's lifetime (fecundity) varies from around one hundred to several thousand. In some species, the flea lives in the nest or burrow and the eggs are deposited on the substrate, but in others, the eggs are laid on the host itself and can easily fall off onto the ground. Because of this, areas where the host rests and sleeps become one of the primary habitats of eggs and developing larvae. The eggs take around two days to two weeks to hatch. Experiments have shown that fleas lay more eggs on hosts which have limited food intakes, and that eggs and larvae survive better under these conditions, perhaps because the host's immune system is compromised.
Larva	Flea larvae emerge from the eggs to feed on any available organic material such as dead insects, faeces, conspecific eggs, and vegetable matter. In laboratory studies, some dietary diversity seems necessary for proper larval development. Blood-only diets allow only 12% of larvae to mature, whereas blood and yeast or dog chow diets allow almost all larvae to mature. Another study also showed that 90% of larvae matured into adults when the diet included nonviable eggs. They are blind and avoid sunlight, keeping to dark, humid places such as sand or soil, cracks and crevices, under carpets and in bedding.
Pupa	Given an adequate supply of food, larvae pupate and weave silken cocoons after three larval stages. Within the cocoon, the larva moults for a final time and undergoes metamorphosis into the adult form. This can take just four days, but may take much longer under adverse conditions, and there follows a variable-length stage during which the pre-emergent adult awaits a suitable opportunity to emerge. Trigger factors for emergence include vibrations (including sound), heat (in warm-blooded hosts), and increased levels of carbon dioxide, all of which stimuli may indicate the presence of a suitable host. Large numbers of pre-emergent fleas may be present in otherwise flea-free environments, and the introduction of a suitable host may trigger a mass emergence.
Adult	Once the flea reaches adulthood, its primary goal is to find blood and then to reproduce. Female fleas can lay 5000 or more eggs over their life, permitting rapid increase in numbers. Generally speaking, an adult flea only lives for 2 or 3 months. Without a host to provide a blood meal, a flea's life can be as short as a few days. Under ideal conditions of temperature, food supply, and humidity, adult fleas can live for up to a year and a half. Completely developed adult fleas can live for several months without eating, so long as they do not emerge from their puparia. Optimum temperatures for the flea's life cycle are 21 °C to 30 °C (70 °F to 85 °F) and optimum humidity is 70%.

Host Relationship

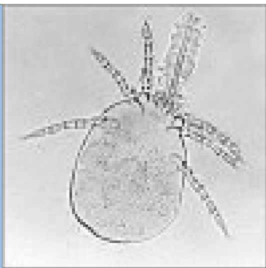
Fleas feed on a wide variety of warm-blooded vertebrates including humans, dogs, cats, rabbits, squirrels, ferrets, rats, mice and birds. Fleas normally specialise in one host species or group of species, but can often feed but not reproduce on other species. Ceratophyllus gallinae affects poultry as well as wild birds. As well as the degree of relatedness of a potential host to the flea's original host, it has been shown that avian fleas that exploit a range of hosts, only parasitise species with low immune responses. In general, host specificity decreases as the size of the host species decreases. Another factor is the opportunities available to the flea to change host species; this is smaller in colonially nesting birds, where the flea may never encounter another species, than it is in solitary nesting birds. A large, long-lived host provides a stable environment that favours host-specific parasites. One theory of human hairlessness is that the loss of hair helped humans to reduce their burden of fleas and other ectoparasites.

Bite Effects

In many species, fleas are principally a nuisance to their hosts, causing an itching sensation which in turn causes the host to try to remove the pest by biting, pecking or scratching. Fleas are not simply a source of annoyance, however. Flea bites cause a slightly raised, swollen itching spot to form; this has a single puncture point at the centre, like a mosquito bite. Besides this, the eczematous itchy skin disease flea allergy dermatitis is common in many host species, including dogs and cats. The bites often appear in clusters or lines of two bites, and can remain itchy and inflamed for up to several weeks afterwards. Fleas can lead to hair loss as a result of frequent scratching and biting by the animal, and can cause anaemia in extreme cases.

Fleas are vectors for viral, bacterial and rickettsial diseases of humans and other animals, as well as of protozoan and helminth parasites. Bacterial diseases carried by fleas include murine or endemic typhus and bubonic plague. Fleas can transmit Rickettsia typhi, Rickettsia felis, Bartonella henselae, and the myxomatosis virus. They can carry Hymenolepiasis tapeworms and Trypanosome protozoans. The chigoe flea or jigger (Tunga penetrans) causes the disease tungiasis, a major public health problem around the world. Fleas that specialize as parasites on specific mammals may use other mammals as hosts; thus, humans may be bitten by cat and dog fleas.

4 Chiggers (Trombiculidae)



Trombiculidae are a family of mites. The best known of the Trombiculidae are the chiggers. The two widely recognized definitions of "chigger" are the scientific (or taxonomic) and the common, the latter of which can be found in English and medical dictionaries. According to most dictionaries, the several species of Trombiculidae that bite their host in their larval stage and cause "intense irritation" or "a wheal, usually with severe itching and dermatitis", are called chiggers. The scientific definition seemingly includes many more, but not all species of Trombiculidae. Trombiculidae live in forests and grasslands and are also found in the vegetation of low, damp areas such as woodlands, berry bushes, orchards, along lakes and streams, and even in drier places where vegetation is low, such as lawns, golf courses, and parks. They are most numerous in early summer when grass, weeds, and other vegetation are heaviest. In their larval stage, they attach to various animals, including humans, and feed on skin, often causing itching. These relatives of ticks are nearly microscopic, measuring 0.4 mm (1/60 of an inch) and have a chrome-orange hue. There is a marked constriction in the front part of the body in the nymph and adult stages.

The best known species of chigger in North America is the hard-biting Trombicula alfreddugesi of the south-eastern United States, humid Midwest and Mexico; in the UK, the most prevalent chigger, called the "harvest mite", is Trombicula autumnalis, with distribution through Western Europe to Eastern Asia. Trombiculid mites go through a lifecycle of egg, larva, nymph, and adult. The larval mites feed on the skin cells of animals. The six-legged parasitic larva feeds on a large variety of creatures, including humans, rabbits, toads, box turtles, quail, and even some insects. After crawling onto their hosts, they inject digestive enzymes into the skin that break down skin cells. They do not actually "bite", but instead form a hole in the skin called a stylostome and chew up tiny parts of the inner skin, thus causing severe irritation and swelling. The severe itching is accompanied by red, pimple-like bumps (papules) or hives and skin rash or lesions on a sun-exposed area. For humans, itching usually occurs after the larvae detach from the skin. After feeding on their hosts, the larvae drop to the ground and become nymphs, then mature into adults which have eight legs and are harmless to humans. In the postlarval stage, they are not parasitic and feed on plant material. The females lay three to eight eggs in a clutch, usually on a leaf or under the roots of a plant, and die by autumn.

Life Cycle
The length of the mite's cycle depends on species and environment but normally lasts two to 12 months. The number of cycles in a year depends on the region. For example, in a temperate region, there might only be three per year, but in tropical regions the cycle might be continuous all year long. Adult harvest mites winter in protected places such as slightly below the soil. Females become active in the spring, and once the ground temperature is regularly above 60°F (16°C), she lays eggs in vegetation, up to 15 eggs per day. The eggs are round and are dormant for about six days, after which the nonfeeding prelarvae emerge, with only three pairs of legs. After about six days, the prelarva grows into its larval stage.

Larva
The larvae, commonly called chiggers, are about 0.17–0.21 mm (0.007–0.008 in) in diameter, normally light red in colour, and covered in hairs; they move quickly relative to size. The larvae congregate in groups on small clods of soil, in matted vegetation, and even on low bushes and plants, where they have more access to prospective hosts. The larval stage is the only parasitic stage of the mite's lifecycle. They are parasites on many animals.

About 30 of the many species in this family, in their larval stage, attach to various animals and feed on skin. This often causes an intensely itchy, red bump in humans. Chiggers attach to the host, pierce the skin, inject enzymes into the bite wound that digest cellular contents, and then suck up the digested tissue through a tube formed by hardened skin cells called a stylostome. They do not burrow into the skin or suck blood, as is commonly assumed.

Itching from a chigger bite may not develop until 24–48 hours after the bite, so the victim may not associate the specific exposure with the bite itself. The red welt/bump on the skin is not where a chigger laid eggs, as is sometimes believed. The larva remains attached to a suitable host for three to five days before dropping off to begin its nymphal stage. They tend to attach where clothing have restrictions, such as belt lines, or behind the knees when wearing jeans. During the wet season, chiggers are usually found in tall grass and other vegetation. During dry seasons, chiggers are mostly found underneath brush and shady areas. Standing still or lying in tall grass gives them more time to climb onto a person.

Nymph
Once the larva has engorged itself on skin and has fallen off its host, it develops to its nymph stage. The nymphs are sexually immature, but more closely resemble the adult. This stage consists of three phases, the protonymph, deutonymph, and tritonymph. The protonymph and tritonymph morphologies are unusual in species of Trombiculidae. The protonymph phase combines larval and protonymph characteristics with deutonymph and tritonymph morphology. The protonymph is an inactive transitional stage. The active deutonymph develops an additional pair of legs (for a total of eight). Lastly, it re-enters inactivity during its transitional tritonymph phase before growing to adulthood.

Adult
As deutonymphs and adults, trombiculid mites are independent predators that feed on small arthropods and their eggs, and are also found to eat plant material. They live in soil, and are often found when digging in yards or gardens or in compost bins.

5 Scabies

Scabies, also known as the seven-year itch, is a contagious skin infestation by the mite Sarcoptes scabiei. The most common symptoms are severe itchiness and a pimple-like rash. Occasionally, tiny burrows may be seen in the skin. In a first-ever infection a person will usually develop symptoms in between two and six weeks. During a second infection symptoms may begin in as little as 24 hours. These symptoms can be present across most of the body or just certain areas such as the wrists, between fingers, or along the waistline.

The head may be affected, but this is typically only in young children. The itch is often worse at night. Scratching may cause skin breakdown and an additional bacterial infection of the skin. Scabies is caused by infection with the female mite Sarcoptes scabiei var. hominis, an ectoparasite. The mites burrow into the skin to live and deposit eggs. The symptoms of scabies are due to an allergic reaction to the mites. Often, only between 10 and 15 mites are involved in an infection.

Scabies is most often spread during a relatively long period of direct skin contact with an infected person (at least 10 minutes) such as that which may occur during sex or living together. Spread of disease may occur even if the person has not developed symptoms yet. Crowded living conditions, such as those found in child-care facilities, group homes, and prisons, increase the risk of spread. Areas with a lack of access to water also have higher rates of disease. Crusted scabies is a more severe form of the disease.

It typically only occurs in those with a poor immune system and people may have millions of mites, making them much more contagious. In these cases, spread of infection may occur during brief contact or by contaminated objects. The mite is very small and usually not directly visible. Diagnosis is based on the signs and symptoms. A number of medications are available to treat those infected, including permethrin, crotamiton, and lindane creams and ivermectin pills. Sexual contacts within the last month and people who live in the same house should also be treated at the same time. Bedding and clothing used in the last three days should be washed in hot water and dried in a hot dryer.

As the mite does not live for more than three days away from human skin, more washing is not needed. Symptoms may continue for two to four weeks following treatment. If after this time symptoms continue, retreatment may be needed. Scabies is one of the three most common skin disorders in children, along with ringworm and bacterial skin infections. As of 2015, it affects about 204 million people (2.8% of the world population).

It is equally common in both sexes. The young and the old are more commonly affected. It also occurs more commonly in the developing world and tropical climates. The word scabies is from Latin: scabere, "to scratch". Other animals do not spread human scabies. Infection in other animals is typically caused by slightly different but related mites and is known as sarcoptic mange.

Signs & Symptoms
The characteristic symptoms of a scabies infection include intense itching and superficial burrows. The burrow tracks are often linear, to the point that a neat "line" of four or more closely placed and equally developed mosquito-like "bites" is almost diagnostic of the disease. Because the host develops the symptoms as a reaction to the mites' presence over time, typically a delay of four to six weeks occurs between the onset of infestation and the onset of itching. Similarly, symptoms often persist for one to several weeks after successful eradication of the mites. As noted, those re-exposed to scabies after successful treatment may exhibit symptoms of the new infestation in a much shorter period—as little as one to four days.

Itching	In the classic scenario, the itch is made worse by warmth, and is usually experienced as being worse at night, possibly because distractions are fewer. As a symptom, it is less common in the elderly.
Rash	The superficial burrows of scabies usually occur in the area of the finger webs, feet, ventral wrists, elbows, back, buttocks, and external genitals. Except in infants and the immunosuppressed, infection generally does not occur in the skin of the face or scalp. The burrows are created by excavation of the adult mite in the epidermis. In most people, the trails of the burrowing mites are linear or S-shaped tracks in the skin often accompanied by rows of small, pimple-like mosquito or insect bites. These signs are often found in crevices of the body, such as on the webs of fingers and toes, around the genital area, in stomach folds of the skin, and under the breasts of women. Symptoms typically appear two to six weeks after infestation for individuals never before exposed to scabies. For those having been previously exposed, the symptoms can appear within several days after infestation. However, symptoms may appear after several months or years. Acropustulosis, or blisters and pustules on the palms and soles of the feet, are characteristic symptoms of scabies in infants.
Crusted Scabies	The elderly, disabled, and people with an impaired immune system, such as HIV, cancer, or those on immunosuppressive medications, are susceptible to crusted scabies (also called Norwegian scabies). On those with weaker immune systems, the host becomes a more fertile breeding ground for the mites, which spread over the host's body, except the face. The mites in crusted scabies are not more virulent than in noncrusted scabies; however, they are much more numerous (up to two million). People with crusted scabies exhibit scaly rashes, slight itching, and thick crusts of skin that contain the large numbers of scabies mites. Due to being infected thus, persons with crusted scabies are more contagious to other persons. Such areas make eradication of mites particularly difficult, as the crusts protect the mites from topical miticides/scabicides, necessitating prolonged treatment of these areas.

6 Demodex

Demodex is a genus of tiny mites that live in or near hair follicles of mammals.
Around 65 species of Demodex are known. Two species live on humans: Demodex folliculorum and Demodex brevis, both frequently referred to as eyelash mites. Different species of animals host different species of Demodex. Demodex canis lives on the domestic dog. Infestation with Demodex is common and usually does not cause any symptoms, although occasionally some skin diseases can be caused by the mites. Older people are much more likely to carry the mites; about a third of children and young adults, half of adults, and two-thirds of elderly people carried them. The lower rate in children may be because children produce less sebum.

Recently, a study of 29 adults (18 and over) in North Carolina, US, found that 70% of those under 18 years of age carried mites, and that all adults over 18 (n = 19) carried them. Demodex were considered commensals but are now considered parasitic. However, in the vast majority of cases the mites go unobserved without any adverse symptoms, though in certain cases (usually related to a suppressed immune system, caused by stress or illness), mite populations can dramatically increase. This results in a condition known as demodicosis or Demodex mite bite, characterised by itching, inflammation, and other skin disorders. Blepharitis (inflammation of the eyelids) can be also caused by Demodex mites. The natural host of Demodex canis is the domestic dog. Although it can temporarily infect humans, D. canis mites cannot survive on the human skin and therefore will die shortly after exposure and are considered not to be zoonotic.

7 Head Louse

The head louse (Pediculus humanus capitis) is an obligate ectoparasite of humans that causes head lice infestation (pediculosis capitis). Head lice are wingless insects spending their entire lives on the human scalp and feeding exclusively on human blood. Humans are the only known hosts of this specific parasite, while chimpanzees host a closely related species, Pediculus schaeffi. Other species of lice infest most orders of mammals and all orders of birds, as well as other parts of the human body. Lice differ from other hematophagic ectoparasites such as fleas in spending their entire lifecycle on a host. Head lice cannot fly, and their short, stumpy legs render them incapable of jumping, or even walking efficiently on flat surfaces. The nondisease-carrying head louse differs from the related disease-carrying body louse (Pediculus humanus humanus) in preferring to attach eggs to scalp hair rather than to clothing. The two subspecies are morphologically almost identical, but do not normally interbreed, although they will do so in laboratory conditions.

A much more distantly related species of hair-clinging louse, the pubic or crab louse (Pthirus pubis), also infests humans. It is visually different from the other two species and is much closer in appearance to the lice which infest other primates. Head lice (especially in children) have been, and still are, subject to various eradication campaigns. Unlike body lice, head lice are not the vectors of any known diseases. Except for rare secondary infections that result from scratching at bites, head lice are harmless, and they have been regarded by some as essentially a cosmetic rather than a medical problem. Head lice infestations might be beneficial in helping to foster a natural immune response against lice which helps humans in defence against the far more dangerous body louse, which is capable of transmission of dangerous diseases.

Like other insects of the suborder Anoplura, adult head lice are small (2.5–3 mm long), dorsoventrally flattened (see anatomical terms of location), and entirely wingless. The thoracic segments are fused, but otherwise distinct from the head and abdomen, the latter being composed of seven visible segments. Head lice are grey in general, but their precise colour varies according to the environment in which they were raised. After feeding, consumed blood causes the louse body to take on a reddish colour.

Head	One pair of antennae, each with five segments, protrudes from the insect's head. Head lice also have one pair of eyes. Eyes are present in all species within the Pediculidae (the family of which the head louse is a member), but are reduced or absent in most other members of the Anoplura suborder. Like other members of the Anoplura, head lice mouth parts are highly adapted for piercing skin and sucking blood. These mouth parts are retracted into the insect's head except during feeding.
Thorax	Six legs project from the fused segments of the thorax. As is typical in the Anoplura, these legs are short and terminate with a single claw and opposing "thumb". Between its claw and thumb, the louse grasps the hair of its host. With their short legs and large claws, lice are well adapted to clinging to the hair of their host. These adaptations leave them incapable of jumping, or even walking efficiently on flat surfaces. Lice can climb up strands of hair very quickly, allowing them to move quickly and reach another host.
Abdomen	Seven segments of the louse abdomen are visible. The first six segments each have a pair of spiracles through which the insect breathes. The last segment contains the anus and (separately) the genitalia.

Louse Eggs	Like most insects, head lice are oviparous. Females lay about three or four eggs per day. Louse eggs are attached near the base of a host hair shaft. Egg-laying behaviour is temperature dependent and likely seeks to place the egg in a location that will be conducive to proper embryo development. In cool climates, eggs are generally laid within 3–5 mm of the scalp surface. In warm climates, and especially the tropics, eggs may be laid 6 inches (15 cm) or more down the hair shaft. Each egg is oval-shaped and about 0.8 mm in length. They are bright, transparent, and tan to coffee-collared so long as they contain an embryo, but appear white after hatching. Head lice hatch typically six to nine days after oviposition.

8 Crab Louse

The crab louse or pubic louse (Pthirus pubis) is an insect that is an obligate ectoparasite of humans, feeding exclusively on blood. The crab louse usually is found in the person's pubic hair. Although the louse cannot jump, it can also live in other areas of the body that are covered with coarse hair, such as the eyelashes. It is of the order Psocodea. Humans are the only known hosts of the crab louse, although a closely related species, Pthirus gorillae, infects gorilla populations.

The human parasite diverged from Pthirus gorillae approximately 3.3 million years ago. An adult crab louse is about 1.3–2 mm long (slightly smaller than the body louse and head louse), and can be distinguished from those other species by its almost round body. Another distinguishing feature is that the rearmost two pairs of legs of a crab louse are much thicker than the front legs and have large claws.

Infestations of crab lice are known as pediculosis pubis or phthiriasis pubis (which, unlike the generic name of the louse, is spelled with a phth). Infestation of the eyelashes is referred to as pediculosis ciliaris or phthiriasis palpebrarum. The main symptom of infestation with crab lice is itching, usually in the pubic-hair area, resulting from hypersensitivity to louse saliva, which can become stronger over two or more weeks following initial infestation. Crab lice usually infect a new host only by close contact between individuals, usually through sexual intercourse.

Adults are more frequently infested than children. Non-sexual transmissions may occur among family and roommates through the use of shared towels, clothing, beds or closets. Pubic lice are not known to transmit disease. Adult pubic lice are 1.1–1.8 mm in length. The pubic hair can typically host up to a dozen on average. Pubic lice typically are found attached to hair in the pubic area but sometimes are found on coarse hair elsewhere on the body (for example, eyebrows, eyelashes, beard, mustache, chest, armpits, etc.).

Crab lice attach to pubic hair that is thicker than other body hair because their claws are adapted to the specific diameter of pubic hair. Pubic lice infestations (pthiriasis) are usually spread through sexual contact. The crab louse can travel up to 10 inches on the body. Pubic lice infestation is found worldwide and occurs in all races and ethnic groups and in all economic levels. Pubic lice usually are spread through sexual contact and are most common in adults.

Occasionally pubic lice may be spread by close personal contact or contact with articles such as clothing, bed linens, and towels that have been used by an infested person. Pubic lice found on the head or eyelashes of children may be an indication of sexual exposure or abuse. Pubic lice do not transmit disease; however, secondary bacterial infection can occur from scratching of the skin. They are much broader in comparison to head and body lice. Adults are found only on the human host and require human blood to survive. If adults are forced off the host, they will die within 24–48 hours without a blood feeding.

Life Cycle
The eggs of the crab louse are laid usually on the coarse hairs of the genital and perianal regions of the human body. Crab lice may also be found on other areas of the body that have coarse and relatively sparse coverings of hair, such as the beard, moustache, eyelashes, and underneath the arms. They do not generally occur on the finer hair of the scalp. The female lays about three eggs a day. The eggs take 6–8 days to hatch, and there are three nymphal stages which together take 10–17 days before the adult develops, making a total life cycle from egg to adult of 16–25 days. Adults live for up to 30 days. Crab lice feed exclusively on blood, and take a blood meal 4–5 times daily. Adults are 1.5–2.0 mm long and flattened. They are much broader in comparison to head and body lice. Adults are found only on the human host and require human blood to survive. If adults are forced off the host, they will die within 24–48 hours without a blood feeding. Pubic lice are transmitted from person to person most-commonly via sexual contact, although fomites (bedding, clothing) may play a minor role in their transmission.

9 Body Louse

The body louse (Pediculus humanus humanus, sometimes called Pediculus humanus corporis) is a louse that infests humans. The condition of being infested with head lice, body lice, or pubic lice is known as pediculosis. Body lice are vectors for the transmission of the human diseases epidemic typhus, trench fever, and relapsing fever.

Life Cycle
Pediculus humanus humanus (the body louse) is indistinguishable in appearance from Pediculus humanus capitis (the head louse) but will interbreed only under laboratory conditions. In their natural state, they occupy different habitats and do not usually meet. In particular, body lice have evolved to attach their eggs to clothes, whereas head lice attach their eggs to the base of hairs. The life cycle of the body louse consists of three stages: egg (also called a nit), nymph, and adult.

1	Nits are louse eggs. They are generally easy to see in the seams of an infested person's clothing, particularly around the waistline, under armpits or even in body hair. They are oval and usually yellow to white in colour. Body lice nits may take 1–2 weeks to hatch.
2	A nymph is an immature louse that hatches from the nit (egg). A nymph looks like an adult body louse, but is smaller. Nymphs mature into adults about 9–12 days after hatching. To live, it must feed on blood.
3	The adult body louse is about the size of a sesame seed (2.5–3.5 mm), has six legs, and is tan to greyish-white. Females lay eggs. To live, lice must feed on blood. If separated from their hosts, lice die.

10 Protozoan Organisms

Protozoa (also protozoan, plural protozoans) is an informal term for a group of single-celled eukaryotes, either free-living or parasitic, which feed on organic matter such as other microorganisms or organic tissues and debris.

Acanthamoeba keratitis (Eye Infection)

Acanthamoeba keratitis is a rare disease in which amoebae invade the cornea of the eye, and affects roughly 1.2 to 3 million people each year. Acanthamoeba are protozoa found nearly ubiquitously in soil and water, and can cause infections of the skin, eyes, and central nervous system. Infection of the cornea by Acanthamoeba is difficult to treat with conventional medications, and Acanthamoeba keratitis (AK) may cause permanent visual impairment or blindness, due to damage to the clear portion of the front of the eye (called the cornea) or through damage to other structures important to vision. The most common source of acanthamoeba keratitis is contact lenses cleaned with contaminated tap water.

ILLNESS | Parasitic | Protozoan Organisms | Acanthamoeba keratitis (Eye In

In the United States, Acanthamoeba keratitis is nearly always associated with soft contact lens use. Acanthamoeba spp. is most commonly introduced to the eye by contact lenses that have been exposed to the organism through the use of contaminated lens solution, using homemade saline-based solution or tap water, or from wearing contact lenses while bathing or swimming.

However, it may also be introduced to the eye by exposure to soil or vegetation, or by trauma. In fact, the first case of Acanthamoeba keratitis described was due to ocular trauma. Once on the contact lens, Acanthamoeba is able to survive in the space between the contact lens and the surface of the eye. Soft contact lenses are more adherent to the corneal surface than hard lenses, which allows the Acanthamoeba organism to bind to mannosylated glycoproteins on the corneal surface.

Expression of these proteins on the corneal surface is increased by contact lens use. This increase in glycoprotein content, along with microtrauma to the corneal epithelial surface due to contact lens use increases the risk for infection. Once the organism has gained access to the surface of the eye, it is able to invade through the epithelium and Bowman's layer. It some cases, the infection can then group around corneal nerves, producing radial deposits (radial keratoneuritis), and causing extreme pain.

The organism is also capable of invading deeper into the cornea; using metalloproteases it is able to penetrate deep into the stroma of the cornea. As the disease progresses, it may penetrate through cornea but very rarely causes infection inside the eye (endophthalmitis) due to a robust neutrophil response in the anterior chamber.

Granulomatous Amoebic Encephalitis (GAE)

Granulomatous amoebic encephalitis (GAE) is a central nervous system disease caused by certain species of free-living amoebae, especially species of Acanthamoeba and Balamuthia mandrillaris. GAE may present in numerous ways. There is no solid definition, as only a handful of patients have presented thus far with GAE. GAE can present with: focal paralysis, seizures, brainstem symptoms, and other neurological problems, some of which may mimic glioma (especially brainstem glioma), or other brain diseases, which may hamper timely diagnosis. These symptoms are caused by inflammatory necrosis of brain tissue brought on by amoebic infiltrates. Even with treatment, the condition is often fatal, and there are very few recorded survivors, almost all of whom suffered permanent neurocognitive deficits. Antifungal drugs including ketoconazole, miconazole, 5-flucytosine and pentamidine have been shown to be effective against GAE-causing organisms in laboratory tests. Source: Via inhalation or skin lesion

Babesiosis

ILLNESS | Parasitic | Protozoan Organisms | Babesiosis

Babesiosis is a malaria-like parasitic disease caused by infection with Babesia, a type of Apicomplexa. Human babesiosis transmission via tick bite is most common in the North-eastern and Midwestern United States and parts of Europe, and sporadic throughout the rest of the world. It occurs in warm weather. People can get infected with Babesia parasites by the bite of an infected tick, by getting a blood transfusion from an infected donor of blood products, or by congenital transmission (an infected mother to her baby).

Ticks transmit the human strain of babesiosis, so it often presents with other tick-borne illnesses such as Lyme disease. After trypanosomes, Babesia is thought to be the second-most common blood parasite of mammals, and they can have a major impact on health of domestic animals in areas without severe winters. Half of all children and a quarter of previously healthy adults are asymptomatic with Babesia infection.

When people do develop symptoms, the most common are fever and hemolytic anaemia, symptoms that are similar to those of malaria. People with symptoms usually become ill 1 to 4 weeks after the bite, or 1 to 9 weeks after transfusion of contaminated blood products. A person infected with babesiosis gradually develops malaise and fatigue, followed by a fever. Hemolytic anaemia, in which red blood cells are destroyed and removed from the blood, also develops. Chills, sweats, and thrombocytopenia are also common symptoms. Symptoms may last from several days to several months. Source: Tick bites, e.g. Ixodes scapularis

ILLNESS | Protozoan Organisms | Babesiosis

Less Common Symptoms ● Headache ● Muscle pain ● Anorexia ● Nonproductive cough (mucus is not coughed up) ● Arthralgias (noninflammatory joint pain, unlike arthritis, which is inflammatory)	● Nausea ● Vomiting ● Sore throat ● Abdominal pain ● Emotional lability ● Pink eye/Conjunctivitis	● Photophobia (abnormal intolerance to visual perception of light) ● Weight loss ● Depression ● Hyperesthesia (more sensitive to stimuli)	In more severe cases, symptoms similar to malaria occur, with fevers up to 40.5 °C (105 °F), shaking chills, and severe anaemia (hemolytic anaemia). Organ failure may follow, including adult respiratory distress syndrome.

Balantidiasis

ILLNESS | Parasitic | Protozoan Organisms | Balantidiasis

Balantidiasis is a protozoan infection caused by infection with Balantidium coli. Symptoms can be local due to involvement of the intestinal mucosa, or systemic in nature and include either diarrhoea or constipation. Balantidiasis is a zoonotic disease and is acquired by humans via the feco-oral route from the normal host, the pig, where it is asymptomatic. “Contaminated water is the most common mechanism of transmission. Equally dangerous, however, is the ingestion of contaminated food.” The diagnosis of balantidiasis can be an intricate process, partly because the related symptoms may or may not be present.

However, the diagnosis of balantidiasis can be considered when a patient has diarrhoea combined with a probable history of current exposure to amebiasis through travel, contact with infected persons, or anal intercourse. In addition, the diagnosis of balantidiasis can be made by microscopic examination of stool or tissue samples. Balantidiasis can be treated with tetracycline, carbarsone, metronidazole, or diiodohydroxyquin. Source: Ingestion of cyst, zoonotic infection acquired from pigs (faeces).

Preventative measures require effective personal and community hygiene. Some specific safeguards include the following:
● Purification of drinking water.
● Proper handling of food.
● Careful disposal of human faeces.
● Monitoring the contacts of balantidiasis patients.

Blastocystosis

ILLNESS | Parasitic | Protozoan Organisms | Blastocystosis

Blastocystosis refers to a medical condition caused by infection with Blastocystis. Blastocystis is a protozoal, single-celled parasite that inhabits the gastrointestinal tracts of humans and other animals. Many different types of Blastocystis exist, and they can infect humans, farm animals, birds, rodents, amphibians, reptiles, fish, and even cockroaches. Blastocystosis has been found to be a possible risk factor for development of irritable bowel syndrome. Source: Eating food contaminated with faeces from an infected human or animal.

Most Commonly Symptoms ● Abdominal pain ● Itching, usually anal itching ● Constipation ● Diarrhoea ● Watery or loose stools ● Weight loss ● Fatigue ● Flatulence	**Less Common Symptoms** ● Skin rash ● Headache, depression ● Arthritic symptoms and joint pain ● Intestinal inflammation		

ILLN Para Protoz

Researchers have sought to develop models to understand the variety of symptoms seen in humans. Some patients do not have symptoms, while others report severe diarrhoea and fatigue. Consumption of Untreated Water (well water): Many studies have linked Blastocystis infection with contaminated drinking water. Contaminated Food: Contamination of leafy vegetables has been implicated as a potential source for transmission of Blastocystis infection, as well as other gastrointestinal protozoa.

Cryptosporidiosis

ILLNESS Parasitic Protozoan Organisms Cryptosporidiosis

Cryptosporidiosis, also known as crypto, is a parasitic disease caused by Cryptosporidium, a genus of protozoan parasites in the phylum Apicomplexa. It affects the distal small intestine and can affect the respiratory tract in both immunocompetent (i.e., individuals with a normal functioning immune system) and immunocompromised (e.g., persons with HIV/AIDS or autoimmune disorders) individuals, resulting in watery diarrhea with or without an unexplained cough. In immunosuppressed individuals, the symptoms are particularly severe and can be fatal. It is primarily spread through the fecal-oral route, often through contaminated water; recent evidence suggests that it can also be transmitted via fomites in respiratory secretions.

Source
Collects on water filters and membranes that cannot be disinfected, human and animal faeces. Drinking water sources become contaminated when faeces containing the parasites are deposited or flushed into water. If treatment is inadequate, drinking water may contain sufficient numbers of parasites to cause illness.

Symptoms
Diarrhoea, Watery Stool, Stomach Cramps, Slight Fever. Watery diarrhoea, abdominal cramps, nausea, and headaches.
These symptoms occur within two to 25 days of infection and usually last one or two weeks; in some cases they persist for up to a month.

Treatment
Fluid Replacement, Wormwood, Colloidal Silver, Olive Leaf Extract. Most healthy people recover within two weeks without medical attention. Anti-motility agents. These medications slow down the movements of your intestines and increase fluid absorption to relieve diarrhoea and restore normal stools (Imodium).

Diagnosis
Identification under a microscope form stool sample or intestinal biopsy.

ILLNESS Parasitic Protozoan Organisms Cryptosporidiosis

Cryptosporidiosis, also known as crypto, is a parasitic disease caused by Cryptosporidium. It affects the distal small intestine and can affect the respiratory tract in both immunocompetent (i.e. functioning immune system) and immunocompromised (e.g., persons with HIV/AIDS) individuals, resulting in watery diarrhoea with or without an unexplained cough. In immunosuppressed individuals, the symptoms are particularly severe and can be fatal. It is primarily spread through the faecal-oral route, often through contaminated water; recent evidence suggests that it can also be transmitted via fomites in respiratory secretions. Cryptosporidium is commonly isolated in HIV-positive patients presenting with diarrhoea.

Despite not being identified until 1976, it is one of the most common waterborne diseases and is found worldwide. The infection beings when a human consumes food or water containing cysts of the Cryptosporidium organism. Cryptosporidiosis may occur as an asymptomatic infection, an acute infection (i.e., duration shorter than 2 weeks), as recurrent acute infections in which symptoms reappear following a brief period of recovery for up to 30 days, and as a chronic infection (i.e., duration longer than 2 weeks) in which symptoms are severe and persistent. It may be fatal in individuals with a severely compromised immune system. Symptoms usually appear 5–10 days after infection (range: 2–28 days) and normally last for up to 2 weeks in immunocompetent individuals; symptoms are usually more severe and persist longer in immunocompromised individuals.

ILLNESS Parasitic Protozoan Organisms Cryptosporidiosis

Symptoms
Following the resolution of diarrhoea, symptoms can reoccur after several days or weeks due to reinfection. The likelihood of re-infection is high in immunocompromised adults, and low in those with normal immune systems

Common Symptoms
- Moderate to severe watery diarrhoea, sometimes contains mucus and rarely contains blood or leukocytes
- Low-grade fever
- Crampy abdominal pain
- Dehydration
- Weight loss
- Fatigue
- Nausea and vomiting
- Epigastric or right upper quadrant tenderness

Rare Symptoms
- Reactive arthritis
- Jaundice
- Ascites

Upper Respiratory Cryptosporidiosis
- Inflammation of the nasal mucosa, sinuses, larynx, or trachea
- Nasal discharge
- Voice change (e.g., hoarseness)

Lower Respiratory Cryptosporidiosis
- Cough
- Shortness of breath
- Fever
- Hypoxemia

ILLNESS Parasitic Protozoan Organisms Cryptosporidiosis

Cryptosporidiosis Transmission
Infection is through contaminated material such as earth, water, uncooked or cross-contaminated food that has been in contact with the faeces of an infected individual or animal. Contact must then be transferred to the mouth and swallowed. It is especially prevalent amongst those in regular contact with bodies of fresh water including recreational water such as swimming pools. Other potential sources include insufficiently treated water supplies, contaminated food, or exposure to faeces. The high resistance of Cryptosporidium oocysts to disinfectants such as chlorine bleach enables them to survive for long periods and still remain infective.

Some outbreaks have happened in day care related to diaper changes. Cases of cryptosporidiosis can occur even in cities that have a properly de-contaminated water supply. In a city with clean water, it may be that cases of cryptosporidiosis have other origins. Testing of water, as well as epidemiological study, are necessary to determine the sources of specific infections. Cryptosporidium is causing serious illness more frequently in immunocompromised than in apparently healthy individuals. It may chronically sicken some children, as well as adults who are exposed and immunocompromised.

Elevated Risks
- Child care workers
- Parents of infected children
- People who take care of other people with cryptosporidiosis
- International travellers
- Backpackers, hikers, and campers who drink unfiltered, untreated water
- People, including swimmers, who swallow water from contaminated sources
- People who handle infected cattle

ILLNESS Parasitic Protozoan Organisms Cryptosporidiosis

Cryptosporidiosis Prevention
Many treatment plants that take raw water from rivers, lakes, and reservoirs for public drinking water production use conventional filtration technologies. This involves a series of processes, including coagulation, flocculation, sedimentation, and filtration. Direct filtration, which is typically used to treat water with low particulate levels, includes coagulation and filtration, but not sedimentation. Other common filtration processes, including slow sand filters, diatomaceous earth filters and membranes will remove 99% of Cryptosporidium. Membranes and bag and cartridge filters remove Cryptosporidium product-specifically.

While Cryptosporidium is highly resistant to chlorine disinfection, with high enough concentrations and contact time, Cryptosporidium will be inactivated by chlorine dioxide and ozone treatment. The required levels of chlorine generally preclude the use of chlorine disinfection as a reliable method to control Cryptosporidium in drinking water. Ultraviolet light treatment at relatively low doses will inactivate Cryptosporidium. Water Research Foundation-funded research originally discovered UV's efficacy in inactivating Cryptosporidium. The most reliable way to decontaminate drinking water that may be contaminated by Cryptosporidium is to boil it.

ILLNESS Parasitic Protozoan Organisms Cryptosporidiosis

In the US the law requires doctors and labs to report cases of cryptosporidiosis to local or state health departments. These departments then report to the Centre for Disease Control and Prevention. The best way to prevent getting and spreading cryptosporidiosis is to have good hygiene and sanitation. An example would be hand-washing. Prevention is through washing hands carefully after going to the bathroom or contacting stool, and before eating. People should avoid contact with animal faeces.

They should also avoid possibly contaminated food and water. In addition, people should refrain from engaging in sexual activities that can expose them to faeces. Standard water filtration may not be enough to eliminate Cryptosporidium; boiling for at least 1 minute (3 minutes above 6,500 feet (2,000 m) of altitude) will decontaminate it. Heating milk at 71.7 °C (161 °F) for 15 seconds pasteurizes it and can destroy the oocysts' ability to infect. Water can also be made safe by filtering with a filter with pore size not greater than 1 micrometre, or by filters that have been approved for “cyst removal” by NSF International National Sanitation Foundation.

Bottled drinking water is less likely to contain Cryptosporidium, especially if the water is from an underground source. People with cryptosporidiosis should not swim in communal areas because the pathogen can reside in the anal and genital areas and be washed off. They should wait until at least two weeks after diarrhoea stops before entering public water sources, since oocysts can still be shed for a while. Also, they should stay away from immunosuppressed people.

Immunocompromised people should take care to protect themselves from water in lakes and streams. They should also stay away from animal stools and wash their hands after touching animals. To be safe, they should boil or filter their water. They should also wash and cook their vegetables. Soak contaminated surfaces for 20 minutes with a 3% hydrogen peroxide (99% kill rate) and then rinse them thoroughly.

Cryptosporidiosis Treatment
Symptomatic treatment primarily involves fluid rehydration, electrolyte replacement (sodium, potassium, bicarbonate, and glucose), and antimotility agents (e.g., loperamide). Supplemental zinc may improve symptoms, particularly in recurrent or persistent infections or in others at risk for zinc deficiency. Immunocompetent individuals with cryptosporidiosis typically suffer a short (i.e., duration of less than 2 weeks) self-limiting course of diarrhoea that may require symptomatic treatment and ends with spontaneous recovery; in some circumstances, antiparasitic medication may be required (e.g., recurrent, severe, or persistent symptoms); however reinfection frequently occurs. In immunocompromised individuals, such as AIDS patients, cryptosporidiosis resolves slowly or not at all, and frequently causes a particularly severe and persistent form of watery diarrhoea coupled with a greatly decreased ability to absorb key nutrients through the intestinal tract. As a result, infected individuals may experience severe dehydration, electrolyte imbalances, malnutrition, wasting, and potentially death. Cryptosporidiosis is found worldwide. It causes 50.8% of water-borne diseases that are attributed to parasites. In developing countries, 8–19% of diarrheal diseases can be attributed to Cryptosporidium. Ten percent of the population in developing countries excretes oocysts. In developed countries, the number is lower at 1–3%. The age group most affected are children from 1 to 9 years old. Roughly 30% of adults in the United States are seropositive for cryptosporidiosis, meaning that they contracted the infection at some point in their lives.

Cyclosporiasis

Cyclosporiasis is a disease caused by infection with Cyclospora cayetanensis, a pathogenic protozoan transmitted by faeces or faeces-contaminated food and water. Outbreaks have been reported due to contaminated fruits and vegetables. It is not spread from person to person, but can be a hazard for travellers as a cause of diarrhoea.

Sources
Sewage, non-treated drinking water.

Symptoms
Cramps, nausea, vomiting, muscle aches, fever, and fatigue.

Treatment
The infection is often treated with trimethaprim-sulfamethaxozol, also known as Bactrim or co-trimoxazole, because traditional anti-protozoal drugs are not sufficient. To prevent transmission, food should be cooked thoroughly and drinking water from streams should be avoided.

Dientamoebiasis

Dientamoebiasis is a medical condition caused by infection with Dientamoeba fragilis, a single-cell parasite that infects the lower gastrointestinal tract of humans. It is an important cause of traveler's diarrhea, chronic abdominal pain, chronic fatigue, and failure to thrive in children.

Symptoms
The most commonly reported symptoms in conjunction with infection with D. fragilis include abdominal pain (69%) and diarrhea (61%). Diarrhea may be intermittent and may not be present in all cases. It is often chronic, lasting over two weeks. The degree of symptoms may vary from asymptomatic to severe, and can include weight loss, vomiting, fever, and involvement of other digestive organs.

Symptoms
- Weight loss
- Fatigue
- Nausea and vomiting
- Fever
- Urticaria (skin rash)
- Pruritus (itchiness)
- Biliary infection

Symptoms
- Weight loss
- Fatigue
- Nausea and vomiting
- Fever
- Urticaria (skin rash)
- Pruritus (itchiness)
- Biliary infection

Treatment
Concomitant pinworm infection should also be excluded, although the association has not been proven. Successful treatment of the infection with iodoquinol, doxycycline, metronidazole, paromomycin, and secnidazole has been reported. Resistance requires the use of combination therapy to eradicate the organism. All persons living in the same residence should be screened for D. fragilis, as asymptomatic carriers may provide a source of repeated infection. Paromomycin is an effective prophylactic for travellers who will encounter poor sanitation and unsafe drinking water.

Amoebiasis

Amoebiasis, also known amoebic dysentery, is an infection caused by any of the amobae of the Entamoeba group. Symptoms are most common during infection by Entamoeba histolytica. Amoebiasis can be present with no, mild, or severe symptoms. Symptoms may include abdominal pain, diarrhea, or bloody diarrhea. Complications can include inflammation and ulceration of the colon with tissue death or perforation, which may result in peritonitis. People affected may develop anemia due to loss of blood. Cysts of Entamoeba can survive for up to a month in soil or for up to 45 minutes under fingernails. Invasion of the intestinal lining results in bloody diarrhea.

If the parasite reaches the bloodstream it can spread through the body, most frequently ending up in the liver where it can cause amoebic liver abscesses. Prevention of amoebiasis is by improved sanitation, including separating food and water from faeces. There is no vaccine. There are two treatment options depending on the location of the infection. Amoebiasis in tissues is treated with either metronidazole, tinidazole, nitazoxanide, dehydroemetine or chloroquine, while luminal infection is treated with diloxanide furoate or iodoquinoline.

Effective treatment against all stages of the disease may require a combination of medications. Infections without symptoms do not require treatment but infected individuals can spread the parasite to others and treatment can be considered. Treatment of other Entamoeba infections apart from E. histolytica is not needed. Sources - Sewage, non-treated drinking water, flies in water supply. Symptoms - Abdominal discomfort, fatigue, weight loss, diarrhea, bloating, fever.

Most infected people, about 90%, are asymptomatic, but this disease has the potential to become serious. It is estimated that about 40,000 to 100,000 people worldwide die annually due to amoebiasis. Infections can sometimes last for years if there is no treatment. Symptoms take from a few days to a few weeks to develop and manifest themselves, but usually it is about two to four weeks. Symptoms can range from mild diarrhea to dysentery with blood, coupled with intense abdominal pains.

The blood comes from bleeding lesions created by the amoebae invading the lining of the colon. In about 10% of invasive cases the amoebae enter the bloodstream and may travel to other organs in the body. Most commonly this means the liver, as this is where blood from the intestine reaches first, but they can end up almost anywhere in the body. Onset time is highly variable and the average asymptomatic infection persists for over a year. It is theorized that the absence of symptoms or their intensity may vary with such factors as strain of amoeba, immune response of the host, and perhaps associated bacteria and viruses.

In asymptomatic infections, the amoeba lives by eating and digesting bacteria and food particles in the gut, a part of the gastrointestinal tract. It does not usually come in contact with the intestine itself due to the protective layer of mucus that lines the gut. Disease occurs when amoeba comes in contact with the cells lining the intestine. It then secretes the same substances it uses to digest bacteria, which include enzymes that destroy cell membranes and proteins. This process can lead to penetration and digestion of human tissues, resulting first in flask-shaped ulcerations in the intestine.

Transmission
Amoebiasis is usually transmitted by the fecal-oral route, but it can also be transmitted indirectly through contact with dirty hands or objects as well as by anal-oral contact. Infection is spread through ingestion of the cyst form of the parasite, a semi-dormant and hardy structure found in feces. Any non-encysted amoebae, or trophozoites, die quickly after leaving the body but may also be present in stool: these are rarely the source of new infections. Since amoebiasis is transmitted through contaminated food and water, it is often endemic in regions of the world with limited modern sanitation systems, including México, Central America, western South America, South Asia, and western and southern Africa. Amoebic dysentery is often confused with "traveler's diarrhea" because of its prevalence in developing nations. In fact, most traveler's diarrhea is bacterial or viral in origin.

Giardiasis

Sources: Untreated water, poor disinfection, pipe breaks, leaks, groundwater contamination, campgrounds where humans and wildlife use same source of water. Beavers and muskrats create ponds that act as reservoirs for Giardia.
Symptoms: Symptoms may present as early as one day after exposure, although it more commonly presents in one to two weeks. Patients complain of watery diarrhea, abdominal cramping, violent (often called "projectile") vomiting, and gas.
Treatment: Metronidazole is the drug of choice in conjunction with oral rehydration. Tinidazole, Nitazoxanide.
Notes: The most common disease-causing parasite in the world is the protozoa Giardia lamblia. It has even been found in backcountry waters in many national parks in the U.S.

Giardiasis, popularly known as beaver fever, is a parasitic disease caused by Giardia lamblia. About 10% of those infected have no symptoms. When symptoms occur they may include diarrhea, abdominal pain, and weight loss. Vomiting, blood in the stool, and fever are less common. Symptoms usually begin 1 to 3 weeks after exposure and without treatment may last up to six weeks. Giardia usually spreads when Giardia lamblia cysts within feces contaminate food or water which is then eaten or drunk. It may also spread between people and from other animals. Risk factors include travel in the developing world, changing diapers, eating food without cooking it, and owning a dog. Cysts may survive for nearly three months in cold water. Diagnosis is via stool tests. Prevention is typically by improved hygiene.

Those without symptoms do not usually need treatment. When symptoms are present treatment is typically with either tinidazole or metronidazole. People who are not already lactose intolerant may become so temporarily after an infection and therefore it is often recommended milk be avoided for a few weeks. Resistance to treatment may occur. Giardia is one of the most common parasitic human diseases globally. In 2013, there were about 280 million people worldwide with symptomatic giardiasis. Rates are as high as 7% in the developed world and 30% in the developing world. The World Health Organization classified it as a neglected disease.

Signs & Symptoms
Symptoms vary from none to severe diarrhea with poor absorption of nutrients. Symptoms typically develop 9–15 days after exposure, but may occur as early as one day. The most common and prominent symptom is chronic diarrhea which can occur for weeks or months if untreated. Diarrhea is often greasy and foul-smelling, with a tendency to float. This characteristic diarrhea is often accompanied by a number of other symptoms, including gas, abdominal cramps, and nausea or vomiting. Some people also experience itchy skin, hives, and swelling of the eyes and joints, although these are less common. Prolonged disease is often characterized by diarrhea along with malabsorption of nutrients in the intestine. This malabsorption results in fatty stools, substantial weight loss, and fatigue. Additionally, those suffering from giardiasis often have difficulty absorbing lactose, vitamin A, folate, and vitamin B12. In children, prolonged giardiasis can cause failure to thrive and may impair mental development. Symptomatic infections are well recognized as causing lactose intolerance, which, while usually temporary, may become permanent.

Prevention
The CDC recommends hand-washing and avoiding potentially contaminated food and untreated water. Boiling suspect water for one minute is the surest method to make water safe to drink and kill disease-causing microorganisms such as Giardia lamblia if in doubt about whether water is infected. Chemical disinfectants or filters may be used. Although the evidence linking the drinking of water in the North American wilderness and giardiasis has been questioned, a number of studies raise concern. Most if not all CDC verified backcountry giardiasis outbreaks have been attributed to water. Surveillance data (for 2013 and 2014) reports six outbreaks (96 cases) of waterborne giardiasis contracted from rivers, streams or springs and less than 1% of reported giardiasis cases are associated with outbreaks. Person-to-person transmission accounts for the majority of Giardia infections and is usually associated with poor hygiene and sanitation. Giardia is found on the surface of the ground, in the soil, in undercooked foods, and in water, and on hands without proper cleaning after handling infected feces. Water-borne transmission is associated with the ingestion of contaminated water. In the U.S., outbreaks typically occur in small water systems using inadequately treated surface water. Venereal transmission happens through fecal-oral contamination. Additionally, diaper changing and inadequate hand washing are risk factors for transmission from infected children. Lastly, food-borne epidemics of Giardia have developed through the contamination of food by infected food-handlers.

Treatment
Treatment is not always necessary as the infection usually resolves on its own. However, if the illness is acute or symptoms persist and medications are needed to treat it, a nitroimidazole medication is used such as metronidazole, tinidazole, secnidazole or ornidazole. The World Health Organization and Infectious Disease Society of America recommend metronidazole as first line therapy. The US CDC lists metronidazole, tinidazole, and nitazoxanide as effective first-line therapies; of these three, only nitazoxanide and tinidazole are approved for the treatment of giardiasis by the US FDA. Resistance has been seen clinically to both nitroimidazoles and albendazole, but not nitazoxanide, though nitazoxanide resistance has been induced in research laboratories so is theoretically possible. The exact mechanism of resistance to all of these medications is not well understood. In the case of nitroimidazole-resistant strains of Giardia, other drugs are available which have showed efficacy in treatment including quinacrine, nitazoxanide, bacitracin zinc, furazolidone and paromomycin.

Isosporiasis

Isosporiasis, also known as cystoisosporiasis, is a human intestinal disease caused by the parasite Isospora belli (now known as Cystoisospora belli). It is found worldwide, especially in tropical and subtropical areas. Infection often occurs in immuno-compromised individuals, notably AIDS patients, and outbreaks have been reported in institutionalized groups in the United States. It is usually spread indirectly, normally through contaminated food or water.

Signs & Symptoms
Infection causes acute, non-bloody diarrhea with crampy abdominal pain, which can last for weeks and result in malabsorption and weight loss. In immunodepressed patients, and in infants and children, the diarrhea can be severe.

Cause
The coccidian parasite Isospora belli infects the epithelial cells of the small intestine, and is the least common of the three intestinal coccidia that infect humans (Toxoplasma, Cryptosporidium, and Isospora).

Transmission
People become infected by swallowing the mature parasite; this normally occurs through the ingestion of contaminated food or water. The infected host then produces an immature form of the parasite in their feces, and when the parasite matures, it is capable of infecting its next host, via food or water containing the parasite.

Prevention
Avoiding food or water that may be contaminated with stool can help prevent the infection of Cystoisospora (Isosporiasis). Good hand-washing, and personal-hygiene practices should be used as well. One should wash their hands with soap and warm water after using the toilet, changing diapers, and before handling food (CDC.gov). It is also important to teach children the importance of washing their hands, and how to properly wash their hands.

Treatment
Isosporiasis is treated with prescription antibiotics, the treatment of choice is trimethoprim-sulfamethoxazole.

Leishmaniasis

Leishmaniasis is a disease caused by parasites of the Leishmania type. It is spread by the bite of certain types of sandflies. The disease can present in three main ways: cutaneous, mucocutaneous, or visceral leishmaniasis. The cutaneous form presents with skin ulcers, while the mucocutaneous form presents with ulcers of the skin, mouth, and nose, and the visceral form starts with skin ulcers and then later presents with fever, low red blood cells, and enlarged spleen and liver. Infections in humans are caused by more than 20 species of Leishmania. Risk factors include poverty, malnutrition, deforestation, and urbanization. All three types can be diagnosed by seeing the parasites under the microscope.

Additionally, visceral disease can be diagnosed by blood tests. Leishmaniasis can be partly prevented by sleeping under nets treated with insecticide. Other measures include spraying insecticides to kill sandflies and treating people with the disease early to prevent further spread. The treatment needed is determined by where the disease is acquired, the species of Leishmania, and the type of infection. Some possible medications used for visceral disease include liposomal amphotericin B, a combination of pentavalent antimonials and paromomycin, and miltefosine. For cutaneous disease, paromomycin, fluconazole, or pentamidine may be effective.

Signs & Symptoms
The symptoms of leishmaniasis are skin sores which erupt weeks to months after the person is bitten by infected sand flies. Leishmaniasis is considered one of the classic causes of a markedly enlarged (and therefore palpable) spleen; the organ, which is not normally felt during examination of the abdomen, may even become larger than the liver in severe cases.

Leishmaniasis may be divided into the following types:
● Cutaneous leishmaniasis is the most common form, which causes an open sore at the bite sites, which heals in a few months to a year and half, leaving an unpleasant-looking scar. Diffuse cutaneous leishmaniasis produces widespread skin lesions which resemble leprosy, and may not heal on its own.
● Mucocutaneous leishmaniasis causes both skin and mucosal ulcers with damage primarily of the nose and mouth.
● Visceral leishmaniasis or kala-azar ('black fever') is the most serious form, and is potentially fatal if untreated. Other consequences, which can occur a few months to years after infection, include fever, damage to the spleen and liver, and anemia.

Causes
Leishmaniasis is transmitted by the bite of infected female phlebotomine sandflies which can transmit the protozoa Leishmania. The sandflies inject the infective stage, metacyclic promastigotes, during blood meals (1). Metacyclic promastigotes that reach the puncture wound are phagocytized by macrophages (2) and transform into amastigotes (3). Amastigotes multiply in infected cells and affect different tissues, depending in part on which Leishmania species is involved (4). These differing tissue specificities cause the differing clinical manifestations of the various forms of leishmaniasis. Sandflies become infected during blood meals on infected hosts when they ingest macrophages infected with amastigotes (5,6). In the sandfly's midgut, the parasites differentiate into promastigotes (7), which multiply, differentiate into metacyclic promastigotes, and migrate to the proboscis (8). Risk Factors: Risk factors include poverty, malnutrition, deforestation, lack of sanitation and urbanization.

Diagnosis
Leishmaniasis is diagnosed in the hematology laboratory by direct visualization of the amastigotes (Leishman-Donovan bodies). Buffy-coat preparations of peripheral blood or aspirates from marrow, spleen, lymph nodes, or skin lesions should be spread on a slide to make a thin smear and stained with Leishman stain or Giemsa stain (pH 7.2) for 20 minutes. Amastigotes are seen within blood and spleen monocytes or, less commonly, in circulating neutrophils and in aspirated tissue macrophages. They are small, round bodies 2–4 μm in diameter with indistinct cytoplasm, a nucleus, and a small, rod-shaped kinetoplast. Occasionally, amastigotes may be seen lying free between cells. However, the retrieval of tissue samples is often painful for the patient and identification of the infected cells can be difficult. So, other indirect immunological methods of diagnosis are developed, including enzyme-linked immunosorbent assay, antigen-coated dipsticks, and direct agglutination test. Although these tests are readily available, they are not the standard diagnostic tests due to their insufficient sensitivity and specificity.

Prevention
Leishmaniasis can be partly prevented by using nets treated with insecticide while sleeping. To provide good protection against sandflies, fine mesh sizes of 0.6 mm or less are required, but a mosquito net with 1.2mm mesh will provide a limited reduction in the number of sandfly bites. Finer mesh sizes have the downside of higher cost and reduced air circulation which can cause overheating. Many Phlebotomine sandfly attacks occur at sunset rather than at night, so it may also be useful to put nets over doors and windows or to use insect repellents. Use of insecticide-impregnated dog collars and treatment or culling of infected dogs. Spraying houses and animal shelters with insecticides.

Treatment
The treatment is determined by where the disease is acquired, the species of Leishmania, and the type of infection. For visceral leishmaniasis in India, South America, and the Mediterranean, liposomal amphotericin B is the recommended treatment and is often used as a single dose. Rates of cure with a single dose of amphotericin have been reported as 95%. In India, almost all infections are resistant to pentavalent antimonials. In Africa, a combination of pentavalent antimonials and paromomycin is recommended. These, however, can have significant side effects. Miltefosine, an oral medication, is effective against both visceral and cutaneous leishmaniasis. Side effects are generally mild, though it can cause birth defects if taken within 3 months of getting pregnant. It does not appear to work for L. major or L. braziliensis. The evidence around the treatment of cutaneous leishmaniasis is poor. A number of topical treatments may be used for cutaneous leishmaniasis. Which treatments are effective depends on the strain, with topical paromomycin effective for L. major, L. tropica, L. mexicana, L. panamensis, and L. braziliensis. Pentamidine is effective for L. guyanensis.

Primary Amoebic Meningoencephalitis (PAM)

Naegleriasis (also known as primary amoebic meningoencephalitis) is an infection of the brain by the free-living unicellular Naegleria fowleri.
N. fowleri is typically found in warm bodies of fresh water, such as ponds, lakes, rivers, and hot springs. It is also found in soil, poorly maintained municipal water supplies, water heaters, near warm-water discharges of industrial plants, and in poorly chlorinated or unchlorinated swimming pools, in an amoeboid or temporary flagellate stage. There is no evidence of it living in salt water. As the disease is rare, it is often not considered. Symptoms are similar to those of meningitis. Although infection occurs rarely, it nearly always results in death, with a case fatality rate greater than 95%.

Signs & Symptoms
Onset of symptoms begins one to nine days following exposure (with an average of five). Initial symptoms include changes in taste and smell, headache, fever, nausea, vomiting, back pain, and a stiff neck. Secondary symptoms are also meningitis-like including confusion, hallucinations, lack of attention, ataxia, cramp and seizures. After the start of symptoms, the disease progresses rapidly over three to seven days, with death usually occurring anywhere from seven to fourteen days later, although it can take longer. In 2013, a man in Taiwan died twenty-five days after being infected by Naegleria fowleri. It affects healthy children or young adults who have recently been exposed to bodies of fresh water. Some people have presented with a clinical triad of edematous brain lesions, immune suppression, and fever.

Cause
N. fowleri invades the central nervous system via the nose, specifically through the olfactory mucosa of the nasal tissues. This usually occurs as the result of the introduction of water that has been contaminated with N. fowleri into the nose during activities such as swimming, bathing, or nasal irrigation. The organism then begins to consume cells of the brain, piecemeal, by means of an amoebostome, a unique actin-rich sucking apparatus extended from its cell surface. It then becomes pathogenic, causing primary amoebic meningoencephalitis (PAM or PAME).

Prevention
Wear nose-clips to prevent insufflation of contaminated water is effective protection against contracting PAM. Prevent fresh water from entering the nostrils and avoid putting their heads down into fresh water or stirring mud in the water with feet. When starting to suffer from fever, headache, nausea, or vomiting subsequent to any kind of exposure to fresh water even if the belief in none of the fresh water has traveled through nostrils, people with such conditions should be carried to hospital quickly and make sure doctors are well-informed about the history of exposure to fresh water.

Treatment
Treatment has often also used combination therapy with multiple other antimicrobials in addition to amphotericin, such as fluconazole, miconazole, rifampicin and azithromycin. They have shown limited success only when administered early in the course of an infection. Less than 1% of people with naegleriasis survive.

Malaria

Malaria is a mosquito-borne infectious disease affecting humans and other animals caused by parasitic single-celled microorganisms belonging to the Plasmodium group. Malaria causes symptoms that typically include fever, tiredness, vomiting, and headaches. In severe cases it can cause yellow skin, seizures, coma, or death. Symptoms usually begin ten to fifteen days after being bitten by an infected mosquito. If not properly treated, people may have recurrences of the disease months later. In those who have recently survived an infection, reinfection usually causes milder symptoms. This partial resistance disappears over months to years if the person has no continuing exposure to malaria.

The disease is most commonly transmitted by an infected female Anopheles mosquito. The mosquito bite introduces the parasites from the mosquito's saliva into a person's blood. The parasites travel to the liver where they mature and reproduce. Five species of Plasmodium can infect and be spread by humans. Most deaths are caused by P. falciparum because P. vivax, P. ovale, and P. malariae generally cause a milder form of malaria. The species P. knowlesi rarely causes disease in humans.

Malaria is typically diagnosed by the microscopic examination of blood using blood films, or with antigen-based rapid diagnostic tests. Methods that use the polymerase chain reaction to detect the parasite's DNA have been developed, but are not widely used in areas where malaria is common due to their cost and complexity.

The risk of disease can be reduced by preventing mosquito bites through the use of mosquito nets and insect repellents, or with mosquito control measures such as spraying insecticides and draining standing water. Several medications are available to prevent malaria in travellers to areas where the disease is common. Occasional doses of the combination medication sulfadoxine/pyrimethamine are recommended in infants and after the first trimester of pregnancy in areas with high rates of malaria.

Despite a need, no effective vaccine exists, although efforts to develop one are ongoing. The recommended treatment for malaria is a combination of antimalarial medications that includes an artemisinin. The second medication may be either mefloquine, lumefantrine, or sulfadoxine/pyrimethamine. Quinine along with doxycycline may be used if an artemisinin is not available. It is recommended that in areas where the disease is common, malaria is confirmed if possible before treatment is started due to concerns of increasing drug resistance.

Resistance among the parasites has developed to several antimalarial medications; for example, chloroquine-resistant P. falciparum has spread to most malarial areas, and resistance to artemisinin has become a problem in some parts of Southeast Asia. The disease is widespread in the tropical and subtropical regions that exist in a broad band around the equator.

Signs & Symptoms
The signs and symptoms of malaria typically begin 8–25 days following infection, but may occur later in those who have taken antimalarial medications as prevention. Initial manifestations of the disease—common to all malaria species—are similar to flu-like symptoms, and can resemble other conditions such as sepsis, gastroenteritis, and viral diseases. The presentation may include headache, fever, shivering, joint pain, vomiting, hemolytic anemia, jaundice, hemoglobin in the urine, retinal damage, and convulsions. The classic symptom of malaria is paroxysm—a cyclical occurrence of sudden coldness followed by shivering and then fever and sweating, occurring every two days (tertian fever) in P. vivax and P. ovale infections, and every three days (quartan fever) for P. malariae. P. falciparum infection can cause recurrent fever every 36–48 hours, or a less pronounced and almost continuous fever. Severe malaria is usually caused by P. falciparum (often referred to as falciparum malaria). Symptoms of falciparum malaria arise 9–30 days after infection. Individuals with cerebral malaria frequently exhibit neurological symptoms, including abnormal posturing, nystagmus, conjugate gaze palsy (failure of the eyes to turn together in the same direction), opisthotonus, seizures, or coma.

Causes
Malaria parasites belong to the genus Plasmodium (phylum Apicomplexa). In humans, malaria is caused by P. falciparum, P. malariae, P. ovale, P. vivax and P. knowlesi. Among those infected, P. falciparum is the most common species identified (~75%) followed by P. vivax (~20%). Although P. falciparum traditionally accounts for the majority of deaths, recent evidence suggests that P. vivax malaria is associated with potentially life-threatening conditions about as often as with a diagnosis of P. falciparum infection. P. vivax proportionally is more common outside Africa.

There have been documented human infections with several species of Plasmodium from higher apes; however, except for P. knowlesi—a zoonotic species that causes malaria in macaques—these are mostly of limited public health importance. Only female mosquitoes feed on blood; male mosquitoes feed on plant nectar and do not transmit the disease. Females of the mosquito genus Anopheles prefer to feed at night. They usually start searching for a meal at dusk and will continue throughout the night until taking a meal.

Malaria parasites can also be transmitted by blood transfusions, although this is rare. Symptoms of malaria can recur after varying symptom-free periods. Depending upon the cause, recurrence can be classified as either recrudescence, relapse, or reinfection. Recrudescence is when symptoms return after a symptom-free period. It is caused by parasites surviving in the blood as a result of inadequate or ineffective treatment. Relapse is when symptoms reappear after the parasites have been eliminated from blood but persist as dormant hypnozoites in liver cells.

Relapse commonly occurs between 8–24 weeks and is often seen in P. vivax and P. ovale infections. However, relapse-like P. vivax recurrences are probably being over-attributed to hypnozoite activation. Global climate change is likely to affect malaria transmission, but the degree of effect and the areas effected is uncertain. Greater rainfall in certain areas of India and following an El Nino event is associated with increased mosquito numbers.

Diagnosis
Owing to the non-specific nature of the presentation of symptoms, diagnosis of malaria in non-endemic areas requires a high degree of suspicion, which might be elicited by any of the following: recent travel history, enlarged spleen, fever, low number of platelets in the blood, and higher-than-normal levels of bilirubin in the blood combined with a normal level of white blood cells. Malaria is usually confirmed by the microscopic examination of blood films or by antigen-based rapid diagnostic tests (RDT). In some areas, RDTs need to be able to distinguish whether the malaria symptoms are caused by Plasmodium falciparum or by other species of parasites since treatment strategies could differ for non-P. falciparum infections. Malaria is classified into either "severe" or "uncomplicated" by the World Health Organization (WHO). It is deemed severe when any of the following criteria are present, otherwise it is considered uncomplicated. Cerebral malaria is defined as a severe P. falciparum-malaria presenting with neurological symptoms, including coma (with a Glasgow coma scale less than 11, or a Blantyre coma scale less than 3), or with a coma that lasts longer than 30 minutes after a seizure.

ILLNESS Parasitic Protozoan Organisms Malaria

Severe/Complicated Symptoms
- Decreased consciousness
- Significant weakness such that the person is unable to walk
- Inability to feed
- Two or more convulsions
- Low blood pressure (less than 70 mmHg in adults and 50 mmHg in children)
- Breathing problems
- Circulatory shock
- Kidney failure or hemoglobin in the urine
- Bleeding problems, or hemoglobin less than 50 g/L (5 g/dL)
- Pulmonary oedema
- Blood glucose less than 2.2 mmol/L (40 mg/dL)

Malaria Types This is a table of the different types of malaria and their effects.

Name	Pathogen	Notes
Algid Malaria	Plasmodium falciparum	Severe malaria affecting the cardiovascular system and causing chills and circulatory shock
Bilious Malaria	Plasmodium falciparum	Severe malaria affecting the liver and causing vomiting and jaundice
Cerebral Malaria	Plasmodium Falciparum	Severe malaria affecting the cerebrum
Congenital Malaria	Various Plasmodia	Plasmodium introduced from the mother via the fetal circulation
Falciparum Malaria, Plasmodium Falciparum Malaria, Pernicious Malaria	Plasmodium Falciparum	None
Ovale Malaria, Plasmodium Ovale Malaria	Plasmodium Ovale	None
Quartan Malaria, Malariae Malaria, Plasmodium Malariae Malaria	Plasmodium Malariae	Paroxysms every fourth day (quartan), counting the day of occurrence as the first day
Quotidian Malaria	Plasmodium Falciparum, Plasmodium Vivax	Paroxysms daily (quotidian)
Tertian Malaria	Plasmodium Falciparum, Plasmodium Ovale, Plasmodium Vivax	Paroxysms every third day (tertian), counting the day of occurrence as the first
Transfusion Malaria	Various Plasmodia	Plasmodium introduced by blood transfusion, needle sharing, or needlestick injury
Vivax Malaria, Plasmodium Vivax Malaria	Plasmodium Vivax	None

Malaria Prevention
Methods used to prevent malaria include medications, mosquito elimination and the prevention of bites. There is no vaccine for malaria. The presence of malaria in an area requires a combination of high human population density, high anopheles mosquito population density and high rates of transmission from humans to mosquitoes and from mosquitoes to humans. If any of these is lowered sufficiently, the parasite will eventually disappear from that area, as happened in North America, Europe and parts of the Middle East.

However, unless the parasite is eliminated from the whole world, it could become re-established if conditions revert to a combination that favors the parasite's reproduction. Furthermore, the cost per person of eliminating anopheles mosquitoes rises with decreasing population density, making it economically unfeasible in some areas.

Prevention of malaria may be more cost-effective than treatment of the disease in the long run, but the initial costs required are out of reach of many of the world's poorest people. There is a wide difference in the costs of control (i.e. maintenance of low endemicity) and elimination programs between countries. For example, in China—whose government in 2010 announced a strategy to pursue malaria elimination in the Chinese provinces—the required investment is a small proportion of public expenditure on health.

In contrast, a similar program in Tanzania would cost an estimated one-fifth of the public health budget. In areas where malaria is common, children under five years old often have anemia which is sometimes due to malaria. Giving children with anemia in these areas preventive antimalarial medication improves red blood cell levels slightly but did not affect the risk of death or need for hospitalization.

For individual protection, the most effective insect repellents are based on DEET or picaridin. Insecticide-treated mosquito nets (ITNs) and indoor residual spraying (IRS) have been shown to be highly effective in preventing malaria among children in areas where malaria is common. Mosquito nets help keep mosquitoes away from people and reduce infection rates and transmission of malaria.

Nets are not a perfect barrier and are often treated with an insecticide designed to kill the mosquito before it has time to find a way past the net. Insecticide-treated nets are estimated to be twice as effective as untreated nets and offer greater than 70% protection compared with no net. Most nets are impregnated with pyrethroids, a class of insecticides with low toxicity. They are most effective when used from dusk to dawn.

It is recommended to hang a large "bed net" above the center of a bed and either tuck the edges under the mattress or make sure it is large enough such that it touches the ground. Indoor residual spraying is the spraying of insecticides on the walls inside a home. After feeding, many mosquitoes rest on a nearby surface while digesting the bloodmeal, so if the walls of houses have been coated with insecticides, the resting mosquitoes can be killed before they can bite another person and transfer the malaria parasite.

Education can also inform people to cover over areas of stagnant, still water, such as water tanks that are ideal breeding grounds for the parasite and mosquito, thus cutting down the risk of the transmission between people. This is generally used in urban areas where there are large centers of population in a confined space and transmission would be most likely in these areas. There are a number of medications that can help prevent or interrupt malaria in travelers to places where infection is common.

Many of these medications are also used in treatment. In places where Plasmodium is resistant to one or more medications, three medications—mefloquine, doxycycline , or the combination of atovaquone/proguanil (Malarone)—are frequently used for prevention. Doxycycline and the atovaquone/proguanil are better tolerated while mefloquine is taken once a week. Areas of the world with chloroquine sensitive malaria are uncommon.

The protective effect does not begin immediately, and people visiting areas where malaria exists usually start taking the drugs one to two weeks before arriving and continue taking them for four weeks after leaving (except for atovaquone/proguanil, which only needs to be started two days before and continued for seven days afterward). The use of preventative drugs is often not practical for those who live in areas where malaria exists, and their use is usually only in pregnant women and short-term visitors.

This is due to the cost of the drugs, side effects from long-term use, and the difficulty in obtaining anti-malarial drugs outside of wealthy nations. During pregnancy, medication to prevent malaria has been found to improve the weight of the baby at birth and decrease the risk of anemia in the mother. The use of preventative drugs where malaria-bearing mosquitoes are present may encourage the development of partial resistance.

Malaria Treatment
Malaria is treated with antimalarial medications; the ones used depends on the type and severity of the disease. While medications against fever are commonly used, their effects on outcomes are not clear. Simple or uncomplicated malaria may be treated with oral medications. The most effective treatment for P. falciparum infection is the use of artemisinins in combination with other antimalarials (known as artemisinin-combination therapy, or ACT), which decreases resistance to any single drug component. These additional antimalarials include: amodiaquine, lumefantrine, mefloquine or sulfadoxine/pyrimethamine.

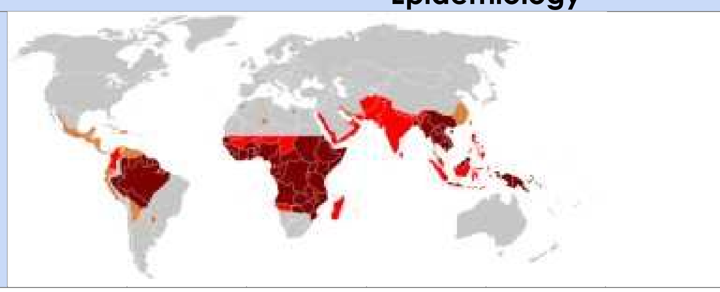
Another recommended combination is dihydroartemisinin and piperaquine. ACT is about 90% effective when used to treat uncomplicated malaria. To treat malaria during pregnancy, the WHO recommends the use of quinine plus clindamycin early in the pregnancy (1st trimester), and ACT in later stages (2nd and 3rd trimesters). In the 2000s (decade), malaria with partial resistance to artemisins emerged in Southeast Asia. Infection with P. vivax, P. ovale or P. malariae usually do not require hospitalization. Treatment of P. vivax requires both treatment of blood stages (with chloroquine or ACT) and clearance of liver forms with primaquine. Treatment with tafenoquine prevents relapses after confirmed P. vivax malaria.

Drug resistance poses a growing problem in 21st-century malaria treatment. Resistance is now common against all classes of antimalarial drugs apart from artemisinins. Treatment of resistant strains became increasingly dependent on this class of drugs. The cost of artemisinins limits their use in the developing world. Malaria strains found on the Cambodia–Thailand border are resistant to combination therapies that include artemisinins, and may, therefore, be untreatable. Exposure of the parasite population to artemisinin monotherapies in subtherapeutic doses for over 30 years and the availability of substandard artemisinins likely drove the selection of the resistant phenotype.

Resistance to artemisinin has been detected in Cambodia, Myanmar, Thailand, and Vietnam, and there has been emerging resistance in Laos. When properly treated, people with malaria can usually expect a complete recovery. However, severe malaria can progress extremely rapidly and cause death within hours or days. In the most severe cases of the disease, fatality rates can reach 20%, even with intensive care and treatment. Over the longer term, developmental impairments have been documented in children who have suffered episodes of severe malaria. Chronic infection without severe disease can occur in an immune-deficiency syndrome associated with a decreased responsiveness to Salmonella bacteria and the Epstein–Barr virus.

Epidemiology

Malaria Prevalence



Distribution of Malaria
Red - Occurrence of chloroquine-resistant malaria
Orange - No Plasmodium falciparum or chloroquine-resistance
Grey - No malaria

It's estimated that in 2015 there were 214 million new cases of malaria resulting in 438,000 deaths. Others have estimated the number of cases at between 350 and 550 million for falciparum malaria The majority of cases (65%) occur in children under 15 years old. About 125 million pregnant women are at risk of infection each year; in Sub-Saharan Africa, maternal malaria is associated with up to 200,000 estimated infant deaths yearly. There are about 10,000 malaria cases per year in Western Europe, and 1300–1500 in the United States. About 900 people died from the disease in Europe between 1993 and 2003. Both the global incidence of disease and resulting mortality have declined in recent years. According to the WHO and UNICEF, deaths attributable to malaria in 2015 were reduced by 60% from a 2000 estimate of 985,000, largely due to the widespread use of insecticide-treated nets and artemisinin-based combination therapies.

In 2012, there were 207 million cases of malaria. That year, the disease is estimated to have killed between 473,000 and 789,000 people, many of whom were children in Africa. Efforts at decreasing the disease in Africa since the turn of millennium have been partially effective, with rates of the disease dropping by an estimated forty percent on the continent. Malaria is presently endemic in a broad band around the equator, in areas of the Americas, many parts of Asia, and much of Africa; in Sub-Saharan Africa, 85–90% of malaria fatalities occur. The geographic distribution of malaria within large regions is complex, and malaria-afflicted and malaria-free areas are often found close to each other. Malaria is prevalent in tropical and subtropical regions because of rainfall, consistent high temperatures and high humidity, along with stagnant waters in which mosquito larvae readily mature, providing them with the environment they need for continuous breeding. In drier areas, outbreaks of malaria have been predicted with reasonable accuracy by mapping rainfall.

Rhinosporidiosis
Rhinosporidiosis is an infection caused by Rhinosporidium seeberi. This organism was previously considered to be a fungus, and rhinosporidiosis is classified as a fungal disease under ICD-10. It is now considered to be a protist classified under Mesomycetozoea. Authors of detailed studies have revealed superficial similarities between Dermocystidium and Rhinosporidium when using light microscopy, but substantial morphological differences between the groups exist. There is some evidence that DNA extracted from purified uncontaminated round bodies (Rhinosporidium seeberi) is of cyanobacterial origin. Rhinosporidiosis is a granulomatous disease affecting the mucous membrane of nasopharynx, oropharynx, conjunctiva, rectum and external genitalia. Though the floor of the nose and inferior turbinate are the most common sites, the lesions may appear elsewhere too. Traumatic inoculation from one site to others is common. Laryngeal rhinosporidiosis, too, has been described and may be due to inoculation from the nose during endotracheal intubation. After inoculation, the organism replicates locally, resulting in hyperplasia of host tissue and localised immune response.
● Infection of nose and nasopharynx - 70%
● Infection of palpebral conjunctiva - 15%

Treatment
● Surgical excision - wide excision with wide area electro-coagulation of the lesion base
● Medical treatment is not so effective but treatment with a year-long course of dapsone has been reported

Toxoplasma Gondii (Toxoplasmosis)

ILLNESS | Parasitic | Protozoan Organisms | Toxoplasmosis

Toxoplasmosis is a parasitic disease caused by Toxoplasma gondii. Infections with toxoplasmosis usually cause no obvious symptoms in adults. Occasionally, people may have a few weeks or months of mild, flu-like illness such as muscle aches and tender lymph nodes. In a small number of people, eye problems may develop. In those with a weak immune system, severe symptoms such as seizures and poor coordination may occur. If infected during pregnancy, a condition known as congenital toxoplasmosis may affect the child. Toxoplasmosis is usually spread by eating poorly cooked food that contains cysts, exposure to infected cat feces, and from a mother to a child during pregnancy if the mother becomes infected. Rarely, the disease may be spread by blood transfusion. It is not otherwise spread between people. The parasite is only known to reproduce sexually in the cat family. However, it can infect most types of warm-blooded animals, including humans. Diagnosis is typically by testing blood for antibodies or by testing amniotic fluid for the parasite's DNA. Prevention is by properly preparing and cooking food. Pregnant women are also recommended not to clean cat litter boxes. Treatment of otherwise healthy people is usually not needed. During pregnancy, spiramycin or pyrimethamine/sulfadiazine and folinic acid may be used for treatment. Up to half of the world's population is infected by toxoplasmosis, but have no symptoms. In the United States, about 23% are affected and in some areas of the world this is up to 95%.

Sources
The most common sources of toxoplasmosis, the disease caused by Toxoplasma, are undercooked meat, animal feces, and transmission from mother to unborn child. Toxoplasma from animal feces can contaminate soil or water. Cats commonly contribute to the spread of Toxoplasma infection by eating small animals carrying the parasite and passing it on through their feces.

Symptoms
Healthy individuals usually become infected with Toxoplasma without exhibiting any symptoms, as their immune systems are able to keep them from experiencing illness. If symptoms do occur, they generally take the form of mild "flu-like" symptoms, such as headache, muscle aches, fever and sore lymph nodes. These can last for several weeks.

Treatment
Most healthy people do not require treatment for toxoplasmosis. However, otherwise-healthy individuals who experience severe symptoms of the disease can be treated with drugs, including Daraprim, an antimalarial drug, or Sulfadiazine, an antibiotic. The same drugs can be used to treat those with compromised immune systems.

Notes
Toxoplasma gondii is one of the world's most common parasites. It is the second leading cause of deaths attributed to foodborne illness in the United States, and the third leading cause of foodborne illness hospitalizations. It is estimated that 22.5% of the population over the age of 12 has been infected with the Toxoplasma parasite. For some populations, this figure is as high as 95%.

Acute Toxoplasmosis
Acute toxoplasmosis is often asymptomatic in healthy adults. However, symptoms may manifest and are often influenza-like: swollen lymph nodes, headaches, fever, and fatigue, or muscle aches and pains that last for a month or more. Rarely will a human with a fully functioning immune system develop severe symptoms following infection.

People with weakened immune systems are likely to experience headache, confusion, poor coordination, seizures, lung problems that may resemble tuberculosis or Pneumocystis jiroveci pneumonia (a common opportunistic infection that occurs in people with AIDS), or blurred vision caused by severe inflammation of the retina (ocular toxoplasmosis). Young children and immunocompromised people, such as those with HIV/AIDS, those taking certain types of chemotherapy, or those who have recently received an organ transplant, may develop severe toxoplasmosis.

This can cause damage to the brain (encephalitis) or the eyes (necrotizing retinochoroiditis). Infants infected via placental transmission may be born with either of these problems, or with nasal malformations, although these complications are rare in newborns. The toxoplasmic trophozoites causing acute toxoplasmosis are referred to as tachyzoites, and are typically found in bodily fluids. Swollen lymph nodes are commonly found in the neck or under the chin, followed by the armpits and the groin.

Swelling may occur at different times after the initial infection, persist, and recur for various times independently of antiparasitic treatment. It is usually found at single sites in adults, but in children, multiple sites may be more common. Enlarged lymph nodes will resolve within 1-2 months in 60% of cases. However, a quarter of those affected take 2-4 months to return to normal, and 8% take 4-6 months. A substantial number (6%) do not return to normal until much later.

Latent Toxoplasmosis
Due to its asymptomatic nature, hosts easily become infected with T. gondii and develop toxoplasmosis without knowing it. Although mild, flu-like symptoms occasionally occur during the first few weeks following exposure, infection with T. gondii produces no readily observable symptoms in healthy human adults. In most immunocompetent people, the infection enters a latent phase, during which only bradyzoites (in tissue cysts) are present; these tissue cysts and even lesions can occur in the retinas, alveolar lining of the lungs (where an acute infection may mimic a Pneumocystis jirovecii infection), heart, skeletal muscle, and the central nervous system (CNS), including the brain. Cysts form in the CNS (brain tissue) upon infection with T. gondii and persist for the lifetime of the host. Most infants who are infected while in the womb have no symptoms at birth, but may develop symptoms later in life. Reviews of serological studies have estimated that 30–50% of the global population has been exposed to and may be chronically infected with latent toxoplasmosis, although infection rates differ significantly from country to country. This latent state of infection has recently been associated with numerous disease burdens, neural alterations, and subtle gender-dependent behavioral changes in immunocompetent humans.

Cutaneous Toxoplasmosis
While rare, skin lesions may occur in the acquired form of the disease, including roseola and erythema multiforme-like eruptions, prurigo-like nodules, urticaria, and maculopapular lesions. Newborns may have punctate macules, ecchymoses, or "blueberry muffin" lesions. Diagnosis of cutaneous toxoplasmosis is based on the tachyzoite form of T. gondii being found in the epidermis. It is found in all levels of the epidermis, is about 6 by 2 μm and bow-shaped, with the nucleus being one-third of its size. It can be identified by electron microscopy or by Giemsa staining tissue where the cytoplasm shows blue, the nucleus red.

Cause
In its lifecycle, T. gondii adopts several forms. Tachyzoites are responsible for acute infection; they divide rapidly and spread through the tissues of the body. Tachyzoites are also known as "tachyzoic merozoites", a descriptive term that conveys more precisely the parasitological nature of this stage. Toxoplasmosis is generally transmitted through the mouth when Toxoplasma gondii oocysts or tissue cysts are accidentally eaten. Congenital transmittance from mother to fetus can also occur. Transmission may also occur during the solid organ transplant process or hematogenous stem cell transplants. Cats excrete the pathogen in their feces for a number of weeks after contracting the disease, generally by eating an infected intermediate host that could include mammals (like rodents) or birds. Oocyst shedding usually starts from the third day after ingestion of infected intermediate hosts, and may continue for weeks. The oocysts are not infective when excreted. After about a day, the oocyst undergoes a process called sporulation and becomes potentially pathogenic. In addition to cats, birds and mammals including human beings are also intermediate host of the parasite and are involved in the transmission process.

Oral Transmission
● Ingestion of raw or partly cooked meat, especially pork, lamb, or venison containing Toxoplasma cysts: Infection prevalence in countries where undercooked meat is traditionally eaten has been related to this transmission method. Tissue cysts may also be ingested during hand-to-mouth contact after handling undercooked meat, or from using knives, utensils, or cutting boards contaminated by raw meat.
● Ingestion of unwashed fruit or vegetables that have been in contact with contaminated soil containing infected cat feces.
● Ingestion of cat feces containing oocysts: This can occur through hand-to-mouth contact following gardening, cleaning a cat's litter box, contact with children's sandpits; the parasite can survive in the environment for months.
● Ingestion of untreated, unfiltered water through direct consumption or utilization of water for food preparation.
● Ingestion of unpasteurized milk and milk products, particularly goat's milk.
● Ingestion of raw seafood.

ILLNESS Parasitic Protozoan Organisms Toxoplasmosis

Treatment
Treatment is often only recommended for people with serious health problems, such as people with HIV whose CD4 counts are under 200 cells/mm3, because the disease is most serious when one's immune system is weak. Trimethoprim/sulfamethoxazole is the drug of choice to prevent toxoplasmosis, but not for treating active disease. A 2012 study shows a promising new way to treat the active and latent form of this disease using two endochin-like quinolones.

Acute
The medications prescribed for acute toxoplasmosis are the following:
- Pyrimethamine — an antimalarial medication
- Sulfadiazine — an antibiotic used in combination with pyrimethamine to treat toxoplasmosis
  - Combination therapy is usually given with folic acid supplements to reduce incidence of thrombocytopaenia.
  - Combination therapy is most useful in the setting of HIV.
- Clindamycin
- Spiramycin — an antibiotic used most often for pregnant women to prevent the infection of their children.

(other antibiotics, such as minocycline, have seen some use as a salvage therapy).
If infected during pregnancy, spiramycin is recommended in the first and early second trimesters while pyrimethamine/sulfadiazine and leucovorin is recommended in the late second and third trimesters.

Latent
In people with latent toxoplasmosis, the cysts are immune to these treatments, as the antibiotics do not reach the bradyzoites in sufficient concentration.
The medications prescribed for latent toxoplasmosis are:
- Atovaquone — an antibiotic that has been used to kill Toxoplasma cysts inside AIDS patients
- Clindamycin — an antibiotic that, in combination with atovaquone, seemed to optimally kill cysts in mice

Trichomoniasis

ILLNESS Parasitic Protozoan Organisms Trichomoniasis

Trichomoniasis (trich) is an infectious disease caused by the parasite Trichomonas vaginalis. About 70% of women and men do not have symptoms when infected. When symptoms do occur they typically begin 5 to 28 days after exposure. Symptoms can include itching in the genital area, a bad smelling thin vaginal discharge, burning with urination, and pain with sex. Having trichomoniasis increases the risk of getting HIV/AIDS. It may also cause complications during pregnancy. Trichomoniasis is a sexually transmitted infection (STI) which is most often spread through vaginal, oral, or anal sex. It can also spread through genital touching. People who are infected may spread the disease even when symptoms are not present. Diagnosis is by finding the parasite in the vaginal fluid using a microscope, culturing the vagina or urine, or testing for the parasite's DNA. If present other sexually transmitted infections should be tested for. Methods of prevention include not having sex, using condoms, not douching, and being tested for STIs before having sex with a new partner. Trichomoniasis can be cured with antibiotics, either metronidazole or tinidazole. Sexual partners should also be treated. About 20% of people get infected again within three months of treatment. There were about 122 million new cases of trichomoniasis in 2015. In the United States there are about 2 million women affected. It occurs more often in women than men. Trichomonas vaginalis was first identified in 1836 by Alfred Donné. It was first recognized as causing this disease in 1916.

Symptoms
Most people infected with trichomonas vaginalis do not have any symptoms and can be undetected for years. Symptoms experienced include pain, burning or itching in the penis, urethra (urethritis), or vagina (vaginitis). Discomfort for both sexes may increase during intercourse and urination. For women there may also be a yellow-green, itchy, frothy, foul-smelling ("fishy" smell) vaginal discharge. In rare cases, lower abdominal pain can occur. Symptoms usually appear within 5 to 28 days of exposure.

Causes
The human genital tract is the only reservoir for this species. Trichomonas is transmitted through sexual or genital contact.
The single-celled protozoan produces mechanical stress on host cells and then ingests cell fragments after cell death.

Prevention
Use of male condoms or female condoms may help prevent the spread of trichomoniasis, although careful studies have never been done that focus on how to prevent this infection. Infection with Trichomoniasis through water is unlikely because Trichomonas vaginalis dies in water after 45–60 minutes, in thermal water after 30 minutes to 3 hours and in diluted urine after 5–6 hours.

Treatment
Treatment for both pregnant and non-pregnant women is usually with metronidazole, by mouth once. Caution should be used in pregnancy, especially in the first trimester. Sexual partners, even if they have no symptoms, should also be treated. For 95-97% of cases, infection is resolved after one dose of metronidazole. Without treatment, trichomoniasis can persist for months to years in women, and is thought to improve without treatment in men.

Sleeping Sickness (African Trypanosomiasis)

ILLNESS Parasitic Protozoan Organisms Sleeping Sickness

African trypanosomiasis, also known as sleeping sickness, is an insect-borne parasitic disease of humans and other animals. It is caused by protozoa of the species Trypanosoma brucei. There are two types that infect humans, Trypanosoma brucei gambiense (TbG) and Trypanosoma brucei rhodesiense (TbR). TbG causes over 98% of reported cases. Both are usually transmitted by the bite of an infected tsetse fly and are most common in rural areas. Initially, in the first stage of the disease, there are fevers, headaches, itchiness and joint pains.

This begins one to three weeks after the bite. Weeks to months later the second stage begins with confusion, poor coordination, numbness, and trouble sleeping. Diagnosis is via finding the parasite in a blood smear or in the fluid of a lymph node. A lumbar puncture is often needed to tell the difference between first and second stage disease. Prevention of severe disease involves screening the population at risk with blood tests for TbG.

Treatment is easier when the disease is detected early and before neurological symptoms occur. Treatment of the first stage is with the medications pentamidine or suramin. Treatment of the second stage involves eflornithine or a combination of nifurtimox and eflornithine for TbG. While melarsoprol works for both stages, it is typically only used for TbR, due to serious side effects. Without treatment it typically results in death. The disease occurs regularly in some regions of sub-Saharan Africa with the population at risk being about 70 million in 36 countries. An estimated 11,000 people are currently infected with 2,800 new infections in 2015. It is classified as a neglected tropical disease. Other animals, such as cows, may carry the disease and become infected in which case it is known as animal trypanosomiasis.

Signs & Symptoms
African trypanosomiasis symptoms occur in two stages. The first stage, known as the hemolymphatic phase, is characterized by fever, headaches, joint pains, and itching. Fever is intermittent, with attacks lasting from a day to a week, separated by intervals of a few days to a month or longer. Invasion of the circulatory and lymphatic systems by the parasites is associated with severe swelling of lymph nodes, often to tremendous sizes. Winterbottom's sign, the tell-tale swollen lymph nodes along the back of the neck, may appear. Occasionally, a chancre (red sore) will develop at the location of the tsetse fly bite. If left untreated, the disease overcomes the host's defenses and can cause more extensive damage, broadening symptoms to include anemia, endocrine, cardiac, and kidney dysfunctions. The second phase of the disease, the neurological phase, begins when the parasite invades the central nervous system by passing through the blood–brain barrier. Disruption of the sleep cycle is a leading symptom of this stage and is the one that gave the disease the name 'sleeping sickness'.

ILLNESS Parasitic Protozoan Organisms Sleeping Sickness

Infected individuals experience a disorganized and fragmented 24-hour rhythm of the sleep-wake cycle, resulting in daytime sleep episodes and nighttime periods of wakefulness. Other neurological symptoms include confusion, tremor, general muscle weakness, hemiparesis, and paralysis of a limb. Parkinson-like movements might arise due to non-specific movement disorders and speech disorders. Individuals may also exhibit psychiatric symptoms such as irritability, psychotic reactions, aggressive behaviour, or apathy which can sometimes dominate the clinical diagnosis. Without treatment, the disease is invariably fatal, with progressive mental deterioration leading to coma, systemic organ failure, and death. An untreated infection with T. b. rhodesiense will cause death within months whereas an untreated infection with T. b. gambiense will cause death after several years. Damage caused in the neurological phase is irreversible.

Cause
Trypanosoma brucei gambiense accounts for the majority of African trypanosomiasis cases, with humans as the main reservoir needed for the transmission, while Trypanosoma brucei rhodesiense is mainly zoonotic, with the occasional human infection. African Trypanosomiasis is dependent on the interaction of the parasite (trypanosome) with the tsetse flies (vector), as well as the host (human for Trypanosoma brucei gambiense, and animals for Trypanosoma brucei rhodesiense). The risk of contracting African Trypanosomiasis is dependent on coming in contact with an infected tsetse fly.

Trypanosoma Brucei
There are two subspecies of the parasite that are responsible for starting the disease in humans. Trypanosoma brucei gambiense causes the diseases in west and central Africa, whereas Trypanosoma brucei rhodesiense has a limited geographical range and is responsible for causing the disease in east and southern Africa.

Vector
The tsetse fly (genus Glossina) is a large, brown, biting fly that serves as both a host and vector for the trypanosome parasites. While taking blood from a mammalian host, an infected tsetse fly injects metacyclic trypomastigotes into skin tissue. From the bite, parasites first enter the lymphatic system and then pass into the bloodstream. Inside the mammalian host, they transform into bloodstream trypomastigotes, and are carried to other sites throughout the body, reach other body fluids (e.g., lymph, spinal fluid), and continue to replicate by binary fission.

Prevention
Currently there are few medically related prevention options for African Trypanosomiasis (i.e. no vaccine exists for immunity). Although the risk of infection from a tsetse fly bite is minor (estimated at less than 0.1%), the use of insect repellants, wearing long-sleeved clothing, avoiding tsetse-dense areas, implementing bush clearance methods and wild game culling are the best options to avoid infection available for local residents of affected areas. Regular active surveillance, involving detection and prompt treatment of new infections, and tsetse fly control is the backbone of the strategy used to control sleeping sickness. Systematic screening of at-risk communities is the best approach, because case-by-case screening is not practical in endemic regions. Systematic screening may be in the form of mobile clinics or fixed screening centres where teams travel daily to areas of high infection rates. Such screening efforts are important because early symptoms are not evident or serious enough to warrant patients with gambiense disease to seek medical attention, particularly in very remote areas. Also, diagnosis of the disease is difficult and health workers may not associate such general symptoms with trypanosomiasis. Systematic screening allows early-stage disease to be detected and treated before the disease progresses, and removes the potential human reservoir. A single case of sexual transmission of West African sleeping sickness has been reported.

Treatment
First Stage
The current treatment for first-stage disease is intravenous or intramuscular pentamidine for T. b. gambiense or intravenous suramin for T. b. rhodesiense.

Second Stage
For T. b. gambiense a regimen involving the combination of nifurtimox and eflornithine, nifurtimox-eflornithine combination treatment (NECT), or eflornithine alone appear to be more effective and result in fewer side effects.

These treatments may replace melarsoprol when available with the combination being first line. NECT has the benefit of requiring less injections of eflornithine. Intravenous melarsoprol was previously the standard treatment for second-stage (neurological phase) disease and is effective for both types. Melarsoprol is the only treatment for second stage T. b. rhodesiense; however, it causes death in 5% of people who take it. Resistance to melarsoprol can occur. If untreated, T. b. gambiense almost always results in death, with only a few individuals shown in a long-term 15 year follow-up to have survived after refusing treatment. T. b. rhodesiense, being a more acute and severe form of the disease, is consistently fatal if not treated. Disease progression greatly varies depending on disease form. For individuals which are infected by T. b. gambiense, which accounts for 98% of all of the reported cases, a person can be infected for months or even years without signs or symptoms until the advanced disease stage, where it is too late to be treated successfully. For individuals affected by T. b. rhodesiense, which accounts for 2% of all reported cases, symptoms appear within weeks or months of the infection. Disease progression is rapid and invades the central nervous system, causing death within a short amount of time.

Chagas' Disease

ILLNESS Parasitic Protozoan Organisms Chagas' Disease

Chagas disease, also known as American trypanosomiasis, is a tropical parasitic disease caused by the protist Trypanosoma cruzi. It is spread mostly by insects known as Triatominae, or "kissing bugs". The symptoms change over the course of the infection. In the early stage, symptoms are typically either not present or mild, and may include fever, swollen lymph nodes, headaches, or local swelling at the site of the bite. After 8–12 weeks, individuals enter the chronic phase of disease and in 60–70% it never produces further symptoms.

The other 30–40% of people develop further symptoms 10–30 years after the initial infection, including enlargement of the ventricles of the heart in 20–30%, leading to heart failure. An enlarged esophagus or an enlarged colon may also occur in 10% of people. T. cruzi is commonly spread to humans and other mammals by the blood-sucking "kissing bugs" of the subfamily Triatominae.

The disease may also be spread through blood transfusion, organ transplantation, eating food contaminated with the parasites, and by vertical transmission (from a mother to her fetus). Diagnosis of early disease is by finding the parasite in the blood using a microscope. Prevention mostly involves eliminating kissing bugs and avoiding their bites. This may involve the use of insecticides or bed-nets. Other preventive efforts include screening blood used for transfusions. A vaccine has not been developed as of 2017.

Early infections are treatable with the medication benznidazole or nifurtimox. Medication nearly always results in a cure if given early, but becomes less effective the longer a person has had Chagas disease. When used in chronic disease, medication may delay or prevent the development of end–stage symptoms. Benznidazole and nifurtimox cause temporary side effects in up to 40% of people including skin disorders, brain toxicity, and digestive system irritation.

Signs & Symptoms
The human disease occurs in two stages: an acute stage, which occurs shortly after an initial infection, and a chronic stage that develops over many years. The acute phase lasts for the first few weeks or months of infection. It usually occurs unnoticed because it is symptom-free or exhibits only mild symptoms that are not unique to Chagas disease. These can include fever, fatigue, body aches, muscle pain, headache, rash, loss of appetite, diarrhea, nausea, and vomiting. The signs on physical examination can include mild enlargement of the liver or spleen, swollen glands, and local swelling (a chagoma) where the parasite entered the body. The most recognized marker of acute Chagas disease is called Romaña's sign, which includes swelling of the eyelids on the side of the face near the bite wound or where the bug feces were deposited or accidentally rubbed into the eye. Rarely, young children, or adults may die from the acute disease due to severe inflammation/infection of the heart muscle (myocarditis) or brain (meningoencephalitis). The acute phase also can be severe in people with weakened immune systems. If symptoms develop during the acute phase, they usually resolve spontaneously within three to eight weeks in approximately 90% of individuals. Although the symptoms resolve, even with treatment the infection persists and enters a chronic phase.

Of individuals with chronic Chagas disease, 60–80% will never develop symptoms (called indeterminate chronic Chagas disease), while the remaining 20–40% will develop life-threatening heart and/or digestive disorders during their lifetime (called determinate chronic Chagas disease). In 10% of individuals, the disease progresses directly from the acute form to a symptomatic clinical form of chronic Chagas disease. The symptomatic (determinate) chronic stage affects the nervous system, digestive system and heart. About two-thirds of people with chronic symptoms have cardiac damage, including dilated cardiomyopathy, which causes heart rhythm abnormalities and may result in sudden death.

About one-third of patients go on to develop digestive system damage, resulting in dilation of the digestive tract (megacolon and megaesophagus), accompanied by severe weight loss. Swallowing difficulties (secondary achalasia) may be the first symptom of digestive disturbances and may lead to malnutrition. 20–50% of individuals with intestinal involvement also exhibit cardiac involvement. Up to 10% of chronically infected individuals develop neuritis that results in altered tendon reflexes and sensory impairment. Isolated cases exhibit central nervous system involvement, including dementia, confusion, chronic encephalopathy and sensory and motor deficits.

Transmission
In Chagas-endemic areas, the main mode of transmission is through an insect vector called a triatomine bug. A triatomine becomes infected with T. cruzi by feeding on the blood of an infected person or animal. During the day, triatomines hide in crevices in the walls and roofs. The bugs emerge at night, when the inhabitants are sleeping. Because they tend to feed on people's faces, triatomine bugs are also known as "kissing bugs". After they bite and ingest blood, they defecate on the person.

Triatomines pass T. cruzi parasites (called trypomastigotes) in feces left near the site of the bite wound. Scratching the site of the bite causes the trypomastigotes to enter the host through the wound, or through intact mucous membranes, such as the conjunctiva. Once inside the host, the trypomastigotes invade cells, where they differentiate into intracellular amastigotes. The amastigotes multiply by binary fission and differentiate into trypomastigotes, which are then released into the bloodstream.

This cycle is repeated in each newly infected cell. Replication resumes only when the parasites enter another cell or are ingested by another vector. Chagas disease affects 8 to 10 million people living in endemic Latin American countries, with an additional 300,000–400,000 living in nonendemic countries, including Spain and the United States. An estimated 41,200 new cases occur annually in endemic countries, and 14,400 infants are born with congenital Chagas disease annually.

In 2010 it resulted in approximately 10,300 deaths up from 9,300 in 1990. The disease is present in 18 countries on the American continents, ranging from the southern United States to northern Argentina. Chagas exists in two different ecological zones. In the Southern Cone region, the main vector lives in and around human homes.

Prevention
There is currently no vaccine against Chagas disease. Prevention is generally focused on decreasing the numbers of the insect that spreads it (Triatoma) and decreasing their contact with humans. This is done by using sprays and paints containing insecticides (synthetic pyrethroids), and improving housing and sanitary conditions in rural areas. For urban dwellers, spending vacations and camping out in the wilderness or sleeping at hostels or mud houses in endemic areas can be dangerous; a mosquito net is recommended. Some measures of vector control include:
● A yeast trap can be used for monitoring infestations of certain species of triatomine bugs (Triatoma sordida, Triatoma brasiliensis, Triatoma pseudomaculata, and Panstrongylus megistus).
● Promising results were gained with the treatment of vector habitats with the fungus Beauveria bassiana.
● Targeting the symbionts of Triatominae through paratransgenesis can be done.

Management
There are two approaches to treating Chagas disease: antiparasitic treatment, to kill the parasite; and symptomatic treatment, to manage the symptoms and signs of the infection. Management uniquely involves addressing selective incremental failure of the parasympathetic nervous system. Autonomic disease imparted by Chagas may eventually result in megaesophagus, megacolon and accelerated dilated cardiomyopathy. The mechanisms that explain why Chagas targets the parasympathetic autonomic nervous system and spares the sympathetic autonomic nervous system remain poorly understood. Antiparasitic treatment is most effective early in the course of infection, but is not limited to cases in the acute phase. Drugs of choice include azole or nitro derivatives, such as benznidazole or nifurtimox. Both agents are limited in their capacity to completely eliminate T. cruzi from the body (parasitologic cure), especially in chronically infected patients, and resistance to these drugs has been reported. Studies suggest antiparasitic treatment leads to parasitological cure in more than 90% of infants but only about 60–85% of adults treated in the first year of acute phase Chagas disease. Children aged six to 12 years with chronic disease have a cure rate of about 60% with benznidazole. While the rate of cure declines the longer an adult has been infected with Chagas, treatment with benznidazole has been shown to slow the onset of heart disease in adults with chronic Chagas infections.

11 Worms

Helminths (Worms)

Tapeworm

Cestoda is a class of parasitic worms in the flatworm phylum (Platyhelminthes). Most of the species—and the best-known—are those in the subclass Eucestoda; they are ribbon-like worms as adults, known as tapeworms. Their bodies consist of many similar units, known as proglottids, which are essentially packages of eggs which are regularly shed into the environment to infect other organisms. Species of the other subclass, Cestodaria, are mainly fish parasites.

Symptoms
Like other species of mammal, humans can become infected with tapeworms. There may be few or no symptoms, and the first indication of the infection may be the presence of one or more proglottids in the stools. The proglottids appear as flat, rectangular, whitish objects about the size of a grain of rice, which may change size or move about. Bodily symptoms which are sometimes present include abdominal pain, nausea, diarrhea, increased appetite and weight loss.

Treatment
There are several classes of anthelminthic drugs, some effective against many kinds of parasite, others more specific; these can be used both preventatively and to treat infections. For example, praziquantel is an effective treatment for tapeworm infection, and is preferred over the older niclosamide. While accidental tapeworm infections in developed countries are quite rare, such infections are more likely to occur in countries with poor sanitation facilities or where food hygiene standards are low.

Diphyllobothriasis - Tapeworm

Diphyllobothriasis is the infection caused by tapeworms of the genus Diphyllobothrium (commonly D. latum and D. nihonkaiense).

Diphyllobothriasis mostly occurs in regions where raw fish is regularly consumed; those who consume raw fish are at risk of infection. The infection is often asymptomatic and usually presents only with mild symptoms, which may include gastrointestinal complaints, weight loss, and fatigue. Rarely, vitamin B12 deficiency (possibly leading to anaemia) and gastrointestinal obstructions may occur. Infection may be long-lasting in absence of treatment. Diphyllobothriasis is generally diagnosed by looking for eggs or tapeworm segments in passed stool. Treatment with antiparasitic medications is straightforward, effective, and safe.

Symptoms
Most infections (~80%) are asymptomatic. Infections may be long-lasting, persisting for many years or decades (up to 25 years) if untreated.
Symptoms (when present) are generally mild. Manifestations may include: abdominal pain and discomfort, diarrhoea, vomiting, constipation, weight loss, and fatigue. Additional symptoms have been reported/described, including: dyspepsia, abdominal distension (commonly as presenting complaint), headache, myalgia, and dizziness.

ILLNESS Parasitic Worms Helminths (Worms)

Treatment

- Praziquantel

The standard treatment for diphyllobothriasis (as well as many other tapeworm infections) is a single dose of praziquantel, 5–10 mg/kg orally once for both adults and children. Praziquantel is not FDA-approved for this indication. Praziquantel has few side effects, many of which are similar to the symptoms of diphyllobothriasis.

- Niclosamide

An alternative treatment is niclosamide, 2 g orally once for adults or 50 mg/kg (max 2 g) for children. Niclosamide is not available for human or even animal use in the United States. Side effects of niclosamide are very rare due to the fact that the medication is not absorbed in the gastrointestinal tract.

- Other

Reportedly, albendazole can also be effective. Gastrografin may be potentially used both as a diagnostic and therapeutic; when introduced into the duodenum it allows for the visualization of the parasite, and has also been shown to cause detachment and passing of the whole worm.

Echinococcosis - Tapeworm

Echinococcosis is a parasitic disease of tapeworms of the Echinococcus type. The two main types of the disease are cystic echinococcosis and alveolar echinococcosis. Less common forms include polycystic echinococcosis and unicystic echinococcosis. The disease often starts without symptoms and this may last for years. The symptoms and signs that occur depend on the cyst's location and size. Alveolar disease usually begins in the liver but can spread to other parts of the body, such as the lungs or brain. When the liver is affected the person may have abdominal pain, weight loss, and turn slightly yellow from jaundice. Lung disease may cause pain in the chest, shortness of breath and coughing.

The disease is spread when food or water that contains the eggs of the parasite is eaten or by close contact with an infected animal. The eggs are released in the stool of meat-eating animals that are infected by the parasite. Commonly infected animals include dogs, foxes and wolves. For these animals to become infected they must eat the organs of an animal that contains the cysts such as sheep or rodents. The type of disease that occurs in people depends on the type of Echinococcus causing the infection. Diagnosis is usually by ultrasound though computer tomography (CT) or magnetic resonance imaging (MRI) may also be used. Blood tests looking for antibodies against the parasite may be helpful as may biopsy.

Symptoms

In the human manifestation of the disease, E. granulosus, E. multilocularis, E. oligarthrus and E. vogeli are localized in the liver (in 75% of cases), the lungs (in 5–15% of cases) and other organs in the body such as the spleen, brain, heart, and kidneys (in 10–20% of cases). In people who are infected with E. granulosus and therefore have cystic echinococcosis, the disease develops as a slow-growing mass in the body. These slow-growing masses, often called cysts, are also found in people that are infected with alveolar and polycystic echinococcosis.

The cysts found in those with cystic echinococcosis are usually filled with a clear fluid called hydatid fluid, are spherical, and typically consist of one compartment and are usually only found in one area of the body. While the cysts found in those with alveolar and polycystic echinococcosis are similar to those found in those with cystic echinococcosis, the alveolar and polycystic echinococcosis cysts usually have multiple compartments and have infiltrative as opposed to expansive growth.

Depending on the location of the cyst in the body, the person could be asymptomatic even though the cysts have grown to be very large, or be symptomatic even if the cysts are absolutely tiny. If the person is symptomatic, the symptoms will depend largely on where the cysts are located. For instance, if the person has cysts in the lungs and is symptomatic, they will have a cough, shortness of breath and/or pain in the chest. On the other hand, if the person has cysts in the liver and is symptomatic, they will suffer from abdominal pain, abnormal abdominal tenderness, hepatomegaly with an abdominal mass, jaundice, fever and/or anaphylactic reaction.

In addition, if the cysts were to rupture while in the body, whether during surgical extraction of the cysts or by trauma to the body, the person would most likely go into anaphylactic shock and suffer from high fever, pruritus (itching), edema (swelling) of the lips and eyelids, dyspnea, stridor and rhinorrhea.

Treatment

Cystic - For simple cases of cystic echinococcosis, the most common form of treatment is open surgical removal of the cysts combined with chemotherapy using albendazole and/or mebendazole before and after surgery. However, if there are cysts in multiple organs or tissues, or the cysts are in risky locations, surgery becomes impractical.

For inoperable cases such as these, chemotherapy and/or PAIR (puncture-aspiration-injection-reaspiration) become alternative options of treatment. In the case of alternative treatment using just chemotherapy, albendazole is preferred twice a day for 1–5 months. An alternative to albendazole is mebendazole for at least 3 to 6 months.

Alveolar - For alveolar echinococcosis, surgical removal of cysts combined with chemotherapy (using albendazole and/or mebendazole) for up to two years after surgery is the only sure way to completely cure the disease. However, in inoperable cases, chemotherapy by itself can also be used. In treatment using just chemotherapy, one could use either mebendazole in three doses or albendazole in two doses.

Polycystic - Since polycystic echinococcosis is constrained to such a particular area of the world and is not well described or found in many people, treatment of polycystic echinococcosis is less defined than that of cystic and alveolar echinococcosis. While surgical removal of cysts was the treatment of choice for the previous two types of echinococcosis, chemotherapy is the recommended treatment approach for polycystic echinococcosis. While albendazole is the preferred drug, mebendazole can also be used if the treatment is to be for an extended period of time. Only if chemotherapy fails or if the lesions are very small is surgery advised.

Hymenolepiasis

Hymenolepiasis is infestation by one of two species of tapeworm: Hymenolepis nana or H. diminuta. Alternative names are dwarf tapeworm infection and rat tapeworm infection. The disease is a type of helminthiasis which is classified as a neglected tropical disease.

Symptoms

Hymenolepiasis does not always have symptoms, but they usually are described as abdominal pain, loss of appetite, itching around the anus, irritability, and diarrhea. However, in one study of 25 patients conducted in Peru, successful treatment of the infection made no significant difference to symptoms. Some authorities report that heavily infected cases are more likely to be symptomatic.

Symptoms in humans are due to allergic responses or systematic toxaemia caused by waste products of the tapeworm. Light infections are usually symptomless, whereas infection with more than 2000 worms can cause enteritis, abdominal pain, diarrhea, loss of appetite, restlessness, irritability, restless sleep, and anal and nasal pruritus. Rare symptoms include increased appetite, vomiting, nausea, bloody diarrhea, hives, extremity pain, headache, dizziness, and behavioral disturbances. Occasionally, epileptic seizures occur in infected children.

Examination of the stool for eggs and parasites confirms the diagnosis. The eggs and proglottids of H. nana are smaller than H. diminuta. Proglottids of both are relatively wide and have three testes. Identifying the parasites to the species level is often unnecessary from a medical perspective, as the treatment is the same for both.

Treatment
The two drugs that have been well-described for the treatment of hymenolepiasis are praziquantel and niclosamide. Praziquantel, which is parasiticidal in a single dose for all the stages of the parasite, is the drug of choice because it acts very rapidly against H. nana. Although structurally unrelated to other anthelminthics, it kills both adult worms and larvae. In vitro, the drug produces vacuolization and disruption of the tegument in the neck of the worms, but not in more posterior portions of the strobila. Praziquantel is well absorbed when taken orally, and it undergoes first-pass metabolism and 80% of the dose is excreted as metabolites in urine within 24 hours. Repeated treatment is required for H. nana at an interval of 7–10 days.

Praziquantel as a single dose (25 mg/kg) is the current treatment of choice for hymenolepiasis and has an efficacy of 96%. Single-dose albendazole (400 mg) is also very efficacious (>95%).

A three-day course of nitazoxanide is 75–93% efficacious. The dose is 1 g daily for adults and children over 12; 400 mg daily for children aged 4 to 11 years; and 200 mg daily for children aged 3 years or younger.

Beef Tapeworm (Taeniasis)

Taeniasis is an infection within the intestines by adult tapeworms belonging to the genus Taenia. There are generally no or only mild symptoms. Symptoms may occasionally include weight loss or abdominal pain. Segments of tapeworm may be seen in the stool. Complications of pork tapeworm may include cysticercosis.

Types of Taenia that cause infections in humans include Taenia solium (pork tapeworm), Taenia saginata (beef tapeworm), and Taenia asiatica (Asian tapeworm). Taenia saginata is due to eating contaminated undercooked beef while Taenia solium and Taenia asiatica is from contaminated undercooked pork. Diagnosis is by examination of stool samples.

Prevention is by properly cooking meat. Treatment is generally with praziquantel, though niclosamide may also be used. Together with cysticercosis, infections affect about 50 million people globally. The disease is most common in the developing world. In the United States less than 1,000 cases occur a year.

Symptoms
Taeniasis generally has few or no symptoms. It takes about 8 weeks from infection for adult worms to form and can last for years without treatment. Infection may be suspected when a portion of the worm is passed in the stool. It is not generally fatal.

Pork Tapeworm - Infection in the intestines by the adult T. solium worms is normally asymptomatic. Heavy infection can result in anaemia and indigestion.
Beef Tapeworm - Taenia saginata infection is asymptomatic, but heavy infection causes weight loss, dizziness, abdominal pain, diarrhea, headaches, nausea, constipation, chronic indigestion, and loss of appetite. It can cause antigen reaction that induce allergic reaction. It is also a rare cause of ileus, pancreatitis, cholecystitis, and cholangitis.
Asian Tapeworm - Taenia asiatica is also usually asymptomatic. It is unclear if T. asiatica can cause cysticercosis.

Treatment
Praziquantel is the treatment of choice. Usual treatments are with praziquantel (5–10 mg/kg, single-administration) or niclosamide (adults and children over 6 years: 2 g, single-administration after a light breakfast, followed after 2 hours by a laxative; children aged 2–6 years: 1 g; children under 2 years: 500 mg). Albendazole is also highly effective. Mepacrine is quite effective but has adverse effects in humans.

Pork Tapeworm (Cysticercosis)

The pork tapeworm, Taenia solium, belongs to the cyclophyllid cestode family Taeniidae. It is found throughout the world and is most common in countries where pork is eaten. It is a tapeworm which has humans as its definitive host and often pigs as intermediate or secondary host. It may be transmitted to pigs through human faeces contaminating their fodder, and back to humans through consumption of uncooked, or under-cooked, pork that contains tapeworm cysts. Pigs ingest tapeworm eggs, which develop into larvae, then into oncospheres, and ultimately into infective tapeworm cysts. An ingested tapeworm cyst grows into an adult worm in human small intestines.

There are two forms of human infection. One is "primary hosting", and is due to eating under-cooked pork that contains the cysts and results in adult worms in the intestines. This form generally is without symptoms; the infected person does not know they have tapeworms. This form is easily treated with medications which eliminate the tapeworm. The other form, "secondary hosting", is due to eating food, or drinking water, contaminated with feces from someone infected by the adult worms, thus ingesting the tapeworm eggs, instead of the cysts. The eggs go on to develop cysts primarily in the muscles, and usually with no symptoms. However some people suffer obvious symptoms, the most harmful and chronic form of which is when the cysts form in the brain. Treatment of this form is more difficult but possible.

Symptoms
Taeniasis is infection in the intestines by the adult T. solium. It generally has mild or non-specific symptoms. This may include abdominal pain, nausea, diarrhea and constipation. Such symptoms will arise when the tapeworm has fully developed in the intestine, this would be around eight weeks after the contraction (ingestion of meat containing cysticerci). These symptoms could continue until the tapeworm dies from the course of treatment but otherwise could continue for many years, as long as the worm lives. If untreated it is common that the infections with T. solium last for approximately 2–3 years. It is possible that infected people may show no symptoms for years.

Treatment
Treatment of cysticercosis must be carefully monitored for inflammation reactions to the dying worms, especially if they have moved into the brain. In some cases the worms can be surgically removed, and in others albendazole with steroids is given to reduce the inflammation.

A vaccine to prevent cysticercosis in pigs has been studied. The life-cycle of the parasite can be terminated in their intermediate host, pigs, thereby preventing further human infection. The large scale use of these vaccine, however, is still under consideration.

Bertielliasis

Bertielliasis is the infection of Bertiella, a cestode tapeworm parasite that primarily infects nonhuman primates, rodents and Australian marsupials. Occasionally, human infections have been documented by one of two species: Bertiella studeri, or Bertiella mucronata. Of 29 different Bertiella species, only these two can infect humans.

These infections present with symptoms similar to most tapeworm cases, and are frequently misdiagnosed. Bertiella transmission is through oribatid mites that are present in the soil of problem areas, and can be easily prevented by avoiding contact with nonhuman primates, rodents and soil in these areas.

Symptoms
Bertielliasis can be asymptomatic, or present with symptoms similar to many other tapeworms. These can include epigastric pain after meals accompanied by nausea, diarrhea, anorexia, loss of weight and, generally, a tender abdomen. Fever is not typically a symptom, but there are also reported cases of constipation. The symptoms may be intermittent or continuous and seem to be more common in children. There are rare cases where the abdominal pain and vomiting have became severe. The incubation period is unknown.

Treatment
Due to the low occurrence of this infection in humans, and non-lethal symptoms, it is not considered a public health crisis where large steps have to be taken toward prevention or the development of a vaccine. The most common way to prevent this infection in humans is to avoid contact with nonhuman primates and the soil in their proximity. In Mauritius and other similar regions, children (specifically) and adults are strongly discouraged from eating guavas that have fallen on the ground.

Sparganosis

ILLNESS Parasitic Worms Helminths (Worms)

Sparganosis is a parasitic infection caused by the plerocercoid larvae of the genus Spirometra including S. mansoni, S. ranarum, S. mansonoides and S. erinacei. It was first described by Patrick Manson from China in 1882, and the first human case was reported by Charles Wardell Stiles from Florida in 1908. The infection is transmitted by ingestion of contaminated water, ingestion of a second intermediate host such as a frog or snake, or contact between a second intermediate host and an open wound or mucous membrane. Humans are the accidental hosts in the life cycle, while dogs, cats, and other mammals are definitive hosts. Copepods (freshwater crustaceans) are the first intermediate hosts, and various amphibians and reptiles are second intermediate hosts.

Symptoms
Clinical presentation of sparganosis most often occurs after the larvae have migrated to a subcutaneous location. The destination of the larvae is often a tissue or muscle in the chest, abdominal wall, extremities, or scrotum, although other sites include the eyes, brain, urinary tract, pleura, pericardium, and spinal canal. The early stages of disease in humans are often asymptomatic, but the spargana typically cause a painful inflammatory reaction in the tissues surrounding the subcutaneous site as they grow. Discrete subcutaneous nodules develop that may appear and disappear over a period of time. The nodules usually itch, swell, turn red, and migrate, and are often accompanied by painful edema.

Seizures, hemiparesis, and headaches are also common symptoms of sparganosis, especially cerebral sparganosis, and eosinophilia is a common sign. Clinical symptoms also vary according to the location of the sparganum; possible symptoms include elephantiasis from location in the lymph channels, peritonitis from location in the intestinal perforation, and brain abscesses from location in the brain. In genital sparganosis, subcutaneous nodules are present in the groin, labia, or scrotum and may appear tumor-like.

Ocular sparganosis a particularly well-described type of sparganosis. Early signs of the ocular form include eye pain, epiphora (excessive watering of the eye), and/or ptosis (drooping of the upper eyelid). Other signs include periorbital edema and/or edematous swelling that resembles Romana's sign in Chagas disease, lacrimation, orbital cellulitis, exophthalmos (protrusion of the eyeball), and/or an exposed cornea ulcer. The most common sign at presentation is a mass lesion in the eye. If untreated, ocular sparganosis can lead to blindness. In one case of brain infestation by Spirometra erinaceieuropaei, a man sought treatment on suffering headaches, seizures, memory flashbacks and strange smells.

Treatment
One treatment for sparganosis is praziquantel, administered at a dose of 120 to 150 mg/kg body weight over 2 days; however, praziquantel has had limited success. In general, infestation by one or a few sparganum larvae is often best treated by surgical removal.

DNA analysis of rare worms removed surgically can provide genome information to identify and characterise each parasite; treatments for the more common tapeworms can be cross-checked to see whether they are also likely to be effective against the species in question.

Flukes

Clonorchiasis

Clonorchiasis is an infectious disease caused by the Chinese liver fluke, Clonorchis sinensis, and two related species. Clonorchiasis is a known risk factor for the development of cholangiocarcinoma, a neoplasm of the biliary system.

Symptoms of opisthorchiasis caused by Opisthorchis viverrini and by O. felineus are indistinguishable from clonorchiasis caused by Clonorchis sinensis, so the disease by these three parasites should be referred as clonorchiasis.

Symptoms
Adult C. sinensis worms can inhabit the bile ducts of humans for 20–25 years without any clear clinical symptoms. This, in addition to the nonspecific symptoms infected persons may develop, can lead to missed diagnoses.

Treatment
Praziquantel is the only medicine recommended by WHO for treatment of clonorchiasis. It should be administered at the dose of 25 mg/kg 3 times daily for 2–3 consecutive days or of 40 mg/kg, single administration.

Liver Fluke – Fasciolosis

Fasciolosis is a parasitic worm infection caused by the common liver fluke Fasciola hepatica as well as by Fasciola gigantica. The disease is a plant-borne trematode zoonosis, and is classified as a neglected tropical disease (NTD). It affects humans, but its main host is ruminants such as cattle and sheep. The disease progresses through four distinct phases; an initial incubation phase of between a few days up to three months with little or no symptoms; an invasive or acute phase which may manifest with: fever, malaise, abdominal pain, gastrointestinal symptoms, urticaria, anemia, jaundice, and respiratory symptoms. The disease later progresses to a latent phase with less symptoms and ultimately into a chronic or obstructive phase months to years later. In the chronic state the disease causes inflammation of the bile ducts, gall bladder and may cause gall stones as well as fibrosis. While chronic inflammation is connected to increased cancer rates, it is unclear whether fasciolosis is associated with increased cancer risk.

Symptoms
The course of fasciolosis in humans has 4 main phases:
1. Incubation phase: from the ingestion of metacercariae to the appearance of the first symptoms; time period: few days to 3 months; depends on number of ingested metacercariae and immune status of host.
2. Invasive or acute phase: fluke migration up to the bile ducts. This phase is a result of mechanical destruction of the hepatic tissue and the peritoneum by migrating juvenile flukes causing localized and or generalized toxic and allergic reactions. The major symptoms of this phase are:
● Fever: usually the first symptom of the disease; 40–42 °C (104–108 °F)
● Abdominal pain
● Gastrointestinal disturbances: loss of appetite, flatulence, nausea, diarrhea
● Urticaria
● Respiratory symptoms (very rare): cough, dyspnoea, chest pain, hemoptysis
● Hepatomegaly and splenomegaly
● Ascites
● Anaemia
● Jaundice
3. Latent phase: This phase can last for months or years. The proportion of asymptomatic subjects in this phase is unknown. They are often discovered during family screening after a patient is diagnosed.
4. Chronic or obstructive phase:
This phase may develop months or years after initial infection. Adult flukes in the bile ducts cause inflammation and hyperplasia of the epithelium. The resulting cholangitis and cholecystitis, combined with the large body of the flukes, are sufficient to cause mechanical obstruction of the biliary duct. In this phase, biliary colic, epigastric pain, fatty food intolerance, nausea, jaundice, pruritus, right upper-quadrant abdominal tenderness, etc., are clinical manifestations indistinguishable from cholangitis, cholecystitis and cholelithiasis of other origins. Hepatic enlargement may be associated with an enlarged spleen or ascites. In case of obstruction, the gall bladder is usually enlarged and edematous with thickening of the wall. Fibrous adhesions of the gall bladder to adjacent organs are common. Lithiasis of the bile duct or gall bladder is frequent and the stones are usually small and multiple.

ILLNESS Parasitic Worms Flukes

Treatment
Several drugs are effective for fascioliasis, both in humans and in domestic animals. The drug of choice in the treatment of fasciolosis is triclabendazole, a member of the benzimidazole family of anthelmintics. The drug works by preventing the polymerization of the molecule tubulin into the cytoskeletal structures, microtubules. Resistance of F. hepatica to triclabendazole has been recorded in Australia in 1995 and Ireland in 1998.

Praziquantel treatment is ineffective. There are case reports of nitazoxanide being successfully used in human fasciolosis treatment in Mexico. There are also reports of bithionol being used successfully.

Nitazoxanide has been found effective in trials, but is currently not recommended.

Fasciolopsiasis – Intestinal Fluke

Fasciolopsiasis results from an infection by the trematode Fasciolopsis buski, the largest intestinal fluke of humans (up to 7.5 cm in length).

Symptoms
Most infections are light, almost asymptomatic. In heavy infections, symptoms can include abdominal pain, chronic diarrhea, anemia, ascites, toxemia, allergic responses, sensitization caused by the absorption of the worms' allergenic metabolites (may eventually cause death of patient), and intestinal obstruction.

Treatment
Praziquantel is the drug of choice for treatment. Treatment is effective in early or light infections. Heavy infections are more difficult to treat. Studies of the effectiveness of various drugs for treatment of children with F. buski have shown tetrachloroethylene as capable of reducing faecal egg counts by up to 99%. Other anthelmintics that can be used include thiabendazole, mebendazole, levamisole and pyrantel pamoate. Oxyclozanide, hexachlorophene and nitroxynil are also highly effective.

Metagonimiasis – Intestinal Fluke

Metagonimiasis is a disease caused by an intestinal trematode, most commonly Metagonimus yokagawai, but sometimes by M. takashii or M. miyatai. The metagonimiasis-causing flukes are one of two minute flukes called the heterophyids. Metagonimiasis was described by Katsurasa in 1911–1913 when he first observed eggs of M. yokagawai in feces (date is disputed in various studies). M. takahashii was described later first by Suzuki in 1930 and then M. miyatai was described in 1984 by Saito.

Symptoms
The main symptoms are diarrhea and colicky abdominal pain. Because symptoms are often mild, infections can often be easily overlooked but diagnosis is important. Flukes attach to the wall of the small intestine, but are often asymptomatic unless in large numbers. Infection can occur from eating a single infected fish source. Peripheral eosinophilia is associated especially in early phase. When present in large numbers, can cause chronic intermittent diarrhea, nausea, and vague abdominal pains. Clinical complaints can also include lethargy and anorexia. In acute metagonimiasis, clinical manifestations are developed only 5–7 days after infection. Heavy infection has also been associated with epigastric distress, fatigue, and malaise.

Occasionally, flukes invade the mucosa and eggs deposited in tissue may gain access to circulation. This can then lead to eggs embolizing in the brain, spinal cord, or heart. Granulomas may form around eggs and can cause seizures, neurologic deficits, or cardiac insufficiency. An interesting case in Japan found diabetes mellitus (DM) to be a sign of chronic infection with intracerebral hemorrhages as the acute sign of aggravation. Two months after administering praziquantel, the hemorrhages were gone, as was the diabetes. This unique case shows the potential of additional symptoms associated with metagonimiasis that are still unknown.

Treatment
Praziquantel is recommended in both adult and pediatric cases with dosages of 75 mg/kg/d in 3 doses for 1 day. Praziquantel is a Praziniozoquinoline derivative that alters the calcium flux through the parasite tectum and causes muscular paralysis and detachment of the fluke. Prizaquantel should be taken with liquids during a meal and as provided commercially as Biltricide. Praziquantel is not approved by the U.S. Food and Drug Administration (FDA) for treatment of metagonimiasis, but is approved for use on other parasitic infections.

Praziquantel has some side effects but they are generally relatively mild and transient and a review of evidence shows it overall a well-tolerated drug. Possible side effects include abdominal pain, allergy, diarrhea, headache, liver problems, nausea or vomiting, exacerbation of porphyries, pruritis, rash, somnolence, vertigo, or dizziness. In fact, in 2002, the World Health Organization recommended the use of Praziquantel in pregnant and lactating women, though controlled trials are still needed to verify this.

Another possible drug option is Tetrachloroethylene, a chlorinated hydrocarbon, but its use has been superseded by new antihelminthic drugs (like Praziquantel). A 1978 study also looked at the efficacy of several drugs on metagonimiasis infection, including bithionol, niclosamide, nicoflan, and Praziquantel. All drugs showed lower prevalence of eggs in feces, however only Praziquantel showed complete radical cure. Therefore, the authors concluded Praziquantel was the most highly effective, was very well tolerated, and was the most promising drug against metagonimiasis.

Metorchiasis

Metorchis conjunctus, common name Canadian liver fluke, is a species of trematode parasite in the family Opisthorchiidae. It can infect mammals that eat raw fish in North America. The first intermediate host is a freshwater snail and the second is a freshwater fish.

Symptoms
After ingestion of fish infected with M. conjunctus, about 1–15 days are needed for symptoms to occur, namely for eggs to be detected in the stool (incubation period).

The acute phase consists of upper abdominal pain and low-grade fever. High concentrations of eosinophil granulocytes are in blood. Also, higher concentrations of liver enzymes are seen. When untreated, symptoms may last from 3 days to 4 weeks. Symptoms of chronic infection were not reported.

Treatment
Eggs of M. conjunctus can be found by stool analysis. Serologic analysis can be also used - ELISA test for IgG antibodies against antigens of M. conjunctus. Drugs used to treat infestation include praziquantel: 75 mg/kg in three doses per day (the same dosage applies for adults and for children).

Paragonimiasis, Lung Fluke

Paragonimiasis is a food-borne parasitic infection caused by the lung fluke, most commonly Paragonimus westermani. It infects an estimated 22 million people yearly worldwide. It is particularly common in East Asia. More than 30 species of trematodes (flukes) of the genus Paragonimus have been reported; among the more than 10 species reported to infect humans, and only 8 bringing about infections in humans, the most common is P. westermani, the oriental lung fluke.

Symptoms
The acute phase (invasion and migration) may be marked by diarrhea, abdominal pain, fever, cough, urticaria, hepatosplenomegaly, pulmonary abnormalities, and eosinophilia. During the chronic phase, pulmonary manifestations include cough, expectoration of discolored sputum containing clumps of eggs, hemoptysis, and chest radiographic abnormalities. Extrapulmonary locations of the adult worms result in more severe manifestations, especially when the brain is involved." "Diagnosis is based on microscopic demonstration of eggs in stool or sputum, but these are not present until 2 to 3 months after infection. (Eggs are also occasionally encountered in effusion fluid or biopsy material.) Concentration techniques may be necessary in patients with light infections. Biopsy may allow diagnostic confirmation and species identification when an adult or developing fluke is recovered.

Treatment
The drug of choice to treat paragonimiasis is praziquantel, although bithionol may also be used.

ILLNESS Parasitic Worms Flukes

Schistosomiasis (Bilharzia) (Snail Fever)

Schistosomiasis, also known as snail fever and bilharzia, is a disease caused by parasitic flatworms called schistosomes. The urinary tract or the intestines may be infected. Symptoms include abdominal pain, diarrhea, bloody stool, or blood in the urine. Those who have been infected for a long time may experience liver damage, kidney failure, infertility, or bladder cancer. In children, it may cause poor growth and learning difficulty. The disease is spread by contact with fresh water contaminated with the parasites.

These parasites are released from infected freshwater snails. The disease is especially common among children in developing countries, as they are more likely to play in contaminated water. Other high-risk groups include farmers, fishermen, and people using unclean water during daily living. It belongs to the group of helminth infections. Diagnosis is by finding eggs of the parasite in a person's urine or stool. It can also be confirmed by finding antibodies against the disease in the blood.

Methods to prevent the disease include improving access to clean water and reducing the number of snails. In areas where the disease is common, the medication praziquantel may be given once a year to the entire group. This is done to decrease the number of people infected, and consequently, the spread of the disease. Praziquantel is also the treatment recommended by the World Health Organization for those who are known to be infected. Schistosomiasis affected about 252 million people worldwide in 2015.

An estimated 4,400 to 200,000 people die from it each year. The disease is most commonly found in Africa, Asia, and South America. Around 700 million people, in more than 70 countries, live in areas where the disease is common. In tropical countries, schistosomiasis is second only to malaria among parasitic diseases with the greatest economic impact. Schistosomiasis is listed as a neglected tropical disease.

Symptoms
Many individuals do not experience symptoms. If symptoms do appear, they usually take 4–6 weeks from the time of infection. The first symptom of the disease may be a general feeling of illness. Within 12 hours of infection, an individual may complain of a tingling sensation or light rash, commonly referred to as "swimmer's itch", due to irritation at the point of entrance. The rash that may develop can mimic scabies and other types of rashes. Other symptoms can occur 2–10 weeks later and can include fever, aching, a cough, diarrhea, chills, or gland enlargement. These symptoms can also be related to avian schistosomiasis, which does not cause any further symptoms in humans.

The manifestations of schistosomal infection vary over time as the cercariae, and later adult worms and their eggs, migrate through the body. If eggs migrate to the brain or spinal cord, seizures, paralysis, or spinal-cord inflammation are possible.

Treatment
Two drugs, praziquantel and oxamniquine, are available for the treatment of schistosomiasis. They are considered equivalent in relation to efficacy against S. mansoni and safety. Because of praziquantel's lower cost per treatment, and oxaminiquine's lack of efficacy against the urogenital form of the disease caused by S. haematobium, in general praziquantel is considered the first option for treatment. The treatment objective is to cure the disease and to prevent the evolution of the acute to the chronic form of the disease. All cases of suspected schistosomiasis should be treated regardless of presentation because the adult parasite can live in the host for years. Schistosomiasis is treatable by taking by mouth a single dose of the drug praziquantel annually.

Intestinal Schistosomiasis

Schistosoma mansoni is a water-borne parasite of humans, and belongs to the group of blood flukes (Schistosoma). The adult lives in the blood vessels (mesenteric veins) near the human intestine. It causes intestinal schistosomiasis (similar to S. japonicum, S. mekongi, S. guineensis, and S. intercalatum). Clinical symptoms are caused by the eggs. As the leading cause of schistosomiasis in the world, it is the most prevalent parasite in humans. It is classified as a neglected tropical disease. As of 2016, 206.5 million people have schistosomiasis and S. mansoni is the major parasite. It is found in Africa, the Middle East, the Caribbean, Brazil, Venezuela and Suriname.

Symptoms
Symptoms and signs depend on the number and location of eggs trapped in the tissues. Initially, the inflammatory reaction is readily reversible. In the latter stages of the disease, the pathology is associated with collagen deposition and fibrosis, resulting in organ damage that may be only partially reversible.

Treatment
The standard drug for S. mansoni infection is praziquantel at a dose of 40 mg/kg. Oxamniquine is also used.

Swimmer's Itch

Swimmer's itch or cercarial dermatitis, is a short-term allergic immune reaction occurring in the skin of humans that have been infected by water-borne schistosomes. Cercarial dermatitis is common in freshwater, brackish and marine habitats worldwide. Incidence may be on the rise, although this may also be attributed to better monitoring. Nevertheless, the condition has been regarded as emerging infectious disease. There are no permanent effects to people from this condition.

Symptoms
Symptoms, which include itchy, raised papules, commonly occur within 1–2 days of infection and do not generally last more than 2–3 weeks. However, people repeatedly exposed to cercariae develop heavier symptoms with faster onset.

Treatment
Orally administered hydroxyzine, an antihistamine, is sometimes prescribed to treat swimmer's itch and similar dermal allergic reactions. In addition, bathing in oatmeal, baking soda, or Epsom salts can also provide relief of symptoms.

Roundworms

Ancylostomiasis / Hookworm

Ancylostomiasis is a hookworm disease caused by infection with Ancylostoma hookworms. The name is derived from Greek ancylos αγκύλος "crooked, bent" and stoma στόμα "mouth".

Ancylostomiasis is also known as miner's anaemia, tunnel disease, brickmaker's anaemia and Egyptian chlorosis. Helminthiasis may also refer to ancylostomiasis, but this term also refers to all other parasitic worm diseases as well. In the United Kingdom, if acquired in the context of working in a mine, the condition is eligible for Industrial Injuries Disability Benefit. It is a prescribed disease (B4) under the relevant legislation. Ancylostomiasis is caused when hookworms, present in large numbers, produce an iron deficiency anemia by sucking blood from the host's intestinal walls.

Symptoms
Depending on the organism, the signs and symptoms vary. Ancylostoma duodenale and Necator americanus can enter the blood stream while Ancylostoma braziliensis cannot. Signs and symptoms of Ancylostoma duodenale and Necator americanus are given in corresponding page.

In Ancylostoma braziliensis as the larvae are in an abnormal host, they do not mature to adults but instead migrate through the skin until killed by the host's inflammatory response. This migration causes local intense itching and a red serpiginous lesion. Treatment with a single dose of oral ivermectin results in cure rates of 94–100%.

ILLNESS Parasitic Worms Roundworms

Treatment
The drug of choice for the treatment of hookworm disease is mebendazole which is effective against both species, and in addition, will remove the intestinal worm Ascaris also, if present. The drug is very efficient, requiring only a single dose and is inexpensive. However, treatment requires more than giving the anthelmintic, the patient should also receive dietary supplements to improve their general level of health, in particular iron supplementation is very important. Iron is an important constituent of a multitude of enzyme systems involved in energy metabolism, DNA synthesis and drug detoxification.

An infection of N. americanus parasites can be treated by using benzimidazoles, albendazole, and mebendazole. A blood transfusion may be necessary in severe cases of anemia. Light infections are usually left untreated in areas where reinfection is common. Iron supplements and a diet high in protein will speed the recovery process. In a case study involving 56–60 men with Trichuris trichiura and/or N. americanus infections, both albendazole and mebendazole were 90% effective in curing T. trichiura. However, albendazole had a 95% cure rate for N. americanus, while mebendazole only had a 21% cure rate. This suggests albendazole is most effective for treating both T. trichiura and N. americanus.

Angiostrongyliasis

Angiostrongyliasis is an infection by a roundworm of the Angiostrongylus type. Symptoms may vary from none, to mild, to meningitis. Infection with Angiostrongylus cantonensis (rat lungworm) can occur after voluntarily or inadvertently consuming raw Giant African land snails, great grey slugs, or other mollusks and even unwashed fruits and vegetables.

In humans, Angiostrongylus is the most common cause of eosinophilic meningitis or meningoencephalitis. Frequently the infection will resolve without treatment or serious consequences, but in cases with a heavy load of parasites the infection can be so severe it can cause permanent damage to the central nervous system or death.

Symptoms
Infection first presents with severe abdominal pain, nausea, vomiting, and weakness, which gradually lessens and progresses to fever, and then to central nervous system (CNS) symptoms and severe headache and stiffness of the neck. CNS symptoms begin with mild cognitive impairment and slowed reactions, and in a very severe form often progress to unconsciousness. Patients may present with neuropathic pain early in the infection. Eventually, severe infection will lead to ascending weakness, quadriparesis, areflexia, respiratory failure, and muscle atrophy, and will lead to death if not treated. Symptoms of eye invasion include visual impairment, pain, keratitis, and retinal edema. Worms usually appear in the anterior chamber and vitreous and can sometimes be removed surgically. The incubation period in humans is usually from 1 week to 1 month after infection, and can be as long as 47 days. This interval varies, since humans are intermediate hosts and the life cycle does not continue predictably as it would in a rat.

Treatment
Treatment of angiostrongyliasis is not well defined, but most strategies include a combination of anti-parasitics to kill the worms, steroids to limit inflammation as the worms die, and pain medication to manage the symptoms of meningitis. Anthelmintics are often used to kill off the worms, however in some cases this may cause patients to worsen due to toxins released by the dying worms. Albendazole, ivermectin, mebendazole, and pyrantel are all commonly used, though albendazole is usually the drug of choice. Studies have shown that anthelmintic drugs may shorten the course of the disease and relieve symptoms. Anthelmintics should generally be paired with corticosteroids in severe infections to limit the inflammatory reaction to the dying parasites. Studies suggest that a two-week regimen of a combination of mebendazole and prednisolone significantly shortened the course of the disease and length of associated headaches without observed harmful side effects. Symptomatic treatment is indicated for symptoms such as nausea, vomiting, headache, and in some cases, chronic pain due to nerve damage or muscle atrophy.

Ascariasis (Roundworm Infection)

Anisakiasis is a human parasitic infection of the gastrointestinal tract caused by the consumption of raw or undercooked seafood containing larvae of the nematode Anisakis simplex. The first case of human infection by a member of the family Anisakidae was reported in the Netherlands by Van Thiel, who described the presence of a marine nematode in a patient suffering from acute abdominal pain. It is frequently reported in areas of the world where fish is consumed raw, lightly pickled, or salted. The areas of highest prevalence are Scandinavia (from cod livers), Japan (after eating sashimi), the Netherlands (by eating infected fermented herrings (maatjes)), Spain (from eating anchovies and other fish marinated in escabeche), and along the Pacific coast of South America (from eating ceviche). The frequency in the United States is unknown, because the disease is not reportable and can go undetected or be mistaken for other illnesses. Anisakiasis was first recognized in the 1960s. During the 1970s, about 10 cases per year were reported in the literature. The frequency is probably much higher, due to home preparation of raw or undercooked fish dishes. In Japan, more than 1,000 cases are reported annually. Development of better diagnostic tools and greater awareness has led to more frequent reporting of anisakiasis.

Symptoms
- Sudden, severe stomach pain
- Nausea
- Vomiting
- Spasmodic abdominal pain
- Fever

Treatment
For the worm, humans are a dead-end host. Anisakis and Pseudoterranova larvae cannot survive in humans, and eventually die. In some cases, the infection resolves with only symptomatic treatment. In other cases, however, infection can lead to small bowel obstruction, which may require surgery, although treatment with albendazole alone (avoiding surgery) has been reported to be successful. Intestinal perforation (an emergency) is also possible.

Roundworm – Parasitic Pneumonia

Parasitic pneumonia is an infection of the lungs by parasites. It is a rare cause of pneumonia, occurring almost exclusively in immunocompromised persons (persons with a weakened or absent immune system). This is a respiratory infection that may or may not be serious. There is a variety of parasites that can affect the lungs. In general, these parasites enter the body through the skin or by being swallowed. Once inside the body, these parasites travel to the lungs, most often through the blood. There, a similar combination of cellular destruction and immune response causes disruption of oxygen transportation. Depending on the type of parasite, antihelmynthic drugs can be prescribed.

Roundworm – Baylisascariasis

Baylisascaris procyonis, common name raccoon roundworm, is a roundworm nematode, found ubiquitously in raccoons, the definitive hosts. It is named after H. A. Baylis, who studied them in the 1920s–30s, and Greek askaris (intestinal worm). Baylisascaris larvae in paratenic hosts can migrate, causing visceral larva migrans (VLM). Baylisascariasis as the zoonotic infection of humans is rare, though extremely dangerous due to the ability of the parasite's larvae to migrate into brain tissue and cause damage. Concern for human infection has been increasing over the years due to urbanization of rural areas resulting in the increase in proximity and potential human interaction with raccoons.

Symptoms
The potential for human infection was noted in 1969 by Paul C. Beaver, who studied infected mice, and the first case was reported 15 years later. Human infection with B. procyonis has been relatively rare, with about 30 cases reported since 1980. However, disease caused by this parasite can be extremely dangerous, causing death or severe symptoms. Reported disease has primarily afflicted children and almost all cases were a result of the ingestion of contaminated soil or feces. Even with treatment, prognosis is poor and patients in nearly all cases experience permanent neurological damage. Infection of the eyes may result in permanent visual damage and loss. The common antihelmintic medicines are able to treat adult worms living in the intestines, but are less effective against migrating larvae. Aggressive and early treatment with corticosteroids and albendazole have in a few instances resulted in complete recoveries. It is possible that human infection is more common than diagnosed and most cases do not reach a clinical stage. Antibodies to B. procyonis have been found in otherwise healthy individuals, suggesting subclinical infections.

Treatment
The fact that no commercial serologic test exists for the diagnosis of B. procyonis infection makes the diagnosis and treatment more difficult. Educating the public about the dangers of contact with raccoons or their feces is the most important preventive step. Parents should encourage their children to practice good hygiene; Hand-washing after outdoor play or contact with animals is very important. Fences can be used to prevent raccoons from visiting homes, garbage, or yards for food. Keeping raccoons as pets is strongly discouraged. Raccoon latrines in and around homes should be checked for and cleaned as soon as possible. Boiling water, steam-cleaning, flaming, or fire are highly effective and are easily accessible means to decontaminate household things or areas. Materials contaminated by B.procyonis should be incinerated. Contaminated areas can be cleaned with a xylene-ethanol mixture. Common chemical disinfectants are not effective against B.procyonis eggs. Disinfectants like 20% bleach (1% sodium hypochlorite) wash away the eggs but do not kill them. Since treatment is not very effective, the best way to escape this parasite is to practice the prevention methods.

Bioterrorism Threat
B. procyonis has become a concern for its potential use as an agent of bioterrorism. The fact that this parasite's eggs are easy to acquire, able to live for years, extremely resistant to many disinfectants, and cause serious infections in humans with poor treatment options could make it a dangerous weapon. Community water supplies are easily susceptible to contamination due to the lack of filtration and treatment methods to get rid of the eggs.

Guinea Worm – Dracunculiasis

Dracunculiasis, also called Guinea-worm disease (GWD), is a parasitic infection by the Guinea worm. A person becomes infected when they drink water that contains water fleas infected with guinea worm larvae. Initially there are no symptoms. About one year later, the female worm forms a painful blister in the skin, usually on a lower limb. Other symptoms at this time may include vomiting and dizziness. The worm then emerges from the skin over the course of a few weeks. During this time, it may be difficult to walk or work. It is very uncommon for the disease to cause death.

Symptoms
Dracunculiasis is diagnosed by seeing the worms emerging from the lesions on the legs of infected individuals and by microscopic examinations of the larvae.

As the worm moves downwards, usually to the lower leg, through the subcutaneous tissues, it leads to intense pain localized to its path of travel. The burning sensation experienced by infected people has led to the disease being called "the fiery serpent". Other symptoms include fever, nausea, and vomiting. Female worms cause allergic reactions during blister formation as they migrate to the skin, causing an intense burning pain. Such allergic reactions produce rashes, nausea, diarrhea, dizziness, and localized edema. When the blister bursts, allergic reactions subside, but skin ulcers form, through which the worm can protrude. Only when the worm is removed is healing complete. Death of adult worms in joints can lead to arthritis and paralysis in the spinal cord.

The pain caused by the worm's emergence—which typically occurs during planting and harvesting seasons—prevents many people from working or attending school for as long as three months. In heavily burdened agricultural villages fewer people are able to tend their fields or livestock, resulting in food shortages and lower earnings. A study in southeastern Nigeria, for example, found that rice farmers in a small area lost US$20 million in just one year due to outbreaks of Guinea worm disease.

Treatment
There is no vaccine or medicine to treat or prevent Guinea worm disease. Untreated cases can lead to secondary infections, disability and amputations. Once a Guinea worm begins emerging, the first step is to do a controlled submersion of the affected area in a bucket of water. This causes the worm to discharge many of its larvae, making it less infectious. The water is then discarded on the ground far away from any water source. Submersion results in subjective relief of the burning sensation and makes subsequent extraction of the worm easier. To extract the worm, a person must wrap the live worm around a piece of gauze or a stick.

The process may take several weeks. Gently massaging the area around the blister can help loosen the worm. Some people have said that extracting a Guinea worm feels like the afflicted area is on fire. However, if the infection is identified before an ulcer forms, the worm can also be surgically removed by a trained doctor in a medical facility. Although Guinea worm disease is usually not fatal, the wound where the worm emerges could develop a secondary bacterial infection such as tetanus, which may be life-threatening—a concern in endemic areas where there is typically limited or no access to health care.

Analgesics can be used to help reduce swelling and pain and antibiotic ointments can help prevent secondary infections at the wound site. At least in the Northern region of Ghana, the Guinea worm team found that antibiotic ointment on the wound site caused the wound to heal too well and too quickly making it more difficult to extract the worm and more likely that pulling would break the worm. The local team preferred to use something called "Tamale oil" (after the regional capital) which lubricated the worm and aided its extraction.

It is of great importance not to break the worm when pulling it out. Broken worms have a tendency to putrefy or petrify. Putrefaction leads to the skin sloughing off around the worm. Petrification is a problem if the worm is in a joint or wrapped around a vein or other important area. Use of metronidazole or thiabendazole may make extraction easier, but also may lead to migration of the worm to other parts of the body.

Pinworm – Enterobiasis

Pinworm infection, also known as enterobiasis, is a human parasitic disease caused by the pinworm. The most common symptom is itching in the anal area. This can make sleeping difficult. The period of time from swallowing eggs to the appearance of new eggs around the anus is 4 to 8 weeks. Some people who are infected do not have symptoms.

Symptoms
One-third of individuals with pinworm infection are totally asymptomatic. The main symptoms are itching in and around the anus and perineum. The itching occurs mainly during the night, and is caused by the female pinworms migrating to lay eggs around the anus. Both the migrating females and the clumps of eggs are irritating, but the mechanisms causing the intense pruritus have not been explained. The intensity of the itching varies, and it can be described as tickling, crawling sensations, or even acute pain.

The itching leads to continuously scratching the area around the anus, which can further result in tearing of the skin and complications such as secondary bacterial infections, including bacterial skin inflammation, and hair follicle inflammation. General symptoms are trouble sleeping, and restlessness. A considerable proportion of children suffer from loss of appetite, weight loss, irritability, emotional instability, and bed wetting.

Pinworms cannot damage the skin, and they do not normally migrate through tissues. However, they may move onto the vulva and into the vagina, from there moving to the external orifice of the uterus, and onwards to the uterine cavity, fallopian tubes, ovaries, and peritoneal cavity. This can cause inflammation of the vulva and vagina. This causes vaginal discharge and itchiness of the vulva. The pinworms can also enter the urethra, and presumably, they carry intestinal bacteria with them.

According to Gutierrez (2000), a statistically significant correlation between pinworm infection and urinary tract infections has been shown; however, Burkhart & Burkhart (2005) maintain that the incidence of pinworms as a cause of urinary tract infections remains unknown. One report indicated that 36% of young girls with a urinary tract infection also had pinworms. Painful urination has been associated with pinworm infection.

ILLNESS Parasitic Worms Roundworms

Treatment
Treatment is typically with two doses of the medications mebendazole, pyrantel pamoate, or albendazole two weeks apart. Everyone who lives with or takes care of an infected person should be treated at the same time. Washing personal items in hot water after each dose of medication is recommended. Good handwashing, daily bathing in the morning, and daily changing of underwear can help prevent reinfection.

Gnathostomiasis

Gnathostomiasis (also known as larva migrans profundus) is the human infection caused by the nematode (roundworm) Gnathostoma spinigerum and/or Gnathostoma hispidum, which infects vertebrates.

Symptoms
A few days after ingestion epigastric pain, fever, vomiting, and loss of appetite resulting from migration of larvae through intestinal wall to the abdominal cavity will appear in the patient. Migration in the subcutaneous tissues (under the skin) causes intermittent, migratory, painful, pruritic swellings (cutaneous larva migrans). Patches of edema appear after the above symptoms clear and are usually found on the abdomen. These lesions vary in size and can be accompanied by pruritus, rash, and stabbing pain. Swellings may last for 1 to 4 weeks in a given area and then reappear in a different location. Migration to other tissues (visceral larva migrans), can result in cough, hematuria, ocular (eye) involvement, meningitis, encephalitis and eosinophilia. Eosinophilic myeloencephalitis may also result from invasion of the central nervous system by the larvae.

Treatment
Surgical removal or treatment with albendazole or ivermectin is recommended. The most prescribed treatment for gnathostomiasis is surgical removal of the larvae but this is only effective when the worms are located in an accessible location. In addition to surgical excision, albendazole and ivermectin have been noted in their ability to eliminate the parasite. Albendazole is recommended to be administered at 400 mg daily for 21 days as an adjunct to surgical excision, while ivermectin is better tolerated as a single dose. Ivermectin can also serve as a replacement for those that can't handle albendazole 200 ug/kg p.o. as a single dose. However, ivermectin has been shown to be less effective than albendazole.

Loa Loa Filariasis, Calabar Swellings (Loiasis)

Loa loa filariasis is a skin and eye disease caused by the nematode worm Loa loa. Humans contract this disease through the bite of a deer fly or mango fly (Chrysops spp), the vectors for Loa loa. The adult Loa loa filarial worm migrates throughout the subcutaneous tissues of humans, occasionally crossing into subconjunctival tissues of the eye where it can be easily observed. Loa loa does not normally affect one's vision but can be painful when moving about the eyeball or across the bridge of the nose. The disease can cause red itchy swellings below the skin called "Calabar swellings". The disease is treated with the drug diethylcarbamazine (DEC), and when appropriate, surgical methods may be employed to remove adult worms from the conjunctiva. Loiasis belongs to the so-called neglected diseases.

Symptoms
A filariasis such as loiasis most often consists of asymptomatic microfilaremia. Some patients can develop lymphatic dysfunction causing lymphedema. Episodic angioedema (Calabar swellings) in the arms and legs, caused by immune reactions, are common. Calabar swellings are 3–10 cm in surface area, sometimes erythematous, and not pitting. When chronic, they can form cyst-like enlargements of the connective tissue around the sheaths of muscle tendons, becoming very painful when moved. The swellings may last for one to three days and may be accompanied by localized urticaria (skin eruptions) and pruritus (itching).

They reappear at referent locations at irregular time intervals. Subconjunctival migration of an adult worm to the eyes can also occur frequently, and this is the reason Loa loa is also called the "African eye worm." The passage over the eyeball can be sensed, but it usually takes less than 15 minutes. Eyeworms affect men and women equally, but advanced age is a risk factor. Eosinophilia is often prominent in filarial infections. Dead worms may cause chronic abscesses, which may lead to the formation of granulomatous reactions and fibrosis.

Treatment
Treatment of loiasis involves chemotherapy or, in some cases, surgical removal of adult worms followed by systemic treatment. The current drug of choice for therapy is diethylcarbamazine (DEC), though ivermectin use while not curative (i.e., it will not kill the adult worms) can substantially reduce the microfilarial load. The recommended dosage of DEC is 8–10 mg/kg/d taken three times daily for 21 days per CDC. The pediatric dose is the same. DEC is effective against microfilariae and somewhat effective against macrofilariae (adult worms).

The recommended dosage of ivermectin is 150 µg/kg in patients with a low microfilaria load (with densities less than 8000 mf/mL). In patients with high microfilaria load and/or the possibility of an onchocerciasis coinfection, treatment with DEC and/or ivermectin may be contraindicated or require a substantially lower initial dose, as the rapid microfilaricidal actions of the drugs can provoke encephalopathy. In these cases, initial albendazole administration has proved helpful (and is superior to ivermectin, which can also be risky despite its slower-acting microfilaricidal effects over DEC).
The CDC recommended dosage for albendazole is 200 mg taken twice a day for 21 days. Also, in cases where two or more DEC treatments have failed to provide a cure, subsequent albendazole treatment can be administered. Management of Loa loa infection in some instances can involve surgery, though the timeframe during which surgical removal of the worm must be carried out is very short. A detailed surgical strategy to remove an adult worm is as follows (from a real case in New York City).

The 2007 procedure to remove an adult worm from a male Gabonian immigrant employed proparacaine and povidone-iodine drops, a wire eyelid speculum, and 0.5 ml 2% lidocaine with epinephrine 1:100,000, injected superiorly. A 2-mm incision was made and the immobile worm was removed with forceps. Gatifloxacin drops and an eye-patch over ointment were utilized post surgery and there were no complications (unfortunately, the patient did not return for DEC therapy to manage the additional worm—and microfilariae—present in his body).

Filariasis / Mansonelliasis

Filariasis is a parasitic disease caused by an infection with roundworms of the Filarioidea type. These are spread by blood-feeding insects such as black flies and mosquitoes. They belong to the group of diseases called helminthiases.

Eight known filarial worms have humans as a definitive host. These are divided into three groups according to the part of the body they affect:
- Lymphatic filariasis is caused by the worms Wuchereria bancrofti, Brugia malayi, and Brugia timori. These worms occupy the lymphatic system, including the lymph nodes; in chronic cases, these worms lead to the syndrome of elephantiasis.
- Subcutaneous filariasis is caused by Loa loa (the eye worm), Mansonella streptocerca, and Onchocerca volvulus. These worms occupy the layer just under the skin. L. loa causes Loa loa filariasis, while O. volvulus causes river blindness.
- Serous cavity filariasis is caused by the worms Mansonella perstans and Mansonella ozzardi, which occupy the serous cavity of the abdomen. Dirofilaria immitis, the dog heartworm, rarely infects humans.

Symptoms
The most spectacular symptom of lymphatic filariasis is elephantiasis – edema with thickening of the skin and underlying tissues—which was the first disease discovered to be transmitted by mosquito bites. Elephantiasis results when the parasites lodge in the lymphatic system.

Elephantiasis affects mainly the lower extremities, while the ears, mucous membranes, and amputation stumps are affected less frequently. However, different species of filarial worms tend to affect different parts of the body; Wuchereria bancrofti can affect the legs, arms, vulva, breasts, and scrotum (causing hydrocele formation), while Brugia timori rarely affects the genitals. Those who develop the chronic stages of elephantiasis are usually free from microfilariae (amicrofilaraemic), and often have adverse immunological reactions to the microfilariae, as well as the adult worms.

The subcutaneous worms present with rashes, urticarial papules, and arthritis, as well as hyper- and hypopigmentation macules. Onchocerca volvulus manifests itself in the eyes, causing "river blindness" (onchocerciasis), one of the leading causes of blindness in the world. Serous cavity filariasis presents with symptoms similar to subcutaneous filariasis, in addition to abdominal pain, because these worms are also deep-tissue dwellers.

ILLNESS Parasitic Worms Roundworms

Treatment
The recommended treatment for people outside the United States is albendazole combined with ivermectin. A combination of diethylcarbamazine and albendazole is also effective. Side effects of the drugs include nausea, vomiting, and headaches. All of these treatments are microfilaricides; they have no effect on the adult worms. While the drugs are critical for treatment of the individual, proper hygiene is also required. There is good evidence that albendazole alone; or addition of albendazole to diethylcarbamazine or ivermectin, makes minimal difference in clearing microfilaria or adult worms from blood circulation. Diethylcarbamazine-medicated salt is effective in controlling lymphatic filariasis while maintaining its coverage at 90% in the community for six months.

Different trials were made to use the known drug at its maximum capacity in absence of new drugs. In a study from India, it was shown that a formulation of albendazole had better anti-filarial efficacy than albendazole itself. In 2003, the common antibiotic doxycycline was suggested for treating elephantiasis.

Onchocerciasis (River Blindness)

Onchocerciasis, also known as river blindness, is a disease caused by infection with the parasitic worm Onchocerca volvulus. Symptoms include severe itching, bumps under the skin, and blindness. It is the second-most common cause of blindness due to infection, after trachoma.

The parasite worm is spread by the bites of a black fly of the Simulium type. Usually, many bites are required before infection occurs. These flies live near rivers, hence the common name of the disease. Once inside a person, the worms create larvae that make their way out to the skin, where they can infect the next black fly that bites the person. There are a number of ways to make the diagnosis, including: placing a biopsy of the skin in normal saline and watching for the larva to come out, looking in the eye for larvae, and looking within the bumps under the skin for adult worms.

Symptoms
Skin involvement typically consists of intense itching, swelling, and inflammation. A grading system has been developed to categorize the degree of skin involvement:
- Acute papular onchodermatitis – scattered pruritic papules
- Chronic papular onchodermatitis – larger papules, resulting in hyperpigmentation
- Lichenified onchodermatitis – hyperpigmented papules and plaques, with edema, lymphadenopathy, pruritus and common secondary bacterial infections
- Skin atrophy – loss of elasticity, the skin resembles tissue paper, 'lizard skin' appearance
- Depigmentation – 'leopard skin' appearance, usually on anterior lower leg
- Glaucoma effect – eyes malfunction, begin to see shadows or nothing

Treatment
In mass drug administration (MDA) programmes, the treatment for onchocerciasis is ivermectin (trade name: Mectizan); infected people can be treated with two doses of ivermectin, six months apart, repeated every three years. The drug paralyses and kills the microfilariae causing fever, itching, and possibly oedema, arthritis and lymphadenopathy. Intense skin itching is eventually relieved, and the progression towards blindness is halted. In addition, while the drug does not kill the adult worms, it does prevent them for a limited time from producing additional offspring. The drug therefore prevents both morbidity and transmission for up to several months. For the treatment of individuals, doxycycline is used to kill the Wolbachia bacteria that live in adult worms. Ivermectin kills the parasite by interfering with the nervous system and muscle function, in particular, by enhancing inhibitory neurotransmission. Moxidectin was approved for onchocerciasis in 2018 for people over the age of 11 in the United States. The safety of multiple doses is unclear.

Strongyloidiasis – Parasitic Pneumonia

Strongyloidiasis is a human parasitic disease caused by the nematode called Strongyloides stercoralis, or sometimes S. fülleborni which is a type of helminth. It belongs to a group of nematodes called roundworms. This intestinal worm can cause a number of symptoms in people, principally skin symptoms, abdominal pain, diarrhea and weight loss, among many other specific and vague symptoms in disseminated disease, and severe life-threatening conditions through hyperinfection. In some people, particularly those who require corticosteroids or other immunosuppressive medication, Strongyloides can cause a hyperinfection syndrome that can lead to death if untreated. The diagnosis is made by blood and stool tests. The medication ivermectin is widely used to treat strongyloidiasis.

Symptoms
Strongyloides infection occurs in five forms. As the infection continues and the larvae matures, there may be respiratory symptoms (Löffler's syndrome). The infection may then become chronic with mainly digestive symptoms. On reinfection (when larvae migrate through the body) from the skin to the lungs and finally to the small intestine, there may be respiratory, skin and digestive symptoms. Finally, the hyperinfection syndrome causes symptoms in many organ systems, including the central nervous system.

Treatment
The consensus drug of choice for the treatment of uncomplicated strongyloidiasis is ivermectin. However, even if it is considered the main drug of choice, recent studies have illustrated the challenges in ivermectin curing strongyloidiasis. Ivermectin does not kill the Strongyloides larvae, only the adult worms, therefore repeat dosing may be necessary to properly eradicate the infection. Other drugs that can be effective are albendazole and thiabendazole (25 mg/kg twice daily for 5 days—400 mg maximum (generally)).

All patients who are at risk of disseminated strongyloidiasis should be treated. The optimal duration of treatment for patients with disseminated infections is not clear. Treatment of strongyloidiasis can be difficult and if ceasing treatment before being entirely cleared Strongyloides via the autoinfective cycle has been known to live in individuals for decades; even after initial or inadequate sustained treatment. Continued treatment, blood and stool monitoring thus may be necessary even if symptoms temporarily resolve.

Due to the fact that some infections are insidiously asymptomatic, and relatively expensive bloodwork is often inconclusive via false-positives or false-negatives, just as stool samples can be unreliable in diagnoses, there is yet unfortunately no real gold standard for proof of cure, mirroring the lack of an efficient and reliable methodology of diagnosis. An objective eradication standard for strongyloidiasis is elusive given the high degree of suspicion needed to even begin treatment, the sometimes difficulty of the only definitive diagnostic criteria of detecting and isolating larvae or adult strongyloides, the importance of early diagnosis, particularly before steroid treatments, and the very wide variability and exclusion/inclusion of differing collections of diffuse symptoms.

Disregarding mis-ascribing bonafide delusional parasitosis disorders, strongyloidiasis should be more well known among medical professionals and have serious consideration for broad educational campaigns in effected geographic locales both within the semi-tropical developed world and otherwise, as well as in the tropical developing world where, among many other neglected tropical diseases, it is endemic.

Thelaziasis

Thelaziasis is the term for infestation with parasitic nematodes of the genus Thelazia. The adults of all Thelazia species discovered so far inhabit the eyes and associated tissues (such as eyelids, tear ducts, etc.) of various mammal and bird hosts, including humans. Thelazia nematodes are often referred to as "eyeworms".

Symptoms
In animal and human hosts, infestation by Thelazia may be asymptomatic, though it frequently causes watery eyes (epiphora), conjunctivitis, corneal opacity, or corneal ulcers (ulcerative keratitis). Infested humans have also reported "foreign body sensation" – the feeling that something is in the eye.

Treatment
Because they live so close to the outside of the body, Thelazia is one of the few nematode infections which can be treated topically. Topical treatment of livestock, dogs and cats with organophosphates (such as ecothiopate iodide or isofluorophate) and systemic treatment with anthelmintics (such as ivermectin, levamisole, and doramectin) are recommended by the Merck Veterinary Manual. Other sources have reported positive results treating dogs with moxidectin, imidacloprid, or milbemycin oxime.

For the treatment of human cases, removal of the worm is suggested. Topical treatment with cocaine or thiabendazole have also been reported to kill the worms in human cases. Because most, if not all, species of Thelazia are spread by flies, sanitary practices which reduce the presence of flies will also reduce the spread of thelaziasis.

Toxocariasis

Toxocariasis is an illness of humans caused by larvae (immature worms) of either the dog roundworm (Toxocara canis), the cat roundworm (Toxocara cati) or the fox roundworm (Toxocara canis). Toxocariasis is often called visceral larva migrans (VLM). Depending on geographic location, degree of eosinophilia, eye and/or pulmonary signs, the terms ocular larva migrans (OLM), Weingarten's disease, Frimodt-Møller's syndrome, and eosinophilic pseudoleukemia are applied to toxocariasis. Other terms sometimes or rarely used include nematode ophthalmitis, toxocaral disease, toxocarose, and covert toxocariasis. This zoonotic, helminthic infection is a rare cause of blindness and may provoke rheumatic, neurologic, or asthmatic symptoms. Humans normally become infected by ingestion of embryonated eggs (each containing a fully developed second stage larva, L2) from contaminated sources (soil, undercooked meat, fresh or unwashed vegetables.)

Symptoms
Physiological reactions to Toxocara infection depend on the host's immune response and the parasitic load. Most cases of Toxocara infection are asymptomatic, especially in adults. When symptoms do occur, they are the result of migration of second stage Toxocara larvae through the body. Covert toxocariasis is the least serious of the three syndromes and is believed to be due to chronic exposure. Signs and symptoms of covert toxocariasis are coughing, fever, abdominal pain, headaches, and changes in behavior and ability to sleep. Upon medical examination, wheezing, hepatomegaly, and lymphadenitis are often noted.

High parasitic loads or repeated infection can lead to visceral larva migrans (VLM). VLM is primarily diagnosed in young children, because they are more prone to exposure and ingestion of infective eggs. Toxocara infection commonly resolves itself within weeks, but chronic eosinophilia may result. In VLM, larvae migration incites inflammation of internal organs and sometimes the central nervous system. Symptoms depend on the organ(s) affected. Patients can present with pallor, fatigue, weight loss, anorexia, fever, headache, skin rash, cough, asthma, chest tightness, increased irritability, abdominal pain, nausea, and vomiting. Sometimes the subcutaneous migration tracks of the larvae can be seen.

Patients are commonly diagnosed with pneumonia, bronchospasms, chronic pulmonary inflammation, hypereosinophilia, hepatomegaly, hypergammaglobulinaemia (IgM, IgG, and IgE classes), leukocytosis, and elevated anti-A and –B isohaemagglutinins. Severe cases have occurred in people who are hypersensitive to allergens; in rare cases, epilepsy, inflammation of the heart, pleural effusion, respiratory failure, and death have resulted from VLM.

Treatment
Toxocariasis will often resolve itself, because the Toxocara larvae cannot mature within human hosts. Corticosteroids are prescribed in severe cases of VLM or if the patient is diagnosed with OLM. Either albendazole (preferred) or mebendazole ("second line therapy") may be prescribed. Granulomas can be surgically removed, or laser photocoagulation and cryoretinopexy can be used to destroy ocular granulomas.

Visceral toxocariasis in humans can be treated with antiparasitic drugs such as albendazole or mebendazole, tiabendazole or diethylcarbamazine usually in combination with anti-inflammatory medications. Steroids have been utilized with some positive results. Anti-helminthic therapy is reserved for severe infections (lungs, brain) because therapy may induce, due to massive larval killing, a strong inflammatory response. Treatment of ocular toxocariasis is more difficult and usually consists of measures to prevent progressive damage to the eye.

Trichinosis

Trichinosis, also known as trichinellosis, is a parasitic disease caused by roundworms of the Trichinella type. During the initial infection, invasion of the intestines can result in diarrhea, abdominal pain, and vomiting. Migration of larvae to muscle, which occurs about a week after being infected, can cause swelling of the face, inflammation of the whites of the eyes, fever, muscle pains, and a rash. Minor infection may be without symptoms. Complications may include inflammation of heart muscle, central nervous system involvement, and inflammation of the lungs.

Trichinosis is mainly spread when undercooked meat containing Trichinella cysts is eaten. Most often this is pork, but infection can also occur from bear and dog meat. Several species of Trichinella can cause disease, with T. spiralis being the most common. After being eaten, the larvae are released from their cysts in the stomach. They then invade the wall of the small intestine, where they develop into adult worms. After one week, the females release new larvae that migrate to voluntarily controlled muscles, where they form cysts. The diagnosis is usually based on symptoms and confirmed by finding specific antibodies in the blood, or larvae on tissue biopsy.

Symptoms
The great majority of trichinosis infections have either minor or no symptoms and no complications. The two main phases for the infection are enteral (affecting the intestines) and parenteral (outside the intestines). The symptoms vary depending on the phase, species of Trichinella, quantity of encysted larvae ingested, age, sex, and host immunity.

● Enteral phase - A large burden of adult worms in the intestines promotes symptoms such as nausea, heartburn, dyspepsia, and diarrhea from two to seven days after infection, while small worm burdens generally are asymptomatic. Eosinophilia presents early and increases rapidly.

● Parenteral phase - The severity of symptoms caused by larval migration from the intestines depends on the number of larvae produced. As the larvae migrate through tissue and vessels, the body's inflammatory response results in edema, muscle pain, fever, and weakness. A classic sign of trichinosis is periorbital edema, swelling around the eyes, which may be caused by vasculitis. Splinter hemorrhage in the nails is also a common symptom. They may very rarely cause enough damage to produce serious neurological deficits (such as ataxia or respiratory paralysis) from worms entering the central nervous system (CNS), which is compromised by trichinosis in 10–24% of reported cases of cerebral venous sinus thrombosis, a very rare form of stroke (three or four cases per million annual incidence in adults). Trichinosis can be fatal depending on the severity of the infection; death can occur 4–6 weeks after the infection, and is usually caused by myocarditis, encephalitis, or pneumonia.

Treatment
As is desirable with most diseases, early treatment is better and decreases the risk of developing disease. If larvae do encyst in skeletal muscle cells, they can remain infectious for months to years.

● Primary treatment - Early administration of anthelmintics, such as mebendazole or albendazole, decreases the likelihood of larval encystation, particularly if given within three days of infection. However, most cases are diagnosed after this time. In humans, mebendazole (200–400 mg three times a day for three days) or albendazole (400 mg twice a day for 8–14 days) is given to treat trichinosis. These drugs prevent newly hatched larvae from developing, but should not be given to pregnant women or children under two years of age.

● Secondary treatment - After infection, steroids, such as prednisone, may be used to relieve muscle pain associated with larval migration.

Trichinella Spiralis (Nematode)

Trichinella spiralis is a viviparous nematode parasite, occurring in rodents, pigs, bears, hyenas and humans, and is responsible for the disease trichinosis. It is sometimes referred to as the "pork worm" due to it being typically encountered in undercooked pork products. It should not be confused with the distantly related pork tapeworm.

Sources
Trichinosis is caused by the parasitic roundworm Trichinella in undercooked meat, mostly from domesticated pigs.

Symptoms
Trichinosis causes diarrhea and other intestinal symptoms, usually starting one to two days after exposure. Fever, headache, itchiness, muscle pains, and swelling around the eyes occur up to 2 weeks later. Recovery is usually slow, even with treatment.

Treatment
Recovery is usually slow, even with treatment with the anti-helminthic (anti-worm) drugs Mebendazole and Albendazole (Albenza).

Whipworm

Trichuris trichiura, Trichocephalus trichiuris or whipworm, is a parasitic roundworm (a type of helminth) that causes trichuriasis (a type of helminthiasis which is one of the neglected tropical diseases) when it infects a human large intestine. It is commonly known as the whipworm which refers to the shape of the worm; it looks like a whip with wider "handles" at the posterior end.

Symptoms
Trichuris trichiura can cause the serious disease Trichuris dysentery syndrome (TDS), with chronic dysentery, anemia, rectal prolapse, and poor growth. TDS is treated with anthelminthics as well as iron supplementation for anemia. Whipworm commonly infects patients also infected with Giardia, Entamoeba histolytica, Ascaris lumbricoides, and hookworms.

Treatment
Trichuris trichiura can be treated with a single dose of albendazole. In Kenya, half of a group of children who had Trichuris trichiura were given albendazole, while the other half of the children received placebos. It was found that the children who received the drug grew significantly better than the group of children who did not receive the treatment. Another treatment that can be used is mebendazole. These medication have been shown to lessen the infection by this parasite through paralyzation. The medication interferes with the parasite's nutrient intake, which eventually leads to death.

Elephantiasis – Lymphatic Filariasis

Lymphatic filariasis is a human disease caused by parasitic worms known as filarial worms. Most cases of the disease have no symptoms. Some people, however, develop a syndrome called elephantiasis, which is marked by severe swelling in the arms, legs, breasts, or genitals. The skin may become thicker as well, and the condition may become painful. The changes to the body have the potential to harm the person's social and economic situation.

The worms are spread by the bites of infected mosquitoes. Three types of worms are known to cause the disease: Wuchereria bancrofti, Brugia malayi, and Brugia timori, with Wuchereria bancrofti being the most common. These worms damage the lymphatic system. The disease is diagnosed by microscopic examination of blood collected during the night. The blood is typically examined as a smear after being stained with Giemsa stain. Testing the blood for antibodies against the disease may also permit diagnosis. Other roundworms from the same family are responsible for river blindness.

Symptoms
The most spectacular symptom of lymphatic filariasis is elephantiasis, a stage 3 lymphedema with thickening of the skin and underlying tissues. This was the first mosquito-borne disease to be discovered. Elephantiasis results when the parasites lodge in the lymphatic system and cause blockages to the flow of lymph. Infections usually begin in childhood. The skin condition the disease causes is called "elephantiasis tropica" (also known as "elephantiasis arabum").

Elephantiasis mainly affects the lower extremities; the ears, mucous membranes, and amputation stumps are affected less frequently. However, various species of filarial worms tend to affect different parts of the body: Wuchereria bancrofti can affect the arms, breasts, legs, scrotum, and vulva (causing hydrocele formation), while Brugia timori rarely affects the genitals. Those who develop the chronic stages of elephantiasis are usually amicrofilaraemic and often have adverse immunological reactions to the microfilariae as well as the adult worms.

The subcutaneous worms present with skin rashes, urticarial papules, and arthritis, as well as hyper- and hypopigmentation macules. The related Onchocerca volvulus manifests itself in the eyes, causing "river blindness" (onchocerciasis), one of the leading causes of blindness in the world. Serous cavity filariasis presents with symptoms similar to subcutaneous filariasis; it may also be associated with ascites following the severe inflammatory reaction in the lymphatics. Elephantiasis leads to marked swelling of the lower half of the body and thickening of the skin, making it look like that of an elephant, a term called "pachyderm".

Treatment
Prevention can be achieved by treating entire groups in which the disease exists, known as mass deworming. This is done every year for about six years, in an effort to rid a population of the disease entirely. Medications used include antiparasitics such as albendazole with ivermectin, or albendazole with diethylcarbamazine. The medications do not kill the adult worms but prevent further spread of the disease until the worms die on their own. Efforts to prevent mosquito bites are also recommended, including reducing the number of mosquitoes and promoting the use of bed nets.

Other Organisms

Myiasis

Myiasis is the parasitic infestation of the body of a live animal by fly larvae (maggots) which grow inside the host while feeding on its tissue. Although flies are most commonly attracted to open wounds and urine- or feces-soaked fur, some species (including the most common myiatic flies—the botfly, blowfly, and screwfly) can create an infestation even on unbroken skin and have been known to use moist soil and non-myiatic flies (such as the common housefly) as vector agents for their parasitic larvae.

Symptoms
How myiasis affects the human body depends on where the larvae are located. Larvae may infect dead, necrotic (prematurely dying) or living tissue in various sites: the skin, eyes, ears, stomach and intestinal tract, or in genitourinary sites. They may invade open wounds and lesions or unbroken skin. Some enter the body through the nose or ears. Larvae or eggs can reach the stomach or intestines if they are swallowed with food and cause gastric or intestinal myiasis.

Syndrome	Symptoms
Cutaneous myiasis	Painful, slow-developing ulcers or furuncle- (boil-) like sores that can last for a prolonged period
Nasal myiasis	Obstruction of nasal passages and severe irritation. In some cases facial edema and fever can develop. Death is not uncommon.
Aural myiasis	Crawling sensations and buzzing noises. Smelly discharge is sometimes present. If located in the middle ear, larvae may get to the brain.

Ophthalmomyiasis	Fairly common, this causes severe irritation, edema, and pain

● Wound
Wound myiasis occurs when fly larvae infest open wounds. It has been a serious complication of war wounds in tropical areas, and is sometimes seen in neglected wounds in most parts of the world. Predisposing factors include poor socioeconomic conditions, extremes of age, neglect, mental disability, psychiatric illness, alcoholism, diabetes, and vascular occlusive disease.

● Eye
Myiasis of the human eye or ophthalmomyiasis can be caused by Hypoderma tarandi, a parasitic botfly of caribou. It is known to lead to uveitis, glaucoma, and retinal detachment. Human ophthalmomyiasis, both external and internal, has been caused by the larvae of the botfly.

Treatment
This applies once an infestation is established. In many circles the first response to cutaneous myiasis once the breathing hole has formed, is to cover the air hole thickly with petroleum jelly. Lack of oxygen then forces the larva to the surface, where it can more easily be dealt with. In a clinical or veterinary setting there may not be time for such tentative approaches, and the treatment of choice might be more direct, with or without an incision. First the larva must be eliminated through pressure around the lesion and the use of forceps. Secondly the wound must be cleaned and disinfected. Further control is necessary to avoid further reinfestation. Livestock may be treated prophylactically with slow release boluses containing ivermectin which can provide long-term protection against the development of the larvae. Sheep also may be dipped, a process which involves drenching the animals in persistent insecticide to poison the larvae before they develop into a problem.

Cochliomyia (Screwworm)

Cochliomyia is a genus in the family Calliphoridae, known as blowflies, in the order Diptera. Cochliomyia is commonly referred to as the New World screwworm flies, as distinct from Old World screwworm flies. Four species are in this genus: C. macellaria, C. hominivorax, C. aldrichi, and C. minima. C. hominivorax is known as the primary screwworm because its larvae produce myiasis and feed on living tissue. This feeding causes deep, pocket-like lesions in the skin, which can be very damaging to the host. C. macellaria is known as the secondary screwworm because its larvae produce myiasis, but feed only on necrotic tissue. Both C. hominivorax and C. macellaria thrive in warm, tropical areas.

Symptoms
The primary screwworm, C. hominivorax, is a parasitic species, whose larvae are renowned for eating and infesting the flesh of living organisms, primarily warm-blooded animals such as cattle and other livestock. Their larvae cause myiasis ("flystrike"), an infestation of maggots in lesions or other wounds and injuries that the host may have. C. hominivorax tends to reproduce only on the flesh of a living host. Unlike most other maggots, these maggots attack and consume healthy living tissue along with decaying tissue (hominivorax literally translates to "man-eating"). The larvae are responsible for their common name, the screwworm, because they possess small spines on each body segment that resemble a screw's threads. After the larvae hatch, they dive into the wound and burrow deeper, perpendicular to the skin surface, eating into live flesh, again resembling a screw being driven into an object. The larvae then continue to feed on the wound fluids and the tissue.

Treatment
Treatment of the victim can be time-consuming and, due to the high incidence of secondary infection, frustrating, but with decisive treatment, a surprisingly positive result is often achieved in all but the worst cases. The obvious first step is the manual removal of the maggots, generally using tweezers or forceps to seize the larva at the posterior end as the spiracles emerge to allow respiration. Once all larvae have been removed, a topical antibiotic smear is applied, often with an oral antibiotic accompaniment. Necrotic tissue may need to be debrided, which can be a painful process. A loose dressing is essential to allow continued fluid drainage from the wound.

2 Bacterial

Bacteria common noun bacteria, singular bacterium) are a type of biological cell. They constitute a large domain of prokaryotic microorganisms. Typically a few micrometres in length, bacteria have a number of shapes, ranging from spheres to rods and spirals. Bacteria were among the first life forms to appear on Earth, and are present in most of its habitats. Bacteria inhabit soil, water, acidic hot springs, radioactive waste, and the deep biosphere of the earth's crust. Bacteria also live in symbiotic and parasitic relationships with plants and animals.

Most bacteria have not been characterised, and only about 27 percent of the bacterial phyla have species that can be grown in the laboratory. The study of bacteria is known as bacteriology, a branch of microbiology. Virtually all animal life on earth is dependent on bacteria for their survival as only bacteria and some archea possess the genes and enzymes necessary to synthesize vitamin B12, also known as cobalamin, and provide it through the food chain. Vitamin B12 is a water-soluble vitamin that is involved in the metabolism of every cell of the human body.

It is a cofactor in DNA synthesis, and in both fatty acid and amino acid metabolism. It is particularly important in the normal functioning of the nervous system via its role in the synthesis of myelin. There are typically 40 million bacterial cells in a gram of soil and a million bacterial cells in a millilitre of fresh water. There are approximately 5×1030 bacteria on Earth, forming a biomass which exceeds that of all plants and animals. Bacteria are vital in many stages of the nutrient cycle by recycling nutrients such as the fixation of nitrogen from the atmosphere. The nutrient cycle includes the decomposition of dead bodies; bacteria are responsible for the putrefaction stage in this process. In the biological communities surrounding hydrothermal vents and cold seeps, extremophile bacteria provide the nutrients needed to sustain life by converting dissolved compounds, such as hydrogen sulphide and methane, to energy.

1 Botulism

ILLNESS Bacterial Botulism

Botulism is a rare and potentially fatal illness caused by a toxin produced by the bacterium Clostridium botulinum. The disease begins with weakness, blurred vision, feeling tired, and trouble speaking. This may then be followed by weakness of the arms, chest muscles, and legs. Vomiting, swelling of the abdomen, and diarrhea may also occur. The disease does not usually affect consciousness or cause a fever. Botulism can be spread in several ways. The bacterial spores which cause it are common in both soil and water.

They produce the botulinum toxin when exposed to low oxygen levels and certain temperatures. Foodborne botulism happens when food containing the toxin is eaten. Infant botulism happens when the bacteria develops in the intestines and releases the toxin. This typically only occurs in children fewer than six months old, as protective mechanisms develop after that time.

Wound botulism is found most often among those who inject street drugs. In this situation, spores enter a wound, and in the absence of oxygen, release the toxin. It is not passed directly between people. The diagnosis is confirmed by finding the toxin or bacteria in the person in question. Prevention is primarily by proper food preparation. The toxin, though not the organism, is destroyed by heating it to more than 85 °C (185 °F) for longer than 5 minutes. Honey can contain the organism, and for this reason, honey should not be fed to children under 12 months.

Treatment is with an antitoxin. In those who lose their ability to breathe on their own, mechanical ventilation may be necessary for months. Antibiotics may be used for wound botulism. Death occurs in 5 to 10% of people. Botulism also affects many other animals. The word is from Latin, botulus, meaning sausage. Early descriptions of botulism date from at least as far back as 1793 in Germany.

Sources

Botulism is a rare but potentially life-threatening bacterial illness. Clostridium Botulinum bacteria grows on food and produces toxins that, when ingested, cause paralysis. Botulism poisoning is extremely rare, but so dangerous that each case is considered a public health emergency. Studies have shown that there is a 35 to 65 percent chance of death for patients who are not treated immediately and effectively with botulism antitoxin.

Symptoms

The muscle weakness of botulism characteristically starts in the muscles supplied by the cranial nerves—a group of twelve nerves that control eye movements, the facial muscles and the muscles controlling chewing and swallowing. Double vision, drooping of both eyelids, loss of facial expression and swallowing problems may therefore occur. In addition to affecting the voluntary muscles, it can also cause disruptions in the autonomic nervous system.

This is experienced as a dry mouth and throat (due to decreased production of saliva), postural hypotension (decreased blood pressure on standing, with resultant lightheadedness and risk of blackouts), and eventually constipation (due to decreased forward movement of intestinal contents). Some of the toxins (B and E) also precipitate nausea, vomiting, and difficulty with talking. The weakness then spreads to the arms (starting in the shoulders and proceeding to the forearms) and legs (again from the thighs down to the feet).

Severe botulism leads to reduced movement of the muscles of respiration, and hence problems with gas exchange. This may be experienced as dyspnea (difficulty breathing), but when severe can lead to respiratory failure, due to the buildup of unexhaled carbon dioxide and its resultant depressant effect on the brain. This may lead to respiratory compromise and death if untreated.

Clinicians frequently think of the symptoms of botulism in terms of a classic triad: bulbar palsy and descending paralysis, lack of fever, and clear senses and mental status ("clear sensorium").

Prevention

Since botulism poisoning most commonly comes from foods improperly canned at home, the most important step in preventing botulism is to follow proper canning procedure. Further botulism prevention techniques include:

- Not eating canned food if the container is bulging or if it smells bad, although not all strains on Clostridium Botulinum smell
- Storing garlic or herb-infused oil in the refrigerator
- Not storing baked potatoes at room temperature

Treatment

Botulism is generally treated with botulism antitoxin and supportive care.

Supportive care for botulism includes monitoring of respiratory function. Respiratory failure due to paralysis may require mechanical ventilation for 2 to 8 weeks, plus intensive medical and nursing care. After this time, paralysis generally improves as new neuromuscular connections are formed.

In some abdominal cases, physicians may try to remove contaminated food still in the digestive tract by inducing vomiting or using enemas. Wounds should be treated, usually surgically, to remove the source of the toxin-producing bacteria.

2 Campylobacteriosis

Campylobacteriosis is an infection by the Campylobacter bacterium, most commonly C. jejuni. It is among the most common bacterial infections of humans, often a foodborne illness. It produces an inflammatory, sometimes bloody, diarrhea or dysentery syndrome, mostly including cramps, fever and pain.

Sources

Drinking water contaminated with feces. This bacteria resides in the intestinal tract of chickens and causes sickness when meat is undercooked or improperly processed.

Symptoms

The prodromal symptoms are fever, headache, and myalgia, which can be severe, lasting as long as 24 hours. After 1–5 days, typically, these are followed by diarrhea (as many as 10 watery, frequently bloody, bowel movements per day) or dysentery, cramps, abdominal pain, and fever as high as 40 °C (104 °F). In most people, the illness lasts for 2–10 days. It is classified as invasive/inflammatory diarrhea, also described as bloody diarrhea or dysentery.

Prevention

ILLNESS Bacterial Campylobacteriosis Prevention

- Pasteurization of milk and chlorination of drinking water destroys the organisms.
- Treatment with antibiotics can reduce fecal excretion.
- Infected health care workers should not provide direct patient care.
- Separate cutting boards should be used for foods of animal origin and other foods.
- Contact with pet saliva and feces should be avoided.
- Food should be properly cooked and hot when served.
- Consume only pasteurized or boiled milk and milk products, never raw milk products.
- Make sure that ice is from safe water.
- If you are not sure of the safety of drinking water, boil it, or disinfect it with chemical disinfectant.
- Wash hands thoroughly and frequently with soap, especially after using the toilet and after contact with pets and farm animals.
- Wash fruits and vegetables thoroughly, especially if they are to be eaten raw. Peel fruits and vegetables whenever possible.

- Food handlers, professionals and at home, should observe hygienic rules during food preparation.
- Professional food handlers should immediately report to their employer any fever, diarrhea, vomiting or visible infected skin lesions.

ILLNESS Bacterial Campylobacteriosis Treatment

Treatment

The infection is usually self-limiting, and in most cases, symptomatic treatment by liquid and electrolyte replacement is enough in human infections.

Antibiotics
Antibiotic treatment only has a marginal effect on the duration of symptoms, and its use is not recommended except in high-risk patients with clinical complications.

Erythromycin can be used in children, and tetracycline in adults. Some studies show, however, that erythromycin rapidly eliminates Campylobacter from the stool without affecting the duration of illness. Nevertheless, children with dysentery due to C. jejuni benefit from early treatment with erythromycin. Treatment with antibiotics, therefore, depends on the severity of symptoms. Quinolones are effective if the organism is sensitive, but high rates of quinolone use in livestock means that quinolones are now largely ineffective. Antimotility agents, such as loperamide, can lead to prolonged illness or intestinal perforation in any invasive diarrhea, and should be avoided. Trimethoprim/sulfamethoxazole and ampicillin are ineffective against Campylobacter.

Notes

Campylobacter jejuni is the second most common cause of food poisoning in the United States and in Europe after Salmonella. The vast majority of cases occur as isolated events, not as part of recognized outbreaks.

ILLNESS Bacterial Cholera

3 Cholera

Cholera is an infection of the small intestine by some strains of the bacterium Vibrio cholerae. Symptoms may range from none, to mild, to severe. The classic symptom is large amounts of watery diarrhea that lasts a few days. Vomiting and muscle cramps may also occur. Diarrhea can be so severe that it leads within hours to severe dehydration and electrolyte imbalance. This may result in sunken eyes, cold skin, decreased skin elasticity, and wrinkling of the hands and feet.

Dehydration can cause the skin to turn bluish. Symptoms start two hours to five days after exposure. Cholera is caused by a number of types of Vibrio cholerae, with some types producing more severe disease than others. It is spread mostly by unsafe water and unsafe food that has been contaminated with human feces containing the bacteria. Undercooked seafood is a common source.

Humans are the only animal affected. Risk factors for the disease include poor sanitation, not enough clean drinking water, and poverty. There are concerns that rising sea levels will increase rates of disease. Cholera can be diagnosed by a stool test. A rapid dipstick test is available but is not as accurate. Prevention methods against cholera include improved sanitation and access to clean water. Cholera vaccines that are given by mouth provide reasonable protection for about six months. They have the added benefit of protecting against another type of diarrhea caused by E. coli. The primary treatment is oral rehydration therapy—the replacement of fluids with slightly sweet and salty solutions.

Sources

Drinking water contaminated with the bacterium.

ILLNESS Bacterial Cholera Symptoms

Symptoms

The primary symptoms of cholera are profuse diarrhea and vomiting of clear fluid. These symptoms usually start suddenly, half a day to five days after ingestion of the bacteria. The diarrhea is frequently described as "rice water" in nature and may have a fishy odor. An untreated person with cholera may produce 10 to 20 litres (3 to 5 US gal) of diarrhea a day. Severe cholera, without treatment, kills about half of affected individuals. If the severe diarrhea is not treated, it can result in life-threatening dehydration and electrolyte imbalances. Estimates of the ratio of asymptomatic to symptomatic infections have ranged from 3 to 100. Cholera has been nicknamed the "blue death" because a person's skin may turn bluish-gray from extreme loss of fluids.

Fever is rare and should raise suspicion for secondary infection. Patients can be lethargic and might have sunken eyes, dry mouth, cold clammy skin, or wrinkled hands and feet. Kussmaul breathing, a deep and labored breathing pattern, can occur because of acidosis from stool bicarbonate losses and lactic acidosis associated with poor perfusion. Blood pressure drops due to dehydration, peripheral pulse is rapid and thready, and urine output decreases with time. Muscle cramping and weakness, altered consciousness, seizures, or even coma due to electrolyte imbalances are common, especially in children.

Prevention

Although cholera may be life-threatening, prevention of the disease is normally straightforward if proper sanitation practices are followed. In developed countries, due to nearly universal advanced water treatment and sanitation practices present there, cholera is rare. For example, the last major outbreak of cholera in the United States occurred in 1910–1911. Cholera is mainly a risk in developing countries. Effective sanitation practices, if instituted and adhered to in time, are usually sufficient to stop an epidemic. There are several points along the cholera transmission path at which its spread may be halted:

ILLNESS Bacterial Cholera Prevention

● Sterilization: Proper disposal and treatment of all materials that may have come into contact with cholera victims' feces (e.g., clothing, bedding, etc.) are essential. These should be sanitized by washing in hot water, using chlorine bleach if possible. Hands that touch cholera patients or their clothing, bedding, etc., should be thoroughly cleaned and disinfected with chlorinated water or other effective antimicrobial agents.
● Sewage and fecal sludge management: In cholera-affected areas, sewage and fecal sludge need to be treated and managed carefully in order to stop the spread of this disease via human excreta. Provision of sanitation and hygiene is an important preventative measure.
● Sources: Warnings about possible cholera contamination should be posted around contaminated water sources.
● Water purification: All water used for drinking, washing, or cooking should be sterilized by either boiling, chlorination, ozone water treatment, ultraviolet light sterilization (e.g., by solar water disinfection), or antimicrobial filtration in any area where cholera may be present. Cloth filters or sari filtration, though very basic, have significantly reduced the occurrence of cholera when used in poor villages in Bangladesh that rely on untreated surface water. Better antimicrobial filters, like those present in advanced individual water treatment hiking kits, are most effective.

Treatment

Aggressive efforts to rehydrate the patient, drops the death rate to only one per cent. Antibiotic therapy with doxycycline or tetracycline seems to shorten the duration of the illness.

Antibiotic treatments for one to three days shorten the course of the disease and reduce the severity of the symptoms. Use of antibiotics also reduces fluid requirements. People will recover without them, however, if sufficient hydration is maintained. The WHO only recommends antibiotics in those with severe dehydration.

Doxycycline is typically used first line, although some strains of V. cholerae have shown resistance. Testing for resistance during an outbreak can help determine appropriate future choices. Other antibiotics proven to be effective include cotrimoxazole, erythromycin, tetracycline, chloramphenicol, and furazolidone. Fluoroquinolones, such as ciprofloxacin, also may be used, but resistance has been reported. Antibiotics improve outcomes in those who are both severely and not severely dehydrated. Azithromycin and tetracycline may work better than doxycycline or ciprofloxacin.

Notes

Caused by the marine and freshwater bacterium Vibrio cholera, Cholera has been the cause of many deaths in both the distant and recent past. It may, once again, be an issue in the uncertain future. Cholera toxins produce a rapid onset of diarrhea and vomiting within a few hours to 2 days of infection. Victims often complain of leg cramps. The body water loss with untreated cholera is associated with a sixty per cent death rate.

ILLNESS Bacterial Mycobacterium marinum

4 Mycobacterium Marinum

Mycobacterium marinum (formerly M. balnei) is a free-living bacterium, which causes opportunistic infections in humans. M. marinum sometimes causes a rare disease known as aquarium granuloma, which typically affects individuals who work with fish or keep home aquariums.

Sources

Naturally occurs in water, most cases from exposure in swimming pools or more frequently aquariums; rare infection since it mostly infects immunocompromised individuals.

Symptoms

Symptoms include lesions typically located on the elbows, knees, and feet (from swimming pools) or lesions on the hands (aquariums). Lesions may be painless or painful.

Prevention

Treatment

The management of M. marinum infections depends on the severity of the infection. A prolonged course of antibiotic therapy is curative in most superficial cases but adjunctive surgical intervention is sometimes indicated in extensive and deep infections. M. marinum is heat sensitive and very hot compresses applied directly to the infected area have been effective in eradicating the bacterium. (The compress should be as hot as can be safely tolerated and the surrounding skin should be protected.) Use of minocycline, clarithromycin, and ethambutol has been described.

ILLNESS Bacterial Dysentery

5 Dysentery

Dysentery is a type of gastroenteritis that results in diarrhea with blood. Other symptoms may include fever, abdominal pain, and a feeling of incomplete defecation. Complications may include dehydration. The cause is usually Shigella, in which case it is known as shigellosis, or Entamoeba histolytica. Other causes may include certain chemicals, other bacteria, other protozoa, or parasitic worms. It may spread between people. Risk factors include contamination of food and water with feces due to poor sanitation.

The underlying mechanism involves inflammation of the intestine, especially of the colon. Efforts to prevent dysentery include hand washing and food safety measures while traveling in areas of high risk. While the condition generally resolves on its own within a week, drinking sufficient fluids such as oral rehydration solution is important. Antibiotics such as azithromycin may be used to treat cases associated with travelling in the developing world. While medications used to decrease diarrhea such as loperamide are not recommended on their own, they may be used together with antibiotics.

Sources

Water contaminated with the bacterium. It is spread through contaminated food and water, and crowded unsanitary conditions.

Symptoms

The most common form of dysentery is bacillary dysentery, which is typically a mild sickness, causing symptoms normally consisting of mild gut pains and frequent passage of stool or diarrhea. Symptoms normally present themselves after 1–3 days, and are usually no longer present after a week. The frequency of urges to defecate, the large volume of liquid feces ejected, and the presence of blood, mucus, or pus depends on the pathogen causing the disease. Temporary lactose intolerance can occur, as well. In some caustic occasions, severe abdominal cramps, fever, shock, and delirium can all be symptoms.

In extreme cases, people may pass more than one liter of fluid per hour. More often, individuals will complain of diarrhea with blood, accompanied by abdominal pain, rectal pain and a low-grade fever. Rapid weight loss and muscle aches sometimes also accompany dysentery, while nausea and vomiting are rare. On rare occasions, the amoebic parasite will invade the body through the bloodstream and spread beyond the intestines. In such cases, it may more seriously infect other organs such as the brain, lungs, and most commonly the liver.

Prevention

Efforts to prevent dysentery include hand washing and food safety measures while traveling in areas of high risk.

Treatment

Dysentery is managed by maintaining fluids using oral rehydration therapy. If this treatment cannot be adequately maintained due to vomiting or the profuseness of diarrhea, hospital admission may be required for intravenous fluid replacement. In ideal situations, no antimicrobial therapy should be administered until microbiological microscopy and culture studies have established the specific infection involved. When laboratory services are not available, it may be necessary to administer a combination of drugs, including an amoebicidal drug to kill the parasite, and an antibiotic to treat any associated bacterial infection.

If shigellosis is suspected and it is not too severe, letting it run its course may be reasonable — usually less than a week. If the case is severe, antibiotics such as ciprofloxacin or TMP-SMX may be useful. However, many strains of Shigella are becoming resistant to common antibiotics, and effective medications are often in short supply in developing countries. If necessary, a doctor may have to reserve antibiotics for those at highest risk for death, including young children, people over 50, and anyone suffering from dehydration or malnutrition. Amoebic dysentery is often treated with two antimicrobial drugs such as metronidazole and paromomycin or iodoquinol.

6 Legionnaires' Disease (Legionellosis)

Legionnaires' disease, also known as legionellosis, is a form of atypical pneumonia caused by any type of Legionella bacteria. Signs and symptoms include cough, shortness of breath, high fever, muscle pains, and headaches. Nausea, vomiting, and diarrhea may also occur. This often begins 2–10 days after exposure. The bacterium is found naturally in fresh water. It can contaminate hot water tanks, hot tubs, and cooling towers of large air conditioners. It is usually spread by breathing in mist that contains the bacteria. It can also occur when contaminated water is aspirated. It typically does not spread directly between people, and most people who are exposed do not become infected. Risk factors for infection include older age, a history of smoking, chronic lung disease, and poor immune function. Those with severe pneumonia and those with pneumonia and a recent travel history should be tested for the disease. Diagnosis is by a urinary antigen test and sputum culture.

Sources

Legionella is a very common organism that reproduces to high numbers in warm water; but only causes severe disease when aerosolized.

Symptoms

The length of time between exposure to the bacteria and the appearance of symptoms (incubation period) is generally 2–10 days, but can rarely extend to as long as 20 days. For the general population, among those exposed, between 0.1 and 5.0% develop the disease, while among those in hospital, between 0.4 and 14% develop the disease.

Those with Legionnaires' disease usually have fever, chills, and a cough, which may be dry or may produce sputum. Almost all experience fever, while around half have cough with sputum, and one-third cough up blood or bloody sputum. Some also have muscle aches, headache, tiredness, loss of appetite, loss of coordination (ataxia), chest pain, or diarrhea and vomiting. Up to half of those with Legionnaires' disease have gastrointestinal symptoms, and almost half have neurological symptoms, including confusion and impaired cognition. "Relative bradycardia" may also be present, which is low to normal heart rate despite the presence of a fever.

Prevention

Although the risk of Legionnaires' disease being spread by large-scale water systems cannot be eliminated, it can be greatly reduced by writing and enforcing a highly detailed, systematic water safety plan appropriate for the specific facility involved (office building, hospital, hotel, spa, cruise ship, etc.) Some of the elements that such a plan may include are:

● Keep water temperature either above or below the 20–50 °C (68–122 °F) range in which the Legionella bacterium thrives.
● Prevent stagnation, for example, by removing from a network of pipes any sections that have no outlet (dead ends). Where stagnation is unavoidable, as when a wing of a hotel is closed for the off-season, systems must be thoroughly disinfected just prior to resuming normal operation.
● Prevent the buildup of biofilm, for example, by not using (or by replacing) construction materials that encourage its development, and by reducing the quantity of nutrients for bacterial growth that enter the system.
● Periodically disinfect the system, by high heat or a chemical biocide, and use chlorination where appropriate. Treatment of water with copper-silver ionization or ultraviolet light may also be effective.
● System design (or renovation) can reduce the production of aerosols and reduce human exposure to them, by directing them well away from building air intakes.

Treatment

Effective antibiotics include most macrolides, tetracyclines, ketolides, and quinolones. Legionella spp. multiply within the cell, so any effective treatment must have excellent intracellular penetration. Current treatments of choice are the respiratory tract quinolones (levofloxacin, moxifloxacin, gemifloxacin) or newer macrolides (azithromycin, clarithromycin, roxithromycin). The antibiotics used most frequently have been levofloxacin, doxycycline, and azithromycin.

Macrolides (azithromycin) are used in all age groups, while tetracyclines (doxycycline) are prescribed for children above the age of 12 and quinolones (levofloxacin) above the age of 18. Rifampicin can be used in combination with a quinolone or macrolide. Whether rifampicin is an effective antibiotic to take for treatment is uncertain. The Infectious Diseases Society of America does not recommend the use of rifampicin with added regimens. Tetracyclines and erythromycin led to improved outcomes compared to other antibiotics in the original American Legion outbreak.

These antibiotics are effective because they have excellent intracellular penetration in Legionella-infected cells. The recommended treatment is 5–10 days of levofloxacin or 3–5 days of azithromycin, but in people who are immunocompromised, have severe disease, or other pre-existing health conditions, longer antibiotic use may be necessary. During outbreaks, prophylactic antibiotics have been used to prevent Legionnaires' disease in high-risk individuals who have possibly been exposed.

7 Lyme Disease

ILLNESS Bacterial Lyme Disease

Lyme disease, also known as Lyme borreliosis, is an infectious disease caused by bacteria of the Borrelia type which is spread by ticks. The most common sign of infection is an expanding area of redness on the skin, known as erythema migrans, that begins at the site of a tick bite about a week after it has occurred. In most cases, the tick must be attached 36-48 hours to spread Lyme disease. A circular, red, expanding rash (erythema migrans, or a “bullseye” rash) is one of the first symptoms of Lyme disease. Other symptoms include fatigue, chills, fever, headache, muscle and joint aches, and swollen lymph nodes. Treatment in the early stages with antibiotics is generally effective.

Sources

Spread by ticks. The risk of infectious transmission increases with the duration of tick attachment. It requires between 36 and 48 hours of attachment for the bacteria that causes Lyme to travel from within the tick into its saliva.

Symptoms

Lyme disease can affect multiple body systems and produce a broad range of symptoms. Not everyone with Lyme disease has all of the symptoms, and many of the symptoms are not specific to Lyme disease but can occur with other diseases, as well.

The incubation period from infection to the onset of symptoms is usually one to two weeks, but can be much shorter (days), or much longer (months to years). Lyme symptoms most often occur from May to September, because the nymphal stage of the tick is responsible for most cases. Asymptomatic infection exists, but occurs in less than 7% of infected individuals in the United States. Asymptomatic infection may be much more common among those infected in Europe.

Prevention

Tick bites may be prevented by avoiding or reducing time in likely tick habitats and taking precautions while in and when getting out of one. As a precaution, CDC recommends soaking or spraying clothes, shoes, and camping gear such as tents, backpacks and sleeping bags with 0.5% permethrin solution and hanging them to dry before use. Permethrin is odorless and safe for humans but highly toxic to ticks. After crawling on permethrin-treated fabric for as few as 10–20 seconds, tick nymphs become irritated and fall off or die. Permethrin-treated closed-toed shoes and socks reduce by 74 times the number of bites from nymphs that make first contact with a shoe of a person also wearing treated shorts (because nymphs usually quest near the ground, this is a typical contact scenario).

Better protection can be achieved by tucking permethrin-treated trousers (pants) into treated socks and a treated long-sleeve shirt into the trousers so as to minimize gaps through which a tick might reach the wearer's skin. Light-colored clothing may make it easier to see ticks and remove them before they bite. Military and outdoor workers' uniforms treated with permethrin have been found to reduce the number of bite cases by 80-95%. Permethrin protection lasts several weeks of wear and washings in customer-treated items and up to 70 washings for factory-treated items. Permethrin should not be used on human skin, underwear or cats.

Treatment

Tick Removal
Attached ticks should be removed promptly. Risk of infection increases with time of attachment, but in North America risk of Lyme disease is small if the tick is removed within 36 hours. CDC recommends inserting a fine-tipped tweezer between the skin and the tick, grasping very firmly, and pulling the closed tweezer straight away from the skin without twisting, jerking, squeezing or crushing the tick. After tick removal, any tick parts remaining in the skin should be removed with the tweezer, if possible. Wound and hands should then be cleaned with alcohol or soap and water.

The tick may be disposed by placing it in a container with alcohol, sealed bag, tape or flushed down the toilet. The bitten person should write down where and when the bite happened so that this can be informed to a doctor if the person gets a rash or flu-like symptoms in the following several weeks. CDC recommends not using fingers, nail polish, petroleum jelly or heat on the tick to try to remove it.

In Australia, where the Australian paralysis tick is prevalent, the Australasian Society of Clinical Immunology and Allergy recommends not using tweezers to remove ticks, because if the person is allergic, anaphylaxis could result. Instead, a product should be sprayed on the tick to cause it to freeze and then drop off. A doctor would use liquid nitrogen, but products available from chemists for freezing warts can be used instead. Another method originating from Australia consists in using about 20 cm of dental floss or fishing line for slowly tying an overhand knot between the skin and the tick and then pulling it away from the skin.

Preventive Antibiotics
If a deer tick that is sufficiently likely to be carrying Borrelia is found attached to a person and removed, and if the tick has been attached for 36 hours or is engorged, a single dose of doxycycline administered within the 72 hours after removal may reduce the risk of Lyme disease. It is not generally recommended for all people bitten, as development of infection is rare: about 50 bitten people would have to be treated this way to prevent one case of erythema migrans (i.e. the typical rash found in about 70–80% of people infected).

8 Leptospirosis

Leptospirosis is an infection caused by corkscrew-shaped bacteria called Leptospira. Signs and symptoms can range from none to mild such as headaches, muscle pains, and fevers to severe with bleeding from the lungs or meningitis. If the infection causes the person to turn yellow, have kidney failure and bleeding, it is then known as Weil's disease. If it also causes bleeding into the lungs then it is known as severe pulmonary haemorrhage syndrome.

Up to ten different genetic types of Leptospira may cause disease in humans. It is transmitted by both wild and domestic animals. The most common animals that spread the disease are rodents. It is often transmitted by animal urine or by water or soil containing animal urine coming into contact with breaks in the skin, eyes, mouth, or nose. In the developing world the disease most commonly occurs in farmers and low-income people who live in cities. In the developed world it most commonly occurs in those involved in outdoor activities in warm and wet areas of the world. Diagnosis is typically by looking for antibodies against the bacterium or finding its DNA in the blood.

Sources

Water contaminated by the animal urine carrying the bacteria. The bacteria can be found in ponds, rivers, puddles, sewers, agricultural fields and moist soil. Pathogenic Leptospira have been found in the form of aquatic biofilms, which may aid survival in the environment.

Symptoms

The symptoms of leptospirosis usually appear one to two weeks after infection, but the incubation period can be as long as a month. As a biphasic disease, the first phase (acute or septic phase) ends after three to seven days of illness. The second phase (immune phase) starts with the resolution of symptoms and the appearance of antibodies. 90% of those infected experience mild symptoms while 10% experience severe leptospirosis.

Leptospiral infection in humans causes a range of symptoms, though some infected persons may have none. The disease begins suddenly with fever accompanied by chills, intense headache, severe muscle aches and abdominal pain. A headache brought on by leptospirosis causes throbbing pain and is characteristically located at the head's bilateral temporal or frontal regions. The person could also have pain behind the eyes and a sensitivity to light. Muscle pain usually involves the calf muscle and the lower back. The most characteristic feature of leptospirosis is the conjunctival suffusion (conjunctivitis without exudate) which is rarely found in other febrile illnesses. Other characteristic findings on the eye include subconjunctival bleeding and jaundice.

A rash is rarely found in leptospirosis. When one is found alternative diagnoses such as dengue fever and chikungunya fever should be considered. Dry cough is observed in 20–57% of people with leptospirosis. Thus, this clinical feature can mislead a doctor to diagnose the disease as a respiratory illness. Additionally, gastrointestinal symptoms such as nausea, vomiting, abdominal pain, and diarrhoea frequently occur. Vomiting and diarrhea may contribute to dehydration. The abdominal pain can be due to acalculous cholecystitis or inflammation of the pancreas. Rarely, the lymph nodes, liver, and spleen may be enlarged and palpable.

There will be a resolution of symptoms for one to three days. The immune phase starts after this and can last from four to 30 days and can be anything from brain to kidney complications. The hallmark of the second phase is inflammation of the membranes covering the brain. Signs and symptoms of meningitis include severe headache and neck stiffness. Kidney involvement is associated with reduced or absent urine output.

The classic form of severe leptospirosis, known as Weil's disease, is characterised by liver damage (causing jaundice), kidney failure, and bleeding, which happens in 5–10% of those infected. Lung and brain damage can also occur. For those with signs of inflammation of membranes covering the brain and the brain itself, altered level of consciousness can happen. A variety of neurological problems such as paralysis of half of the body, complete inflammation of a whole horizontal section of spinal cord, and muscle weakness due to immune damage of the nerves supplying the muscles are the complications. Signs of bleeding such as non-traumatic bruises at 1 mm (0.039 in), non-traumatic bruises more than 1 cm (0.39 in), nose bleeding, blackish stools due to bleeding in the stomach, vomiting blood and bleeding from the lungs can also be found.

Prolongation of prothrombin time in coagulation testing is associated with severe bleeding manifestation. However, low platelet count is not associated with severe bleeding. Pulmonary haemorrhage is alveolar haemorrhage (bleeding into the alveoli of the lungs) leading to massive coughing up of blood, and causing acute respiratory distress syndrome, where the risk of death is more than 50%. Rarely, inflammation of the heart muscles, inflammation of membranes covering the heart, abnormalities in the heart's natural pacemaker and abnormal heart rhythms may occur.

Prevention

Rates of leptospirosis can be reduced by improving housing, infrastructure, and sanitation standards. Rodent abatement efforts and flood mitigation projects can also help to prevent it. Proper use of personal protective equipment (PPE) by people who have a high risk of occupational exposure can prevent leptospirosis infections in most cases.

Treatment

Most leptospiral cases resolve spontaneously. Early initiation of antibiotics may prevent the progression to severe disease. Therefore, in resource-limited settings, antibiotics can be started once leptospirosis is suspected after history taking and examination.

For mild leptospirosis, antibiotic recommendations such as doxycycline, azithromycin, ampicillin and amoxicillin were based solely on in vitro testing. In 2001, the WHO recommended oral doxycycline (2 mg/kg up to 100 mg every 12 hours) for five to seven days for those with mild leptospirosis. Tetracycline, ampicillin, and amoxicillin can also be used in such cases. However, in areas where rickettsia and leptospirosis are both endemic, azithromycin and doxycycline are the drugs of choice.

9 Otitis Externa

Otitis externa, also called swimmer's ear, is inflammation of the ear canal. It often presents with ear pain, swelling of the ear canal, and occasionally decreased hearing. Typically there is pain with movement of the outer ear. A high fever is typically not present except in severe cases.

Otitis externa may be acute (lasting less than six weeks) or chronic (lasting more than three months). Acute cases are typically due to bacterial infection, and chronic cases are often due to allergies and autoimmune disorders. Risk factors for acute cases include swimming, minor trauma from cleaning, using hearing aids and ear plugs, and other skin problems, such as psoriasis and dermatitis. People with diabetes are at risk of a severe form of malignant otitis externa. Diagnosis is based on the signs and symptoms. Culturing the ear canal may be useful in chronic or severe cases.

Sources

Swimming in water contaminated by the responsible pathogens.

Symptoms

Ear pain is the predominant complaint and the only symptom directly related to the severity of acute external otitis. Unlike other forms of ear infections, the pain of acute external otitis is worsened when the outer ear is touched or pulled gently. Pushing the tragus, the tablike portion of the auricle that projects out just in front of the ear canal opening, also typically causes pain in this condition as to be diagnostic of external otitis on physical examination. People may also experience ear discharge and itchiness. When enough swelling and discharge in the ear canal is present to block the opening, external otitis may cause temporary conductive hearing loss.

Because the symptoms of external otitis lead many people to attempt to clean out the ear canal (or scratch it) with slim implements, self-cleaning attempts generally lead to additional traumas of the injured skin, so rapid worsening of the condition often occurs.

Prevention

Treatment

ILLNESS Bacterial Otitis Externa Treatment

Medications
Effective solutions for the ear canal include acidifying and drying agents, used either singly or in combination. When the ear canal skin is inflamed from the acute otitis externa, the use of dilute acetic acid may be painful.

Burow's solution is a very effective remedy against both bacterial and fungal external otitis. This is a buffered mixture of aluminum sulfate and acetic acid, and is available without prescription in the United States.

Ear drops are the mainstays of treatment for external otitis. Some contain antibiotics, either antibacterial or antifungal, and others are simply designed to mildly acidify the ear canal environment to discourage bacterial growth. Some prescription drops also contain anti-inflammatory steroids, which help to resolve swelling and itching. Although there is evidence that steroids are effective at reducing the length of treatment time required, fungal otitis externa (also called otomycosis) may be caused or aggravated by overly prolonged use of steroid-containing drops.

Antibiotics by mouth should not be used to treat uncomplicated acute otitis externa. Antibiotics by mouth are not a sufficient response to bacteria which cause this condition and have significant side effects including increased risk of opportunistic infection. In contrast, topical products can treat this condition. Oral anti-pseudomonal antibiotics can be used in case of severe soft tissue swelling extending into the face and neck and may hasten recovery.

Although the acute external otitis generally resolves in a few days with topical washes and antibiotics, complete return of hearing and cerumen gland function may take a few more days. Once healed completely, the ear canal is again self-cleaning. Until it recovers fully, it may be more prone to repeat infection from further physical or chemical insult.

Effective medications include ear drops containing antibiotics to fight infection, and corticosteroids to reduce itching and inflammation. In painful cases, a topical solution of antibiotics such as aminoglycoside, polymyxin or fluoroquinolone is usually prescribed. Antifungal solutions are used in the case of fungal infections. External otitis is almost always predominantly bacterial or predominantly fungal so that only one type of medication is necessary and indicated.

10 Salmonellosis (Salmonella)

Salmonellosis is a symptomatic infection caused by bacteria of the Salmonella type. The most common symptoms are diarrhea, fever, abdominal cramps, and vomiting. Symptoms typically occur between 12 hours and 36 hours after exposure, and last from two to seven days. Occasionally more significant disease can result in dehydration. The old, young, and others with a weakened immune system are more likely to develop severe disease. Specific types of Salmonella can result in typhoid fever or paratyphoid fever.

There are two species of Salmonella: Salmonella bongori and Salmonella enterica with many subspecies. Infection is usually spread by eating contaminated meat, eggs, or milk. Other foods may spread the disease if they have come into contact with manure. A number of pets including cats, dogs, and reptiles can also carry and spread the infection. Diagnosis is by a stool test or blood tests.

Sources

Drinking water contaminated with the bacteria. More common as a food borne illness. Salmonella infection usually occurs when a person eats food contaminated with the feces of animals or humans carrying the bacteria. Salmonella outbreaks are commonly associated with eggs, meat and poultry, but these bacteria can also contaminate other foods such as fruits and vegetables. Foods that are most likely to contain Salmonella include raw or undercooked eggs, raw milk, contaminated water, and raw or undercooked meats.

Symptoms

Symptoms of Salmonella infection, or Salmonellosis, range widely, and are sometimes absent altogether. The most common symptoms include diarrhea, abdominal cramps, and fever.

Typical Symptoms of Salmonella infection: Appear 6 to 72 hours after eating contaminated food and last for 3 to 7 days without treatment.

- Diarrhea
- Abdominal Cramps
- Fever of 100 F to 102 F
- Additional symptoms:
- Bloody diarrhea
- Vomiting
- Headache
- Body Aches

Enteritis
After a short incubation period of a few hours to one day, the bacteria multiply in the small intestine, causing an intestinal inflammation (enteritis). Most people with salmonellosis develop diarrhea, fever, vomiting, and abdominal cramps 12 to 72 hours after infection. Diarrhea is often watery and non-bloody but may be mucoid and bloody. In most cases, the illness lasts four to seven days, and does not require treatment. In some cases, though, the diarrhea may be so severe that the patient becomes dangerously dehydrated and must be hospitalized.

At the hospital, the patient may receive fluids intravenously to treat the dehydration, and may be given medications to provide symptomatic relief, such as fever reduction. In severe cases, the Salmonella infection may spread from the intestines to the blood stream, and then to other body sites, and can cause death, unless the person is treated promptly with antibiotics.

In otherwise healthy adults, the symptoms can be mild. Normally, no sepsis occurs, but it can occur exceptionally as a complication in the immunocompromised. However, in people at risk such as infants, small children, and the elderly, Salmonella infections can become very serious, leading to complications. In infants, dehydration can cause a state of severe toxicity. Extraintestinal localizations are possible, especially Salmonella meningitis in children, osteitis, etc. Children with sickle-cell anemia who are infected with Salmonella may develop osteomyelitis. Treatment of osteomyelitis, in this case, will be to use fluoroquinolones (ciprofloxacin, levofloxacin, etc., and nalidixic acid).

Typhoid Fever
Typhoid fever occurs when Salmonella bacteria enter the lymphatic system and cause a systemic form of salmonellosis. Endotoxins first act on the vascular and nervous apparatus, resulting in increased permeability and decreased tone of the vessels, upset thermal regulation, vomiting, and diarrhea. In severe forms of the disease, enough liquid and electrolytes are lost to upset the fluid balance, cause an electrolyte imbalance, decrease the circulating blood volume and arterial pressure, and cause hypovolemic shock. Septic shock may also develop. Shock of mixed character (with signs of both hypovolemic and septic shock) are more common in severe salmonellosis. Oliguria and azotemia develop in severe cases as a result of renal involvement due to hypoxia and toxemia.

Long-Term
Salmonellosis is associated with later irritable bowel syndrome and inflammatory bowel disease. Evidence however does not support it being a direct cause of the latter.

A small number of people afflicted with salmonellosis experience reactive arthritis, which can last months or years and can lead to chronic arthritis. In sickle-cell anemia, osteomyelitis due to Salmonella infection is much more common than in the general population. Though Salmonella infection is frequently the cause of osteomyelitis in people with sickle-cell, it is not the most common cause, which is Staphylococcus infection.

Those infected may become asymptomatic carriers, but this is relatively uncommon, with shedding observed in only 0.2 to 0.6% of cases after a year.

ILLNESS Bacterial Salmonellosis (Salmone

Prevention

The US Food and Drug Administration (FDA) has published guidelines to help reduce the chance of food-borne salmonellosis. Food must be cooked to 145–165 °F (63–74 °C), and liquids such as soups or gravies should be boiled when reheating. Freezing kills some Salmonella, but it is not sufficient to reliably reduce them below infectious levels. While Salmonella is usually heat-sensitive, it acquires heat-resistance in high-fat environments such as peanut butter.

Treatment

Salmonella infections generally last 3 to 7 days, and often do not require treatment. People with severe dehydration may need rehydration through an IV. Antibiotics are recommended for those at risk of invasive disease, including infants under three months old. Typhoid fever is treated with a 14-day course of antibiotics. Unfortunately, treatment of Salmonella has become more difficult as it has become more resistant to antibiotics. Finding the right antibiotic for a case of Salmonella is crucial to treating this bacterial infection.

11 Typhus

ILLNESS Bacterial Typhus

Typhus, also known as typhus fever, is a group of infectious diseases that include epidemic typhus, scrub typhus, and murine typhus. Common symptoms include fever, headache, and a rash. Typically these begin one to two weeks after exposure. The diseases are caused by specific types of bacterial infection. Epidemic typhus is due to Rickettsia prowazekii spread by body lice, scrub typhus is due to Orientia tsutsugamushi spread by chiggers, and murine typhus is due to Rickettsia typhi spread by fleas.

Currently no vaccine is commercially available. Prevention is by reducing exposure to the organisms that spread the disease. Treatment is with the antibiotic doxycycline. Epidemic typhus generally occurs in outbreaks when poor sanitary conditions and crowding are present. While once common, it is now rare. Scrub typhus occurs in Southeast Asia, Japan, and northern Australia. Murine typhus occurs in tropical and subtropical areas of the world

Sources

Typhus

Transmitted by fleas and ticks to humans in unsanitary surroundings.

Symptoms

Signs and symptoms begin with sudden onset of fever, and other flu-like symptoms about one to two weeks after being infected. Five to nine days after the symptoms have started, a rash typically begins on the trunk and spreads to the extremities. This rash eventually spreads over most of the body, sparing the face, palms, and soles. Signs of meningoencephalitis begin with the rash and continue into the second or third weeks. Other signs of meningoencephalitis include sensitivity to light (photophobia), altered mental status (delirium), or coma. Untreated cases are often fatal.

Prevention

Typhus

As of 2020, no vaccine is commercially available. A vaccine has been in development for scrub typhus known as the scrub typhus vaccine.

Treatment

Doxycycline is the drug of choice for this disease. The American Public Health Association recommends treatment based upon clinical findings and before culturing confirms the diagnosis. Without treatment, death may occur in 10% to 60% of people with epidemic typhus, with people over age 60 having the highest risk of death. In the antibiotic era, death is uncommon if doxycycline is given. In one study of 60 people hospitalized with epidemic typhus, no one died when given doxycycline or chloramphenicol. Some people also may need oxygen and intravenous fluids.

12 Typhoid Fever

ILLNESS Bacterial Typhoid Fever

Typhoid fever, also known simply as typhoid, is a bacterial infection due to a specific type of Salmonella that causes symptoms. Symptoms may vary from mild to severe, and usually begin 6 to 30 days after exposure. Often there is a gradual onset of a high fever over several days. This is commonly accompanied by weakness, abdominal pain, constipation, headaches, and mild vomiting. Some people develop a skin rash with rose colored spots. In severe cases, people may experience confusion. Without treatment, symptoms may last weeks or months. Diarrhea is uncommon. Other people may carry the bacterium without being affected; however, they are still able to spread the disease to others. Typhoid fever is a type of enteric fever, along with paratyphoid fever.

The cause is the bacterium Salmonella enterica subsp. enterica growing in the intestines and blood. Typhoid is spread by eating or drinking food or water contaminated with the feces of an infected person. Risk factors include poor sanitation and poor hygiene. Those who travel in the developing world are also at risk. Only humans can be infected. Symptoms are similar to those of many other infectious diseases. Diagnosis is by either culturing the bacteria or detecting their DNA in the blood, stool, or bone marrow. Culturing the bacterium can be difficult. Bone-marrow testing is the most accurate.

Infection with the bacteria Salmonella typhi is called "Typh-oid fever", because it is often confused with Typhus. Contamination with Salmonella in food occurs more often than with any other bacteria in the United States. In Typhoid fever, there is a gradual onset of high fevers over the course of several days. Abdominal pain, intestinal hemorrhage, weakness, headaches, constipation, and bloody diarrhea may occur. A number of people develop a spotty, rose-colored rash.

Sources

ILLNESS Bacterial Typhoid Fever Symptoms

Ingestion of water contaminated with feces of an infected person.

Symptoms

Characterized by sustained fever up to 40°C (104°F), profuse sweating; diarrhea may occur. Symptoms progress to delirium, and the spleen and liver enlarge if untreated. In this case it can last up to four weeks and cause death. Some people with typhoid fever develop a rash called "rose spots", small red spots on the abdomen and chest.

Classically, the progression of untreated typhoid fever is divided into four distinct stages, each lasting about a week. Over the course of these stages, the patient becomes exhausted and emaciated.

● In the first week, the body temperature rises slowly, and fever fluctuations are seen with relative bradycardia (Faget sign), malaise, headache, and cough. A bloody nose (epistaxis) is seen in a quarter of cases, and abdominal pain is also possible. A decrease in the number of circulating white blood cells (leukopenia) occurs with eosinopenia and relative lymphocytosis; blood cultures are positive for Salmonella enterica subsp. enterica serovar Typhi. The Widal test is usually negative in the first week.

● In the second week, the person is often too tired to get up, with high fever in plateau around 40 °C (104 °F) and bradycardia (sphygmothermic dissociation or Faget sign), classically with a dicrotic pulse wave. Delirium can occur, where the patient is often calm, but sometimes becomes agitated. This delirium has led to typhoid receiving the nickname "nervous fever". Rose spots appear on the lower chest and abdomen in around a third of patients. Rhonchi (rattling breathing sounds) are heard in the base of the lungs. The abdomen is distended and painful in the right lower quadrant, where a rumbling sound can be heard. Diarrhea can occur in this stage, but constipation is also common. The spleen and liver are enlarged (hepatosplenomegaly) and tender, and liver transaminases are elevated. The Widal test is strongly positive, with antiO and antiH antibodies. Blood cultures are sometimes still positive at this stage.

NESS er

ILLNESS Bacterial Typhoid Fever Symptoms

- In the third week of typhoid fever, a number of complications can occur:
  - Intestinal haemorrhage due to bleeding in congested Peyer's patches occurs; this can be very serious, but is usually not fatal.
  - Intestinal perforation in the distal ileum is a very serious complication and is frequently fatal. It may occur without alarming symptoms until septicaemia or diffuse peritonitis sets in.
  - Encephalitis
  - Respiratory diseases such as pneumonia and acute bronchitis
  - Neuropsychiatric symptoms (described as "muttering delirium" or "coma vigil"), with picking at bedclothes or imaginary objects
  - Metastatic abscesses, cholecystitis, endocarditis, and osteitis
  - The fever is still very high and oscillates very little over 24 hours. Dehydration ensues, and the patient is delirious (typhoid state). One-third of affected individuals develop a macular rash on the trunk.
  - Low platelet count (thrombocytopenia) can sometimes be seen.

ILLNESS Bacterial Typhoid Fever

Prevention

Sanitation and hygiene are important to prevent typhoid. It can only spread in environments where human feces are able to come into contact with food or drinking water. Careful food preparation and washing of hands are crucial to prevent typhoid. Industrialization, and in particular, the invention of the automobile, contributed greatly to the elimination of typhoid fever, as it eliminated the public-health hazards associated with having horse manure in public streets, which led to large number of flies, which are known as vectors of many pathogens, including Salmonella spp. According to statistics from the United States Centers for Disease Control and Prevention, the chlorination of drinking water has led to dramatic decreases in the transmission of typhoid fever in the United States.

ILLNESS Bacterial Typhoid Fever Treatment

Treatment

Ciprofloxacin is the antibiotic of choice but most victims improve with rehydration therapy.

Oral rehydration therapy
The rediscovery of oral rehydration therapy in the 1960s provided a simple way to prevent many of the deaths of diarrheal diseases in general.

Antibiotics
Where resistance is uncommon, the treatment of choice is a fluoroquinolone such as ciprofloxacin. Otherwise, a third-generation cephalosporin such as ceftriaxone or cefotaxime is the first choice. Cefixime is a suitable oral alternative. Typhoid fever, when properly treated, is not fatal in most cases. Antibiotics, such as ampicillin, chloramphenicol, trimethoprim-sulfamethoxazole, amoxicillin, and ciprofloxacin, have been commonly used to treat typhoid fever. Treatment of the disease with antibiotics reduces the case-fatality rate to about 1%.

Without treatment, some patients develop sustained fever, bradycardia, hepatosplenomegaly, abdominal symptoms, and occasionally, pneumonia. In white-skinned patients, pink spots, which fade on pressure, appear on the skin of the trunk in up to 20% of cases. In the third week, untreated cases may develop gastrointestinal and cerebral complications, which may prove fatal in up to 10–20% of cases. The highest case fatality rates are reported in children under 4 years. Around 2–5% of those who contract typhoid fever become chronic carriers, as bacteria persist in the biliary tract after symptoms have resolved.

ILLNESS Bacterial Vibrio Cholerae

13 Vibrio Cholerae

Vibrio cholerae is a Gram-negative, comma-shaped bacterium. The bacterium's natural habitat is brackish or saltwater and attach themselves easily to the chitin-containing shells of crabs, shrimps, and other shellfish. Some strains of V. cholerae cause the disease cholera, which can be derived from the consumption of undercooked or raw marine life species. V. cholerae is a facultative anaerobe and has a flagellum at one cell pole as well as pili. V. cholerae can undergo respiratory and fermentative metabolism. When ingested, V. cholerae can cause diarrhea and vomiting in a host within several hours to 2–3 days of ingestion. V. cholerae was first isolated as the cause of cholera by Italian anatomist Filippo Pacini in 1854, but his discovery was not widely known until Robert Koch, working independently 30 years later, publicized the knowledge and the means of fighting the disease.

Sources

Can enter wounds from contaminated water. Also acquired by drinking contaminated water or eating undercooked oysters.

Symptoms

Symptoms include abdominal tenderness, agitation, bloody stools, chills, confusion, difficulty paying attention (attention deficit), delirium, fluctuating mood, hallucination, nosebleeds, severe fatigue, slow, sluggish, lethargic feeling, weakness.

ILLNESS Bacterial Vibrio Cholerae

Prevention

When visiting areas with epidemic cholera, the following precautions should be observed: drink and use bottled water; frequently wash hands with soap and safe water; use chemical toilets or bury feces if no restroom is available; do not defecate in any body of water and cook food thoroughly. Supplying proper, safe water is important. A precaution to take is to properly sanitize. Hand hygiene is an essential in areas where soap and water is not available. When there is no sanitation available for hand washing, scrub hands with ash or sand and rinse with clean water. A single dose vaccine is available for those traveling to an area where cholera is common.

Treatment

The basic, overall treatment for Cholera is re-hydration, to replace the fluids that have been lost. Those with mild dehydration can be treated orally with an oral re hydration solution also known as, (ORS). When patients are severely dehydrated and unable to take in the proper amount of ORS, IV fluid treatment is generally pursued. Antibiotics are used in some cases, typically fluoroquinolones and tetracyclines.

ILLNESS Bacterial Clostridium Perfringens

14 Clostridium Perfringens

Clostridium perfringens (formerly known as C. welchii, or Bacillus welchii) is a Gram-positive, rod-shaped, anaerobic, spore-forming pathogenic bacterium of the genus Clostridium. C. perfringens is ever-present in nature and can be found as a normal component of decaying vegetation, marine sediment, the intestinal tract of humans and other vertebrates, insects, and soil. It has the shortest reported generation time of any organism at 6.3 minutes in thioglycolate medium. C. perfringens is one of the most common causes of food poisoning in the United States, alongside norovirus, Salmonella, Campylobacter, and Staphylococcus aureus. However, it can sometimes be ingested and cause no harm.

Infections due to C. perfringens show evidence of tissue necrosis, bacteremia, emphysematous cholecystitis, and gas gangrene, also known as clostridial myonecrosis. The specific name perfringens is derived from the Latin per (meaning through) and frango (burst), referring to the disruption of tissue that occurs during gas gangrene. The toxin involved in gas gangrene is α-toxin, which inserts into the plasma membrane of cells, producing gaps in the membrane that disrupt normal cellular function. C. perfringens can participate in polymicrobial anaerobic infections. It is commonly encountered in infections as a component of the normal flora. In this case, its role in disease is minor.

ILLNESS Bacterial Clostridium Perfringens

Sources

Beef, poultry, gravies, and dried or pre-cooked foods are common sources of C. perfringens infections. C. perfringens infection often occurs when foods are prepared in large quantities and kept warm for a long time before serving.

Symptoms

People infected with C. perfringens develop diarrhea and abdominal cramps within 6 to 24 hours (typically 8 to 12 hours). The illness usually begins suddenly and lasts for less than 24 hours. People infected with C. perfringens usually do not have fever or vomiting. The illness is not passed from one person to another.

Prevention

To prevent infection by Clostridium perfringens, follow the these tips: Cook foods containing meat thoroughly. If keeping foods out, make sure they maintain a temperature of 140 F (60 C). When storing food in the refrigerator, divide it into pieces with a thickness of three inches or less so that it cools faster. Reheat foods to at least 165°F (74°C).

Treatment

Recovery usually occurs within 24 hours. Keep well hydrated. The most important aspect of treatment is prompt and extensive surgical debridement of the involved area and excision of all devitalized tissue, in which the organisms are prone to grow. Administration of antimicrobial drugs, particularly penicillin, is begun at the same time. Hyperbaric oxygen may be of help in the medical management of clostridial tissue infections. It is said to "detoxify" patients rapidly.

ILLNESS Bacterial Escherichia Coli

15 Escherichia Coli

Escherichia coli, also known as E. coli, is a Gram-negative, facultative anaerobic, rod-shaped, coliform bacterium of the genus Escherichia that is commonly found in the lower intestine of warm-blooded organisms (endotherms). Most E. coli strains are harmless, but some serotypes can cause serious food poisoning in their hosts, and are occasionally responsible for product recalls due to food contamination. The harmless strains are part of the normal microbiota of the gut, and can benefit their hosts by producing vitamin K2, (which helps blood to clot when you have a cut to form a scab) and preventing colonisation of the intestine with pathogenic bacteria, having a symbiotic relationship. E. coli is expelled into the environment within fecal matter. The bacterium grows massively in fresh fecal matter under aerobic conditions for 3 days, but its numbers decline slowly afterwards.

Sources

E. coli O157:H7 is most commonly found in cows, although chickens, deer, sheep, and pigs have also been known to carry it. Meat becomes contaminated during slaughter, when infected animal intestines or feces come in contact with the carcass. Other foods that sometimes become contaminated with E. coli bacteria include unpasteurized milk and cheese, unpasteurized juices, alfalfa and radish sprouts, lettuce, spinach, and water.

Symptoms

E. coli symptoms change as the infection progresses. Symptoms usually begin two to five days after infection. The initial symptoms include the sudden onset of cramps and abdominal pain, followed by diarrhea within 24 hours. Diarrhea will become increasingly watery, and then noticeably bloody. People with E. coli infection also often feel nauseated and experience headaches. Less common symptoms include fever and chills.

Prevention

Proven prevention methods for E. coli transmission include handwashing and improved sanitation and drinking water, as transmission occurs through fecal contamination of food and water supplies. Additionally, thoroughly cooking meat and avoiding consumption of raw, unpasteurized beverages, such as juices and milk are other proven methods for preventing E.coli. Lastly, avoid cross-contamination of utensils and work spaces when preparing food.

ILLNESS Bacterial Escherichia Coli Treatment

Treatment

Illness from E. coli usually goes away within a week and does not cause any long-term problems. One should make sure to remain hydrated and get proper nutrition while sick. Antibiotics are not used as E. coli treatment, as they do not improve the illness, and some studies show that they can increase the risk of HUS.

Although the rate of resistance to commonly used antibiotics is increasing and they are generally not recommended. The antibiotic used depends upon susceptibility patterns in the particular geographical region. Currently, the antibiotics of choice are fluoroquinolones or azithromycin, with an emerging role for rifaximin. Oral rifaximin, a semisynthetic rifamycin derivative, is an effective and well-tolerated antibacterial for the management of adults with non-invasive traveller's diarrhea. Rifaximin was significantly more effective than placebo and no less effective than ciprofloxacin in reducing the duration of diarrhea. While rifaximin is effective in patients with E. coli-predominant traveller's diarrhea, it appears ineffective in patients infected with inflammatory or invasive enteropathogens.

ILLNESS Bacterial Shigella

16 Shigella

Shigella is a genus of bacteria that is Gram-negative, facultative anaerobic, non-spore-forming, nonmotile, rod-shaped and genetically closely related to E. coli. The genus is named after Kiyoshi Shiga, who first discovered it in 1897. The causative agent of human shigellosis, Shigella causes disease in primates, but not in other mammals. It is only naturally found in humans and gorillas. During infection, it typically causes dysentery.

Shigella is one of the leading bacterial causes of diarrhea worldwide, causing an estimated 80–165 million cases. The number of deaths it causes each year is estimated at between 74,000 and 600,000. It is one of the top four pathogens that cause moderate-to-severe diarrhea in African and South Asian children.

Sources

Shigella bacteria are generally transmitted through a fecal-oral route. Foods that come into contact with human or animal waste can transmit Shigella. Thus, handling toddlers' diapers, eating vegetables from a field contaminated with sewage, or drinking pool water are all activities that can lead to shigellosis.

Symptoms

ILLNESS Bacterial Shigella

Symptoms of Shigella poisoning most commonly develop one to three days after exposure to Shigella bacteria, and usually go away within five to seven days. It is also possible to get Shigella but experience no symptoms, and still be contagious to others, a condition known as being asymptomatic.

- Diarrhea: Diarrhea ranges from mild to severe. It is bloody in 25 to 50 percent of cases and usually contains mucus
- Fever
- Stomach cramps
- Rectal spasms

Prevention

Steps for Preventing the Spread of Shigella Infection:
- If a child in diapers has shigellosis, wash your hands after changing their diaper and wipe down the changing area with disinfectant.
- People with Shigella should not prepare food for others for at least two days after diarrhea has stopped.
- Drink only treated or boiled water while traveling and only eat fruits you peel yourself.
- Only swim in pools maintaining a chlorine level of 0.5 parts per million and stay clear of pools where children not yet toilet trained are swimming.

Treatment

A Shigella infection usually goes away on its own in five to seven days, although bowel movements may continue to be abnormal for up to a month following infection. Antibiotics, however, can shorten the course of the illness. A doctor can prescribe antibiotics after testing a stool sample for the presence of Shigella bacteria. Some strains of shigellosis are resistant to antibiotics, meaning that antibiotics might not always be an effective treatment. Antidiarrheal medication should be avoided, as it can actually make the illness worse.

17 Staphylococcus Aureus

ILLNESS Bacterial Staphylococcus Aureus

Staphylococcus aureus is a Gram-positive, round-shaped bacterium that is a member of the Firmicutes, and it is a usual member of the microbiota of the body, frequently found in the upper respiratory tract and on the skin. It is often positive for catalase and nitrate reduction and is a facultative anaerobe that can grow without the need for oxygen. Although S. aureus usually acts as a commensal of the human microbiota it can also become an opportunistic pathogen, being a common cause of skin infections including abscesses, respiratory infections such as sinusitis, and food poisoning. Pathogenic strains often promote infections by producing virulence factors such as potent protein toxins, and the expression of a cell-surface protein that binds and inactivates antibodies. The emergence of antibiotic-resistant strains of S. aureus such as methicillin-resistant S. aureus (MRSA) is a worldwide problem in clinical medicine. Despite much research and development, no vaccine for S. aureus has been approved.

Sources

S. aureus is also responsible for food poisoning. It is capable of generating toxins that produce food poisoning in the human body.

Symptoms

Prevention

Preventive measures one can take to help prevent the spread of the disease include washing hands thoroughly with soap and water before preparing food. Stay away from any food if ill, and wear gloves if any open wounds occur on hands or wrists while preparing food. If storing food for longer than 2 hours, keep the food below 5 or above 63 °C.

Treatment

ILLNESS Bacterial Staphylococcus Aureus Treatment

The treatment of choice for S. aureus infection is penicillin. An antibiotic derived from some Penicillium fungal species, penicillin inhibits the formation of peptidoglycan cross-linkages that provide the rigidity and strength in a bacterial cell wall. The four-membered β-lactam ring of penicillin is bound to enzyme DD-transpeptidase, an enzyme that when functional, cross-links chains of peptidoglycan that form bacterial cell walls. The binding of β-lactam to DD-transpeptidase inhibits the enzyme's functionality and it can no longer catalyze the formation of the cross-links. As a result, cell wall formation and degradation are imbalanced, thus resulting in cell death.

In most countries, however, penicillin resistance is extremely common, and first-line therapy is most commonly a penicillinase-resistant β-lactam antibiotic (for example, oxacillin or flucloxacillin, both of which have the same mechanism of action as penicillin). Combination therapy with gentamicin may be used to treat serious infections, such as endocarditis, but its use is controversial because of the high risk of damage to the kidneys. The duration of treatment depends on the site of infection and on severity. Adjunctive rifampicin has been historically used in the management of S aureus bacteraemia, but randomised controlled trial evidence has shown this to be of no overall benefit over standard antibiotic therapy.

18 Staphylococcal Enteritis

ILLNESS Bacterial Staphylococcal Enteritis

Staphylococcal enteritis is an inflammation that is usually caused by eating or drinking substances contaminated with staph enterotoxin. The toxin, not the bacterium, settles in the small intestine and causes inflammation and swelling. This in turn can cause abdominal pain, cramping, dehydration, diarrhea and fever.

Staphylococcus aureus is a Gram-positive, facultative anaerobe, coccal (round shaped) bacteria that appears in grape-like clusters that can thrive in high salt and low water activity habitats. S. aureus bacteria can live on the skin which is one of the primary modes of transmission. S. aureus can cause a range of illnesses from minor skin infections to Staphylococcus aureus food poisoning enteritis. Since humans are the primary source, cross-contamination is the most common way the microorganism is introduced into foods. Foods at high risks are those prepared in large quantities. Staphylococcus aureus is a true food poisoning organism. It produces a heat stable enterotoxin when allowed to grow for several hours in foods such as cream-filled baked goods, poultry meat, gravies, eggs, meat salads, puddings and vegetables. It is important to note that the toxins may be present in dangerous amounts in foods that have no signs of spoilage, such as a bad smell, any off color, odor, or textural or flavor change.

Sources

Symptoms

ILLNESS Bacterial

Common symptoms of Staphylococcus aureus food poisoning include: a rapid onset which is usually 1–6 hours, nausea, explosive vomiting for up to 24 hours, abdominal cramps/pain, headache, weakness, diarrhea and usually a subnormal body temperature. Symptoms usually start one to six hours after eating and last less than 12 hours. The duration of some cases may take two or more days to fully resolve.

ILLNESS Bacterial Staphylococcal Enteritis

Prevention

Staphylococcal enteritis may be avoided by using proper hygiene and sanitation with food preparation. This includes thoroughly cooking all meats. If food is to be stored longer than two hours, keep hot foods hot (over 140 °F) and cold foods cold (40 °F or under). Ensure to refrigerate leftovers promptly and store cooked food in a wide, shallow container and refrigerate as soon as possible. Sanitation is very important. Keep kitchens and food-serving areas clean and sanitized. Finally, as most staphylococcal food poisoning are the result of food handling, hand washing is critical. Food handlers should use hand sanitizers with alcohol or thorough hand washing with soap and water.

Treatment

Treatment is supportive and based upon symptoms, with fluid and electrolyte replacement as the primary goal. Dehydration caused by diarrhea and vomiting is the most common complication. To prevent dehydration, it is important to take frequent sips of a rehydration drink (like water) or try to drink a cup of water or rehydration drink for each large, loose stool.

Dietary management of enteritis consists of starting with a clear liquid diet until vomiting and diarrhea end and then slowly introduce solid foods. It is also important to avoid foods that are high in fiber or are possibly difficult to digest.

19 MRSA

Methicillin-resistant Staphylococcus aureus (MRSA) refers to a group of Gram-positive bacteria that are genetically distinct from other strains of Staphylococcus aureus. MRSA is responsible for several difficult-to-treat infections in humans. MRSA is any strain of S. aureus that has developed, through horizontal gene transfer and natural selection, multiple drug resistance to beta-lactam antibiotics. β-lactam antibiotics are a broad-spectrum group that include some penams (penicillin derivatives such as methicillin and oxacillin) and cephems such as the cephalosporins. Strains unable to resist these antibiotics are classified as methicillin-susceptible S. aureus, or MSSA.

MRSA is common in hospitals, prisons, and nursing homes, where people with open wounds, invasive devices such as catheters, and weakened immune systems are at greater risk of hospital-acquired infection. MRSA began as a hospital-acquired infection, but has become community-acquired, as well as livestock-acquired. The terms HA-MRSA (healthcare-associated or hospital-acquired MRSA), CA-MRSA (community-associated MRSA), and LA-MRSA (livestock-associated MRSA) reflect this.

Sources

While MRSA bacteria are usually carried on the human skin and in the nose, recent studies have shown that livestock also carry MRSA, and that it can be transmitted from these animals to farmers and veterinarians, who can then pass it on to other humans. MRSA bacteria have also been shown to be present in retail foods, including pork, beef, and dairy products, although MRSA outbreaks from food contamination are rare.

Symptoms

MRSA infections usually appear as skin or soft tissue infections, such as boils or abscesses. Some people report them looking like a spider bite: red and swollen. However, MRSA skin infections are also painful and can pus or drain. Symptoms of a MRSA infection from food generally resemble other food poisoning symptoms, including nausea, vomiting, and stomach cramps.

Prevention

The Centers for Disease Control and Prevention offers suggestions for preventing the contraction and spread of MRSA infection which are applicable to those in community settings, including incarcerated populations, childcare center employees, and athletes. To prevent the spread of MRSA, the recommendations are to wash hands thoroughly and regularly using soap and water or an alcohol-based sanitizer. Additional recommendations are to keep wounds clean and covered, avoid contact with other people's wounds, avoid sharing personal items such as razors or towels, shower after exercising at athletic facilities, and shower before using swimming pools or whirlpools.

Glycopeptides, cephalosporins, and in particular, quinolones are associated with an increased risk of colonisation of MRSA. Reducing use of antibiotic classes that promote MRSA colonisation, especially fluoroquinolones, is recommended in current guidelines.

Mathematical models describe one way in which a loss of infection control can occur after measures for screening and isolation seem to be effective for years, as happened in the UK. In the "search and destroy" strategy that was employed by all UK hospitals until the mid-1990s, all hospitalized people with MRSA were immediately isolated, and all staff were screened for MRSA and were prevented from working until they had completed a course of eradication therapy that was proven to work.

Loss of control occurs because colonised people are discharged back into the community and then readmitted; when the number of colonised people in the community reaches a certain threshold, the "search and destroy" strategy is overwhelmed. One of the few countries not to have been overwhelmed by MRSA is the Netherlands: an important part of the success of the Dutch strategy may have been to attempt eradication of carriage upon discharge from hospital.

Maintaining the necessary cleanliness may be difficult for people if they do not have access to facilities such as public toilets with handwashing facilities. In the United Kingdom, the Workplace (Health, Safety and Welfare) Regulations 1992 require businesses to provide toilets for their employees, along with washing facilities including soap or other suitable means of cleaning.

Guidance on how many toilets to provide and what sort of washing facilities should be provided alongside them is given in the Workplace (Health, Safety and Welfare) Approved Code of Practice and Guidance L24, available from Health and Safety Executive Books, but no legal obligations exist on local authorities in the United Kingdom to provide public toilets, and although in 2008, the House of Commons Communities and Local Government Committee called for a duty on local authorities to develop a public toilet strategy, this was rejected by the Government.

Treatment

Staph infections on the skin can be treated by being drained. A laboratory test may also determine that a specific antibiotic can be used to treat a case of MRSA.

ILLNESS Bacterial MRSA Treatment

Antibiotics
Treatment of MRSA infection is urgent and delays can be fatal. The location and history related to the infection determines the treatment. The route of administration of an antibiotic varies. Antibiotics effective against MRSA can be given by IV, oral, or a combination of both, and depend on the specific circumstances and patient characteristics. The use of concurrent treatment with vancomycin or other beta-lactam agents may have a synergistic effect.

Both CA-MRSA and HA-MRSA are resistant to traditional anti-staphylococcal beta-lactam antibiotics, such as cephalexin. CA-MRSA has a greater spectrum of antimicrobial susceptibility to sulfa drugs (like co-trimoxazole (trimethoprim/sulfamethoxazole), tetracyclines (like doxycycline and minocycline) and clindamycin (for osteomyelitis). MRSA can be eradicated with a regimen of linezolid, though treatment protocols vary and serum levels of antibiotics vary widely from person to person and may affect outcomes. The effective treatment of MRSA with linezolid has been successful in 87% of people. Linezolid is more effective in soft tissue infections than vancomycin. This is compared to eradication of infection in those with MRSA treated with vancomycin.

Treatment with vancomycin is successful in approximately 49% of people. Linezolid belongs to the newer oxazolidinone class of antibiotics which has been shown to be effective against both CA-MRSA and HA-MRSA. The Infectious Disease Society of America recommends vancomycin, linezolid, or clindamycin (if susceptible) for treating those with MRSA pneumonia. Ceftaroline, a fifth-generation cephalosporin, is the first beta-lactam antibiotic approved in the US to treat MRSA infections in skin and soft tissue or community-acquired pneumonia.

Vancomycin and teicoplanin are glycopeptide antibiotics used to treat MRSA infections. Teicoplanin is a structural congener of vancomycin that has a similar activity spectrum but a longer half-life. Because the oral absorption of vancomycin and teicoplanin is very low, these agents can be administered intravenously to control systemic infections. Treatment of MRSA infection with vancomycin can be complicated, due to its inconvenient route of administration. Moreover, the efficacy of vancomycin against MRSA is inferior to that of anti-staphylococcal beta-lactam antibiotics against methicillin-susceptible S. aureus (MSSA).

Skin and soft-tissue infections
In skin abscesses, the primary treatment recommended is removal of dead tissue, incision, and drainage. More information is needed to determine the effectiveness of specific antibiotics therapy in surgical site infections (SSIs). Examples of soft-tissue infections from MRSA include ulcers, impetigo, abscesses, and SSIs. In surgical wounds, evidence is weak (high risk of bias) that linezolid may be better than vancomycin to eradicate MRSA SSIs.

MRSA colonization is also found in nonsurgical wounds such as traumatic wounds, burns, and chronic ulcers (i.e.: diabetic ulcer, pressure ulcer, arterial insufficiency ulcer, venous ulcer). No conclusive evidence has been found about the best antibiotic regimen to treat MRSA colonization.

20 Strep Throat

Streptococcal pharyngitis, also known as strep throat, is an infection of the back of the throat including the tonsils caused by group A streptococcus (GAS). Common symptoms include fever, sore throat, red tonsils, and enlarged lymph nodes in the neck. A headache, and nausea or vomiting may also occur. Some develop a sandpaper-like rash which is known as scarlet fever. Symptoms typically begin one to three days after exposure and last seven to ten days.

Strep throat is spread by respiratory droplets from an infected person. It may be spread directly or by touching something that has droplets on it and then touching the mouth, nose, or eyes. Some people may carry the bacteria without symptoms. It may also be spread by skin infected with group A strep. The diagnosis is made based on the results of a rapid antigen detection test or throat culture in those who have symptoms.

Prevention is by washing hands and not sharing eating utensils. There is no vaccine for the disease. Treatment with antibiotics is only recommended in those with a confirmed diagnosis. Those infected should stay away from other people until fever is gone and for at least 12 hours after starting treatment. Pain can be treated with paracetamol (acetaminophen) and nonsteroidal anti-inflammatory drugs (NSAIDS) such as ibuprofen.

Strep throat is a common bacterial infection in children. It is the cause of 15–40% of sore throats among children and 5–15% among adults. Cases are more common in late winter and early spring. Potential complications include rheumatic fever and peritonsillar abscess.

Sources

It is spread by direct, close contact with an infected person; thus crowding, as may be found in the military and schools, increases the rate of transmission. Dried bacteria in dust are not infectious, although moist bacteria on toothbrushes or similar items can persist for up to fifteen days. Contaminated food can result in outbreaks, but this is rare. Of children with no signs or symptoms, 12% carry GAS in their pharynx, and, after treatment, approximately 15% of those remain positive, and are true "carriers".

Signs & Symptoms

The typical signs and symptoms of streptococcal pharyngitis are a sore throat, fever of greater than 38 °C (100 °F), tonsillar exudates (pus on the tonsils), and large cervical lymph nodes. Other symptoms include: headache, nausea and vomiting, abdominal pain, muscle pain, or a scarlatiniform rash or palatal petechiae, the latter being an uncommon but highly specific finding.

Symptoms typically begin one to three days after exposure and last seven to ten days. Strep throat is unlikely when any of the symptoms of red eyes, hoarseness, runny nose, or mouth ulcers are present. It is also unlikely when there is no fever.

Diagnosis

A number of scoring systems exist to help with diagnosis; however, their use is controversial due to insufficient accuracy. The modified Centor criteria are a set of five criteria; the total score indicates the probability of a streptococcal infection.

One point is given for each of the criteria:
- Absence of a cough
- Swollen and tender cervical lymph nodes
- Temperature >38.0 °C (100.4 °F)
- Tonsillar exudate or swelling
- Age less than 15 (a point is subtracted if age >44)

A score of one may indicate no treatment or culture is needed or it may indicate the need to perform further testing if other high risk factors exist, such as a family member having the disease.

Prevention

Tonsillectomy may be a reasonable preventive measure in those with frequent throat infections (more than three a year). However, the benefits are small and episodes typically lessen in time regardless of measures taken. Recurrent episodes of pharyngitis which test positive for GAS may also represent a person who is a chronic carrier of GAS who is getting recurrent viral infections. Treating people who have been exposed but who are without symptoms is not recommended. Treating people who are carriers of GAS is not recommended as the risk of spread and complications is low.

ILLNESS Bacterial Strep Throat Treatment

Treatment

Untreated streptococcal pharyngitis usually resolves within a few days. Treatment with antibiotics shortens the duration of the acute illness by about 16 hours. The primary reason for treatment with antibiotics is to reduce the risk of complications such as rheumatic fever and retropharyngeal abscesses. Antibiotics prevent acute rheumatic fever if given within 9 days of the onset of symptoms.

Pain Medication
Pain medication such as NSAIDs and paracetamol (acetaminophen) helps in the management of pain associated with strep throat. Viscous lidocaine may also be useful. While steroids may help with the pain, they are not routinely recommended. Aspirin may be used in adults but is not recommended in children due to the risk of Reye syndrome.

Antibiotics
The antibiotic of choice in the United States for streptococcal pharyngitis is penicillin V, due to safety, cost, and effectiveness. Amoxicillin is preferred in Europe. In India, where the risk of rheumatic fever is higher, intramuscular benzathine penicillin G is the first choice for treatment.

Appropriate antibiotics decrease the average 3–5 day duration of symptoms by about one day, and also reduce contagiousness. They are primarily prescribed to reduce rare complications such as rheumatic fever and peritonsillar abscess. The arguments in favor of antibiotic treatment should be balanced by the consideration of possible side effects, and it is reasonable to suggest that no antimicrobial treatment be given to healthy adults who have adverse reactions to medication or those at low risk of complications. Antibiotics are prescribed for strep throat at a higher rate than would be expected from how common it is.

Erythromycin and other macrolides or clindamycin are recommended for people with severe penicillin allergies. First-generation cephalosporins may be used in those with less severe allergies and some evidence supports cephalosporins as superior to penicillin. These late-generation antibiotics show a similar effect when prescribed for 3–7 days in comparison to the standard 10-days of penicillin when used in areas of low rheumatic heart disease. Streptococcal infections may also lead to acute glomerulonephritis; however, the incidence of this side effect is not reduced by the use of antibiotics.

Prognosis

The symptoms of strep throat usually improve within three to five days, irrespective of treatment. Treatment with antibiotics reduces the risk of complications and transmission; children may return to school 24 hours after antibiotics are administered. The risk of complications in adults is low. In children, acute rheumatic fever is rare in most of the developed world. It is, however, the leading cause of acquired heart disease in India, sub-Saharan Africa, and some parts of Australia.

● Acute Fheumatic Fever ● Scarlet Fever ● Streptococcal Toxic Shock Syndrome	● PANDAS Syndrome ● Peritonsillar Abscess ● Cervical Lymphadenitis	● Glomerulonephritis ● Mastoiditis

21 Vibrio Parahaemolyticus

Vibrio parahaemolyticus is a curved, rod-shaped, Gram-negative bacterium found in brackish, saltwater, which, when ingested, causes gastrointestinal illness in humans. V. parahaemolyticus is oxidase positive, facultatively aerobic, and does not form spores. Like other members of the genus Vibrio, this species is motile, with a single, polar flagellum.

Sources

Vibrio parahaemolyticus infection can be acquired by eating raw or undercooked shellfish or drinking contaminated water. Eating raw oysters is the most common way the infection is spread as the organism naturally lives in the warm tidal waters where oysters grow.

Symptoms

Vibrio parahaemolyticus infection causes symptoms of gastro including: Watery diarrhoea (occasionally bloody diarrhoea), Abdominal cramps, Nausea, Vomiting, Fever, Headache. Usually symptoms are mild to moderate in severity and lasts around 3 days (range from 8 hours to 12 days). However, the infection can be severe in people with immunosuppression, such as people receiving cancer treatment.

Prevention

Treatment

Antibiotic treatment is not usually needed for V. parahaemolytiticus gastro, however, in cases with prolonged diarrhoea, antibiotic therapy may be needed. The following are general recommendations for the treatment of gastro: Give plenty of fluids. Oral rehydration solution is highly recommended for children and adults with mild to moderate dehydration. It is available at pharmacies and should be administered following the instructions on the packaging.

22 Vibrio Vulnificus

Vibrio vulnificus is a species of Gram-negative, motile, curved rod-shaped (bacillus), pathogenic bacteria of the genus Vibrio. Present in marine environments such as estuaries, brackish ponds, or coastal areas, V. vulnificus is related to V. cholerae, the causative agent of cholera.

Sources

Symptoms

V. vulnificus is an extremely virulent bacterium that can cause three types of infections:
● Acute gastroenteritis from eating raw or undercooked shellfish: V. vulnificus causes an infection often incurred after eating seafood, especially raw or undercooked oysters. It does not alter the appearance, taste, or odor of oysters. Symptoms include vomiting, diarrhea, and abdominal pain.
● Necrotizing wound infections can occur in injured skin exposed to contaminated marine water. V. vulnificus bacteria can enter the body through open wounds when swimming or wading in infected waters, or by puncture wounds from the spines of fishes such as stingrays. People may develop a blistering dermatitis sometimes mistaken for pemphigus or pemphigoid.
● Invasive sepsis can occur after eating raw or undercooked shellfish, especially oysters. V. vulnificus is 80 times more likely to spread into the bloodstream in people with compromised immune systems, especially those with chronic liver disease. When this happens, severe symptoms including blistering skin lesions and septic shock can sometimes lead to death. This severe infection may occur regardless of whether the infection began from contaminated food or an open wound.

ILLNESS Bacterial Vibrio Vulnificus

Among healthy people, ingestion of V. vulnificus can cause vomiting, diarrhea, and abdominal pain. In someone with a compromised immune system, particularly those with chronic liver disease, it can infect the bloodstream, causing a severe and life-threatening illness characterized by fever and chills, decreased blood pressure (septic shock), and blistering skin lesions. While men have been shown to be more at risk from this infection than women, co-morbidities such as alcoholic cirrhosis and diseases affecting the endocrine system (diabetes, rheumatoid arthritis, etc.) put a person far more at risk to develop infection from V. vulnificus.

Prevention

Treatment

V. vulnificus wound infections have a mortality rate around 25%. In people in whom the infection worsens into sepsis, typically following ingestion, the mortality rate rises to 50%. The majority of these people die within the first 48 hours of infection. The optimal treatment is not known, but in one retrospective study of 93 people in Taiwan, use of a third-generation cephalosporin and a tetracycline (e.g., ceftriaxone and doxycycline, respectively) was associated with an improved outcome. Prospective clinical trials are needed to confirm this finding, but in vitro data support the supposition that this combination is synergistic against V. vulnificus. Likewise, the American Medical Association and the Centers for Disease Control and Prevention (CDC) recommend treating the person with a quinolone or intravenous doxycycline with ceftazidime. The first successful documented treatment of fulminant V. vulnificus sepsis was in 1995. Treatment was ceftazidime and intravenous (IV) ciprofloxacin and IV doxycycline, which proved successful. Prevention of secondary infections from respiratory failure and acute renal failure is crucial. Key to the diagnosis and treatment were the early recognition of bullae in an immunocompromised person with liver cirrhosis and oyster ingestion within the previous 48 hours, and the request by the physician for STAT Gram staining and blood cultures for V. vulnificus. V. vulnificus often causes large, disfiguring ulcers that require extensive debridement or even amputation.

23 Listeria (Listeriosis)

Listeriosis is a bacterial infection most commonly caused by Listeria monocytogenes, although L. ivanovii and L. grayi have been reported in certain cases. Listeriosis can cause severe illness, including severe sepsis, meningitis, or encephalitis, sometimes resulting in lifelong harm and even death. Those at risk of severe illness are the elderly, unborn babies, newborns and those who are immunocompromised. In pregnant women it may cause stillbirth or spontaneous abortion, and preterm birth is common. Listeriosis may cause mild, self-limiting gastroenteritis and fever in anyone.

Listeria is ubiquitous and is primarily transmitted via the oral route after ingestion of contaminated food products, after which the bacteria penetrates the intestinal tract to cause systemic infections. The diagnosis of listeriosis requires the isolation of the causative bacteria from the blood and/or the cerebrospinal fluid. Treatment includes prolonged administration of antibiotics, primarily ampicillin and gentamicin, to which the organism is usually susceptible.

Listeria is unlike many other germs because it can grow even in the cold temperature of the refrigerator. Listeria is killed by cooking and pasteurization.

Sources

Listeria monocytogenes is ubiquitous in the environment. Listeria is found in soil and water and some animals, including poultry and cattle. It can be present in raw milk and foods made from raw milk. It can also live in food processing plants and contaminate a variety of processed meats. Ready-to-eat deli meats and hot dogs, Refrigerated pâtés or meat spreads, Unpasteurized (raw) milk and dairy products, Soft cheese made with unpasteurized milk, such as queso fresco, Feta, Brie, Camembert, Refrigerated smoked seafood and Raw sprouts.

Symptoms

The disease primarily affects older adults, persons with weakened immune systems, pregnant women, and newborns. Rarely, people without these risk factors can also be affected. A person with listeriosis usually has fever and muscle aches, often preceded by diarrhea or other gastrointestinal symptoms. Almost everyone who is diagnosed with listeriosis has invasive infection (meaning that the bacteria spread from their intestines to their bloodstream or other body sites). Disease may occur as much as two months after eating contaminated food.

The symptoms vary with the infected person:
● High-risk people other than pregnant women: Symptoms can include fever, muscle aches, headache, stiff neck, confusion, loss of balance, and convulsions.
● Pregnant women: Pregnant women typically experience only a mild, flu-like illness. However, infections during pregnancy can lead to miscarriage, stillbirth, premature delivery, or life-threatening infection of the newborn.
● Previously healthy people: People who were previously healthy but were exposed to a very large dose of Listeria can develop a non-invasive illness (meaning that the bacteria have not spread into their blood stream or other body sites). Symptoms can include diarrhea and fever.

If an animal has eaten food contaminated with Listeria and does not have any symptoms, most experts believe that no tests or treatment are needed, even for people at high risk for listeriosis.

Prevention

The main means of prevention is through the promotion of safe handling, cooking and consumption of food. This includes washing raw vegetables and cooking raw food thoroughly, as well as reheating leftover or ready-to-eat foods like hot dogs until steaming hot.

Another aspect of prevention is advising high-risk groups such as pregnant women and immunocompromised patients to avoid unpasteurized pâtés and foods such as soft cheeses like feta, Brie, Camembert cheese, and bleu. Cream cheeses, yogurt, and cottage cheese are considered safe. In the United Kingdom, advice along these lines from the Chief Medical Officer posted in maternity clinics led to a sharp decline in cases of listeriosis in pregnancy in the late 1980s.

Treatment

Bacteremia should be treated for 2 weeks, meningitis for 3 weeks, and brain abscess for at least 6 weeks. Ampicillin generally is considered antibiotic of choice; gentamicin is added frequently for its synergistic effects. Overall mortality rate is 20–30%; of all pregnancy-related cases, 22% resulted in fetal loss or neonatal death, but mothers usually survive. Try activated charcoal, syrup of ipecac, garlic, and/or alcohol-free goldenseal to treat food poisoning in general.

24 Bacillus Cereus

Bacillus cereus is a Gram-positive, rod-shaped, facultatively anaerobic, motile, beta-hemolytic, spore forming bacterium commonly found in soil and food. The specific name, cereus, meaning "waxy" in Latin, refers to the appearance of colonies grown on blood agar. Some strains are harmful to humans and cause foodborne illness, while other strains can be beneficial as probiotics for animals. The bacteria is classically contracted from fried rice dishes that have been sitting at room temperature for hours. B. cereus bacteria are facultative anaerobes, and like other members of the genus Bacillus, can produce protective endospores. Its virulence factors include cereolysin and phospholipase C.

Sources

A variety of foods, particularly rice and leftovers, as well as sauces, soups, and other prepared foods that have sat out too long at room temperature. B. cereus is responsible for a minority of foodborne illnesses (2–5%), causing severe nausea, vomiting, and diarrhea.

Symptoms

- Diarrheal: Watery diarrhea and abdominal cramps
- Emetic (vomiting): Nausea and vomiting

Prevention

Bacillus foodborne illnesses occur due to survival of the bacterial endospores when infected food is not, or inadequately, cooked. Cooking temperatures less than or equal to 100°C (212°F) allow some B. cereus spores to survive. This problem is compounded when food is then improperly refrigerated, allowing the endospores to germinate. Cooked foods not meant for either immediate consumption or rapid cooling and refrigeration should be kept at temperatures below 10°C (50°F) or above 50°C (122°F). Germination and growth generally occur between 10°C and 50°C, though some strains can grow at low temperatures. Bacterial growth results in production of enterotoxins, one of which is highly resistant to heat and acids (pH levels between 2 and 11); ingestion leads to two types of illness: diarrheal and emetic (vomiting) syndrome.

Treatment

Drink plenty of fluids and get rest. If you cannot drink enough fluids to prevent dehydration, call your doctor.

25 Anthrax

Anthrax is an infection caused by the bacterium Bacillus anthracis. It can occur in four forms: skin, lungs, intestinal, and injection. Symptoms begin between one day and two months after the infection is contracted. The skin form presents with a small blister with surrounding swelling that often turns into a painless ulcer with a black center. The inhalation form presents with fever, chest pain, and shortness of breath. The intestinal form presents with diarrhea which may contain blood, abdominal pains, and nausea and vomiting. The injection form presents with fever and an abscess at the site of drug injection.

Anthrax is spread by contact with the bacterium's spores, which often appear in infectious animal products. Contact is by breathing, eating, or through an area of broken skin. It does not typically spread directly between people. Risk factors include people who work with animals or animal products, travelers, postal workers, and military personnel. Diagnosis can be confirmed based on finding antibodies or the toxin in the blood or by culture of a sample from the infected site.

Sources

Anthrax is spread by contact with the bacterium's spores, which often appear in infectious animal products. Contact is by breathing, eating, or through an area of broken skin. It does not typically spread directly between people. Risk factors include people who work with animals or animal products, travelers, postal workers, and military personnel. Diagnosis can be confirmed by finding antibodies or the toxin in the blood or by culture of a sample from the infected site.

Symptoms

Skin
Cutaneous anthrax, also known as hide-porter's disease, is when anthrax occurs on the skin. It is the most common form (>90% of anthrax cases). It is also the least dangerous form (low mortality with treatment, 20% mortality without). Cutaneous anthrax presents as a boil-like skin lesion that eventually forms an ulcer with a black center (eschar). The black eschar often shows up as a large, painless, necrotic ulcer (beginning as an irritating and itchy skin lesion or blister that is dark and usually concentrated as a black dot, somewhat resembling bread mold) at the site of infection. In general, cutaneous infections form within the site of spore penetration between two and five days after exposure. Unlike bruises or most other lesions, cutaneous anthrax infections normally do not cause pain. Nearby lymph nodes may become infected, reddened, swollen, and painful. A scab forms over the lesion soon, and falls off in a few weeks. Complete recovery may take longer. Cutaneous anthrax is typically caused when B. anthracis spores enter through cuts on the skin. This form is found most commonly when humans handle infected animals and/or animal products. Cutaneous anthrax is rarely fatal if treated, because the infection area is limited to the skin, preventing the lethal factor, edema factor, and protective antigen from entering and destroying a vital organ. Without treatment, about 20% of cutaneous skin infection cases progress to toxemia and death.

Lungs
Inhalation anthrax usually develops within a week after exposure, but may take up to 2 months. During the first few days of illness, most people have fever, chills, and fatigue. These symptoms may be accompanied by cough, shortness of breath, chest pain, and nausea or vomiting, making inhalation anthrax difficult to distinguish from influenza and community-acquired pneumonia. This is often described as the prodromal period.

Over the next day or so, shortness of breath, cough, and chest pain become more common, and complaints not involving the chest such as nausea, vomiting, altered mental status, sweats, and headache develop in one-third or more of people. Upper respiratory tract symptoms occur in only a quarter of people, and muscle pains are rare. Altered mental status or shortness of breath generally brings people to healthcare and marks the fulminant phase of illness. Before 2001, fatality rates for inhalation anthrax were 90%; since then, they have fallen to 45%.

It infects the lymph nodes in the chest first, rather than the lungs themselves, a condition called hemorrhagic mediastinitis, causing bloody fluid to accumulate in the chest cavity, therefore causing shortness of breath. The second (pneumonia) stage occurs when the infection spreads from the lymph nodes to the lungs. Symptoms of the second stage develop suddenly after hours or days of the first stage. Symptoms include high fever, extreme shortness of breath, shock, and rapid death within 48 hours in fatal cases.

Gastrointestinal
Gastrointestinal (GI) infection is most often caused by consuming anthrax-infected meat and is characterized by diarrhea, potentially with blood, abdominal pains, acute inflammation of the intestinal tract, and loss of appetite. Occasional vomiting of blood can occur. Lesions have been found in the intestines and in the mouth and throat. After the bacterium invades the gastrointestinal system, it spreads to the bloodstream and throughout the body, while continuing to make toxins. GI infections can be treated, but usually result in fatality rates of 25% to 60%, depending upon how soon treatment commences. This form of anthrax is the rarest.

Prevention

Precautions are taken to avoid contact with the skin and any fluids exuded through natural body openings of a deceased body that is suspected of harboring anthrax. The body should be put in strict quarantine. A blood sample is collected and sealed in a container and analyzed in an approved laboratory to ascertain if anthrax is the cause of death. The body should be sealed in an airtight body bag and incinerated to prevent transmission of anthrax spores. Microscopic visualization of the encapsulated bacilli, usually in very large numbers, in a blood smear stained with polychrome methylene blue (McFadyean stain) is fully diagnostic, though culture of the organism is still the gold standard for diagnosis. Full isolation of the body is important to prevent possible contamination of others.

Protective, impermeable clothing and equipment such as rubber gloves, rubber apron, and rubber boots with no perforations are used when handling the body. No skin, especially if it has any wounds or scratches, should be exposed. Disposable personal protective equipment is preferable, but if not available, decontamination can be achieved by autoclaving. Used disposable equipment is burned and/or buried after use. All contaminated bedding or clothing is isolated in double plastic bags and treated as biohazard waste. Respiratory equipment capable of filtering small particles, such the US National Institute for Occupational Safety and Health- and Mine Safety and Health Administration-approved high-efficiency respirator, is worn.

Antibiotics
Preventive antibiotics are recommended in those who have been exposed. Early detection of sources of anthrax infection can allow preventive measures to be taken. In response to the anthrax attacks of October 2001, the United States Postal Service (USPS) installed biodetection systems (BDSs) in their large-scale mail processing facilities. BDS response plans were formulated by the USPS in conjunction with local responders including fire, police, hospitals, and public health. Employees of these facilities have been educated about anthrax, response actions, and prophylactic medication. Because of the time delay inherent in getting final verification that anthrax has been used, prophylactic antibiotic treatment of possibly exposed personnel must be started as soon as possible.

Treatment

Anthrax cannot be spread directly from person to person, but a person's clothing and body may be contaminated with anthrax spores. Effective decontamination of people can be accomplished by a thorough wash-down with antimicrobial soap and water. Waste water is treated with bleach or another antimicrobial agent. Effective decontamination of articles can be accomplished by boiling them in water for 30 minutes or longer. Chlorine bleach is ineffective in destroying spores and vegetative cells on surfaces, though formaldehyde is effective. Burning clothing is very effective in destroying spores. After decontamination, there is no need to immunize, treat, or isolate contacts of persons ill with anthrax unless they were also exposed to the same source of infection.

Antibiotics
Early antibiotic treatment of anthrax is essential; delay significantly lessens chances for survival. Treatment for anthrax infection and other bacterial infections includes large doses of intravenous and oral antibiotics, such as fluoroquinolones (ciprofloxacin), doxycycline, erythromycin, vancomycin, or penicillin. FDA-approved agents include ciprofloxacin, doxycycline, and penicillin. In possible cases of pulmonary anthrax, early antibiotic prophylaxis treatment is crucial to prevent possible death. Many attempts have been made to develop new drugs against anthrax, but existing drugs are effective if treatment is started soon enough.

26 Brucellosis

Brucellosis is a highly contagious zoonosis caused by ingestion of unpasteurized milk or undercooked meat from infected animals, or close contact with their secretions. It is also known as undulant fever, Malta fever, and Mediterranean fever.

Brucella species are small, Gram-negative, nonmotile, nonspore-forming, rod-shaped (coccobacilli) bacteria. They function as facultative intracellular parasites, causing chronic disease, which usually persists for life. Four species infect humans: B. abortus, B. canis, B. melitensis, and B. suis. B. abortus is less virulent than B. melitensis and is primarily a disease of cattle. B. canis affects dogs. B. melitensis is the most virulent and invasive species; it usually infects goats and occasionally sheep. B. suis is of intermediate virulence and chiefly infects pigs. Symptoms include profuse sweating and joint and muscle pain. Brucellosis has been recognized in animals and humans since the 20th century.

Sources

Ingestion of unpasteurized milk or undercooked meat from infected animals, or close contact with their secretions.

Symptoms

The symptoms are like those associated with many other febrile diseases, but with emphasis on muscular pain and night sweats. The duration of the disease can vary from a few weeks to many months or even years. In the first stage of the disease, bacteremia occurs and leads to the classic triad of undulant fevers, sweating (often with characteristic foul, moldy smell sometimes likened to wet hay), and migratory arthralgia and myalgia (joint and muscle pain).

Blood tests characteristically reveal a low number of white blood cells and red blood cells, show some elevation of liver enzymes such as aspartate aminotransferase and alanine aminotransferase, and demonstrate positive Bengal rose and Huddleston reactions. Gastrointestinal symptoms occur in 70% of cases and include nausea, vomiting, decreased appetite, unintentional weight loss, abdominal pain, constipation, diarrhea, an enlarged liver, liver inflammation, liver abscess, and an enlarged spleen.

This complex is, at least in Portugal, Israel, Syria, and Jordan, known as Malta fever. During episodes of Malta fever, melitococcemia (presence of brucellae in the blood) can usually be demonstrated by means of blood culture in tryptose medium or Albini medium. If untreated, the disease can give origin to focalizations or become chronic.

The focalizations of brucellosis occur usually in bones and joints, and osteomyelitis or spondylodiscitis of the lumbar spine accompanied by sacroiliitis is very characteristic of this disease. Orchitis is also common in men. The consequences of Brucella infection are highly variable and may include arthritis, spondylitis, thrombocytopenia, meningitis, uveitis, optic neuritis, endocarditis, and various neurological disorders collectively known as neurobrucellosis.

Prevention

Surveillance using serological tests, as well as tests on milk such as the milk ring test, can be used for screening and play an important role in campaigns to eliminate the disease. Also, individual animal testing both for trade and for disease-control purposes is practiced. In endemic areas, vaccination is often used to reduce the incidence of infection. An animal vaccine is available that uses modified live bacteria. The World Organisation for Animal Health Manual of Diagnostic Test and Vaccines for Terrestrial Animals provides detailed guidance on the production of vaccines. As the disease is closer to being eliminated, a test and eradication program is required to completely eliminate it.

The main way of preventing brucellosis is by using fastidious hygiene in producing raw milk products, or by pasteurizing all milk that is to be ingested by human beings, either in its unaltered form or as a derivative, such as cheese.

Treatment

ILLNESS Bacterial Brucellosis Treatment

Antibiotics such as tetracyclines, rifampin, and the aminoglycosides streptomycin and gentamicin are effective against Brucella bacteria. However, the use of more than one antibiotic is needed for several weeks, because the bacteria incubate within cells.

The gold standard treatment for adults is daily intramuscular injections of streptomycin 1 g for 14 days and oral doxycycline 100 mg twice daily for 45 days (concurrently). Gentamicin 5 mg/kg by intramuscular injection once daily for 7 days is an acceptable substitute when streptomycin is not available or contraindicated. Another widely used regimen is doxycycline plus rifampin twice daily for at least 6 weeks. This regimen has the advantage of oral administration. A triple therapy of doxycycline, with rifampin and co-trimoxazole, has been used successfully to treat neurobrucellosis. Doxycycline plus streptomycin regimen (for 2 to 3 weeks) is more effective than doxycycline plus rifampicin regimen (for 6 weeks).

Doxycycline is able to cross the blood–brain barrier, but requires the addition of two other drugs to prevent relapse. Ciprofloxacin and co-trimoxazole therapy is associated with an unacceptably high rate of relapse. In brucellic endocarditis, surgery is required for an optimal outcome. Even with optimal antibrucellic therapy, relapses still occur in 5 to 10% of patients with Malta fever.

27 Bubonic Plague

ILLNESS Bacterial Bubonic Plague

Bubonic plague is one of three types of plague caused by bacterium Yersinia pestis. One to seven days after exposure to the bacteria, flu-like symptoms develop. These symptoms include fever, headaches, and vomiting. Swollen and painful lymph nodes occur in the area closest to where the bacteria entered the skin. Occasionally, the swollen lymph nodes may break open.

The three types of plague are the result of the route of infection: bubonic plague, septicemic plague, and pneumonic plague. Bubonic plague is mainly spread by infected fleas from small animals. It may also result from exposure to the body fluids from a dead plague-infected animal. In the bubonic form of plague, the bacteria enter through the skin through a flea bite and travel via the lymphatic vessels to a lymph node, causing it to swell. Diagnosis is made by finding the bacteria in the blood, sputum, or fluid from lymph nodes.

Sources

ILLNESS Bacterial Bubonic Plague Sources

The three types of plague are the result of the route of infection: bubonic plague, septicemic plague, and pneumonic plague. Bubonic plague is mainly spread by infected fleas from small animals. It may also result from exposure to the body fluids from a dead plague-infected animal. In the bubonic form of plague, the bacteria enter through the skin through a flea bite and travel via the lymphatic vessels to a lymph node, causing it to swell. Diagnosis is made by finding the bacteria in the blood, sputum, or fluid from lymph nodes.

Bubonic plague is an infection of the lymphatic system, usually resulting from the bite of an infected flea, Xenopsylla cheopis (the rat flea). In very rare circumstances, as in the septicemic plague, the disease can be transmitted by direct contact with infected tissue or exposure to the cough of another human. The flea is parasitic on house and field rats, and seeks out other prey when its rodent hosts die. The bacteria remain harmless to the flea, allowing the new host to spread the bacteria. The bacteria form aggregates in the gut of infected fleas and this results in the flea regurgitating ingested blood, which is now infected, into the bite site of a rodent or human host. Once established, bacteria rapidly spread to the lymph nodes and multiply.

Symptoms

ILLNESS Bacterial Bubonic Plague Symptoms

The best-known symptom of bubonic plague is one or more infected, enlarged, and painful lymph nodes, known as buboes. After being transmitted via the bite of an infected flea, the Y. pestis bacteria become localized in an inflamed lymph node, where they begin to colonize and reproduce. Buboes associated with the bubonic plague are commonly found in the armpits, upper femoral, groin and neck region. Bubonic plague symptoms appear suddenly a few days after exposure to the bacterium. Symptoms include:
● Chills
● General ill feeling (malaise)
● High fever >39 °C (102.2 °F)
● Muscle cramps
● Seizures

● Smooth, painful lymph gland swelling called a bubo, commonly found in the groin, but may occur in the armpits or neck, most often near the site of the initial infection (bite or scratch)
● Pain may occur in the area before the swelling appears
● Gangrene of the extremities such as toes, fingers, lips, and tip of the nose.

Other symptoms include heavy breathing, continuous vomiting of blood (hematemesis), aching limbs, coughing, and extreme pain caused by the decay or decomposition of the skin while the person is still alive. Additional symptoms include extreme fatigue, gastrointestinal problems, lenticulae (black dots scattered throughout the body), delirium, coma, and death. Other forms of the disease include septicemic plague and pneumonic plague in which the bacterium reproduces in the persons blood and lungs respectively.

Prevention

Targeted chemoprophylaxis, sanitation, and vector control played a role in controlling the 2003 Oran outbreak of the bubonic plague.

Treatment

ILLNESS Bacterial Bubonic Plague Treatment

Several classes of antibiotics are effective in treating bubonic plague. These include aminoglycosides such as streptomycin and gentamicin, tetracyclines (especially doxycycline), and the fluoroquinolone ciprofloxacin. Mortality associated with treated cases of bubonic plague is about 1–15%, compared to a mortality of 40–60% in untreated cases.

People potentially infected with the plague need immediate treatment and should be given antibiotics within 24 hours of the first symptoms to prevent death. Other treatments include oxygen, intravenous fluids, and respiratory support. People who have had contact with anyone infected by pneumonic plague are given prophylactic antibiotics. Using the broad-based antibiotic streptomycin has proven to be dramatically successful against the bubonic plague within 12 hours of infection.

28 Pneumonic Plague

ILLNESS Pneumonic Plague

Pneumonic plague is a severe lung infection caused by the bacterium Yersinia pestis. Symptoms include fever, headache, shortness of breath, chest pain, and cough. They typically start about three to seven days after exposure. It is one of three forms of plague, the other two being septicemic plague and bubonic plague. The pneumonic form may occur following an initial bubonic or septicemic plague infection. It may also result from breathing in airborne droplets from another person or cat infected with pneumonic plague. The difference between the forms of plague is the location of infection; in pneumonic plague the infection is in the lungs, in bubonic plague the lymph nodes, and in septicemic plague within the blood. Diagnosis is by testing the blood, sputum, or fluid from a lymph node.

While vaccines are being worked on, in most countries they are not yet commercially available. Prevention is by avoiding contact with infected rodents, people, or cats. It is recommended that those infected be isolated from others. Treatment of pneumonic plague is with antibiotics.

Sources

Pneumonic plague can be caused in two ways: primary, which results from the inhalation of aerosolised plague bacteria, or secondary, when septicaemic plague spreads into lung tissue from the bloodstream. Pneumonic plague is not exclusively vector-borne like bubonic plague; instead it can be spread from person to person. There have been cases of pneumonic plague resulting from the dissection or handling of contaminated animal tissue. This is one of the types of the plague formerly known as the Black Death.

Symptoms

The most apparent symptom of pneumonic plague is coughing, often with hemoptysis (coughing up blood). With pneumonic plague, the first signs of illness are fever, headache, weakness and rapidly developing pneumonia with shortness of breath, chest pain, cough and sometimes bloody or watery sputum. The pneumonia progresses for two to four days and may cause respiratory failure and shock. Patients will die without early treatment, some within 36 hours.

Initial pneumonic plague symptoms can often include the following:
- Fever
- Weakness
- Headaches
- Nausea

Rapidly developing pneumonia with:
- Shortness of breath
- Chest pain
- Cough
- Bloody or watery sputum (saliva and discharge from respiratory passages).

Prevention

Treatment

Pneumonic plague is a very aggressive infection requiring early treatment. Antibiotics must be given within 24 hours of first symptoms to reduce the risk of death. Streptomycin, gentamicin, tetracyclines and chloramphenicol are all able to kill the causative bacterium. Antibiotic treatment for seven days will protect people who have had direct, close contact with infected patients. Wearing a close-fitting surgical mask also protects against infection. The mortality rate from untreated pneumonic plague approaches 100%.

29 Diphtheria

Diphtheria is an infection caused by the bacterium Corynebacterium diphtheriae. Signs and symptoms may vary from mild to severe. They usually start two to five days after exposure. Symptoms often come on fairly gradually, beginning with a sore throat and fever. In severe cases, a grey or white patch develops in the throat. This can block the airway and create a barking cough as in croup. The neck may swell in part due to enlarged lymph nodes. A form of diphtheria which involves the skin, eyes or genitals also exists. Complications may include myocarditis, inflammation of nerves, kidney problems, and bleeding problems due to low levels of platelets. Myocarditis may result in an abnormal heart rate and inflammation of the nerves may result in paralysis.

Diphtheria is usually spread between people by direct contact or through the air. It may also be spread by contaminated objects. Some people carry the bacterium without having symptoms, but can still spread the disease to others. The three main types of C. diphtheriae cause different severities of disease. The symptoms are due to a toxin produced by the bacterium. Diagnosis can often be made based on the appearance of the throat with confirmation by microbiological culture. Previous infection may not protect against future infection.

Sources

Diphtheria is usually spread between people by direct contact or through the air. It may also be spread by contaminated objects. Some people carry the bacterium without having symptoms, but can still spread the disease to others. Human-to-human transmission of diphtheria typically occurs through the air when an infected individual coughs or sneezes. Breathing in particles released from the infected individual leads to infection. Contact with any lesions on the skin can also lead to transmission of diphtheria, but this is uncommon. Indirect infections can occur, as well. If an infected individual touches a surface or object, the bacteria can be left behind and remain viable. Also, some evidence indicates diphtheria has the potential to be zoonotic, but this has yet to be confirmed. Corynebacterium ulcerans has been found in some animals, which would suggest zoonotic potential.

Symptoms

The symptoms of diphtheria usually begin two to seven days after infection. Symptoms of diphtheria include fever of 38 °C (100.4 °F) or above; chills; fatigue; bluish skin coloration (cyanosis); sore throat; hoarseness; cough; headache; difficulty swallowing; painful swallowing; difficulty breathing; rapid breathing; foul-smelling and bloodstained nasal discharge; and lymphadenopathy. Within two to three days, diphtheria may destroy healthy tissues in the respiratory system. The dead tissue forms a thick, gray coating that can build up in the throat or nose. This thick gray coating is called a "pseudomembrane". It can cover tissues in the nose, tonsils, voice box, and throat, making it very hard to breathe and swallow. Symptoms can also include cardiac arrhythmias, myocarditis, and cranial and peripheral nerve palsies.

Prevention

Quinvaxem is a widely administered pentavalent vaccine, which is a combination of five vaccines in one that protect babies from diphtheria, among other common childhood diseases. Diphtheria vaccine is usually combined at least with tetanus vaccine (Td) and often with pertussis (DTP, DTaP, TdaP, Tdap) vaccines, as well.

Treatment

The disease may remain manageable, but in more severe cases, lymph nodes in the neck may swell, and breathing and swallowing are more difficult. People in this stage should seek immediate medical attention, as obstruction in the throat may require intubation or a tracheotomy. Abnormal cardiac rhythms can occur early in the course of the illness or weeks later, and can lead to heart failure. Diphtheria can also cause paralysis in the eye, neck, throat, or respiratory muscles. Patients with severe cases are put in a hospital intensive care unit and given a diphtheria antitoxin (consisting of antibodies isolated from the serum of horses that have been challenged with diphtheria toxin). Since antitoxin does not neutralize toxin that is already bound to tissues, delaying its administration increases risk of death. Therefore, the decision to administer diphtheria antitoxin is based on clinical diagnosis, and should not await laboratory confirmation.

Antibiotics have not been demonstrated to affect healing of local infection in diphtheria patients treated with antitoxin. Antibiotics are used in patients or carriers to eradicate C. diphtheriae and prevent its transmission to others. The Centers for Disease Control and Prevention recommends either:

ILLNESS Diphtheria Treatment

- Metronidazole
- Erythromycin is given (orally or by injection) for 14 days (40 mg/kg per day with a maximum of 2 g/d), or
- Procaine penicillin G is given intramuscularly for 14 days (300,000 U/d for patients weighing <10 kg and 600,000 U/d for those weighing >10 kg); patients with allergies to penicillin G or erythromycin can use rifampin or clindamycin.

In cases that progress beyond a throat infection, diphtheria toxin spreads through the blood and can lead to potentially life-threatening complications that affect other organs, such as the heart and kidneys. Damage to the heart caused by the toxin affects the heart's ability to pump blood or the kidneys' ability to clear wastes. It can also cause nerve damage, eventually leading to paralysis. About 40% to 50% of those left untreated can die.

ILLNESS Bacterial

30 Meningococcal

Meningococcal

Neisseria meningitidis, often referred to as meningococcus, is a Gram-negative bacterium that can cause meningitis and other forms of meningococcal disease such as meningococcemia, a life-threatening sepsis. The bacterium is referred to as a coccus because it is round, and more specifically, diplococcus because of its tendency to form pairs. About 10% of adults are carriers of the bacteria in their nasopharynx. As an exclusively human pathogen it is the main cause of bacterial meningitis in children and young adults, causing developmental impairment and death in about 10% of cases. It causes the only form of bacterial meningitis known to occur epidemically, mainly Africa and Asia. It occurs worldwide in both epidemic and endemic form. N. meningitidis is spread through saliva and respiratory secretions during coughing, sneezing, kissing, chewing on toys and even through sharing a source of fresh water. It has also been reported to be transmitted through oral sex and cause urethritis in men. It infects its host cells by sticking to them with long thin extensions called pili and the surface-exposed proteins Opa and Opc and has several virulence factors.

Sources

N. meningitidis is a part of the normal nonpathogenic flora in the nasopharynx of up to 5–15% of adults. It colonizes and infects only humans, and has never been isolated from other animals. This is thought to stem from the bacterium's inability to get iron from sources other than human transferrin and lactoferrin.

ILLNESS Bacterial Meningococcal Symptoms

Symptoms

Meningococcus can cause meningitis and other forms of meningococcal disease. It initially produces general symptoms like fatigue, fever, and headache and can rapidly progress to neck stiffness, coma and death in 10% of cases. Petechiae occur in about 50% of cases. Chance of survival is highly correlated with blood cortisol levels, and so a reduction in cortisol can be used to determine likelihood of patient mortality. Symptoms of meningococcal meningitis are easily confused with those caused by other bacteria, such as Haemophilus influenzae and Streptococcus pneumoniae. Suspicion of meningitis is a medical emergency and immediate medical assessment is recommended.

Current guidance in the United Kingdom is that if a case of meningococcal meningitis or septicaemia (infection of the blood) is suspected, intravenous antibiotics should be given and the ill person admitted to the hospital. This means that laboratory tests may be less likely to confirm the presence of Neisseria meningitidis as the antibiotics will dramatically lower the number of bacteria in the body. The UK guidance is based on the idea that the reduced ability to identify the bacteria is outweighed by reduced chance of death.

ILLNESS Meningococcal Symptoms

Septicaemia caused by Neisseria meningitidis has received much less public attention than meningococcal meningitis even though septicaemia has been linked to infant deaths. Meningococcal septicaemia typically causes a purpuric rash, that does not lose its color when pressed with a glass slide ("non-blanching") and does not cause the classical symptoms of meningitis. This means the condition may be ignored by those not aware of the significance of the rash. Septicaemia carries an approximate 50% mortality rate over a few hours from initial onset.

Other severe complications include Waterhouse–Friderichsen syndrome, a massive, usually bilateral, hemorrhage into the adrenal glands caused by fulminant meningococcemia, adrenal insufficiency, and disseminated intravascular coagulation.

Not all instances of a purpura-like rash are due to meningococcal septicaemia; other possible causes, such as idiopathic thrombocytopenic purpura (ITP; a platelet disorder) and Henoch–Schönlein purpura, also need prompt investigation.

ILLNESS Bacterial Prevention

Prevention

All recent contacts of the infected patient over the 7 days before onset should receive medication to prevent them from contracting the infection. This especially includes young children and their child caregivers or nursery-school contacts, as well as anyone who had direct exposure to the patient through kissing, sharing utensils, or medical interventions such as mouth-to-mouth resuscitation. Anyone who frequently ate, slept or stayed at the patient's home during the 7 days before the onset of symptom, or those who sat beside the patient on an airplane flight or classroom for 8 hours or longer, should also receive chemoprophylaxis. The agent of choice is usually oral rifampicin for a few days.

Receiving a dose of the Meningococcal vaccine before traveling to a country in the "meningitis belt" or having a booster meningitis vaccine, normally five years apart could prevent someone from getting an infection from the pathogen.

Meningococcal Treatment

Treatment

Persons with confirmed N. meningitidis infection should be hospitalized immediately for treatment with antibiotics. Because meningococcal disease can disseminate very rapidly, a single dose of intramuscular antibiotic is often given at the earliest possible opportunity, even before hospitalization, if disease symptoms look suspicious enough. Third-generation cephalosporin antibiotics (i.e. cefotaxime, ceftriaxone) should be used to treat a suspected or culture-proven meningococcal infection before antibiotic susceptibility results are available. Empirical treatment should also be considered if a lumbar puncture, to collect CSF for laboratory testing, cannot be done within 30 minutes of admission to hospital. Antibiotic treatment may affect the results of microbiology tests, but a diagnosis may be made on the basis of blood-cultures and clinical examination.

ILLNESS Bacterial Pertussis (Whooping Cough)

31 Pertussis (Whooping Cough)

Whooping cough, also known as pertussis or 100-day cough, is a highly contagious bacterial disease. Initially, symptoms are usually similar to those of the common cold with a runny nose, fever, and mild cough. This is followed by weeks of severe coughing fits. Following a fit of coughing, a high-pitched whoop sound or gasp may occur as the person breathes in. The coughing may last for 10 or more weeks, hence the phrase "100-day cough". A person may cough so hard that they vomit, break ribs, or become very tired from the effort. Children less than one year old may have little or no cough and instead have periods where they do not breathe. The time between infection and the onset of symptoms is usually seven to ten days. Disease may occur in those who have been vaccinated, but symptoms are typically milder.

Pertussis is caused by the bacterium Bordetella pertussis. It is spread easily through the coughs and sneezes of an infected person. People are infectious from the start of symptoms until about three weeks into the coughing fits. Those treated with antibiotics are no longer infectious after five days. Diagnosis is by collecting a sample from the back of the nose and throat. This sample can then be tested by either culture or by polymerase chain reaction.

Sources

Symptoms

The classic symptoms of pertussis are a paroxysmal cough, inspiratory whoop, and fainting, or vomiting after coughing. The cough from pertussis has been documented to cause subconjunctival hemorrhages, rib fractures, urinary incontinence, hernias, and vertebral artery dissection. Violent coughing can cause the pleura to rupture, leading to a pneumothorax. Vomiting after a coughing spell or an inspiratory whooping sound on coughing, almost doubles the likelihood that the illness is pertussis. The absence of a paroxysmal cough or posttussive emesis, though, makes it almost half as likely. The illness usually starts with mild respiratory symptoms include mild coughing, sneezing, or a runny nose (known as the catarrhal stage). After one to two weeks, the coughing classically develops into uncontrollable fits, sometimes followed by a high-pitched "whoop" sound, as the person tries to inhale. About 50% of children and adults "whoop" at some point in diagnosed pertussis cases during the paroxysmal stage.

This stage usually lasts two to eight weeks, or sometimes longer. A gradual transition then occurs to the convalescent stage, which usually lasts one to four weeks. This stage is marked by a decrease in paroxysms of coughing, although paroxysms may occur with subsequent respiratory infection for many months after the onset of pertussis.

Symptoms of pertussis can be variable, especially between immunized and non-immunized people. Those that are immunized can present with a more mild infection; they may only have the paroxysmal cough for a couple of weeks, and it may lack the "whooping" characteristic. Although immunized people have a milder form of the infection, they can spread the disease to others who are not immune.

Prevention

The primary method of prevention for pertussis is vaccination. Evidence is insufficient to determine the effectiveness of antibiotics in those who have been exposed, but are without symptoms. Preventive antibiotics, however, are still frequently used in those who have been exposed and are at high risk of severe disease (such as infants).

Treatment

The antibiotics erythromycin, clarithromycin, or azithromycin are typically the recommended treatment. Newer macrolides are frequently recommended due to lower rates of side effects. Trimethoprim-sulfamethoxazole (TMP/SMX) may be used in those with allergies to first-line agents or in infants who have a risk of pyloric stenosis from macrolides.

A reasonable guideline is to treat people age >1 year within 3 weeks of cough onset and infants age <1 year and pregnant women within 6 weeks of cough onset. If the person is diagnosed late, antibiotics will not alter the course of the illness, and even without antibiotics, they should no longer be spreading pertussis. When used early, antibiotics decrease the duration of infectiousness, and thus prevent spread. Short-term antibiotics (azithromycin for 3–5 days) are as effective as long-term treatment (erythromycin 10–14 days) in eliminating B. pertussis with fewer and less severe side effects. People with pertussis are most infectious during the first two weeks following the onset of symptoms. Effective treatments of the cough associated with this condition have not been developed. The use of over the counter cough medications is discouraged and has not been found helpful.

32 Scarlet Fever

Scarlet fever is a disease which can occur as a result of a group A streptococcus (group A strep) infection, also known as Streptococcus pyogenes. The signs and symptoms include a sore throat, fever, headaches, swollen lymph nodes, and a characteristic rash. The rash is red and feels like sandpaper and the tongue may be red and bumpy. It most commonly affects children between five and 15 years of age.

Scarlet fever affects a small number of people who have strep throat or streptococcal skin infections. The bacteria are usually spread by people coughing or sneezing. It can also be spread when a person touches an object that has the bacteria on it and then touches their mouth or nose. The characteristic rash is due to the erythrogenic toxin, a substance produced by some types of the bacterium. The diagnosis is typically confirmed by culturing the throat.

Sources

Strep throat spreads by close contact among people, via respiratory droplets (for example, saliva or nasal discharge). A person in close contact with another person infected with group A streptococcal pharyngitis has a 35% chance of becoming infected. One in ten children who are infected with group A streptococcal pharyngitis will develop scarlet fever.

Symptoms

Rash which has a characteristic appearance, spreading pattern, and desquamating process "Strawberry tongue"
● The tongue initially has a white coating on it, while the papillae of the tongue are swollen and reddened. The protrusion of the red papillae through the white coating gives the tongue a "white strawberry" appearance.
● A few days later (following the desquamating process, or the shedding of the tissue which created the white coating), the whiteness disappears, and the red and enlarged papillae give the tongue the "red strawberry" appearance. The symptomatic appearance of the tongue is part of the rash that is characteristic of scarlet fever.
● Pastia's lines
● Lines of petechiae, which appear as pink/red areas located in arm pits and elbow pits
● Vomiting and abdominal pain

Strep throat
Typical symptoms of streptococcal pharyngitis (also known as strep throat):
● Sore throat, painful swallowing
● Fever - typically over 39 °C (102.2 °F)
● Fatigue
● Enlarged and reddened tonsils with yellow or white exudates present (this is typically an exudative pharyngitis)
● Enlarged and tender lymph nodes usually located on the front of the neck

The following symptoms will usually be absent: cough, hoarseness, runny nose, diarrhea, and conjunctivitis. Such symptoms indicate what is more likely a viral infection.

Rash
The rash begins 1–2 days following the onset of symptoms caused by the strep pharyngitis (sore throat, fever, fatigue). This characteristic rash has been denoted as "scarlatiniform," and it appears as a diffuse redness of the skin with small papules, or bumps, which resemble goose bumps. These bumps are what give the characteristic sandpaper texture to the rash. The reddened skin will blanch when pressure is applied to it. The skin may feel itchy, but it will not be painful. The rash generally starts at the flexion of the elbow and other surfaces. It appears next on the trunk and gradually spreads out to the arms and legs. The palms, soles and face are usually left uninvolved by the rash. The face, however, is usually flushed, most prominently in the cheeks, with a ring of paleness around the mouth. After the rash spreads, it becomes more pronounced in creases in the skin, such as the skin folds in the inguinal and axillary regions of the body. Also in those areas, Pastia's Lines may appear: petechiae arranged in a linear pattern. Within 1 week of onset, the rash begins to fade followed by a longer process of desquamation, or shedding of the outer layer of skin. This lasts several weeks. The desquamation process usually begins on the face and progresses downward on the body. After the desquamation, the skin will be left with a sunburned appearance.

Mouth
The streptococcal pharyngitis, which is the usual presentation of scarlet fever in combination with the characteristic rash, commonly involves the tonsils. The tonsils will appear swollen and reddened. The palate and uvula are also commonly affected by the infection. The involvement of the soft palate can be seen as tiny red and round spots known as Forchheimer spots.

Variable Presentations
The features of scarlet fever can differ depending on the age and race of the person. Children less than 5 years old can have atypical presentations. Children less than 3 years old can present with nasal congestion and a lower grade fever. Infants may present with symptoms of increased irritability and decreased appetite.

Children who have darker skin can have a different presentation, as the redness of the skin involved in the rash and the ring of paleness around the mouth can be less obvious. Suspicion based on accompanying symptoms and diagnostic studies are important in these cases.

Prevention

One method is long-term use of antibiotics to prevent future group A streptococcal infections. This method is only indicated for people who have had complications like recurrent attacks of acute rheumatic fever or rheumatic heart disease. Antibiotics are limited in their ability to prevent these infections since there are a variety of subtypes of group A streptococci that can cause the infection.

The vaccine approach has a greater likelihood of effectively preventing group A streptococcal infections because vaccine formulations can target multiple subtypes of the bacteria. A vaccine developed by George and Gladys Dick in 1924 was discontinued due to poor efficacy and the introduction of antibiotics. Difficulties in vaccine development include the considerable strain variety of group A streptococci present in the environment and the amount of time and number of people needed for appropriate trials for safety and efficacy of any potential vaccine. There have been several attempts to create a vaccine in the past few decades. These vaccines, which are still in the development phase, expose the person to proteins present on the surface of the group A streptococci to activate an immune response that will prepare the person to fight and prevent future infections. There used to be a diphtheria scarlet fever vaccine. It was, however, found not to be effective. This product was discontinued by the end of World War II.

Treatment

Antibiotics to combat the streptococcal infection are the mainstay of treatment for scarlet fever. Prompt administration of appropriate antibiotics decreases the length of illness. Peeling of the outer layer of skin, however, will happen despite treatment. One of the main goals of treatment is to prevent the child from developing one of the suppurative or nonsuppurative complications, especially acute rheumatic fever. As long as antibiotics are started within nine days, it is very unlikely for the child to develop acute rheumatic fever.

Antibiotic therapy has not been shown to prevent the development of post-streptococcal glomerulonephritis. Another important reason for prompt treatment with antibiotics is the ability to prevent transmission of the infection between children. An infected individual is most likely to pass on the infection to another person during the first 2 weeks. A child is no longer contagious (able to pass the infection to another child) after 24 hours of antibiotics.

The antibiotic of choice is penicillin V which is taken by mouth in pill form. Children who are not able to take pills can be given amoxicillin which comes in a liquid form and is equally effective. Duration of treatment is 10 days. Benzathine Penicillin G can be given as a one time intramuscular injection as another alternative if swallowing pills is not possible. If the person is allergic to the family of antibiotics which both penicillin and amoxicillin are a part of (beta-lactam antibiotics), a first generation cephalosporin is used.

Cephalosporin antibiotics, however, can still cause adverse reactions in people whose allergic reaction to penicillin is a Type 1 Hypersensitivity reaction. In those cases it is appropriate to choose clindamycin or erythromycin instead. Tonsillectomy, although once a reasonable treatment for recurrent streptococcal pharyngitis, is not indicate, as a person can still be infected with group A streptococcus without their tonsils.

33 Shigellosis (Shigella)

Shigella is a genus of bacteria that is Gram-negative, facultative anaerobic, non-spore-forming, nonmotile, rod-shaped and genetically closely related to E. coli. The genus is named after Kiyoshi Shiga, who first discovered it in 1897. The causative agent of human shigellosis, Shigella causes disease in primates, but not in other mammals. It is only naturally found in humans and gorillas. During infection, it typically causes dysentery.

Shigella is one of the leading bacterial causes of diarrhea worldwide, causing an estimated 80–165 million cases. The number of deaths it causes each year is estimated at between 74,000 and 600,000. It is one of the top four pathogens that cause moderate-to-severe diarrhea in African and South Asian children.

Sources

Symptoms

Signs and symptoms may range from mild abdominal discomfort to full-blown dysentery characterized by cramps, diarrhea, with slimy-consistent stools, fever, blood, pus, or mucus in stools or tenesmus. Onset time is 12 to 96 hours, and recovery takes 5 to 7 days. Infections are associated with mucosal ulceration, rectal bleeding, and drastic dehydration. Reactive arthritis and hemolytic uremic syndrome are possible sequelae that have been reported in the aftermath of shigellosis. The most common neurological symptom includes seizures.

Prevention

Simple precautions can be taken to prevent getting shigellosis: wash hands before handling food and thoroughly cook all food before eating. The primary prevention methods are improved sanitation and personal and food hygiene, but a low-cost and efficacious vaccine would complement these methods. Since shigellosis is spread very quickly among children, keeping infected children out of daycare for 24 hours after their symptoms have disappeared, will decrease the occurrence of shigellosis in daycares.

Treatment

Treatment consists mainly of replacing fluids and salts lost because of diarrhea. Replacement by mouth is satisfactory for most people, but some may need to receive fluids intravenously. Antidiarrheal drugs (such as diphenoxylate or loperamide) may prolong the infection and should not be used.

Antibiotics
Antibiotics should only be used in severe cases or for certain populations with mild symptoms (elderly, immunocompromised, food service industry workers, child care workers). For Shigella-associated diarrhea, antibiotics shorten the length of infection, but they are usually avoided in mild cases because many Shigella strains are becoming resistant to common antibiotics. Furthermore, effective medications are often in short supply in developing countries, which carry the majority of the disease burden from Shigella. Antidiarrheal agents may worsen the sickness, and should be avoided.

ILLNESS | Bacterial

In most cases, the disease resolves within four to eight days without antibiotics. Severe infections may last three to six weeks. Antibiotics, such as trimethoprim-sulfamethoxazole, ciprofloxacin may be given when the person is very young or very old, when the disease is severe, or when the risk of the infection spreading to other people is high. Additionally, ampicillin (but not amoxicillin) was effective in treating this disease previously, but now the first choice of drug is pivmecillinam.

34 Tuberculosis

Tuberculosis (TB) is an infectious disease usually caused by Mycobacterium tuberculosis (MTB) bacteria. Tuberculosis generally affects the lungs, but can also affect other parts of the body. Most infections do not have symptoms, in which case it is known as latent tuberculosis. About 10% of latent infections progress to active disease which, if left untreated, kills about half of those affected. The classic symptoms of active TB are a chronic cough with blood-containing mucus, fever, night sweats, and weight loss. It was historically called "consumption" due to the weight loss. Infection of other organs can cause a wide range of symptoms.

Tuberculosis is spread through the air when people who have active TB in their lungs cough, spit, speak, or sneeze. People with latent TB do not spread the disease. Active infection occurs more often in people with HIV/AIDS and in those who smoke. Diagnosis of active TB is based on chest X-rays, as well as microscopic examination and culture of body fluids. Diagnosis of latent TB relies on the tuberculin skin test (TST) or blood tests.

Sources

Tuberculosis is spread from one person to the next through the air when people who have active TB in their lungs cough, spit, speak, or sneeze. People with latent TB do not spread the disease. Active infection occurs more often in people with HIV/AIDS and in those who smoke.

Symptoms

Tuberculosis may infect any part of the body, but most commonly occurs in the lungs (known as pulmonary tuberculosis). Extrapulmonary TB occurs when tuberculosis develops outside of the lungs, although extrapulmonary TB may coexist with pulmonary TB. General signs and symptoms include fever, chills, night sweats, loss of appetite, weight loss, and fatigue. Significant nail clubbing may also occur.

Pulmonary
If a tuberculosis infection does become active, it most commonly involves the lungs (in about 90% of cases). Symptoms may include chest pain and a prolonged cough producing sputum. About 25% of people may not have any symptoms (i.e. they remain "asymptomatic"). Occasionally, people may cough up blood in small amounts, and in very rare cases, the infection may erode into the pulmonary artery or a Rasmussen's aneurysm, resulting in massive bleeding.

Tuberculosis may become a chronic illness and cause extensive scarring in the upper lobes of the lungs. The upper lung lobes are more frequently affected by tuberculosis than the lower ones. The reason for this difference is not clear. It may be due to either better air flow, or poor lymph drainage within the upper lungs.

Extrapulmonary
In 15–20% of active cases, the infection spreads outside the lungs, causing other kinds of TB. These are collectively denoted as "extrapulmonary tuberculosis". Extrapulmonary TB occurs more commonly in people with a weakened immune system and young children. In those with HIV, this occurs in more than 50% of cases.

Notable extrapulmonary infection sites include the pleura (in tuberculous pleurisy), the central nervous system (in tuberculous meningitis), the lymphatic system (in scrofula of the neck), the genitourinary system (in urogenital tuberculosis), and the bones and joints (in Pott disease of the spine), among others. A potentially more serious, widespread form of TB is called "disseminated tuberculosis", it is also known as miliary tuberculosis. Miliary TB currently makes up about 10% of extrapulmonary cases.

Prevention

Tuberculosis prevention and control efforts rely primarily on the vaccination of infants and the detection and appropriate treatment of active cases. The World Health Organization (WHO) has achieved some success with improved treatment regimens, and a small decrease in case numbers.

Treatment

Treatment of TB uses antibiotics to kill the bacteria. Effective TB treatment is difficult, due to the unusual structure and chemical composition of the mycobacterial cell wall, which hinders the entry of drugs and makes many antibiotics ineffective.

Active TB is best treated with combinations of several antibiotics to reduce the risk of the bacteria developing antibiotic resistance. The routine use of rifabutin instead of rifampicin in HIV-positive people with tuberculosis is of unclear benefit as of 2007

35 Meningitis (All Types)

Meningitis is an acute inflammation of the protective membranes covering the brain and spinal cord, known collectively as the meninges. The most common symptoms are fever, headache, and neck stiffness. Other symptoms include confusion or altered consciousness, vomiting, and an inability to tolerate light or loud noises. Young children often exhibit only nonspecific symptoms, such as irritability, drowsiness, or poor feeding. If a rash is present, it may indicate a particular cause of meningitis; for instance, meningitis caused by meningococcal bacteria may be accompanied by a characteristic rash.

The inflammation may be caused by infection with viruses, bacteria, or other microorganisms, and less commonly by certain drugs. Meningitis can be life-threatening because of the inflammation's proximity to the brain and spinal cord; therefore, the condition is classified as a medical emergency. A lumbar puncture, in which a needle is inserted into the spinal canal to collect a sample of cerebrospinal fluid (CSF), can diagnose or exclude meningitis.

Sources

Meningitis is typically caused by an infection with microorganisms. Most infections are due to viruses, with bacteria, fungi, and protozoa being the next most common causes. It may also result from various non-infectious causes. The term aseptic meningitis refers to cases of meningitis in which no bacterial infection can be demonstrated. This type of meningitis is usually caused by viruses but it may be due to bacterial infection that has already been partially treated, when bacteria disappear from the meninges, or pathogens infect a space adjacent to the meninges (e.g. sinusitis).

Endocarditis (an infection of the heart valves which spreads small clusters of bacteria through the bloodstream) may cause aseptic meningitis. Aseptic meningitis may also result from infection with spirochetes, a group of bacteria that includes Treponema pallidum (the cause of syphilis) and Borrelia burgdorferi (known for causing Lyme disease). Meningitis may be encountered in cerebral malaria (malaria infecting the brain) or amoebic meningitis, meningitis due to infection with amoebae such as Naegleria fowleri, contracted from freshwater sources.

Bacterial
In premature babies and newborns up to three months old, common causes are group B streptococci (subtypes III which normally inhabit the vagina and are mainly a cause during the first week of life) and bacteria that normally inhabit the digestive tract such as Escherichia coli (carrying the K1 antigen). Listeria monocytogenes (serotype IVb) is transmitted by the mother before birth and may cause meningitis in the newborn.
Older children are more commonly affected by Neisseria meningitidis (meningococcus) and Streptococcus pneumoniae (serotypes 6, 9, 14, 18 and 23) and those under five by Haemophilus influenzae type B (in countries that do not offer vaccination).

In adults, Neisseria meningitidis and Streptococcus pneumoniae together cause 80% of bacterial meningitis cases. Risk of infection with Listeria monocytogenes is increased in persons over 50 years old. The introduction of pneumococcal vaccine has lowered rates of pneumococcal meningitis in both children and adults.

Recent skull trauma potentially allows nasal cavity bacteria to enter the meningeal space. Similarly, devices in the brain and meninges, such as cerebral shunts, extraventricular drains or Ommaya reservoirs, carry an increased risk of meningitis. In these cases, the persons are more likely to be infected with Staphylococci, Pseudomonas, and other Gram-negative bacteria. These pathogens are also associated with meningitis in people with an impaired immune system. An infection in the head and neck area, such as otitis media or mastoiditis, can lead to meningitis in a small proportion of people. Recipients of cochlear implants for hearing loss are more at risk for pneumococcal meningitis.

Tuberculous meningitis, which is meningitis caused by Mycobacterium tuberculosis, is more common in people from countries in which tuberculosis is endemic, but is also encountered in persons with immune problems, such as AIDS.

Recurrent bacterial meningitis may be caused by persisting anatomical defects, either congenital or acquired, or by disorders of the immune system. Anatomical defects allow continuity between the external environment and the nervous system. The most common cause of recurrent meningitis is a skull fracture, particularly fractures that affect the base of the skull or extend towards the sinuses and petrous pyramids.

Approximately 59% of recurrent meningitis cases are due to such anatomical abnormalities, 36% are due to immune deficiencies (such as complement deficiency, which predisposes especially to recurrent meningococcal meningitis), and 5% are due to ongoing infections in areas adjacent to the meninges.

Viral
Viruses that cause meningitis include enteroviruses, herpes simplex virus (generally type 2, which produces most genital sores; less commonly type 1), varicella zoster virus (known for causing chickenpox and shingles), mumps virus, HIV, LCMV, Arboviruses (acquired from a mosquito or other insect), and the Influenza virus. Mollaret's meningitis is a chronic recurrent form of herpes meningitis; it is thought to be caused by herpes simplex virus type 2.

Fungal
There are a number of risk factors for fungal meningitis, including the use of immunosuppressants (such as after organ transplantation), HIV/AIDS, and the loss of immunity associated with aging. It is uncommon in those with a normal immune system but has occurred with medication contamination. Symptom onset is typically more gradual, with headaches and fever being present for at least a couple of weeks before diagnosis. The most common fungal meningitis is cryptococcal meningitis due to Cryptococcus neoformans. In Africa, cryptococcal meningitis is now the most common cause of meningitis in multiple studies, and it accounts for 20–25% of AIDS-related deaths in Africa. Other less common fungal pathogens which can cause meningitis include: Coccidioides immitis, Histoplasma capsulatum, Blastomyces dermatitidis, and Candida species.

Parasitic
A parasitic cause is often assumed when there is a predominance of eosinophils (a type of white blood cell) in the CSF. The most common parasites implicated are Angiostrongylus cantonensis, Gnathostoma spinigerum, Schistosoma, as well as the conditions cysticercosis, toxocariasis, baylisascariasis, paragonimiasis, and a number of rarer infections and noninfective conditions.

Non-Infectious
Meningitis may occur as the result of several non-infectious causes: spread of cancer to the meninges (malignant or neoplastic meningitis) and certain drugs (mainly non-steroidal anti-inflammatory drugs, antibiotics and intravenous immunoglobulins). It may also be caused by several inflammatory conditions, such as sarcoidosis (which is then called neurosarcoidosis), connective tissue disorders such as systemic lupus erythematosus, and certain forms of vasculitis (inflammatory conditions of the blood vessel wall), such as Behçet's disease. Epidermoid cysts and dermoid cysts may cause meningitis by releasing irritant matter into the subarachnoid space. Rarely, migraine may cause meningitis, but this diagnosis is usually only made when other causes have been eliminated.

Symptoms

In adults, the most common symptom of meningitis is a severe headache, occurring in almost 90% of cases of bacterial meningitis, followed by neck stiffness (the inability to flex the neck forward passively due to increased neck muscle tone and stiffness). The classic triad of diagnostic signs consists of neck stiffness, sudden high fever, and altered mental status; however, all three features are present in only 44–46% of bacterial meningitis cases. If none of the three signs are present, acute meningitis is extremely unlikely. Other signs commonly associated with meningitis include photophobia (intolerance to bright light) and phonophobia (intolerance to loud noises). Small children often do not exhibit the aforementioned symptoms, and may only be irritable and look unwell. The fontanelle (the soft spot on the top of a baby's head) can bulge in infants aged up to 6 months. Other features that distinguish meningitis from less severe illnesses in young children are leg pain, cold extremities, and an abnormal skin color.

Nuchal rigidity occurs in 70% of bacterial meningitis in adults. Other signs include the presence of positive Kernig's sign or Brudziński sign. Kernig's sign is assessed with the person lying supine, with the hip and knee flexed to 90 degrees. In a person with a positive Kernig's sign, pain limits passive extension of the knee. A positive Brudzinski's sign occurs when flexion of the neck causes involuntary flexion of the knee and hip. Although Kernig's sign and Brudzinski's sign are both commonly used to screen for meningitis, the sensitivity of these tests is limited. They do, however, have very good specificity for meningitis: the signs rarely occur in other diseases. Another test, known as the "jolt accentuation maneuver" helps determine whether meningitis is present in those reporting fever and headache. A person is asked to rapidly rotate the head horizontally; if this does not make the headache worse, meningitis is unlikely.

Other problems can produce symptoms similar to those above, but from non-meningitic causes. This is called meningism or pseudomeningitis.

Prevention

For some causes of meningitis, protection can be provided in the long term through vaccination, or in the short term with antibiotics. Some behavioral measures may also be effective. Bacterial and viral meningitis are contagious, but neither is as contagious as the common cold or flu. Both can be transmitted through droplets of respiratory secretions during close contact such as kissing, sneezing or coughing on someone, but cannot be spread by only breathing the air where a person with meningitis has been. Viral meningitis is typically caused by enteroviruses, and is most commonly spread through fecal contamination. The risk of infection can be decreased by changing the behavior that led to transmission.

Treatment

Antibiotics
Short-term antibiotic prophylaxis is another method of prevention, particularly of meningococcal meningitis. In cases of meningococcal meningitis, preventative treatment in close contacts with antibiotics (e.g. rifampicin, ciprofloxacin or ceftriaxone) can reduce their risk of contracting the condition, but does not protect against future infections. Resistance to rifampicin has been noted to increase after use, which has caused some to recommend considering other agents. While antibiotics are frequently used in an attempt to prevent meningitis in those with a basilar skull fracture there is not enough evidence to determine whether this is beneficial or harmful. This applies to those with or without a CSF leak.

Management
Meningitis is potentially life-threatening and has a high mortality rate if untreated; delay in treatment has been associated with a poorer outcome. Thus, treatment with wide-spectrum antibiotics should not be delayed while confirmatory tests are being conducted. If meningococcal disease is suspected in primary care, guidelines recommend that benzylpenicillin be administered before transfer to hospital. Intravenous fluids should be administered if hypotension (low blood pressure) or shock are present.

It is not clear whether intravenous fluid should be given routinely or whether this should be restricted. Given that meningitis can cause a number of early severe complications, regular medical review is recommended to identify these complications early and to admit the person to an intensive care unit if deemed necessary.

Mechanical ventilation may be needed if the level of consciousness is very low, or if there is evidence of respiratory failure. If there are signs of raised intracranial pressure, measures to monitor the pressure may be taken; this would allow the optimization of the cerebral perfusion pressure and various treatments to decrease the intracranial pressure with medication (e.g. mannitol).

Seizures are treated with anticonvulsants. Hydrocephalus (obstructed flow of CSF) may require insertion of a temporary or long-term drainage device, such as a cerebral shunt. The osmotic therapy, glycerol, has an unclear effect on mortality but may decrease hearing problems.

36 Tetanus (Lockjaw)

Tetanus, also known as lockjaw, is a bacterial infection characterized by muscle spasms. In the most common type, the spasms begin in the jaw and then progress to the rest of the body. Each spasm usually lasts a few minutes. Spasms occur frequently for three to four weeks. Some spasms may be severe enough to fracture bones. Other symptoms of tetanus may include fever, sweating, headache, trouble swallowing, high blood pressure, and a fast heart rate. Onset of symptoms is typically three to twenty-one days following infection. Recovery may take months. About ten percent of cases prove fatal.

Tetanus is caused by an infection with the bacterium Clostridium tetani, which is commonly found in soil, saliva, dust, and manure. The bacteria generally enter through a break in the skin such as a cut or puncture wound by a contaminated object. They produce toxins that interfere with normal muscle contractions. Diagnosis is based on the presenting signs and symptoms. The disease does not spread between people.

Tetanus can be prevented by immunization with the tetanus vaccine. In those who have a significant wound and have had fewer than three doses of the vaccine, both vaccination and tetanus immune globulin are recommended. The wound should be cleaned and any dead tissue should be removed. In those who are infected, tetanus immune globulin or, if unavailable, intravenous immunoglobulin (IVIG) is used. Muscle relaxants may be used to control spasms. Mechanical ventilation may be required if a person's breathing is affected.

Tetanus occurs in all parts of the world but is most frequent in hot and wet climates where the soil has a high organic content. In 2015 there were about 209,000 infections and about 59,000 deaths globally. This is down from 356,000 deaths in 1990.

Signs and Symptoms

Tetanus often begins with mild spasms in the jaw muscles—also known as lockjaw or trismus. The spasms can also affect the facial muscles resulting in an appearance called risus sardonicus. Chest, neck, back, abdominal muscles, and buttocks may be affected. Back muscle spasms often cause arching, called opisthotonos. Sometimes the spasms affect muscles that help with breathing, which can lead to breathing problems.

Prolonged muscular action causes sudden, powerful, and painful contractions of muscle groups, which is called "tetany". These episodes can cause fractures and muscle tears. Other symptoms include fever, headache, restlessness, irritability, feeding difficulties, breathing problems, burning sensation during urination, urinary retention and loss of stool control.

Even with treatment, about 10% of people who contract tetanus die. The mortality rate is higher in unvaccinated people and people over 60 years of age.

Incubation Period
The incubation period of tetanus may be up to several months, but is usually about ten days. In general, the farther the injury site is from the central nervous system, the longer the incubation period. The shorter the incubation period, the more severe the symptoms. In neonatal tetanus (trismus nascentium), symptoms usually appear from 4 to 14 days after birth, averaging about 7 days. On the basis of clinical findings, four different forms of tetanus have been described.

Generalized Tetanus
Generalized tetanus is the most common type of tetanus, representing about 80% of cases. The generalized form usually presents with a descending pattern. The first sign is trismus, or lockjaw, and the facial spasms called risus sardonicus, followed by stiffness of the neck, difficulty in swallowing, and rigidity of pectoral and calf muscles. Other symptoms include elevated temperature, sweating, elevated blood pressure, and episodic rapid heart rate. Spasms may occur frequently and last for several minutes with the body shaped into a characteristic form called opisthotonos. Spasms continue for up to four weeks, and complete recovery may take months.

Neonatal Tetanus
Neonatal tetanus (trismus nascentium) is a form of generalized tetanus that occurs in newborns, usually those born to mothers who themselves have not been vaccinated. If the mother has been vaccinated against tetanus, the infants acquire passive immunity and are thus protected. It usually occurs through infection of the unhealed umbilical stump, particularly when the stump is cut with a non-sterile instrument. As of 1998 neonatal tetanus was common in many developing countries and was responsible for about 14% (215,000) of all neonatal deaths. In 2010 the worldwide death toll was 58,000 newborns. As the result of a public health campaign, the death toll from neonatal tetanus was reduced by 90% between 1990 and 2010, and by 2013 the disease had been largely eliminated from all but 25 countries. Neonatal tetanus is rare in developed countries.

Local Tetanus
Local tetanus is an uncommon form of the disease, in which people have persistent contraction of muscles in the same anatomic area as the injury. The contractions may persist for many weeks before gradually subsiding. Local tetanus is generally milder; only about 1% of cases are fatal, but it may precede the onset of generalized tetanus.

Tetanus (Lockjaw) Sources

Cephalic Tetanus
Cephalic tetanus is the rarest form of the disease (0.9–3% of cases) and is limited to muscles and nerves in the head. It usually occurs after trauma to the head area, including skull fracture, laceration, eye injury, dental extraction, and otitis media, but it has been observed from injuries to other parts of the body. Paralysis of the facial nerve is most frequently implicated, which may cause lockjaw, facial palsy, or ptosis, but other cranial nerves can also be affected. Cephalic tetanus may progress to a more generalized form of the disease. Due to its rarity, clinicians may be unfamiliar with the clinical presentation and may not suspect tetanus as the illness. Treatment can be complicated as symptoms may be concurrent with the initial injury that caused the infection. Cephalic tetanus is more likely than other forms of tetanus to be fatal, with the progression to generalized tetanus carrying a 15–30% case fatality rate.

Cause

Tetanus is caused by the tetanus bacterium Clostridium tetani. Tetanus is an international health problem, as C. tetani endospores are ubiquitous. Endospores can be introduced into the body through a puncture wound (penetrating trauma). Due to C. tetani being an anaerobic bacterium, it and its endospores thrive in environments that lack oxygen, such as a puncture wound. With the changes in oxygen levels, the drum stick-shaped endospore can result in quick spread.

The disease occurs almost exclusively in persons inadequately immunized. It is more common in hot, damp climates with soil rich in organic matter. Manure-treated soils may contain spores, as they are widely distributed in the intestines and feces of many animals such as horses, sheep, cattle, dogs, cats, rats, guinea pigs, and chickens. In agricultural areas, a significant number of human adults may harbor the organism.

The spores can also be found on skin surfaces and in contaminated heroin. Heroin users, particularly those who inject the drug subcutaneously, appear to be at high risk of contracting tetanus. Rarely, tetanus can be contracted through surgical procedures, intramuscular injections, compound fractures, and dental infections. Animal bites can transmit tetanus.

Tetanus is often associated with rust, especially rusty nails. Although rust itself does not cause tetanus, objects that accumulate rust are often found outdoors or in places that harbor anaerobic bacteria. Additionally, the rough surface of rusty metal provides crevices for dirt containing C. tetani, while a nail affords a means to puncture skin and deliver endospores deep within the body at the site of the wound. An endospore is a non-metabolizing survival structure that begins to metabolize and cause infection once in an adequate environment. Hence, stepping on a nail (rusty or not) may result in a tetanus infection, as the low-oxygen (anaerobic) environment may exist under the skin, and the puncturing object can deliver endospores to a suitable environment for growth. It is a common misconception that rust itself is the cause and that a puncture from a rust-free nail is not a risk.

Prevention

Unlike many infectious diseases, recovery from naturally acquired tetanus does not usually result in immunity to tetanus. This is due to the extreme potency of the tetanospasmin toxin. Tetanospasmin will likely be lethal before it will provoke an immune response.

Tetanus can be prevented by vaccination with tetanus toxoid. The CDC recommends that adults receive a booster vaccine every ten years, and standard care practice in many places is to give the booster to any person with a puncture wound who is uncertain of when he or she was last vaccinated, or if he or she has had fewer than three lifetime doses of the vaccine. The booster may not prevent a potentially fatal case of tetanus from the current wound, however, as it can take up to two weeks for tetanus antibodies to form.

In children under the age of seven, the tetanus vaccine is often administered as a combined vaccine, DPT/DTaP vaccine, which also includes vaccines against diphtheria and pertussis. For adults and children over seven, the Td vaccine (tetanus and diphtheria) or Tdap (tetanus, diphtheria, and acellular pertussis) is commonly used.

Treatment

Mild Tetanus
Mild cases of tetanus can be treated with:
- Tetanus immunoglobulin (TIG), also called tetanus antibodies or tetanus antitoxin. It can be given as intravenous therapy or by intramuscular injection.
- Antibiotic therapy to reduce toxin production. Metronidazole IV is a preferred treatment.
- Benzodiazepines can be used to control muscle spasms. Options include diazepam and lorazepam, oral or IV.

Severe Tetanus
Severe cases will require admission to intensive care. In addition to the measures listed above for mild tetanus:
- Human tetanus immunoglobulin injected intrathecally (increases clinical improvement from 4% to 35%)
- Tracheotomy and mechanical ventilation for 3 to 4 weeks. Tracheotomy is recommended for securing the airway because the presence of an endotracheal tube is a stimulus for spasm
- Magnesium sulfate, as an intravenous (IV) infusion, to control spasm and autonomic dysfunction
- Diazepam as a continuous IV infusion
- The autonomic effects of tetanus can be difficult to manage (alternating hyper- and hypotension hyperpyrexia/hypothermia) and may require IV labetalol, magnesium, clonidine, or nifedipine

Drugs such as diazepam or other muscle relaxants can be given to control the muscle spasms. In extreme cases it may be necessary to paralyze the person with curare-like drugs and use a mechanical ventilator.

In order to survive a tetanus infection, the maintenance of an airway and proper nutrition are required. An intake of 3,500 to 4,000 calories and at least 150 g of protein per day is often given in liquid form through a tube directly into the stomach (percutaneous endoscopic gastrostomy), or through a drip into a vein (parenteral nutrition). This high-caloric diet maintenance is required because of the increased metabolic strain brought on by the increased muscle activity. Full recovery takes 4 to 6 weeks because the body must regenerate destroyed nerve axon terminals.

The antibiotic of choice is metronidazole. It can be given as intravenously, by mouth, or by rectum. Of likewise efficiency is penicillin, but some raise the concern of provoking spasms because it inhibits GABA receptor, which is already affected by tetanospasmin.

3 Viral

A virus is a small infectious agent that replicates only inside the living cells of an organism. Viruses can infect all types of life forms, from animals and plants to microorganisms, including bacteria and archaea. There are millions of types of viruses. They can be found in almost every ecosystem on Earth and are the most numerous type of biological entity. While not inside an infected cell or in the process of infecting a cell, viruses exist in the form of independent particles, or virions, consisting of:
- **(i)** the genetic material, long molecules of DNA or RNA that encode the structure of the proteins by which the virus acts;
- **(ii)** a protein coat, the capsid, which surrounds and protects the genetic material; and in some cases
- **(iii)** an outside envelope of lipids. The shapes of these virus particles range from simple helical and icosahedral forms for some species to more complex structures for others. Most virus species have virions too small to be seen with an optical microscope, about one hundredth the size of most bacteria.

These are some tips on what to do when you have a virus.

- Let the fever do it's work but ensure it's under 39.5°C (103.1°F)
- Wear wet cotton socks overnight to stimulate increased circulation
- Rest and conserve energy
- Eat light, simple foods that are easily digested
- Eat a lot of Vitamin C, Zinc and protein foods
- Drink plenty of water

Thieves oil is a mix of essential oils which supposedly helps prevent (and kill) viruses. It was used in the 14th century to protect the user from the black plague.

Thieves Oil
- Clove Oil
- Cinnamon Bark Oil
- Eucalyptus Oil
- Rosemary Oil
- Lemon Oil

1 SARS (Severe Acute Respiratory Syndrome)

Severe acute respiratory syndrome (SARS) is a viral respiratory disease of zoonotic origin caused by the SARS coronavirus (SARS-CoV). Between November 2002 and July 2003, an outbreak of SARS in southern China caused an eventual 8,098 cases, resulting in 774 deaths reported in 37 countries, with the majority of cases in China and Hong Kong (9.6% fatality rate) according to the World Health Organization (WHO). No cases of SARS have been reported worldwide since 2004. In late 2017, Chinese scientists traced the virus through the intermediary of civets to cave-dwelling horseshoe bats in Yunnan province.

Sources

Manifests itself in improperly treated water.

Symptoms

Initial symptoms are flu-like and may include fever, muscle pain, lethargy symptoms, cough, sore throat, and other nonspecific symptoms. The only symptom common to all patients appears to be a fever above 38 °C (100 °F). SARS may eventually lead to shortness of breath and pneumonia; either direct viral pneumonia or secondary bacterial pneumonia. The average incubation period for SARS is 4–6 days, although rarely it could be as short as 1 day or as long as 14 days.

Prevention

There is no vaccine for SARS, although immunologist Anthony Fauci mentioned that the CDC developed one and placed it in the US national stockpile. That vaccine, however, is a prototype and not field-ready as of March 2020. Clinical isolation and quarantine remain the most effective means to prevent the spread of SARS. Other preventive measures include:
- Hand-washing with soap and water, or use of alcohol-based hand sanitizer
- Disinfection of surfaces of fomites to remove viruses
- Avoiding contact with bodily fluids
- Washing the personal items of someone with SARS in hot, soapy water (eating utensils, dishes, bedding, etc.)
- Keeping children with symptoms home from school
- Simple hygiene measures
- Isolating oneself as much as possible to minimize the chances of transmission of the virus

Treatment

As SARS is a viral disease, antibiotics do not have direct effect but may be used against bacterial secondary infection. Treatment of SARS is mainly supportive with antipyretics, supplemental oxygen and mechanical ventilation as needed. While Ribavirin is commonly used to treat SARS, there seems to have little to no effect on SARS-CoV, and no impact on patient's outcomes. There is currently no proven antiviral therapy. Tested substances, include ribavirin, lopinavir, ritonavir, type I interferon, that have thus far shown no conclusive contribution to the disease's course. Administration of corticosteroids, is recommended by the British Thoracic Society/British Infection Society/Health Protection Agency in patients with severe disease and O2 saturation of <90%.

People with SARS-CoV must be isolated, preferably in negative-pressure rooms, with complete barrier nursing precautions taken for any necessary contact with these patients, to limit the chances of medical personnel becoming infected. In certain cases, natural ventilation by opening doors and windows is documented to help decreasing indoor concentration of virus particles.

Some of the more serious damage caused by SARS may be due to the body's own immune system reacting in what is known as cytokine storm.

ILLNESS

Viral

Poliomyelitis (Polio)

2 Poliomyelitis (Polio)

Polio, short for poliomyelitis, or infantile paralysis, is an infectious disease caused by the poliovirus. In about 0.5 percent of cases, there is muscle weakness resulting in an inability to move. This can occur over a few hours to a few days. The weakness most often involves the legs, but may less commonly involve the muscles of the head, neck and diaphragm. Many people fully recover. In those with muscle weakness, about 2 to 5 percent of children and 15 to 30 percent of adults die. Another 25 percent of people have minor symptoms such as fever and a sore throat, and up to 5 percent have headache, neck stiffness and pains in the arms and legs.

These people are usually back to normal within one or two weeks. In up to 70 percent of infections there are no symptoms. Years after recovery, post-polio syndrome may occur, with a slow development of muscle weakness similar to that which the person had during the initial infection. Poliovirus is usually spread from person to person through infected fecal matter entering the mouth. It may also be spread by food or water containing human feces and less commonly from infected saliva. Those who are infected may spread the disease for up to six weeks even if no symptoms are present. The disease may be diagnosed by finding the virus in the feces or detecting antibodies against it in the blood. The disease only occurs naturally in humans.

Sources

Enters water through the feces of infected individuals.

Poliomyelitis is caused by infection with a member of the genus Enterovirus known as poliovirus (PV). This group of RNA viruses colonize the gastrointestinal tract – specifically the oropharynx and the intestine. The incubation time (to the first signs and symptoms) ranges from three to 35 days, with a more common span of six to 20 days. PV infects and causes disease in humans alone. Its structure is very simple, composed of a single (+) sense RNA genome enclosed in a protein shell called a capsid.

In addition to protecting the virus' genetic material, the capsid proteins enable poliovirus to infect certain types of cells. Three serotypes of poliovirus have been identified – poliovirus type 1 (PV1), type 2 (PV2), and type 3 (PV3) – each with a slightly different capsid protein. All three are extremely virulent and produce the same disease symptoms. PV1 is the most commonly encountered form, and the one most closely associated with paralysis.

Individuals who are exposed to the virus, either through infection or by immunization with polio vaccine, develop immunity. In immune individuals, IgA antibodies against poliovirus are present in the tonsils and gastrointestinal tract, and are able to block virus replication; IgG and IgM antibodies against PV can prevent the spread of the virus to motor neurons of the central nervous system. Infection or vaccination with one serotype of poliovirus does not provide immunity against the other serotypes, and full immunity requires exposure to each serotype.

Symptoms

90-95% of patients show no symptoms, 4-8% have minor symptoms (comparatively) with delirium, headache, fever, and occasional seizures, and spastic paralysis, 1% have symptoms of non-paralytic aseptic meningitis. The rest have serious symptoms resulting in paralysis or death.

The term "poliomyelitis" is used to identify the disease caused by any of the three serotypes of poliovirus. Two basic patterns of polio infection are described: a minor illness which does not involve the central nervous system (CNS), sometimes called abortive poliomyelitis, and a major illness involving the CNS, which may be paralytic or nonparalytic. In most people with a normal immune system, a poliovirus infection is asymptomatic. Rarely, the infection produces minor symptoms; these may include upper respiratory tract infection (sore throat and fever), gastrointestinal disturbances (nausea, vomiting, abdominal pain, constipation or, rarely, diarrhea), and influenza-like illness.

The virus enters the central nervous system in about 1 percent of infections. Most patients with CNS involvement develop nonparalytic aseptic meningitis, with symptoms of headache, neck, back, abdominal and extremity pain, fever, vomiting, lethargy, and irritability. About one to five in 1000 cases progress to paralytic disease, in which the muscles become weak, floppy and poorly controlled, and, finally, completely paralyzed; this condition is known as acute flaccid paralysis.

Depending on the site of paralysis, paralytic poliomyelitis is classified as spinal, bulbar, or bulbospinal. Encephalitis, an infection of the brain tissue itself, can occur in rare cases, and is usually restricted to infants. It is characterized by confusion, changes in mental status, headaches, fever, and, less commonly, seizures and spastic paralysis.

Prevention

In 1950, William Hammon at the University of Pittsburgh purified the gamma globulin component of the blood plasma of polio survivors. Hammon proposed the gamma globulin, which contained antibodies to poliovirus, could be used to halt poliovirus infection, prevent disease, and reduce the severity of disease in other patients who had contracted polio. The results of a large clinical trial were promising; the gamma globulin was shown to be about 80 percent effective in preventing the development of paralytic poliomyelitis. It was also shown to reduce the severity of the disease in patients who developed polio. Due to the limited supply of blood plasma gamma globulin was later deemed impractical for widespread use and the medical community focused on the development of a polio vaccine.

Treatment

There is no cure for polio. The focus of modern treatment has been on providing relief of symptoms, speeding recovery and preventing complications. Supportive measures include antibiotics to prevent infections in weakened muscles, analgesics for pain, moderate exercise and a nutritious diet. Treatment of polio often requires long-term rehabilitation, including occupational therapy, physical therapy, braces, corrective shoes and, in some cases, orthopedic surgery.

Portable ventilators may be required to support breathing. Historically, a noninvasive, negative-pressure ventilator, more commonly called an iron lung, was used to artificially maintain respiration during an acute polio infection until a person could breathe independently (generally about one to two weeks). Today, many polio survivors with permanent respiratory paralysis use modern jacket-type negative-pressure ventilators worn over the chest and abdomen. Other historical treatments for polio include hydrotherapy, electrotherapy, massage and passive motion exercises, and surgical treatments, such as tendon lengthening and nerve grafting.

3 Polyomavirus

Polyomaviridae is a family of viruses whose natural hosts are primarily mammals and birds. As of the most recent (2018) taxonomy release by the International Committee on Taxonomy of Viruses, there were 89 recognized species in this family contained within four genera, as well as 9 species that could not be assigned to a genus. 13 species are known to infect humans, while others, such as Simian Virus 40, have been identified in humans to a lesser extent. Most of these viruses are very common and typically asymptomatic in most human populations studied. BK virus is associated with nephropathy in renal transplant and non-renal solid organ transplant patients, JC virus with progressive multifocal leukoencephalopathy, and Merkel cell virus with Merkel cell cancer.

Sources

Very widespread, can manifest itself in water, ~80% of the population has antibodies to Polyomavirus.

ILLNESS

Viral

Polyomavirus

Symptoms

BK virus produces a mild respiratory infection and can infect the kidneys of immunosuppressed transplant patients. JC virus infects the respiratory system, kidneys or can cause progressive multifocal leukoencephalopathy in the brain (which is fatal).

Prevention

Treatment

4 Avian Influenza (H5 N1)

Avian Influenza (Flu)

Avian influenza—known informally as avian flu or bird flu is a variety of influenza caused by viruses adapted to birds. The type with the greatest risk is highly pathogenic avian influenza (HPAI). Bird flu is similar to swine flu, dog flu, horse flu and human flu as an illness caused by strains of influenza viruses that have adapted to a specific host. Out of the three types of influenza viruses (A, B, and C), influenza A virus is a zoonotic infection with a natural reservoir almost entirely in birds. Avian influenza, for most purposes, refers to the influenza A virus.

Though influenza A is adapted to birds, it can also stably adapt and sustain person-to person transmission. Recent influenza research into the genes of the Spanish flu virus shows it to have genes adapted from both human and avian strains. Pigs can also be infected with human, avian, and swine influenza viruses, allowing for mixtures of genes (reassortment) to create a new virus, which can cause an antigenic shift to a new influenza A virus subtype which most people have little to no immune protection against.

ILLNESS

Viral

Avian Influenza (Flu)

Sources

Sources

Mostly, the bird flu virus is only dangerous for other birds however it can offer health risks to the people. In 1997, the first case of a man who was infected by the bird flu came into limelight in Hong Kong. The bird flu is since then knowingly spreading in the birds of Asia, Africa and Europe.

Such infection in human beings is not very common but unfortunately the bird flu virus in birds can mutate to infect the humankind that can easily lead into a global illness or a pandemic. When bird flu outbreak, sickness prevails in people who are in direct contact of the birds. The bird flu can possibly spread on eating the improperly cooked meat of an infected animal or by coming into contact of another infected human being. No vaccine is found yet. The flu can either make people exceptionally sick or kill them. Until now the bird flu has resulted into the death of billions of domestic and wild birds and a fraction of human beings.

Symptoms

Headache, Fever, Cough, Nausea, Shortness of Breath and Muscle aches.

ILLNESS

Avian Influenza (Flu)

Prevention

Prevention

People who do not regularly come into contact with birds are not at high risk for contracting avian influenza. Those at high risk include poultry farm workers, animal control workers, wildlife biologists, and ornithologists who handle live birds. Organizations with high-risk workers should have an avian influenza response plan in place before any cases have been discovered. Biosecurity of poultry flocks is also important for prevention. Flocks should be isolated from outside birds, especially wild birds, and their waste; vehicles used around the flock should be regularly disinfected and not shared between farms; and birds from slaughter channels should not be returned to the farm.

With proper infection control and use of personal protective equipment (PPE), the chance for infection is low. Protecting the eyes, nose, mouth, and hands is important for prevention because these are the most common ways for the virus to enter the body. Appropriate personal protective equipment includes aprons or coveralls, gloves, boots or boot covers, and a head cover or hair cover. Disposable PPE is recommended. An N-95 respirator and unvented/indirectly vented safety goggles are also part of appropriate PPE. A powered air purifying respirator (PAPR) with hood or helmet and face shield is also an option.

Treatment

Many influenza viruses have become resistant to the effects of a category of antiviral drugs that includes amantadine and rimantadine (Flumadine). Health officials recommend the use of oseltamivir (Tamiflu) or, if oseltamivir can't be used, zanamivir (Relenza). These drugs must be taken within two days after the appearance of symptoms.

5 Chikungunya

ILLNESS

Viral

Chikungunya

Chikungunya is an infection caused by the chikungunya virus (CHIKV). Symptoms include fever and joint pain. These typically occur two to twelve days after exposure. Other symptoms may include headache, muscle pain, joint swelling, and a rash. Symptoms usually improve within a week; however, occasionally the joint pain may last for months or years. The risk of death is around 1 in 1,000. The very young, old, and those with other health problems are at risk of more severe disease.

The virus is spread between people by two types of mosquitos: Aedes albopictus and Aedes aegypti. They mainly bite during the day. The virus may circulate within a number of animals including birds and rodents. Diagnosis is by either testing the blood for the virus's RNA or antibodies to the virus. The symptoms can be mistaken for those of dengue fever and Zika fever. After a single infection it is believed most people become immune.

Sources

Symptoms

ILLNESS Viral Chikungunya Symptoms

The incubation period ranges from one to twelve days, and is most typically three to seven. The disease may be asymptomatic, but generally is not, as 72% to 97% of those infected will develop symptoms. Characteristic symptoms include sudden onset with high fever, joint pain, and rash. Other symptoms may occur, including headache, fatigue, digestive complaints, and conjunctivitis.

Information gained during recent epidemics suggests that chikungunya fever may result in a chronic phase as well as the phase of acute illness. Within the acute phase, two stages have been identified: a viral stage during the first five to seven days, during which viremia occurs, followed by a convalescent stage lasting approximately ten days, during which symptoms improve and the virus cannot be detected in the blood. Typically, the disease begins with a sudden high fever that lasts from a few days to a week, and sometimes up to ten days. The fever is usually above 39 °C (102 °F) and sometimes reaching 40 °C (104 °F) and may be biphasic—lasting several days, breaking, and then returning. Fever occurs with the onset of viremia, and the level of virus in the blood correlates with the intensity of symptoms in the acute phase. When IgM, an antibody that is a response to the initial exposure to an antigen, appears in the blood, viremia begins to diminish. However, headache, insomnia and an extreme degree of exhaustion remain, usually about five to seven days.

Prevention

Chikungunya Prevention

Because no approved vaccine exists, the most effective means of prevention are protection against contact with the disease-carrying mosquitoes and controlling mosquito populations by limiting their habitat. Mosquito control focuses on eliminating the standing water where mosquitos lay eggs and develop as larva; if elimination of the standing water is not possible, insecticides or biological control agents can be added. Methods of protection against contact with mosquitos include using insect repellents with substances such as DEET, icaridin, PMD (p-menthane-3,8-diol, a substance derived from the lemon eucalyptus tree), or ethyl butylacetylaminopropionate (IR3535). However, increasing insecticide resistance presents a challenge to chemical control methods.

Wearing bite-proof long sleeves and trousers also offers protection, and garments can be treated with pyrethroids, a class of insecticides that often has repellent properties. Vaporized pyrethroids (for example in mosquito coils) are also insect repellents. As infected mosquitoes often feed and rest inside homes, securing screens on windows and doors will help to keep mosquitoes out of the house. In the case of the day-active A. aegypti and A. albopictus, however, this will have only a limited effect, since many contacts between the mosquitoes and humans occur outdoors.

Treatment

ILLNESS Viral Chikungunya Treatment

Currently, no specific treatment for chikungunya is available. Supportive care is recommended, and symptomatic treatment of fever and joint swelling includes the use of nonsteroidal anti-inflammatory drugs such as naproxen, non-aspirin analgesics such as paracetamol (acetaminophen) and fluids. Aspirin is not recommended due to the increased risk of bleeding. Despite anti-inflammatory effects, corticosteroids are not recommended during the acute phase of disease, as they may cause immunosuppression and worsen infection.

Passive immunotherapy has potential benefit in treatment of chikungunya. Studies in animals using passive immunotherapy have been effective, and clinical studies using passive immunotherapy in those particularly vulnerable to severe infection are currently in progress. Passive immunotherapy involves administration of anti-CHIKV hyperimmune human intravenous antibodies (immunoglobulins) to those exposed to a high risk of chikungunya infection. No antiviral treatment for Chikungunya virus is currently available, though testing has shown several medications to be effective in vitro.

Chronic Arthritis
In those who have more than two weeks of arthritis, ribavirin may be useful. The effect of chloroquine is not clear. It does not appear to help acute disease, but tentative evidence indicates it might help those with chronic arthritis. Steroids do not appear to be an effective treatment. NSAIDs and simple analgesics can be used to provide partial symptom relief in most cases. Methotrexate, a drug used in the treatment of rheumatoid arthritis, has been shown to have benefit in treating inflammatory polyarthritis resulting from chikungunya, though the drug mechanism for improving viral arthritis is unclear.

6 Hepatitis

Hepatitis A

ILLNESS Hepatitis Hepatitis A

Hepatitis A is an infectious disease of the liver caused by Hepatovirus A (HAV). Many cases have few or no symptoms, especially in the young. The time between infection and symptoms, in those who develop them, is between two and six weeks. When symptoms occur, they typically last eight weeks and may include nausea, vomiting, diarrhea, jaundice, fever, and abdominal pain. Around 10–15% of people experience a recurrence of symptoms during the six months after the initial infection. Acute liver failure may rarely occur, with this being more common in the elderly.

It is usually spread by eating food or drinking water contaminated with infected feces. Shellfish which have not been sufficiently cooked are a relatively common source. It may also be spread through close contact with an infectious person. While children often do not have symptoms when infected, they are still able to infect others. After a single infection, a person is immune for the rest of his or her life. Diagnosis requires blood testing, as the symptoms are similar to those of a number of other diseases. It is one of five known hepatitis viruses: A, B, C, D, and E.

Sources

ILLNESS Viral Hepatitis Hepatitis A

Hepatitis A is a contagious disease. It travels in feces, and can spread from person to person, or can be contracted from food or water. In cases of contaminated food, it is usually the person preparing the food who contaminates it. The food handler will probably not know they have the virus, since the virus is most likely to be passed on in the first two weeks of illness, before a person begins to show symptoms.

Symptoms

Symptoms of hepatitis A usually appear around 28 days after infection, but can start as early as two weeks after catching the virus. Only 30 percent of children with the virus actually develop symptoms. Early symptoms of this hepatitis virus include: Muscle aches, Headache, Loss of appetite, Abdominal discomfort, Fever, Weakness and fatigue. After a few days of experiencing these symptoms, 70 percent of patients develop jaundice, a yellowing of the skin, eyes, and mucous membranes. Jaundice also causes dark urine and light, clay-colored feces.

Prevention

Hepatitis Hepatitis A

Hepatitis A is completely avoidable, since a hepatitis A vaccine exists to prevent it. However, since the vaccine only became recommended for all children in 2006, many people are not vaccinated. Hepatitis transmission is still possible, and prevention techniques are still important. Food handlers should always wash hands after using the bathroom or changing a diaper and before preparing food.

Treatment

Once the symptoms for hepatitis A appear, there is no direct treatment for the virus. Patients should rest according to how tired they feel, and should receive enough nutrition either by eating or through fluids, since the disease can cause a lack of appetite.

Hepatitis B

Hepatitis B (HB) is an infectious disease caused by the hepatitis B virus (HBV) that affects the liver. It can cause both acute and chronic infections. Many people have no symptoms during the initial infection. Some develop a rapid onset of sickness with vomiting, yellowish skin, tiredness, dark urine and abdominal pain. Often these symptoms last a few weeks and rarely does the initial infection result in death. It may take 30 to 180 days for symptoms to begin. In those who get infected around the time of birth 90% develop chronic hepatitis B while less than 10% of those infected after the age of five do.

Most of those with chronic disease have no symptoms; however, cirrhosis and liver cancer may eventually develop. Cirrhosis or liver cancer occur in about 25% of those with chronic disease. The virus is transmitted by exposure to infectious blood or body fluids. Infection around the time of birth or from contact with other people's blood during childhood is the most frequent method by which hepatitis B is acquired in areas where the disease is common. In areas where the disease is rare, intravenous drug use and sexual intercourse are the most frequent routes of infection.

Other risk factors include working in healthcare, blood transfusions, dialysis, living with an infected person, travel in countries where the infection rate is high, and living in an institution. Tattooing and acupuncture led to a significant number of cases in the 1980s; however, this has become less common with improved sterilization. The hepatitis B viruses cannot be spread by holding hands, sharing eating utensils, kissing, hugging, coughing, sneezing, or breastfeeding. The infection can be diagnosed 30 to 60 days after exposure. The diagnosis is usually confirmed by testing the blood for parts of the virus and for antibodies against the virus. It is one of five main hepatitis viruses: A, B, C, D, and E.

Sources

Symptoms

Acute infection with hepatitis B virus is associated with acute viral hepatitis, an illness that begins with general ill-health, loss of appetite, nausea, vomiting, body aches, mild fever, and dark urine, and then progresses to development of jaundice. The illness lasts for a few weeks and then gradually improves in most affected people. A few people may have a more severe form of liver disease known as fulminant hepatic failure and may die as a result. The infection may be entirely asymptomatic and may go unrecognized.

Chronic infection with hepatitis B virus either may be asymptomatic or may be associated with a chronic inflammation of the liver (chronic hepatitis), leading to cirrhosis over a period of several years. This type of infection dramatically increases the incidence of hepatocellular carcinoma (HCC; liver cancer). Across Europe, hepatitis B and C cause approximately 50% of hepatocellular carcinomas. Chronic carriers are encouraged to avoid consuming alcohol as it increases their risk for cirrhosis and liver cancer. Hepatitis B virus has been linked to the development of membranous glomerulonephritis (MGN).

Symptoms outside of the liver are present in 1–10% of HBV-infected people and include serum-sickness–like syndrome, acute necrotizing vasculitis (polyarteritis nodosa), membranous glomerulonephritis, and papular acrodermatitis of childhood (Gianotti–Crosti syndrome). The serum-sickness–like syndrome occurs in the setting of acute hepatitis B, often preceding the onset of jaundice. The clinical features are fever, skin rash, and polyarteritis. The symptoms often subside shortly after the onset of jaundice but can persist throughout the duration of acute hepatitis B. About 30–50% of people with acute necrotizing vasculitis (polyarteritis nodosa) are HBV carriers.

HBV-associated nephropathy has been described in adults but is more common in children. Membranous glomerulonephritis is the most common form. Other immune-mediated hematological disorders, such as essential mixed cryoglobulinemia and aplastic anemia have been described as part of the extrahepatic manifestations of HBV infection, but their association is not as well-defined; therefore, they probably should not be considered etiologically linked to HBV.

Prevention

Vaccines for the prevention of hepatitis B have been routinely recommended for babies since 1991 in the United States. The first dose is generally recommended within a day of birth. The hepatitis B vaccine was the first vaccine capable of preventing cancer, specifically liver cancer.

Most vaccines are given in three doses over a course of months. A protective response to the vaccine is defined as an anti-HBs antibody concentration of at least 10 mIU/ml in the recipient's serum. The vaccine is more effective in children and 95 percent of those vaccinated have protective levels of antibody. This drops to around 90% at 40 years of age and to around 75 percent in those over 60 years. The protection afforded by vaccination is long lasting even after antibody levels fall below 10 mIU/ml. For newborns of HBsAg-positive mothers: hepatitis B vaccine alone, hepatitis B immunoglobulin alone, or the combination of vaccine plus hepatitis B immunoglobulin, all prevent hepatitis B occurrence. Furthermore, the combination of vaccine plus hepatitis B immunoglobulin is superior to vaccine alone. This combination prevents HBV transmission around the time of birth in 86% to 99% of cases.

Treatment

Acute hepatitis B infection does not usually require treatment and most adults clear the infection spontaneously. Early antiviral treatment may be required in fewer than 1% of people, whose infection takes a very aggressive course (fulminant hepatitis) or who are immunocompromised. On the other hand, treatment of chronic infection may be necessary to reduce the risk of cirrhosis and liver cancer. Chronically infected individuals with persistently elevated serum alanine aminotransferase, a marker of liver damage, and HBV DNA levels are candidates for therapy. Treatment lasts from six months to a year, depending on medication and genotype. Treatment duration when medication is taken by mouth, however, is more variable and usually longer than one year.

Although none of the available medications can clear the infection, they can stop the virus from replicating, thus minimizing liver damage. As of 2018, there are eight medications licensed for the treatment of hepatitis B infection in the United States. These include antiviral medications lamivudine, adefovir, tenofovir disoproxil, tenofovir alafenamide, telbivudine, and entecavir, and the two immune system modulators interferon alpha-2a and PEGylated interferon alpha-2a. In 2015 the World Health Organization recommended tenofovir or entecavir as first-line agents. Those with current cirrhosis are in most need of treatment.

Hepatitis C

Hepatitis C is an infectious disease caused by the hepatitis C virus (HCV) that primarily affects the liver. During the initial infection people often have mild or no symptoms. Occasionally a fever, dark urine, abdominal pain, and yellow tinged skin occurs. The virus persists in the liver in about 75% to 85% of those initially infected. Early on chronic infection typically has no symptoms. Over many years however, it often leads to liver disease and occasionally cirrhosis. In some cases, those with cirrhosis will develop serious complications such as liver failure, liver cancer, or dilated blood vessels in the esophagus and stomach.

HCV is spread primarily by blood-to-blood contact associated with intravenous drug use, poorly sterilized medical equipment, needlestick injuries in healthcare, and transfusions. Using blood screening, the risk from a transfusion is less than one per two million. It may also be spread from an infected mother to her baby during birth. It is not spread by superficial contact. It is one of five known hepatitis viruses: A, B, C, D, and E. Diagnosis is by blood testing to look for either antibodies to the virus or its RNA. Testing is recommended in all people who are at risk.

Sources

The primary route of transmission in the developed world is intravenous drug use (IDU), while in the developing world the main methods are blood transfusions and unsafe medical procedures. The cause of transmission remains unknown in 20% of cases; however, many of these are believed to be accounted for by IDU.

Symptoms

Acute Infection
Acute symptoms develop in some 20–30% of those infected. When this occurs, it is generally 4–12 weeks following infection (but it may take from 2 weeks to 6 months for acute symptoms to appear).

Symptoms are generally mild and vague, and may include fatigue, nausea and vomiting, fever, muscle or joint pains, abdominal pain, decreased appetite and weight loss, jaundice (occurs in ~25% of those infected), dark urine, and clay-coloured stools. There is no evidence that acute hepatitis C can alone cause acute liver failure, though liver injury and elevated liver enzymes may occur. Symptoms and laboratory findings suggestive of liver disease should prompt further tests and can thus help establish a diagnosis of hepatitis C infection early on.

Following the acute phase, the infection may resolve spontaneously in 10–50% of affected people; this occurs more frequently in young people, and females.

Chronic Infection
About 80% of those exposed to the virus develop a chronic infection. This is defined as the presence of detectable viral replication for at least six months. Most experience minimal or no symptoms during the initial few decades of the infection. Chronic hepatitis C can be associated with fatigue and mild cognitive problems. Chronic infection after several years may cause cirrhosis or liver cancer. The liver enzymes are normal in 7–53%. Late relapses after apparent cure have been reported, but these can be difficult to distinguish from reinfection.

Fatty changes to the liver occur in about half of those infected and are usually present before cirrhosis develops. Usually (80% of the time) this change affects less than a third of the liver. Worldwide hepatitis C is the cause of 27% of cirrhosis cases and 25% of hepatocellular carcinoma. About 10–30% of those infected develop cirrhosis over 30 years. Cirrhosis is more common in those also infected with hepatitis B, schistosoma, or HIV, in alcoholics and in those of male sex. In those with hepatitis C, excess alcohol increases the risk of developing cirrhosis 100-fold. Those who develop cirrhosis have a 20-fold greater risk of hepatocellular carcinoma. This transformation occurs at a rate of 1–3% per year. Being infected with hepatitis B in addition to hepatitis C increases this risk further.

Liver cirrhosis may lead to portal hypertension, ascites (accumulation of fluid in the abdomen), easy bruising or bleeding, varices (enlarged veins, especially in the stomach and esophagus), jaundice, and a syndrome of cognitive impairment known as hepatic encephalopathy. Ascites occurs at some stage in more than half of those who have a chronic infection.

Prevention

As of 2016, no approved vaccine protects against contracting hepatitis C. A combination of harm reduction strategies, such as the provision of new needles and syringes and treatment of substance use, decreases the risk of hepatitis C in intravenous drug users by about 75%. The screening of blood donors is important at a national level, as is adhering to universal precautions within healthcare facilities. In countries where there is an insufficient supply of sterile syringes, medications should be given orally rather than via injection (when possible).

Treatment

Those with chronic hepatitis C are advised to avoid alcohol and medications toxic to the liver. They should also be vaccinated against hepatitis A and hepatitis B due to the increased risk if also infected. Use of acetaminophen is generally considered safe at reduced doses. Nonsteroidal anti-inflammatory drugs (NSAIDs) are not recommended in those with advanced liver disease due to an increased risk of bleeding. Ultrasound surveillance for hepatocellular carcinoma is recommended in those with accompanying cirrhosis. Coffee consumption has been associated with a slower rate of liver scarring in those infected with HCV.

Medications
Approximately 90% of chronic cases clear with treatment. Treatment with antiviral medication is recommended in all people with proven chronic hepatitis C who are not at high risk of dying from other causes. People with the highest complication risk should be treated first, with the risk of complications based on the degree of liver scarring. The initial recommended treatment depends on the type of hepatitis C virus, if the person has received previous hepatitis C treatment, and whether or not a person has cirrhosis. Direct-acting antivirals (DAAs) may reduce the number of the infected people.

Hepatitis D

Hepatitis D (hepatitis delta) is a disease caused by the hepatitis D virus (HDV), a small spherical enveloped virusoid. This is one of five known hepatitis viruses: A, B, C, D, and E. HDV is considered to be a subviral satellite because it can propagate only in the presence of the hepatitis B virus (HBV). Transmission of HDV can occur either via simultaneous infection with HBV (coinfection) or superimposed on chronic hepatitis B or hepatitis B carrier state (superinfection).

Both superinfection and coinfection with HDV result in more severe complications compared to infection with HBV alone. These complications include a greater likelihood of experiencing liver failure in acute infections and a rapid progression to liver cirrhosis, with an increased risk of developing liver cancer in chronic infections. In combination with hepatitis B virus, hepatitis D has the highest fatality rate of all the hepatitis infections, at 20%.

Sources

The routes of transmission of hepatitis D are similar to those for hepatitis B. Infection is largely restricted to persons at high risk of hepatitis B infection, particularly injecting drug users and persons receiving clotting factor concentrates. Worldwide more than 15 million people are co-infected. HDV is rare in most developed countries, and is mostly associated with intravenous drug use. However, HDV is much more common in the immediate Mediterranean region, sub-Saharan Africa, the Middle East, and the northern part of South America. In all, about 20 million people may be infected with HDV.

Symptoms

Feeling tired, nausea and vomiting.

Prevention

The vaccine for hepatitis B protects against hepatitis D virus because of the latter's dependence on the presence of hepatitis B virus for it to replicate.
In absence of a specific vaccine against delta virus, the vaccine against HBV must be given soon after birth in risk groups.

Treatment

Hepatitis D is generally considered the dominant virus over hepatitis B except in rare instances. Current established treatments for chronic hepatitis D include conventional or pegylated interferon alpha therapy. Latest evidence suggests that pegylated interferon alpha is effective in reducing the viral load and the effect of the disease during the time the drug is given, but the benefit generally stops if the drug is discontinued. The efficiency of this treatment does not usually exceed ~20%, and late relapse after therapy has been reported.

Hepatitis E

ILLNESS Viral Hepatitis Hepatitis E

Hepatitis E is inflammation of the liver caused by infection with the hepatitis E virus (HEV). Hepatitis E has mainly a fecal-oral transmission route that is similar to hepatitis A, but the viruses are unrelated. In retrospect, the earliest known epidemic of hepatitis E occurred in 1955 in New Delhi, but the virus was not isolated until 1983, by Russian scientists investigating an outbreak in Afghanistan. One of five known human hepatitis viruses: hepatitis A, B, C, D, and E, HEV is a positive-sense, single-stranded, nonenveloped, RNA icosahedral virus.

Like hepatitis A, hepatitis E usually follows an acute and self-limiting course of illness (the condition is temporary and the individual recovers) with low death rates in resource-rich areas; however, it can be more severe in pregnant women and people with a weakened immune system, with substantially higher death rates. In pregnant women, especially in the third trimester, the disease is more often severe and is associated with a clinical syndrome called fulminant liver failure, with death rates around 20%. Whereas pregnant women may have a rapid and severe course, organ transplant recipients who receive medications to weaken the immune system and prevent organ rejection can develop a slower and more persistent form called chronic hepatitis E, which is so diagnosed after 3 months of continuous viremia. HEV can be clustered genetically into 8 genotypes, and genotypes 3 and 4 tend to be the ones that cause chronic hepatitis in the immunosuppressed.

Sources

Hepatitis E is transmitted via the faecal-oral route and can be spread by eating or drinking contaminated food or water. The highest rates of hepatitis E infection occur in regions where there is poor sanitation and sewage management that promotes the transmission of the virus.

Symptoms

The time between infection with hepatitis E and development of symptoms ranges from 15 to 60 days, with an average of 40 days. Common symptoms of acute hepatitis E are similar to those of other types of viral hepatitis and include: Fever, Weakness, Fatigue, Loss of Appetite, Nausea, Vomiting, Jaundice (yellowish eyes and skin, dark urine and pale-coloured faeces).

Prevention

As hepatitis E is spread through the faecal-oral route, prevention of hepatitis E relies primarily on the provision of clean drinking water and good personal hygiene. Travellers to developing countries are advised to take precautions against drinking contaminated water (including beverages with ice), eating uncooked shellfish and uncooked fruits and vegetables that are not peeled or prepared by the traveller.

Treatment

There is no treatment for hepatitis E. Hepatitis E is caused by a virus, therefore, antibiotics are of no value in the treatment of the infection. Treatment of hepatitis E infection is supportive and involves bed rest and fluid replacement.

7 Conjunctivitis (Pink Eye)

ILLNESS Viral Conjunctivitis (Pink Eye)

Conjunctivitis, also known as pink eye, is inflammation of the outermost layer of the white part of the eye and the inner surface of the eyelid. It makes the eye appear pink or reddish. Pain, burning, scratchiness, or itchiness may occur. The affected eye may have increased tears or be "stuck shut" in the morning. Swelling of the white part of the eye may also occur. Itching is more common in cases due to allergies. Conjunctivitis can affect one or both eyes. The most common infectious causes are viral followed by bacterial. The viral infection may occur along with other symptoms of a common cold. Both viral and bacterial cases are easily spread between people. Allergies to pollen or animal hair are also a common cause. Diagnosis is often based on signs and symptoms. Occasionally, a sample of the discharge is sent for culture.

Prevention is partly by handwashing. Treatment depends on the underlying cause. In the majority of viral cases, there is no specific treatment. Most cases due to a bacterial infection also resolve without treatment; however, antibiotics can shorten the illness. People who wear contact lenses and those whose infection is caused by gonorrhea or chlamydia should be treated. Allergic cases can be treated with antihistamines or mast cell inhibitor drops.

Sources

Infective conjunctivitis is most commonly caused by a virus. Bacterial infections, allergies, other irritants, and dryness are also common causes. Both bacterial and viral infections are contagious, passing from person to person or spread through contaminated objects or water. Contact with contaminated fingers is a common cause of conjunctivitis. Bacteria may also reach the conjunctiva from the edges of the eyelids and the surrounding skin, from the nasopharynx, from infected eye drops or contact lenses, from the genitals or the bloodstream. Infection by human adenovirus accounts for 65% to 90% of cases of viral conjunctivitis.

Symptoms

Red eye, swelling of the conjunctiva, and watering of the eyes are symptoms common to all forms of conjunctivitis. However, the pupils should be normally reactive, and the visual acuity normal. Conjunctivitis is identified by irritation and redness of the conjunctiva. Except in obvious pyogenic or toxic/chemical conjunctivitis, a slit lamp (biomicroscope) is needed to confirm the diagnosis. Examination of the eyelid conjunctiva is usually more diagnostic than examination of the scleral conjunctiva.

Prevention

The most effective prevention is good hygiene, especially avoiding rubbing the eyes with infected hands. Vaccination against adenovirus, Haemophilus influenzae, pneumococcus, and Neisseria meningitidis is also effective. Povidone-iodine eye solution has been found to prevent neonatal conjunctivitis. It is becoming more commonly used globally because of its low cost.

Treatment

Conjunctivitis resolves in 65% of cases without treatment, within 2–5 days. The prescription of antibiotics is not necessary in most cases.

Viral
Viral conjunctivitis usually resolves on its own and does not require any specific treatment. Antihistamines (e.g., diphenhydramine) or mast cell stabilizers (e.g., cromolyn) may be used to help with the symptoms. Povidone-iodine has been suggested as a treatment, but as of 2008, evidence to support it was poor.

Allergic
For allergic conjunctivitis, cool water poured over the face with the head inclined downward constricts capillaries, and artificial tears sometimes relieve discomfort in mild cases. In more severe cases, nonsteroidal anti-inflammatory medications and antihistamines may be prescribed. Persistent allergic conjunctivitis may also require topical steroid drops.

Viral

Conjunctivitis (Pink

Treatment

Bacterial
Bacterial conjunctivitis usually resolves without treatment. Topical antibiotics may be needed only if no improvement is observed after 3 days. No serious effects were noted either with or without treatment. Because antibiotics do speed healing in bacterial conjunctivitis, their use may be considered. Antibiotics are also recommended for those who wear contact lenses, are immunocompromised, have disease which is thought to be due to chlamydia or gonorrhea, have a fair bit of pain, or have copious discharge. Gonorrheal or chlamydial infections require both oral and topical antibiotics. The choice of antibiotic varies based on the strain or suspected strain of bacteria causing the infection. Fluoroquinolones, sodium sulfacetamide, or trimethoprim/polymyxin may be used, typically for 7–10 days. Cases of meningococcal conjunctivitis can also be treated with systemic penicillin, as long as the strain is sensitive to penicillin.

When investigated as a treatment, povidone-iodine ophthalmic solution has also been observed to have some effectiveness against bacterial and chlamydial conjunctivitis, with a possible role suggested in locations where topical antibiotics are unavailable or costly.

ILLNESS

8 Ebola

Ebola

Ebola virus disease (EVD), also known as Ebola hemorrhagic fever (EHF) or simply Ebola, is a viral hemorrhagic fever of humans and other primates caused by ebolaviruses. Signs and symptoms typically start between two days and three weeks after contracting the virus with a fever, sore throat, muscular pain, and headaches. Vomiting, diarrhea and rash usually follow, along with decreased function of the liver and kidneys. At this time, some people begin to bleed both internally and externally. The disease has a high risk of death, killing 25% to 90% of those infected, with an average of about 50%. This is often due to low blood pressure from fluid loss, and typically follows 6 to 16 days after symptoms appear.

The virus spreads through direct contact with body fluids, such as blood from infected humans or other animals. Spread may also occur from contact with items recently contaminated with bodily fluids. Spread of the disease through the air between primates, including humans, has not been documented in either laboratory or natural conditions. Semen or breast milk of a person after recovery from EVD may carry the virus for several weeks to months. Fruit bats are believed to be the normal carrier in nature, able to spread the virus without being affected by it. Other diseases such as malaria, cholera, typhoid fever, meningitis and other viral hemorrhagic fevers may resemble EVD. Blood samples are tested for viral RNA, viral antibodies or for the virus itself to confirm the diagnosis.

ILLNESS

Viral

Ebola

Sources

The virus spreads through direct contact with body fluids, such as blood from infected humans or other animals. Spread may also occur from contact with items recently contaminated with bodily fluids. Spread of the disease through the air between primates, including humans, has not been documented in either laboratory or natural conditions. Semen or breast milk of a person after recovery from EVD may carry the virus for several weeks to months. Fruit bats are believed to be the normal carrier in nature, able to spread the virus without being affected by it.

Symptoms

Ebola

Symptoms

Onset
The length of time between exposure to the virus and the development of symptoms (incubation period) is between two and 21 days, and usually between four and ten days. However, recent estimates based on mathematical models predict that around 5% of cases may take greater than 21 days to develop.

Symptoms usually begin with a sudden influenza-like stage characterised by feeling tired, fever, weakness, decreased appetite, muscular pain, joint pain, headache, and sore throat. The fever is usually higher than 38.3°C (101°F). This is often followed by nausea, vomiting, diarrhoea, abdominal pain, and sometimes hiccups. The combination of severe vomiting and diarrhoea often leads to severe dehydration. Next, shortness of breath and chest pain may occur, along with swelling, headaches, and confusion. In about half of the cases, the skin may develop a maculopapular rash, a flat red area covered with small bumps, five to seven days after symptoms begin.

ILLNESS

Bleeding
In some cases, internal and external bleeding may occur. This typically begins five to seven days after the first symptoms. All infected people show some decreased blood clotting. Bleeding from mucous membranes or from sites of needle punctures has been reported in 40–50% of cases. This may cause vomiting blood, coughing up of blood, or blood in stool. Bleeding into the skin may create petechiae, purpura, ecchymoses or haematomas (especially around needle injection sites). Bleeding into the whites of the eyes may also occur. Heavy bleeding is uncommon; if it occurs, it is usually in the gastrointestinal tract. The incidence of bleeding into the gastrointestinal tract was reported to be ~58% in the 2001 outbreak in Gabon, but in the 2014-15 outbreak in the US it was ~18%, possibly due to improved prevention of disseminated intravascular coagulation.

Viral

Ebola

Symptoms

Recovery and Death
Recovery may begin between seven and 14 days after first symptoms. Death, if it occurs, follows typically six to sixteen days from first symptoms and is often due to low blood pressure from fluid loss. In general, bleeding often indicates a worse outcome, and blood loss may result in death. People are often in a coma near the end of life.

Those who survive often have ongoing muscular and joint pain, liver inflammation, and decreased hearing, and may have continued tiredness, continued weakness, decreased appetite, and difficulty returning to pre-illness weight. Problems with vision may develop.

Survivors develop antibodies against Ebola that last at least 10 years, but it is unclear whether they are immune to additional infections.

Prevention

Ebola

ILLNESS

Vaccines
An Ebola vaccine, rVSV-ZEBOV, was approved in the United States in December 2019. It appears to be fully effective ten days after being given. It was studied in Guinea between 2014, and 2016. More than 100,000 people have been vaccinated against Ebola as of 2019.

Ebola

Prevention

Infection Control
People who care for those infected with Ebola should wear protective clothing including masks, gloves, gowns and goggles. The U.S. Centers for Disease Control (CDC) recommend that the protective gear leaves no skin exposed. These measures are also recommended for those who may handle objects contaminated by an infected person's body fluids. In 2014, the CDC began recommending that medical personnel receive training on the proper suit-up and removal of personal protective equipment (PPE); in addition, a designated person, appropriately trained in biosafety, should be watching each step of these procedures to ensure they are done correctly. In Sierra Leone, the typical training period for the use of such safety equipment lasts approximately 12 days.

Patients and Household Members
The infected person should be in barrier-isolation from other people. All equipment, medical waste, patient waste and surfaces that may have come into contact with body fluids need to be disinfected. During the 2014 outbreak, kits were put together to help families treat Ebola disease in their homes, which included protective clothing as well as chlorine powder and other cleaning supplies. Education of caregivers in these techniques, and providing such barrier-separation supplies has been a priority of Doctors Without Borders.

al

ILLNESS Viral Ebola Prevention

Disinfection
Ebolaviruses can be eliminated with heat (heating for 30 to 60 minutes at 60 °C or boiling for five minutes). To disinfect surfaces, some lipid solvents such as some alcohol-based products, detergents, sodium hypochlorite (bleach) or calcium hypochlorite (bleaching powder), and other suitable disinfectants may be used at appropriate concentrations.

Corpses, Burial
If a person with Ebola disease dies, direct contact with the body should be avoided. Certain burial rituals, which may have included making various direct contacts with a dead body, require reformulation so that they consistently maintain a proper protective barrier between the dead body and the living. Social anthropologists may help find alternatives to traditional rules for burials.

Treatment

ILLNESS Viral Ebola Treatment

While there is no approved treatment for Ebola as of 2019, two treatments (REGN-EB3 and mAb114) are associated with improved outcomes. The U.S. Food and Drug Administration (FDA) advises people to be careful of advertisements making unverified or fraudulent claims of benefits supposedly gained from various anti-Ebola products.

Standard Support
Treatment is primarily supportive in nature. Early supportive care with rehydration and symptomatic treatment improves survival. Rehydration may be via the oral or intravenous route. These measures may include pain management, and treatment for nausea, fever, and anxiety. The World Health Organization (WHO) recommends avoiding aspirin or ibuprofen for pain management, due to the risk of bleeding associated with these medications.

Blood products such as packed red blood cells, platelets, or fresh frozen plasma may also be used. Other regulators of coagulation have also been tried including heparin in an effort to prevent disseminated intravascular coagulation and clotting factors to decrease bleeding. Antimalarial medications and antibiotics are often used before the diagnosis is confirmed, though there is no evidence to suggest such treatment helps. Several experimental treatments are being studied. Where hospital care is not possible, the WHO's guidelines for home care have been relatively successful. Recommendations include using towels soaked in a bleach solution when moving infected people or bodies and also applying bleach on stains. It is also recommended that the caregivers wash hands with bleach solutions and cover their mouth and nose with a cloth.

Notes

ILLNESS Ebola Notes

EVD has a risk of death in those infected of between 25% and 90%. As of September 2014, the average risk of death among those infected is 50%. The highest risk of death was 90% in the 2002–2003 Republic of the Congo outbreak. Death, if it occurs, follows typically six to sixteen days after symptoms appear and is often due to low blood pressure from fluid loss. Early supportive care to prevent dehydration may reduce the risk of death.

If an infected person survives, recovery may be quick and complete. Prolonged cases are often complicated by the occurrence of long-term problems, such as inflammation of the testicles, joint pains, fatigue, hearing loss, mood and sleep disturbances, muscular pain, abdominal pain, menstrual abnormalities, miscarriages, skin peeling, or hair loss. Inflammation and swelling of the uveal layer of the eye is the most common eye complication in survivors of Ebola virus disease. Eye symptoms, such as light sensitivity, excess tearing, and vision loss have been described.

Ebola can stay in some body parts like the eyes, breasts, and testicles after infection. Sexual transmission after recovery has been suspected. If sexual transmission occurs following recovery it is believed to be a rare event. One case of a condition similar to meningitis has been reported many months after recovery, as of October 2015. A study of 44 survivors of the Ebola virus in Sierra Leone reported musculoskeletal pain in 70%, headache in 48%, and eye problems in 14%.

9 Gastroenteritis

ILLNESS Viral Gastroenteritis

Gastroenteritis, also known as infectious diarrhea, is inflammation of the gastrointestinal tract—the stomach and small intestine. Symptoms may include diarrhea, vomiting and abdominal pain. Fever, lack of energy and dehydration may also occur. This typically lasts less than two weeks. It is not related to influenza, though it has erroneously been called the "stomach flu". Gastroenteritis is usually caused by viruses. However, bacteria, parasites, and fungus can also cause gastroenteritis.

In children, rotavirus is the most common cause of severe disease. In adults, norovirus and Campylobacter are common causes. Eating improperly prepared food, drinking contaminated water or close contact with a person who is infected can spread the disease. Treatment is generally the same with or without a definitive diagnosis, so testing to confirm is usually not needed.

Prevention includes hand washing with soap, drinking clean water, proper disposal of human waste and breastfeeding babies instead of using formula. The rotavirus vaccine is recommended as a prevention for children. Treatment involves getting enough fluids. For mild or moderate cases, this can typically be achieved by drinking oral rehydration solution (a combination of water, salts and sugar).

In those who are breastfed, continued breastfeeding is recommended. For more severe cases, intravenous fluids may be needed. Fluids may also be given by a nasogastric tube. Zinc supplementation is recommended in children. Antibiotics are generally not needed. However, antibiotics are recommended for young children with a fever and bloody diarrhea.

Sources

ILLNESS Gastroenteritis

Viruses (particularly rotavirus) and the bacteria Escherichia coli and Campylobacter species are the primary causes of gastroenteritis. There are, however, many other infectious agents that can cause this syndrome including parasites and fungus. Non-infectious causes are seen on occasion, but they are less likely than a viral or bacterial cause. Risk of infection is higher in children due to their lack of immunity. Children are also at higher risk because they are less likely to practice good hygiene habits. Children living in areas without easy access to water and soap are especially vulnerable.

Symptoms

ILLNESS Viral Gastroenteritis Symptoms

Gastroenteritis usually involves both diarrhea and vomiting. Sometimes, only one or the other is present. This may be accompanied by abdominal cramps. Signs and symptoms usually begin 12–72 hours after contracting the infectious agent. If due to a virus, the condition usually resolves within one week. Some viral infections also involve fever, fatigue, headache and muscle pain. If the stool is bloody, the cause is less likely to be viral and more likely to be bacterial. Some bacterial infections cause severe abdominal pain and may persist for several weeks.

Children infected with rotavirus usually make a full recovery within three to eight days. However, in poor countries treatment for severe infections is often out of reach and persistent diarrhea is common. Dehydration is a common complication of diarrhea. Severe dehydration in children may be recognized if the skin color and position returns slowly when pressed. This is called "prolonged capillary refill" and "poor skin turgor". Abnormal breathing is another sign of severe dehydration. Repeat infections are typically seen in areas with poor sanitation, and malnutrition. Stunted growth and long-term cognitive delays can result.

Reactive arthritis occurs in 1% of people following infections with Campylobacter species. Guillain–Barré syndrome occurs in 0.1%. Hemolytic uremic syndrome (HUS) may occur due to infection with Shiga toxin-producing Escherichia coli or Shigella species. HUS causes low platelet counts, poor kidney function, and low red blood cell count (due to their breakdown). Children are more predisposed to getting HUS than adults. Some viral infections may produce benign infantile seizures.

Prevention

A supply of easily accessible uncontaminated water and good sanitation practices are important for reducing rates of infection and clinically significant gastroenteritis. Personal measures (such as hand washing with soap) have been found to decrease rates of gastroenteritis in both the developing and developed world by as much as 30%. Alcohol-based gels may also be effective. Food or drink that is thought to be contaminated should be avoided. Breastfeeding is important, especially in places with poor hygiene, as is improvement of hygiene generally. Breast milk reduces both the frequency of infections and their duration.

Treatment

Gastroenteritis is usually an acute and self-limiting disease that does not require medication. The preferred treatment in those with mild to moderate dehydration is oral rehydration therapy (ORT). For children at risk of dehydration from vomiting, taking a single dose of the anti vomiting medication metoclopramide or ondansetron, may be helpful, and butylscopolamine is useful in treating abdominal pain.

Rehydration
The primary treatment of gastroenteritis in both children and adults is rehydration. This is preferably achieved by drinking rehydration solution, although intravenous delivery may be required if there is a decreased level of consciousness or if dehydration is severe. Drinking replacement therapy products made with complex carbohydrates (i.e. those made from wheat or rice) may be superior to those based on simple sugars. Drinks especially high in simple sugars, such as soft drinks and fruit juices, are not recommended in children under 5 years of age as they may increase diarrhea. Plain water may be used if more specific ORT preparations are unavailable or the person is not willing to drink them. A nasogastric tube can be used in young children to administer fluids if warranted. In those who require intravenous fluids, one to four hours' worth is often sufficient.

Dietary
It is recommended that breast-fed infants continue to be nursed in the usual fashion, and that formula-fed infants continue their formula immediately after rehydration with ORT. Lactose-free or lactose-reduced formulas usually are not necessary. Children should continue their usual diet during episodes of diarrhea with the exception that foods high in simple sugars should be avoided. The BRAT diet (bananas, rice, applesauce, toast and tea) is no longer recommended, as it contains insufficient nutrients and has no benefit over normal feeding.

Some probiotics have been shown to be beneficial in reducing both the duration of illness and the frequency of stools. They may also be useful in preventing and treating antibiotic associated diarrhea. Fermented milk products (such as yogurt) are similarly beneficial. Zinc supplementation appears to be effective in both treating and preventing diarrhea among children in the developing world.

Antiemetics
Antiemetic medications may be helpful for treating vomiting in children. Ondansetron has some utility, with a single dose being associated with less need for intravenous fluids, fewer hospitalizations, and decreased vomiting. Metoclopramide might also be helpful. However, the use of ondansetron might possibly be linked to an increased rate of return to hospital in children. The intravenous preparation of ondansetron may be given orally if clinical judgment warrants. Dimenhydrinate, while reducing vomiting, does not appear to have a significant clinical benefit.

Antibiotics
Antibiotics are not usually used for gastroenteritis, although they are sometimes recommended if symptoms are particularly severe or if a susceptible bacterial cause is isolated or suspected. If antibiotics are to be employed, a macrolide (such as azithromycin) is preferred over a fluoroquinolone due to higher rates of resistance to the latter. Pseudomembranous colitis, usually caused by antibiotic use, is managed by discontinuing the causative agent and treating it with either metronidazole or vancomycin. Bacteria and protozoans that are amenable to treatment include Shigella Salmonella typhi, and Giardia species. In those with Giardia species or Entamoeba histolytica, tinidazole treatment is recommended and superior to metronidazole. The World Health Organization (WHO) recommends the use of antibiotics in young children who have both bloody diarrhea and fever.

10 HFMD (Hand Foot and Mouth Disease)

Hand, foot, and mouth disease (HFMD) is a common infection caused by a group of viruses. It typically begins with a fever and feeling generally unwell. This is followed a day or two later by flat discolored spots or bumps that may blister, on the hands, feet and mouth and occasionally buttocks and groin. Signs and symptoms normally appear 3–6 days after exposure to the virus. The rash generally resolves on its own in about a week. Fingernail and toenail loss may occur a few weeks later, but they will regrow with time.

The viruses that cause HFMD are spread through close personal contact, through the air from coughing and the feces of an infected person. Contaminated objects can also spread the disease. Coxsackievirus A16 is the most common cause, and enterovirus 71 is the second-most common cause. Other strains of coxsackievirus and enterovirus can also be responsible. Some people may carry and pass on the virus despite having no symptoms of disease. Other animals are not involved. Diagnosis can often be made based on symptoms. Occasionally, a throat or stool sample may be tested for the virus.

Sources

The viruses that cause the disease are of the Picornaviridae family. Coxsackievirus A16 is the most common cause of HFMD. Enterovirus 71 (EV-71) is the second-most common cause. Many other strains of coxsackievirus and enterovirus can also be responsible. HFMD is highly contagious and is transmitted by nasopharyngeal secretions such as saliva or nasal mucus, by direct contact, or by fecal-oral transmission. It is possible to be infectious for days to weeks after the symptoms have resolved.

Symptoms

Common constitutional signs and symptoms of the HFMD include fever, nausea, vomiting, feeling tired, generalized discomfort, loss of appetite, and irritability in infants and toddlers. Skin lesions frequently develop in the form of a rash of flat discolored spots and bumps which may be followed by vesicular sores with blisters on palms of the hands, soles of the feet, buttocks, and sometimes on the lips. The rash is rarely itchy for children, but can be extremely itchy for adults. Painful facial ulcers, blisters, or lesions may also develop in or around the nose or mouth. HFMD usually resolves on its own after 7–10 days. Most cases of the disease are relatively harmless, but complications including encephalitis, meningitis, and paralysis that mimics the neurological symptoms of polio can occur.

Prevention

Preventive measures include avoiding direct contact with infected individuals (including keeping infected children home from school), proper cleaning of shared utensils, disinfecting contaminated surfaces, and proper hand hygiene. These measures have been shown to be effective in decreasing the transmission of the viruses responsible for HFMD.

Protective habits include hand washing and disinfecting surfaces in play areas. Breast-feeding has also shown to decrease rates of severe HFMD, though does not reduce the risk for the infection of the disease.

Treatment

ILLNESS Viral HFMD (Ha Treatment

Medications are usually not needed as hand, foot, and mouth disease is a viral disease that typically resolves on its own. Currently, there is no specific curative treatment for hand, foot and mouth disease. Disease management typically focuses on achieving symptomatic relief. Pain from the sores may be eased with the use of analgesic medications. Infection in older children, adolescents, and adults is typically mild and lasts approximately 1 week, but may occasionally run a longer course. Fever reducers and lukewarm baths can help decrease body temperature.

A minority of individuals with hand, foot and mouth disease may require hospital admission due to complications such as inflammation of the brain, inflammation of the meninges, or acute flaccid paralysis. Non-neurologic complications such as inflammation of the heart, fluid in the lungs, or bleeding into the lungs may also occur.

11 HIV/AIDS

ILLNESS Viral HIV/AIDS

Human immunodeficiency virus infection and acquired immune deficiency syndrome (HIV/AIDS) is a spectrum of conditions caused by infection with the human immunodeficiency virus (HIV). Following initial infection a person may not notice any symptoms, or may experience a brief period of influenza-like illness. Typically, this is followed by a prolonged period with no symptoms.

As the infection progresses, it interferes more with the immune system, increasing the risk of developing common infections such as tuberculosis, as well as other opportunistic infections, and tumors which are otherwise rare in people who have normal immune function. These late symptoms of infection are referred to as acquired immunodeficiency syndrome (AIDS). This stage is often also associated with unintended weight loss.

HIV is spread primarily by unprotected sex (including anal and oral sex), contaminated blood transfusions, hypodermic needles, and from mother to child during pregnancy, delivery, or breastfeeding. Some bodily fluids, such as saliva, sweat and tears, do not transmit the virus. HIV is a member of the group of viruses known as retroviruses. Methods of prevention include safe sex, needle exchange programs, treating those who are infected, pre- and post-exposure prophylaxis, and male circumcision.

Disease in a baby can often be prevented by giving both the mother and child antiretroviral medication. There is no cure or vaccine; however, antiretroviral treatment can slow the course of the disease and may lead to a near-normal life expectancy. Treatment is recommended as soon as the diagnosis is made. Without treatment, the average survival time after infection is 11 years.

Sources

ILLNESS HIV/AIDS

HIV is spread by three main routes: sexual contact, significant exposure to infected body fluids or tissues, and from mother to child during pregnancy, delivery, or breastfeeding (known as vertical transmission). There is no risk of acquiring HIV if exposed to feces, nasal secretions, saliva, sputum, sweat, tears, urine, or vomit unless these are contaminated with blood. It is also possible to be co-infected by more than one strain of HIV—a condition known as HIV superinfection.

Symptoms

Viral HIV/AIDS Symptoms

There are three main stages of HIV infection: acute infection, clinical latency, and AIDS.

Acute Infection
The initial period following the contraction of HIV is called acute HIV, primary HIV or acute retroviral syndrome. Many individuals develop an influenza-like illness or a mononucleosis-like illness 2–4 weeks after exposure while others have no significant symptoms. Symptoms occur in 40–90% of cases and most commonly include fever, large tender lymph nodes, throat inflammation, a rash, headache, tiredness, and/or sores of the mouth and genitals. The rash, which occurs in 20–50% of cases, presents itself on the trunk and is maculopapular, classically. Some people also develop opportunistic infections at this stage. Gastrointestinal symptoms, such as vomiting or diarrhea may occur. Neurological symptoms of peripheral neuropathy or Guillain–Barré syndrome also occurs. The duration of the symptoms varies, but is usually one or two weeks.

Owing to their nonspecific character, these symptoms are not often recognized as signs of HIV infection. Even cases that do get seen by a family doctor or a hospital are often misdiagnosed as one of the many common infectious diseases with overlapping symptoms. Thus, it is recommended that HIV be considered in people presenting with an unexplained fever who may have risk factors for the infection.

ILLNESS HIV/AIDS Symptoms

Clinical Latency
The initial symptoms are followed by a stage called clinical latency, asymptomatic HIV, or chronic HIV. Without treatment, this second stage of the natural history of HIV infection can last from about three years to over 20 years (on average, about eight years). While typically there are few or no symptoms at first, near the end of this stage many people experience fever, weight loss, gastrointestinal problems and muscle pains. Between 50% and 70% of people also develop persistent generalized lymphadenopathy, characterized by unexplained, non-painful enlargement of more than one group of lymph nodes (other than in the groin) for over three to six months.

Although most HIV-1 infected individuals have a detectable viral load and in the absence of treatment will eventually progress to AIDS, a small proportion (about 5%) retain high levels of CD4+ T cells (T helper cells) without antiretroviral therapy for more than five years. These individuals are classified as "HIV controllers" or long-term nonprogressors (LTNP). Another group consists of those who maintain a low or undetectable viral load without anti-retroviral treatment, known as "elite controllers" or "elite suppressors". They represent approximately 1 in 300 infected persons.

ILLNESS Viral HIV/AIDS Symptoms

The World Health Organization first proposed a definition for AIDS in 1986. Since then, the WHO classification has been updated and expanded several times, with the most recent version being published in 2007. The WHO system uses the following categories:
● Primary HIV infection: May be either asymptomatic or associated with acute retroviral syndrome
● Stage I: HIV infection is asymptomatic with a CD4+ T cell count (also known as CD4 count) greater than 500 per microlitre (µl or cubic mm) of blood. May include generalized lymph node enlargement.
● Stage II: Mild symptoms, which may include minor mucocutaneous manifestations and recurrent upper respiratory tract infections. A CD4 count of less than 500/µl
● Stage III: Advanced symptoms, which may include unexplained chronic diarrhea for longer than a month, severe bacterial infections including tuberculosis of the lung, and a CD4 count of less than 350/µl
● Stage IV or AIDS: severe symptoms, which include toxoplasmosis of the brain, candidiasis of the esophagus, trachea, bronchi, or lungs, and Kaposi's sarcoma. A CD4 count of less than 200/µl

Prevention

Sexual Contact
Consistent condom use reduces the risk of HIV transmission by approximately 80% over the long term. When condoms are used consistently by a couple in which one person is infected, the rate of HIV infection is less than 1% per year. There is some evidence to suggest that female condoms may provide an equivalent level of protection. Application of a vaginal gel containing tenofovir (a reverse transcriptase inhibitor) immediately before sex seems to reduce infection rates by approximately 40% among African women. By contrast, use of the spermicide nonoxynol-9 may increase the risk of transmission due to its tendency to cause vaginal and rectal irritation.

Circumcision in Sub-Saharan Africa "reduces the acquisition of HIV by heterosexual men by between 38% and 66% over 24 months". Owing to these studies, both the World Health Organization and UNAIDS recommended male circumcision in 2007 as a method of preventing female-to-male HIV transmission in areas with high rates of HIV. However, whether it protects against male-to-female transmission is disputed, and whether it is of benefit in developed countries and among men who have sex with men is undetermined. The International Antiviral Society, however, does recommend it for all sexually active heterosexual males and that it be discussed as an option with men who have sex with men. Some experts fear that a lower perception of vulnerability among circumcised men may cause more sexual risk-taking behavior, thus negating its preventive effects.

Treatment

There is currently no cure, nor an effective HIV vaccine. Treatment consists of highly active antiretroviral therapy (HAART) which slows progression of the disease. As of 2010 more than 6.6 million people were receiving this in low- and middle-income countries. Treatment also includes preventive and active treatment of opportunistic infections. As of March 2020, two persons have been successfully cleared of HIV. Rapid initiation of anti-retroviral therapy within one week of diagnosis appear to improve treatment outcomes in low and medium-income settings.

Antiviral Therapy
A white prescription bottle with the label Stribild. Next to it are ten green oblong pills with the marking 1 on one side and GSI on the other.
Stribild – a common once-daily ART regime consisting of elvitegravir, emtricitabine, tenofovir and the booster cobicistat
Current HAART options are combinations (or "cocktails") consisting of at least three medications belonging to at least two types, or "classes", of antiretroviral agents.

12 Hemorrhagic Fever

Viral hemorrhagic fevers (VHFs) are a diverse group of animal and human illnesses in which fever and hemorrhage are caused by a viral infection. VHFs may be caused by five distinct families of RNA viruses: the families Arenaviridae, Filoviridae, Bunyaviridae, Flaviviridae, and Rhabdoviridae. All types of VHF are characterized by fever and bleeding disorders and all can progress to high fever, shock and death in many cases. Some of the VHF agents cause relatively mild illnesses, such as the Scandinavian nephropathia epidemica (a hantavirus), while others, such as Ebola virus, can cause severe, life-threatening disease.

Sources

Five families of RNA viruses have been recognised as being able to cause hemorrhagic fevers.
- The family Arenaviridae include the viruses responsible for Lassa fever (Lassa virus), Lujo virus, Argentine (Junin virus), Bolivian (Machupo virus), Brazilian (Sabiá virus), Chapare hemorrhagic fever (Chapare virus), Venezuelan (Guanarito virus) and Whitewater Arroyo virus hemorrhagic fevers.
- The family Bunyaviridae include the causative agents of Hantavirus hemorrhagic fever with renal syndrome (HV-HFRS), the Crimean-Congo hemorrhagic fever (CCHF) virus from the genus Nairovirus, Garissa virus and Ilesha virus from the Orthobunyavirus and the Rift Valley fever (RVF) virus from the genus Phlebovirus.
- The family Filoviridae include Ebola virus and Marburg virus.
- The family Flaviviridae include dengue, yellow fever, and two viruses in the tick-borne encephalitis group that cause VHF: Omsk hemorrhagic fever virus and Kyasanur Forest disease virus.
- In September 2012 scientists writing in the journal PLOS Pathogens reported the isolation of a member of the Rhabdoviridae responsible for 2 fatal and 2 non-fatal cases of hemorrhagic fever in the Bas-Congo district of the Democratic Republic of Congo. The virus was named Bas-Congo virus. The non-fatal cases occurred in healthcare workers involved in the treatment of the other two, suggesting the possibility of person-to-person transmission. This virus is related to the Ephemerovirus and Tibrovirus genera.

Symptoms

Signs and symptoms of VHFs include (by definition) fever and bleeding. Manifestations of VHF often also include flushing of the face and chest, small red or purple spots (petechiae), bleeding, swelling caused by edema, low blood pressure (hypotension), and shock. Malaise, muscle pain, headache, vomiting, and diarrhea occur frequently. The severity of symptoms varies with the type of virus. The "VHF syndrome" (capillary leak, bleeding diathesis, and circulatory compromise leading to shock) appears in a majority of people with filovirus hemorrhagic fevers (e.g., Ebola and Marburg virus), Crimean–Congo hemorrhagic fever (CCHF), and the South American hemorrhagic fevers caused by arenaviruses, but only in a small minority of patients with dengue, Rift Valley fever, and Lassa fever.

Prevention

With the exception of yellow fever vaccine neither vaccines nor experimental vaccines are readily available. Prophylactic (preventive) ribavirin may be effective for some bunyavirus and arenavirus infections (available only as an investigational new drug (IND)).

VHF isolation guidelines dictate that all VHF patients (with the exception of dengue patients) should be cared for using strict contact precautions, including hand hygiene, double gloves, gowns, shoe and leg coverings, and face shield or goggles. Lassa, CCHF, Ebola, and Marburg viruses may be particularly prone to nosocomial (hospital-based) spread. Airborne precautions should be utilized including, at a minimum, a fit-tested, HEPA filter-equipped respirator (such as an N-95 mask), a battery-powered, air-purifying respirator, or a positive pressure supplied air respirator to be worn by personnel coming within 1,8 meter (six feet) of a VHF patient. Groups of patients should be cohorted (sequestered) to a separate building or a ward with an isolated air-handling system. Environmental decontamination is typically accomplished with hypochlorite (e.g. bleach) or phenolic disinfectants.

Treatment

Medical management of VHF patients may require intensive supportive care. Antiviral therapy with intravenous ribavirin may be useful in Bunyaviridae and Arenaviridae infections (specifically Lassa fever, RVF, CCHF, and HFRS due to Old World Hantavirus infection) and can be used only under an experimental protocol as IND approved by the U.S. Food and Drug Administration (FDA). Interferon may be effective in Argentine or Bolivian hemorrhagic fevers (also available only as IND).

13 Encephalitis B (Japanese Encephalitis)

Japanese encephalitis (JE) is an infection of the brain caused by the Japanese encephalitis virus (JEV). While most infections result in little or no symptoms, occasional inflammation of the brain occurs. In these cases, symptoms may include headache, vomiting, fever, confusion and seizures. This occurs about 5 to 15 days after infection. JEV is generally spread by mosquitoes, specifically those of the Culex type. Pigs and wild birds serve as a reservoir for the virus. The disease mostly occurs outside of cities. Diagnosis is based on blood or cerebrospinal fluid testing.

Prevention is generally with the Japanese encephalitis vaccine, which is both safe and effective. Other measures include avoiding mosquito bites. Once infected, there is no specific treatment, with care being supportive. This is generally carried out in hospital. Permanent problems occur in up to half of people who recover from JE. The disease occurs in Southeast Asia and the Western Pacific. About 3 billion people live in areas where the disease occurs. About 68,000 symptomatic cases occur a year, with about 17,000 deaths.

ILLNESS | Viral | Encephalitis B (Japanese Encephalitis)

Sources

It is a disease caused by the mosquito-borne Japanese encephalitis virus (JEV).

Symptoms

The Japanese encephalitis virus (JEV) has an incubation period of 2 to 26 days. The vast majority of infections are asymptomatic: only 1 in 250 infections develop into encephalitis. Severe rigors may mark the onset of this disease in humans. Fever, headache and malaise are other non-specific symptoms of this disease which may last for a period of between 1 and 6 days. Signs which develop during the acute encephalitic stage include neck rigidity, cachexia, hemiparesis, convulsions and a raised body temperature between 38–41 °C (100.4–105.8 °F).

Mental retardation is usually developed.Mortality of this disease varies but is generally higher in children. Transplacental spread has been noted. Lifelong neurological defects such as deafness, emotional lability and hemiparesis may occur in those who have had central nervous system involvement. In known cases, some effects also include nausea, headache, fever, and vomiting.

Increased microglial activation following Japanese Encephalitis infection has been found to influence the outcome of viral pathogenesis. Microglia are the resident immune cells of the central nervous system (CNS) and have a critical role in host defense against invading microorganisms. Activated microglia secrete cytokines, such as interleukin-1 (IL-1) and tumor necrosis factor alpha (TNF-α), which can cause toxic effects in the brain. Additionally, other soluble factors such as neurotoxins, excitatory neurotransmitters, prostaglandin, reactive oxygen, and nitrogen species are secreted by activated microglia.

Prevention

Infection with Japanese encephalitis confers lifelong immunity. There are currently three vaccines available: SA14-14-2, IXIARO (IC51, also marketed in Australia, New Zealand as JESPECT and India as JEEV) and ChimeriVax-JE (marketed as IMOJEV). All current vaccines are based on the genotype III virus.

A formalin-inactivated mouse-brain derived vaccine was first produced in Japan in the 1930s and was validated for use in Taiwan in the 1960s and in Thailand in the 1980s. The widespread use of vaccine and urbanization has led to control of the disease in Japan, Korea, Taiwan, and Singapore. The high cost of this vaccine, which is grown in live mice, means that poorer countries have not been able to afford to give it as part of a routine immunization program.

The most common adverse effects are redness and pain at the injection site. Uncommonly, an urticarial reaction can develop about four days after injection. Vaccines produced from mouse brain have a risk of autoimmune neurological complications of around 1 per million vaccinations. However where the vaccine is not produced in mouse brains but in vitro using cell culture there is little adverse effects compared to placebo, the main side effects are headache and myalgia.

The neutralizing antibody persists in the circulation for at least two to three years, and perhaps longer. The total duration of protection is unknown, but because there is no firm evidence for protection beyond three years, boosters are recommended every three years for people who remain at risk. Furthermore, there is also no data available regarding the interchangeability of other JE vaccines and IXIARO.

Treatment

There is no specific treatment for Japanese encephalitis and treatment is supportive, with assistance given for feeding, breathing or seizure control as required. Raised intracranial pressure may be managed with mannitol. There is no transmission from person to person and therefore patients do not need to be isolated.

A breakthrough in the field of Japanese encephalitis therapeutics is the identification of macrophage receptor involvement in the disease severity. A recent report of an Indian group demonstrates the involvement of monocyte and macrophage receptor CLEC5A in severe inflammatory response in Japanese Encephalitis infection of the brain. This transcriptomic study provides a hypothesis of neuroinflammation and a new lead in development of appropriate therapeutic against Japanese encephalitis.

The effectiveness of intravenous immunoglobulin for the management of encephalitis is unclear due to a lack of evidence. Intravenous immunoglobulin for Japanese encephalitis appeared to have no benefit.

14 Influenza

Sources

Strains of all subtypes of influenza A virus have been isolated from wild birds, although disease is uncommon. Some isolates of influenza A virus cause severe disease both in domestic poultry and, rarely, in humans. Occasionally, viruses are transmitted from wild aquatic birds to domestic poultry, and this may cause an outbreak or give rise to human influenza pandemics.

Symptoms

Approximately 33% of people with influenza are asymptomatic. Symptoms of influenza can start quite suddenly one to two days after infection. Usually the first symptoms are chills and body aches, with fever also common early in the infection, with body temperatures ranging from 38 to 39°C (approximately 100 to 103°F). Many people are so ill that they are confined to bed for several days, with aches and pains throughout their bodies, which are worse in their backs and legs.

It can be difficult to distinguish between the common cold and influenza in the early stages of these infections. Influenza symptoms are a mixture of symptoms of common cold and pneumonia, body ache, headache, and fatigue. Diarrhea is not usually a symptom of influenza in adults, although it has been seen in some human cases of the H5N1 "bird flu" and can be a symptom in children. The symptoms most reliably seen in influenza are shown in the adjacent table.

The specific combination of fever and cough has been found to be the best predictor; diagnostic accuracy increases with a body temperature above 38 °C (100.4 °F). Two decision analysis studies suggest that during local outbreaks of influenza, the prevalence will be over 70%. Even in the absence of a local outbreak, diagnosis may be justified in the elderly during the influenza season as long as the prevalence is over 15%.

- Fever and chills
- Cough
- Nasal congestion
- Runny nose
- Sore throat
- Hoarseness
- Earache
- Muscle pains
- Fatigue
- Headache
- Irritated, watering eyes
- Reddened eyes, skin (especially face), mouth, throat and nose
- Petechial rash
- In children, gastrointestinal symptoms such as vomiting, diarrhea, and abdominal pain (may be severe in children with influenza B)

Prevention

Infection Control
These are the main ways that influenza spreads
- By direct transmission (when an infected person sneezes mucus directly into the eyes, nose or mouth of another person);
- The airborne route (when someone inhales the aerosols produced by an infected person coughing, sneezing or spitting);
- Through hand-to-eye, hand-to-nose, or hand-to-mouth transmission, either from contaminated surfaces or from direct personal contact such as a hand-shake.

When vaccines and antiviral medications are limited, non-pharmaceutical interventions are essential to reduce transmission and spread. The lack of controlled studies and rigorous evidence of the effectiveness of some measures has hampered planning decisions and recommendations. Nevertheless, strategies endorsed by experts for all phases of flu outbreaks include hand and respiratory hygiene, self-isolation by symptomatic individuals and the use of face masks by them and their caregivers, surface disinfection, rapid testing and diagnosis, and contact tracing. In some cases, other forms of social distancing including school closures and travel restrictions are recommended.

Reasonably effective ways to reduce the transmission of influenza include good personal health and hygiene habits such as: not touching the eyes, nose or mouth; frequent hand washing (with soap and water, or with alcohol-based hand rubs); covering coughs and sneezes with a tissue or sleeve; avoiding close contact with sick people; and staying home when sick. Avoiding spitting is also recommended. Although face masks might help prevent transmission when caring for the sick, there is mixed evidence on beneficial effects in the community. Smoking raises the risk of contracting influenza, as well as producing more severe disease symptoms.

Since influenza spreads through both aerosols and contact with contaminated surfaces, surface sanitizing may help prevent some infections. Alcohol is an effective sanitizer against influenza viruses, while quaternary ammonium compounds can be used with alcohol so that the sanitizing effect lasts for longer. In hospitals, quaternary ammonium compounds and bleach are used to sanitize rooms or equipment that have been occupied by people with influenza symptoms. At home, this can be done effectively with a diluted chlorine bleach.

Social distancing strategies used during past pandemics, such as quarantines, travel restrictions, and the closing of schools, churches and theaters, have been employed to slow the spread of influenza viruses. Researchers have estimated that such interventions during the 1918 Spanish flu pandemic in the US reduced the peak death rate by up to 50%, and the overall mortality by about 10–30%, in areas where multiple interventions were implemented. The more moderate effect on total deaths was attributed to the measures being employed too late, or lifted too early, most after six weeks or less.

For typical flu outbreaks, routine cancellation of large gatherings or mandatory travel restrictions have received little agreement, particularly as they may be disruptive and unpopular. School closures have been found by most empirical studies to reduce community spread, but some findings have been contradictory. Recommendations for these community restrictions are usually on a case-by-case basis.

Treatment

People with the flu are advised to get plenty of rest, drink plenty of liquids, avoid using alcohol and tobacco and, if necessary, take medications such as acetaminophen (paracetamol) to relieve the fever and muscle aches associated with the flu. In contrast, there is not enough evidence to support corticosteroids as additional therapy for influenza. It is advised to avoid close contact with others to prevent spread of infection. Children and teenagers with flu symptoms (particularly fever) should avoid taking aspirin during an influenza infection (especially influenza type B), because doing so can lead to Reye's syndrome, a rare but potentially fatal disease of the liver.

Since influenza is caused by a virus, antibiotics have no effect on the infection; unless prescribed for secondary infections such as bacterial pneumonia. Antiviral medication may be effective, if given early (within 48 hours to first symptoms), but some strains of influenza can show resistance to the standard antiviral medications and there is concern about the quality of the research. High-risk individuals such as young children, pregnant women, the elderly, and those with compromised immune systems should visit the doctor for antiviral medications. Those with the emergency warning signs should visit the emergency room at once.

Antivirals
The two classes of antiviral medications used against influenza are neuraminidase inhibitors (oseltamivir, zanamivir, laninamivir and peramivir) and M2 protein inhibitors (adamantane derivatives). In Russia, umifenovir is sold for treatment of influenza and in the first quarter of 2020 had a 16 percent share in the antiviral market.

Notes

Seasonal Variations
Seasonal risk areas for influenza: November–April (blue), April–November (red), and year-round (yellow).
Influenza reaches peak prevalence in winter, and because the Northern and Southern Hemispheres have winter at different times of the year, there are actually two different flu seasons each year. This is why the World Health Organization (assisted by the National Influenza Centers) makes recommendations for two different vaccine formulations every year; one for the Northern, and one for the Southern Hemisphere.

A long-standing puzzle has been why outbreaks of the flu occur seasonally rather than uniformly throughout the year. One possible explanation is that, because people are indoors more often during the winter, they are in close contact more often, and this promotes transmission from person to person. Increased travel due to the Northern Hemisphere winter holiday season may also play a role. Another factor is that cold temperatures lead to drier air, which may dehydrate mucus particles. Dry particles are lighter and can thus remain airborne for a longer period. The virus also survives longer on surfaces at colder temperatures and aerosol transmission of the virus is highest in cold environments (less than 5 °C) with low relative humidity. The lower air humidity in winter seems to be the main cause of seasonal influenza transmission in temperate regions.

However, seasonal changes in infection rates also occur in tropical regions, and in some countries these peaks of infection are seen mainly during the rainy season. Seasonal changes in contact rates from school terms, which are a major factor in other childhood diseases such as measles and pertussis, may also play a role in the flu. A combination of these small seasonal effects may be amplified by dynamical resonance with the endogenous disease cycles. H5N1 exhibits seasonality in both humans and birds.

An alternative hypothesis to explain seasonality in influenza infections is an effect of vitamin D levels on immunity to the virus. This idea was first proposed by Robert Edgar Hope-Simpson in 1981. He proposed that the cause of influenza epidemics during winter may be connected to seasonal fluctuations of vitamin D, which is produced in the skin under the influence of solar (or artificial) UV radiation. This could explain why influenza occurs mostly in winter and during the tropical rainy season, when people stay indoors, away from the sun, and their vitamin D levels fall.

Influenza A (The Flu)

Influenza A virus causes influenza in birds and some mammals, and is the only species of the genus Alphainfluenzavirus of the virus family Orthomyxoviridae. Strains of all subtypes of influenza A virus have been isolated from wild birds, although disease is uncommon. Some isolates of influenza A virus cause severe disease both in domestic poultry and, rarely, in humans. Occasionally, viruses are transmitted from wild aquatic birds to domestic poultry, and this may cause an outbreak or give rise to human influenza pandemics.

Influenza B (The Flu)

Influenza B virus is the only species in the genus Betainfluenzavirus in the virus family Orthomyxoviridae. Influenza B virus is only known to infect humans and seals with influenza. This limited host range is apparently responsible for the lack of associated influenza pandemics in contrast with those caused by the morphologically similar influenza A virus as both mutate by both antigenic drift and reassortment. There are two known circulating lineages of Influenza B virus based on the antigenic properties of the surface glycoprotein hemagglutinin. The lineages are termed B/Yamagata/16/88-like and B/Victoria/2/87-like viruses. The quadrivalent influenza vaccine licensed by the CDC is currently designed to protect against both co-circulating lineages and has been shown to have greater effectiveness in prevention of influenza caused by Influenza B virus than the previous trivalent vaccine.

Further diminishing the impact of this virus, "in humans, influenza B viruses evolve slower than A viruses and faster than C viruses". Influenzavirus B mutates at a rate 2 to 3 times slower than type A. Nevertheless, it is accepted that Influenza B virus cause significant morbidity and mortality worldwide, and significantly impacts adolescents and schoolchildren.

Influenza C (The Flu)

Influenza C virus is the species in the genus Influenzavirus C, in the virus family Orthomyxoviridae, which like other influenza viruses, causes influenza. Influenza C viruses are known to infect humans and pigs. Flu due to the Type A species is rare compared to Types B or C, but can be severe and can cause local epidemics. Type C has 7 RNA segments and encodes 9 proteins, while Types A and B have 8 RNA segments and encode at least 10 proteins.

Influenza D (The Flu)

Influenza D virus is a species in the virus genus Deltainfluenzavirus, in the family Orthomyxoviridae, that causes influenza. Influenza D viruses are known to infect pigs and cattle; no human infections from this virus have been observed. First isolated from pigs in 2011, the virus was categorized as a new genus of Orthomyxoviridae in 2016, distinct from the previously-known Influenzavirus C genus; before then, Influenza D virus was thought to be a subtype of Influenzavirus C.

Cases of infections from the Type D virus are rare compared to Types A, B, and C. Similar to Type C, Type D has 7 RNA segments and encodes 9 proteins, while Types A and B have 8 RNA segments and encode at least 10 proteins.

15 Lassa Fever

Lassa fever, also known as Lassa hemorrhagic fever (LHF), is a type of viral hemorrhagic fever caused by the Lassa virus. Many of those infected by the virus do not develop symptoms. When symptoms occur they typically include fever, weakness, headaches, vomiting, and muscle pains. Less commonly there may be bleeding from the mouth or gastrointestinal tract. The risk of death once infected is about one percent and frequently occurs within two weeks of the onset of symptoms. Among those who survive about a quarter have hearing loss, which improves within three months in about half of these cases.

The disease is usually initially spread to people via contact with the urine or feces of an infected multimammate mouse. Spread can then occur via direct contact between people. Diagnosis based on symptoms is difficult. Confirmation is by laboratory testing to detect the virus's RNA, antibodies for the virus, or the virus itself in cell culture. Other conditions that may present similarly include Ebola, malaria, typhoid fever, and yellow fever. The Lassa virus is a member of the Arenaviridae family of viruses.

Sources

Lassa virus commonly spreads to humans from other animals, specifically the natal multimammate mouse or African rat, also called the natal multimammate rat (Mastomys natalensis). This is probably the most common mouse in equatorial Africa, common in human households and eaten as a delicacy in some areas. The multimammate mouse can quickly produce a large number of offspring, tends to colonize human settlements increasing the risk of rodent-human contact, and is found throughout the west, central and eastern parts of the African continent. Once the mouse has become a carrier, it will excrete the virus throughout the rest of its lifetime through feces and urine creating ample opportunity for exposure. The virus is probably transmitted by contact with the feces or urine of animals accessing grain stores in residences. No study has proven presence in breast milk, but the high level of viremia suggests it may be possible.

Symptoms

Onset of symptoms is typically 7 to 21 days after exposure. In 80% of those who are infected little or no symptoms occur. These mild symptoms may include fever, tiredness, weakness, and headache. In 20% of people more severe symptoms such as bleeding gums, breathing problems, vomiting, chest pain, or dangerously low blood pressure may occur. Long term complications may include hearing loss. In those who are pregnant, miscarriage may occur in 95%.

In cases in which death occurs, this typically occurs within 14 days of onset. About 1% of all Lassa virus infections result in death. Approximately 15%-20% of those who have required hospitalization for Lassa fever die. The risk of death is greater in those who are pregnant. A "Swollen baby syndrome" may occur in newborns, infants and toddlers with pitting edema, abdominal distension and bleeding.

Prevention

Control of the Mastomys rodent population is impractical, so measures focus on keeping rodents out of homes and food supplies, encouraging effective personal hygiene, storing grain and other foodstuffs in rodent-proof containers, and disposing of garbage far from the home to help sustain clean households. Gloves, masks, laboratory coats, and goggles are advised while in contact with an infected person, to avoid contact with blood and body fluids. These issues in many countries are monitored by a department of public health. In less developed countries, these types of organizations may not have the necessary means to effectively control outbreaks.

Treatment

Treatment is directed at addressing dehydration and improving symptoms. All persons suspected of Lassa fever infection should be admitted to isolation facilities and their body fluids and excreta properly disposed of.

Medications
The antiviral medication ribavirin has been recommended, but evidence to support its use is weak. Some evidence has found that it may worsen outcomes in certain cases. Fluid replacement, blood transfusions, and medication for low blood pressure may be required. Intravenous interferon therapy has also been used.

Pregnancy
When Lassa fever infects pregnant women late in their third trimester, inducing delivery is necessary for the mother to have a good chance of survival. This is because the virus has an affinity for the placenta and other highly vascular tissues. The fetus has only a one in ten chance of survival no matter what course of action is taken; hence, the focus is always on saving the life of the mother. Following delivery, women should receive the same treatment as other people with Lassa fever.

Notes

About 15–20% of hospitalized people with Lassa fever will die from the illness. The overall case fatality rate is estimated to be 1%, but during epidemics, mortality can climb as high as 50%. The mortality rate is greater than 80% when it occurs in pregnant women during their third trimester; fetal death also occurs in nearly all those cases. Abortion decreases the risk of death to the mother. Some survivors experience lasting effects of the disease, and can include partial or complete deafness. Because of treatment with ribavirin, fatality rates have declined.

16 Dengue Fever

Dengue fever is a mosquito-borne tropical disease caused by the dengue virus. Symptoms typically begin three to fourteen days after infection. These may include a high fever, headache, vomiting, muscle and joint pains, and a characteristic skin rash. Recovery generally takes two to seven days. In a small proportion of cases, the disease develops into severe dengue, also known as dengue hemorrhagic fever, resulting in bleeding, low levels of blood platelets and blood plasma leakage, or into dengue shock syndrome, where dangerously low blood pressure occurs.

Dengue is spread by several species of female mosquitoes of the Aedes type, principally A. aegypti. The virus has five types; infection with one type usually gives lifelong immunity to that type, but only short-term immunity to the others. Subsequent infection with a different type increases the risk of severe complications. A number of tests are available to confirm the diagnosis including detecting antibodies to the virus or its RNA.

A vaccine for dengue fever has been approved and is commercially available in a number of countries. The vaccine, however, is only recommended in those who have been previously infected. Other methods of prevention include reducing mosquito habitat and limiting exposure to bites. This may be done by getting rid of or covering standing water and wearing clothing that covers much of the body. Treatment of acute dengue is supportive and includes giving fluid either by mouth or intravenously for mild or moderate disease.

For more severe cases, blood transfusion may be required. About half a million people require hospital admission every year. Paracetamol (acetaminophen) is recommended instead of nonsteroidal anti-inflammatory drugs (NSAIDs) for fever reduction and pain relief in dengue due to an increased risk of bleeding from NSAID use.

Sources

Dengue virus is primarily transmitted by Aedes mosquitos, particularly A. aegypti. These mosquitos usually live between the latitudes of 35° North and 35° South below an elevation of 1,000 metres (3,300 ft). They typically bite during the early morning and in the evening, but they may bite and thus spread infection at any time of day. Other Aedes species that transmit the disease include A. albopictus, A. polynesiensis and A. scutellaris. Humans are the primary host of the virus, but it also circulates in nonhuman primates.

An infection can be acquired via a single bite. A female mosquito that takes a blood meal from a person infected with dengue fever, during the initial 2- to 10-day febrile period, becomes itself infected with the virus in the cells lining its gut. About 8–10 days later, the virus spreads to other tissues including the mosquito's salivary glands and is subsequently released into its saliva. The virus seems to have no detrimental effect on the mosquito, which remains infected for life. Aedes aegypti is particularly involved, as it prefers to lay its eggs in artificial water containers, to live in close proximity to humans, and to feed on people rather than other vertebrates.

Dengue can also be transmitted via infected blood products and through organ donation. In countries such as Singapore, where dengue is endemic, the risk is estimated to be between 1.6 and 6 per 10,000 transfusions. Vertical transmission (from mother to child) during pregnancy or at birth has been reported. Other person-to-person modes of transmission, including sexual transmission, have also been reported, but are very unusual. The genetic variation in dengue viruses is region specific, suggestive that establishment into new territories is relatively infrequent, despite dengue emerging in new regions in recent decades.

Symptoms

Typically, people infected with dengue virus are asymptomatic (80%) or have only mild symptoms such as an uncomplicated fever. Others have more severe illness (5%), and in a small proportion it is life-threatening. The incubation period (time between exposure and onset of symptoms) ranges from 3 to 14 days, but most often it is 4 to 7 days. Therefore, travelers returning from endemic areas are unlikely to have dengue fever if symptoms start more than 14 days after arriving home. Children often experience symptoms similar to those of the common cold and gastroenteritis (vomiting and diarrhea) and have a greater risk of severe complications, though initial symptoms are generally mild but include high fever.

Prevention

Prevention depends on control of and protection from the bites of the mosquito that transmits it. The World Health Organization recommends an Integrated Vector Control program consisting of five elements:

1. Advocacy, social mobilization and legislation to ensure that public health bodies and communities are strengthened;
2. Collaboration between the health and other sectors (public and private);
3. An integrated approach to disease control to maximize the use of resources;
4. Evidence-based decision making to ensure any interventions are targeted appropriately; and
5. Capacity-building to ensure an adequate response to the local situation.

The primary method of controlling A. aegypti is by eliminating its habitats. This is done by getting rid of open sources of water, or if this is not possible, by adding insecticides or biological control agents to these areas. Generalized spraying with organophosphate or pyrethroid insecticides, while sometimes done, is not thought to be effective. Reducing open collections of water through environmental modification is the preferred method of control, given the concerns of negative health effects from insecticides and greater logistical difficulties with control agents.

People can prevent mosquito bites by wearing clothing that fully covers the skin, using mosquito netting while resting, and/or the application of insect repellent (DEET being the most effective). While these measures can be an effective means of reducing an individual's risk of exposure, they do little in terms of mitigating the frequency of outbreaks, which appear to be on the rise in some areas, probably due to urbanization increasing the habitat of A. aegypti. The range of the disease also appears to be expanding possibly due to climate change.

Treatment

There are no specific antiviral drugs for dengue; however, maintaining proper fluid balance is important. Treatment depends on the symptoms. Those who can drink, are passing urine, have no "warning signs" and are otherwise healthy can be managed at home with daily follow-up and oral rehydration therapy. Those who have other health problems, have "warning signs", or cannot manage regular follow-up should be cared for in hospital. In those with severe dengue care should be provided in an area where there is access to an intensive care unit.

Intravenous hydration, if required, is typically only needed for one or two days. In children with shock due to dengue a rapid dose of 20 mL/kg is reasonable. The rate of fluid administration is then titrated to a urinary output of 0.5–1 mL/kg/h, stable vital signs and normalization of hematocrit. The smallest amount of fluid required to achieve this is recommended.

Notes

Most people with dengue recover without any ongoing problems. The risk of death among those with severe dengue is 0.8% to 2.5%, and with adequate treatment this is less than 1%. However, those who develop significantly low blood pressure may have a fatality rate of up to 26%. The risk of death among children less than five years old is four times greater than among those over the age of 10. Elderly people are also at higher risk of a poor outcome

17 Measles

Measles is a highly contagious infectious disease caused by the measles virus. Symptoms usually develop 10–12 days after exposure to an infected person and last 7–10 days. Initial symptoms typically include fever, often greater than 40 °C (104 °F), cough, runny nose, and inflamed eyes. Small white spots known as Koplik's spots may form inside the mouth two or three days after the start of symptoms. A red, flat rash which usually starts on the face and then spreads to the rest of the body typically begins three to five days after the start of symptoms. Common complications include diarrhea (in 8% of cases), middle ear infection (7%), and pneumonia (6%). These occur in part due to measles-induced immunosuppression.

Less commonly seizures, blindness, or inflammation of the brain may occur. Other names include morbilli, rubeola, red measles, and English measles. Both rubella, also known as "German measles", and roseola are different diseases caused by unrelated viruses. Measles is an airborne disease which spreads easily through the coughs and sneezes of infected people. It may also be spread through direct contact with mouth or nasal secretions. It is extremely contagious–nine out of ten people who are not immune and share living space with an infected person will be infected. People are infectious to others from four days before to four days after the start of the rash. Most people do not get the disease more than once. Testing for the measles virus in suspected cases is important for public health efforts.

Sources

Measles is caused by the measles virus, a single-stranded, negative-sense, enveloped RNA virus of the genus Morbillivirus within the family Paramyxoviridae.

The virus is highly contagious and is spread by coughing and sneezing via close personal contact or direct contact with secretions. Measles is the most contagious transmissible virus known. It remains infective for up to two hours in that airspace or nearby surfaces. Measles is so contagious that if one person has it, 90% of nearby non-immune people will also become infected. Humans are the only natural hosts of the virus, and no other animal reservoirs are known to exist.

Risk factors for measles virus infection include immunodeficiency caused by HIV or AIDS, immunosuppression following receipt of an organ or a stem cell transplant, alkylating agents, or corticosteroid therapy, regardless of immunization status; travel to areas where measles commonly occurs or contact with travelers from such an area; and the loss of passive, inherited antibodies before the age of routine immunization.

Symptoms

Symptoms typically begin 10–14 days after exposure. The classic symptoms include a four-day fever (the 4 D's) and the three C's—cough, coryza (head cold, fever, sneezing), and conjunctivitis (red eyes)—along with a maculopapular rash. Fever is common and typically lasts for about one week; the fever seen with measles is often as high as 40 °C (104 °F).

Koplik's spots seen inside the mouth are diagnostic for measles, but are temporary and therefore rarely seen. Koplik spots are small white spots that are commonly seen on the inside of the cheeks opposite the molars. They appear as "grains of salt on a reddish background." Recognizing these spots before a person reaches their maximum infectiousness can help reduce the spread of the disease.

The characteristic measles rash is classically described as a generalized red maculopapular rash that begins several days after the fever starts. It starts on the back of the ears and, after a few hours, spreads to the head and neck before spreading to cover most of the body, often causing itching. The measles rash appears two to four days after the initial symptoms and lasts for up to eight days. The rash is said to "stain", changing color from red to dark brown, before disappearing. Overall, measles usually resolves after about three weeks.

Prevention

Mothers who are immune to measles pass antibodies to their children while they are still in the womb, especially if the mother acquired immunity through infection rather than vaccination. Such antibodies will usually give newborn infants some immunity against measles, but these antibodies are gradually lost over the course of the first nine months of life.Infants under one year of age whose maternal anti-measles antibodies have disappeared become susceptible to infection with the measles virus.

In developed countries, it is recommended that children be immunized against measles at 12 months, generally as part of a three-part MMR vaccine (measles, mumps, and rubella). The vaccine is generally not given before this age because such infants respond inadequately to the vaccine due to an immature immune system. A second dose of the vaccine is usually given to children between the ages of four and five, to increase rates of immunity. Measles vaccines have been given to over a billion people. Vaccination rates have been high enough to make measles relatively uncommon. Adverse reactions to vaccination are rare, with fever and pain at the injection site being the most common. Life-threatening adverse reactions occur in less than one per million vaccinations (<0.0001%).

ILLNESS | Viral | Measles | Prevention

In developing countries where measles is common, the World Health Organization (WHO) recommends two doses of vaccine be given, at six and nine months of age. The vaccine should be given whether the child is HIV-infected or not. The vaccine is less effective in HIV-infected infants than in the general population, but early treatment with antiretroviral drugs can increase its effectiveness. Measles vaccination programs are often used to deliver other child health interventions as well, such as bed nets to protect against malaria, antiparasite medicine and vitamin A supplements, and so contribute to the reduction of child deaths from other causes. The Advisory Committee on Immunization Practices (ACIP) recommends that all adult international travelers who do not have positive evidence of previous measles immunity receive two doses of MMR vaccine before traveling. Those born in the United States before 1957 are presumed to be immune because they would have had the disease in their childhood before any vaccination was available.

There have been false claims of an association between the measles vaccine and autism; this incorrect concern has reduced the rate of vaccination and increased the number of cases of measles where immunization rates became too low to maintain herd immunity. Additionally, there have been false claims that measles infection protects against cancer. A form of passive immunization could be effective up to the seventh day after exposure. Compared to no treatment, the risk of infection was reduced by 76%; however, the effectiveness is not clear in comparison to active measles vaccine.

Treatment

There is no specific antiviral treatment if measles develops. Instead the medications are generally aimed at treating superinfections, maintaining good hydration with adequate fluids, and pain relief. Some groups, like young children and the severely malnourished, are also given vitamin A, which act as an immunomodulator that boosts the antibody responses to measles and decreases the risk of serious complications.

Medications
Treatment is supportive, with ibuprofen or paracetamol (acetaminophen) to reduce fever and pain and, if required, a fast-acting medication to dilate the airways for cough. As for aspirin, some research has suggested a correlation between children who take aspirin and the development of Reye syndrome.

The use of vitamin A during treatment is recommended to decrease the risk of blindness; however, it does not prevent or cure the disease. A systematic review of trials into its use found no reduction in overall mortality, but two doses (200 000 IU) of vitamin A was shown to reduce mortality for measles in children younger than two years of age. It is unclear if zinc supplementation in children with measles affects outcomes as it has not been sufficiently studied.

Notes

Most people survive measles, though in some cases, complications may occur. About 1 in 4 individuals will be hospitalized and 1–2 in 1000 will die. Complications are more likely in children under age 5 and adults over age 20. Pneumonia is the most common fatal complication of measles infection and accounts for 56-86% of measles-related deaths.

Possible consequences of measles virus infection include laryngotracheobronchitis, sensorineural hearing loss, and—in about 1 in 10,000 to 1 in 300,000 cases—panencephalitis, which is usually fatal. Acute measles encephalitis is another serious risk of measles virus infection. It typically occurs two days to one week after the measles rash breaks out and begins with very high fever, severe headache, convulsions and altered mentation. A person with measles encephalitis may become comatose, and death or brain injury may occur. For people having had measles, it is rare to ever have a symptomatic reinfection.

The measles virus can kill cells that make antibodies, and thus weakens the immune system which can cause deaths from other diseases. Suppression of the immune system by measles lasts about two years and has been epidemiologically implicated in up to 90% of childhood deaths in third world countries, and historically may have caused rather more deaths in the United States, the UK and Denmark than were directly caused by measles.

18 Meningitis (Viral)

See the full meningitis section in 'Bacterial'.

19 Mumps

Mumps is a viral disease caused by the mumps virus. Initial signs and symptoms often include fever, muscle pain, headache, poor appetite, and feeling generally unwell. This is then usually followed by painful swelling of one or both parotid salivary glands. Symptoms typically occur 16 to 18 days after exposure and resolve after 7 to 10 days. Symptoms are often more severe in adults than in children. About a third of people have mild or no symptoms. Complications may include meningitis (15%), pancreatitis (4%), inflammation of the heart, permanent deafness, and testicular inflammation, which uncommonly results in infertility. Women may develop ovarian swelling, but this does not increase the risk of infertility.

Mumps is highly contagious and spreads rapidly among people living in close quarters. The virus is transmitted by respiratory droplets or direct contact with an infected person. Only humans get and spread the disease. People are infectious from about 7 days before onset of parotid inflammation to about 8 days after. Once an infection has run its course, a person is typically immune for life. Reinfection is possible, but the ensuing infection tends to be mild. Diagnosis is usually suspected due to parotid swelling and can be confirmed by isolating the virus on a swab of the parotid duct. Testing for IgM antibodies in the blood is simple and may be useful; however, it can be falsely negative in those who have been immunized.

Sources

The mumps virus is an enveloped, single-stranded, linear negative-sense RNA virus of the genus Orthorubulavirus and family Paramyxovirus. The genome consists of 15,384 bases encoding nine proteins. Proteins involved in viral replication are the nucleoprotein, phosphoprotein, and polymerase protein while the genomic RNA forms the ribonucleocapsid. Humans are the only natural host for the virus.

Mumps is spread from person to person through contact with respiratory secretions, such as saliva from an infected person. When an infected person coughs or sneezes, the droplets aerosolize and can enter the eyes, nose, or mouth of another person. Mumps can also be spread by sharing eating utensils or cups. The virus can also survive on surfaces and then be spread after contact in a similar manner. A person infected with mumps is contagious from around 7 days before the onset of symptoms until about 8 days after symptoms start. The incubation period (time until symptoms begin) can be from 12–25 days, but is typically 16–18 days. About 20-40% of persons infected with the mumps virus do not show symptoms, so being infected and spreading the virus without knowing it is possible.

Symptoms

Mumps is usually preceded by a set of prodromal symptoms, including low-grade fever, headache, and feeling generally unwell. This is followed by progressive swelling of one or both parotid glands. Parotid gland swelling usually lasts about a week. Other symptoms of mumps can include dry mouth, sore face and/or ears, and difficulty speaking.

ILLNESS | Viral | Mumps | Symptoms

Complications

- Painful testicular inflammation develops in 15–40% of men who have completed puberty and contract the mumps virus. This testicular inflammation is generally one-sided (both testicles are swollen in 15–30% of mumps orchitis cases) and typically occurs about 10 days after the parotid gland becomes inflamed. Testicular swelling has been documented as late as 6 weeks after parotid-gland swelling. Decreased fertility is an uncommon consequence of testicular inflammation from mumps and infertility is rare.
- Studies have reached differing conclusions regarding whether infection with the mumps virus during pregnancy leads to an increased rate of spontaneous abortion.
- Before vaccination, about 10% of cases of aseptic meningitis were due to mumps. The symptoms generally resolve within 10 days. Infection of the brain itself (encephalitis) occurs in between 0.02 and 0.3% of cases.
- Ovarian inflammation occurs in about 5% percent of adolescent and adult females.

- Deafness is one of the most serious complications of mumps and occurs in 4% of cases. Profound (91 decibel or more) but rare sensorineural hearing loss can occur, which can affect one or both ears. Deafness affecting only one ear occurs in about 0.005% of cases.
- Acute pancreatic inflammation occurs in about 4% of cases, manifesting as abdominal pain and vomiting.
- Brain inflammation is very rare, and fatal in about 1% of the cases when it occurs.

Prevention

ILLNESS | Viral | Mumps | Prevention

The most common preventive measure against mumps is a vaccination with a mumps vaccine, developed by American microbiologist Maurice Hilleman at Merck. The vaccine may be given separately or as part of the MMR vaccine or MMRV vaccine. The World Health Organization (WHO) recommends the use of mumps vaccines in all countries with well-functioning childhood vaccination programmes. In the United Kingdom, they are routinely given to children at age 13 months with a booster at 3–5 years (preschool). The American Academy of Pediatrics recommends the routine administration of MMR vaccine at ages 12–15 months and at 4–6 years.

In some locations, the vaccine is given again between 4 and 6 years of age, or between 11 and 12 years of age if not previously given. The efficacy of the vaccine depends on its strain, but is usually around 80%. The Jeryl Lynn strain is most commonly used in developed countries, but has been shown to have reduced efficacy in epidemic situations. The Leningrad-Zagreb strain commonly used in developing countries appears to have superior efficacy in epidemic situations.

Because of the outbreaks within college and university settings, many governments have established vaccination programs to prevent large-scale outbreaks. In Canada, provincial governments and the Public Health Agency of Canada have all participated in awareness campaigns to encourage students ranging from grade one to college and university to get vaccinated.

Treatment

ILLNESS | Mumps | Treatment

The treatment of mumps is supportive. Symptoms may be relieved by the application of intermittent ice or heat to the affected neck/testicular area and by acetaminophen for pain relief. Warm saltwater gargles, soft foods, and extra fluids may also help relieve symptoms. Acetylsalicylic acid (aspirin) is not used to treat children due to the risk of Reye syndrome.

No effective postexposure recommendation is made to prevent secondary transmission, nor is the postexposure use of vaccine or immunoglobulin effective. Also, no available evidence regarding the Chinese herbal medicine.

Mumps is considered most contagious in the 5 days after the onset of symptoms, and isolation is recommended during this period. In someone who has been admitted to the hospital, standard and droplet precautions are needed. People who work in healthcare cannot work for 5 days.

20 MERS

ILLNESS | Viral | MERS

Middle East respiratory syndrome (MERS), also known as camel flu, is a viral respiratory infection caused by the MERS-coronavirus (MERS-CoV). Symptoms may range from mild to severe. They include fever, cough, diarrhea, and shortness of breath. Disease is typically more severe in those with other health problems. Mortality is about one-third of diagnosed cases.

MERS-CoV is a betacoronavirus derived from bats. Camels have been shown to have antibodies to MERS-CoV but the exact source of infection in camels has not been identified. Camels are believed to be involved in its spread to humans but it is unclear how. Spread between humans typically requires close contact with an infected person. Its spread is uncommon outside of hospitals. Thus, its risk to the global population is currently deemed to be fairly low. As of 2019 there was no specific vaccine or treatment for the disease; a number of antiviral medications were being studied. The World Health Organization recommends that those who come in contact with camels wash their hands frequently and do not touch sick camels, and that camel-based food products be appropriately cooked. Treatments that help with the symptoms may be given to those infected.

Sources

ILLNESS | MERS | Sources

Middle East respiratory syndrome is caused by the MERS coronavirus (MERS-CoV), a species with single-stranded RNA belonging to the genus betacoronavirus which is distinct from SARS coronavirus and the common-cold coronavirus. Its genomes are phylogenetically classified into two clades, Clades A and B. Early cases of MERS were of Clade A clusters (EMC/2012 and Jordan-N3/2012) while new cases are genetically different in general (Clade B). The virus grows readily on Vero cells and LLC-MK2 cells. In November 2012, Egyptian virologist Dr. Ali Zaki sent a virus sample from the first confirmed case in Saudi Arabia to virologist Ron Fouchier, a leading coronavirus researcher at the Erasmus Medical Center (EMC) in Rotterdam, The Netherlands. The second laboratory-proven case was in London, confirmed by the UK Health Protection Agency (HPA). The HPA named the virus the London1_novel CoV 2012.

ILLNESS | MERS | Sources

Camels

A study performed between 2010 and 2013, in which the incidence of MERS was evaluated in 310 dromedary camels, revealed high titers of neutralizing antibodies to MERS-CoV in the blood serum of these animals. A further study sequenced MERS-CoV from nasal swabs of dromedary camels in Saudi Arabia and found they had sequences identical to previously sequenced human isolates. Some individual camels were also found to have more than one genomic variant in their nasopharynx. There is also a report of a Saudi Arabian man who became ill seven days after applying topical medicine to the noses of several sick camels and later he and one of the camels were found to have identical strains of MERS-CoV. It is still unclear how the virus is transmitted from camels to humans. The World Health Organization advises avoiding contact with camels and to eat only fully cooked camel meat, pasteurized camel milk, and to avoid drinking camel urine. The Saudi Ministry of Agriculture has advised people to avoid contact with camels or wear breathing masks when around them. In response "some people have refused to listen to the government's advice" and kiss their camels in defiance of their government's advice.

ILLNESS | Viral | MERS

Between People

There has been evidence of limited, but not sustained spread of MERS-CoV from person to person, both in households as well as in health care settings like hospitals. Most transmission has occurred "in the circumstances of close contact with severely ill persons in healthcare or household settings" and there is no evidence of transmission from asymptomatic cases. Cluster sizes have ranged from 1 to 26 people, with an average of 2.7.

Symptoms

ILLNESS Viral MERS Symptoms

Early reports compared the viruses to severe acute respiratory syndrome (SARS), and it has been referred to as Saudi Arabia's SARS-like virus. The first person, in June 2012, had a fever, cough, expectoration, and shortness of breath. One review of 47 laboratory confirmed cases in Saudi Arabia gave the most common presenting symptoms as fever in 98%, cough in 83%, shortness of breath in 72% and myalgia in 32% of people. There were also frequent gastrointestinal symptoms with diarrhea in 26%, vomiting in 21%, abdominal pain in 17% of people. 72% of people required mechanical ventilation. There were also 3.3 males for every female. One study of a hospital-based outbreak of MERS had an estimated incubation period of 5.5 days (95% confidence interval 1.9 to 14.7 days). MERS can range from asymptomatic disease to severe pneumonia leading to acute respiratory distress syndrome (ARDS). Kidney failure, disseminated intravascular coagulation (DIC), and pericarditis have also been reported.

Prevention

While the mechanism of spread of MERS-CoV is currently not known, based on experience with prior coronaviruses, such as SARS, the WHO currently recommends that all individuals coming into contact with MERS suspects should (in addition to standard precautions):
● Wear a medical mask
● Wear eye protection (i.e. goggles or a face shield)
● Wear a clean, non sterile, long sleeved gown; and gloves (some procedures may require sterile gloves)
● Perform hand hygiene before and after contact with the person and his or her surroundings and immediately after removal of personal protective equipment (PPE)

For procedures which carry a risk of aerosolization, such as intubation, the WHO recommends that care providers also:
● Wear a particulate respirator and, when putting on a disposable particulate respirator, always check the seal
● Wear eye protection (i.e. goggles or a face shield)
● Wear a clean, non-sterile, long-sleeved gown and gloves (some of these procedures require sterile gloves)
● Wear an impermeable apron for some procedures with expected high fluid volumes that might penetrate the gown
● Perform procedures in an adequately ventilated room; i.e. minimum of 6 to 12 air changes per hour in facilities with a mechanically ventilated room and at least 60 liters/second/patient in facilities with natural ventilation
● Limit the number of persons present in the room to the absolute minimum required for the person's care and support
● Perform hand hygiene before and after contact with the person and his or her surroundings and after PPE removal.

The duration of infectivity is also unknown so it is unclear how long people must be isolated, but current recommendations are for 24 hours after resolution of symptoms. In the SARS outbreak the virus was not cultured from people after the resolution of their symptoms.

Treatment

As of 2020 there is no specific vaccine or treatment for the disease. Using extra-corporeal membrane oxygenation (ECMO) seems to improve outcomes significantly. Neither the combination of antivirals and interferons (ribavirin + interferon alfa-2a or interferon alfa-2b) nor corticosteroids improved outcomes.

21 MERS-CoV

ILLNESS Viral MERS-CoV

Middle East respiratory syndrome-related coronavirus (MERS-CoV), or EMC/2012 (HCoV-EMC/2012), is a novel positive-sense, single-stranded RNA virus of the genus Betacoronavirus. Initially called novel coronavirus 2012 or simply novel coronavirus, it was first reported in 2012 after genome sequencing of a virus isolated from sputum samples from a person who fell ill in a 2012 outbreak of a new flu.

As of July 2015, MERS-CoV cases have been reported in over 21 countries, including Saudi Arabia, Jordan, Qatar, Egypt, the United Arab Emirates, Kuwait, Turkey, Oman, Algeria, Bangladesh, Indonesia (none were confirmed), Austria, the United Kingdom, South Korea, the United States, Mainland China, Thailand, and the Philippines. MERS-CoV is one of several viruses identified by WHO as a likely cause of a future epidemic. They list it for urgent research and development.

Sources

The virus appears to have originated in bats. The virus itself has been isolated from a bat. This virus is closely related to the Tylonycteris bat coronavirus HKU4 and Pipistrellus bat coronavirus HKU5. Serological evidence shows that these viruses have infected camels for at least 20 years. The most recent common ancestor of several human strains has been dated to March 2012 (95% confidence interval December 2011 to June 2012).

It is thought that the viruses have been present in bats for some time and had spread to camels by the mid-1990s. The viruses appear to have spread from camels to humans in the early 2010s. The original bat host species and the time of initial infection in this species has yet to be determined. Examination of the sequences of 238 isolates suggested that this virus has evolved into three clades differing in codon usage, host, and geographic distribution.

Symptoms

It is possible for MERS to be symptomless, and early research has shown that up to 20% of cases show no signs of active infection but have MERS-CoV antibodies in their blood.

Prevention

● Wash your hands often with soap and water for at least 20 seconds, and help young children do the same. If soap and water are not available, use an alcohol-based hand sanitizer.
● Cover your nose and mouth with a tissue when you cough or sneeze, then throw the tissue in the trash.
● Avoid touching your eyes, nose, and mouth with unwashed hands.
● Avoid personal contact, such as kissing, or sharing cups or eating utensils, with sick people.
● Clean and disinfect frequently touched surfaces and objects, such as doorknobs.

Treatment

Treatment includes rest, fluids, pain relievers and oxygen therapy in severe cases. Analgesics.

22 Monkeypox

Monkeypox is an infectious disease caused by the monkeypox virus that can occur in certain animals including humans. Symptoms begin with fever, headache, muscle pains, swollen lymph nodes, and feeling tired. This is followed by a rash that forms blisters and crusts over. The time from exposure to onset of symptoms is around 10 days. The duration of symptoms is typically 2 to 5 weeks.

Monkeypox may be spread from handling bush meat, an animal bite or scratch, body fluids, contaminated objects, or close contact with an infected person. The virus is believed to normally circulate among certain rodents in Africa. Diagnosis can be confirmed by testing a lesion for the virus's DNA. The disease can appear similar to chickenpox.

The smallpox vaccine is believed to prevent infection. In 2019 a vaccine was approved for the disorder in the United States. There is no known cure. Cidofovir or brincidofovir may be useful. The risk of death in those infected is up to 10%.

Sources

Monkeypox virus causes the disease in both humans and animals. It was first identified in 1958 as a pathogen of crab-eating macaque monkeys (Macaca fascicularis) being used as laboratory animals. The crab-eating macaque is often used for neurological experiments. Monkeypox virus is an Orthopoxvirus, a genus of the family Poxviridae that contains other viral species that target mammals. The virus is found mainly in tropical rainforest regions of Central and West Africa. The virus was first discovered in monkeys (hence the name) in 1958, and in humans in 1970. Between 1970 and 1986, over 400 cases in humans were reported.

Small viral outbreaks with a death rate in the range of 10% and a secondary human-to-human infection rate of about the same amount occur routinely in equatorial Central and West Africa. The primary route of infection is thought to be contact with the infected animals or their bodily fluids. The first reported outbreak outside of the African continent occurred in the United States in 2003 in the Midwestern states of Illinois, Indiana, and Wisconsin, with one occurrence in New Jersey. The outbreak was traced to a prairie dog infected from an imported Gambian pouch rat. No deaths occurred.

Humans can be infected by an animal via a bite, or by direct contact with an infected animal's bodily fluids. The virus can also spread from human to human, by respiratory (airborne) contact or by contact with an infected person's bodily fluids. Risk factors for transmission include sharing a bed or room, or using the same utensils as an infected person. An increased transmission risk is associated with factors involving introduction of virus to the oral mucosa. The incubation period is 10–14 days.

Prodromal symptoms include swelling of lymph nodes, muscle pain, headache, and fever prior to the emergence of the rash. The rash is usually only present on the trunk, but may spread to the palms and soles of the feet in a centrifugal distribution. The initial macular lesions exhibit a papular, then vesicular and pustular appearance.

Symptoms

Monkeypox is similar to smallpox, although it is often milder. Limited person-to-person spread of infection has been reported in disease-endemic areas in Africa.

Prevention

The smallpox vaccine is the only known way to prevent smallpox in an exposed person. If given within 4 days of viral exposure, the vaccine can prevent or significantly lessen the severity of smallpox symptoms. Vaccination 4-7 days after exposure may offer some protection from the disease and may lessen its severity. Vaccination against smallpox is assumed to provide protection against human monkeypox infection, because they are closely related viruses and the vaccine protects animals from experimental lethal monkeypox challenge. This has not been conclusively demonstrated in humans, because routine smallpox vaccination was discontinued following the apparent eradication of smallpox and owing to safety concerns with the vaccine.

Smallpox vaccine has been reported to reduce the risk of monkeypox among previously vaccinated persons in Africa. The decrease in immunity to poxviruses in exposed populations is a factor in the prevalence of monkeypox. It is attributed both to waning cross-protective immunity among those vaccinated before 1980 when mass smallpox vaccinations were discontinued, and to the gradually increasing proportion of unvaccinated individuals.

The United States Centers for Disease Control and Prevention (CDC) recommends that persons investigating monkeypox outbreaks and involved in caring for infected individuals or animals should receive a smallpox vaccination to protect against monkeypox. Persons who have had close or intimate contact with individuals or animals confirmed to have monkeypox should also be vaccinated. The CDC does not recommend pre-exposure vaccination for unexposed veterinarians, veterinary staff, or animal control officers, unless such persons are involved in field investigations.

Treatment

Currently, no treatment for monkeypox has been shown to be effective or safe. A number of measures may be used to try to decrease spread of the disease including the smallpox vaccine, cidofovir, and vaccinia immune globulin (VIG).

23 Nipah Virus

Nipah virus infection is a viral infection caused by the Nipah virus. Symptoms from infection vary from none to fever, cough, headache, shortness of breath, and confusion. This may worsen into a coma over a day or two. Complications can include inflammation of the brain and seizures following recovery. The Nipah virus is a type of RNA virus in the genus Henipavirus. It can both spread between people and from other animals to people. Spread typically requires direct contact with an infected source. The virus normally circulates among specific types of fruit bats. Diagnosis is based on symptoms and confirmed by laboratory testing.

Management involves supportive care. As of 2018 there is no vaccine or specific treatment. Prevention is by avoiding exposure to bats and sick pigs and not drinking raw date palm sap. As of May 2018 about 700 human cases of Nipah virus are estimated to have occurred and 50 to 75 percent of those who were infected died.

Sources

Nipah virus has been isolated from Lyle's flying fox (Pteropus lylei) in Cambodia and viral RNA found in urine and saliva from P. lylei and Horsfield's roundleaf bat (Hipposideros larvatus) in Thailand. Infective virus has also been isolated from environmental samples of bat urine and partially eaten fruit in Malaysia. Antibodies to henipaviruses have also been found in fruit bats in Madagascar (Pteropus rufus, Eidolon dupreanum) and Ghana (Eidolon helvum) indicating a wide geographic distribution of the viruses. No infection of humans or other species have been observed in Cambodia, Thailand or Africa as of May 2018.

Symptoms

Infected people initially develop symptoms including fever, headaches, myalgia (muscle pain), vomiting and sore throat. This can be followed by dizziness, drowsiness, altered consciousness, and neurological signs that indicate acute encephalitis.

Prevention

ILLNESS Viral Nipah Virus

- Practice handwashing regularly with soap and water.
- Avoid contact with sick bats or pigs.
- Avoid areas where bats are known to roost.
- Avoid consumption of raw date palm sap.
- Avoid consumption of fruits that may be contaminated by bats.
- Avoid contact with the blood or body fluids of any person known to be infected with NiV.

Treatment

Currently there are no licensed treatments available for Nipah virus (NiV) infection. Treatment is limited to supportive care, including rest, hydration, and treatment of symptoms as they occur.

24 Rabies

Rabies is a viral disease that causes inflammation of the brain in humans and other mammals. Early symptoms can include fever and tingling at the site of exposure. These symptoms are followed by one or more of the following symptoms: violent movements, uncontrolled excitement, fear of water, an inability to move parts of the body, confusion, and loss of consciousness. Once symptoms appear, the result is nearly always death. The time period between contracting the disease and the start of symptoms is usually one to three months, but can vary from less than one week to more than one year. The time depends on the distance the virus must travel along peripheral nerves to reach the central nervous system.

Rabies is caused by lyssaviruses, including the rabies virus and Australian bat lyssavirus. It is spread when an infected animal scratches or bites a human or other animal. Saliva from an infected animal can also transmit rabies if the saliva comes into contact with the eyes, mouth, or nose. Globally, dogs are the most common animal involved. In countries where dogs commonly have the disease, more than 99% of rabies cases are the direct result of dog bites. In the Americas, bat bites are the most common source of rabies infections in humans, and less than 5% of cases are from dogs. Rodents are very rarely infected with rabies. The disease can be diagnosed only after the start of symptoms.

Sources

Rabies is caused by a number of lyssaviruses including the rabies virus and Australian bat lyssavirus. Duvenhage lyssavirus may cause a rabies-like infection. All warm-blooded species, including humans, may become infected with the rabies virus and develop symptoms. Birds were first artificially infected with rabies in 1884; however, infected birds are largely, if not wholly, asymptomatic, and recover. Other bird species have been known to develop rabies antibodies, a sign of infection, after feeding on rabies-infected mammals.

The virus has also adapted to grow in cells of cold-blooded vertebrates. Most animals can be infected by the virus and can transmit the disease to humans. Infected bats, monkeys, raccoons, foxes, skunks, cattle, wolves, coyotes, dogs, cats, and mongooses (normally either the small Asian mongoose or the yellow mongoose) present the greatest risk to humans.

Rabies may also spread through exposure to infected bears, domestic farm animals, groundhogs, weasels, and other wild carnivorans. However, lagomorphs, such as hares and rabbits, and small rodents such as chipmunks, gerbils, guinea pigs, hamsters, mice, rats, and squirrels, are almost never found to be infected with rabies and are not known to transmit rabies to humans. Bites from mice, rats, or squirrels rarely require rabies prevention because these rodents are typically killed by any encounter with a larger, rabid animal, and would, therefore, not be carriers. The Virginia opossum is resistant but not immune to rabies.

The virus is usually present in the nerves and saliva of a symptomatic rabid animal. The route of infection is usually, but not always, by a bite. In many cases, the infected animal is exceptionally aggressive, may attack without provocation, and exhibits otherwise uncharacteristic behavior. This is an example of a viral pathogen modifying the behavior of its host to facilitate its transmission to other hosts. After a typical human infection by bite, the virus enters the peripheral nervous system.

It then travels along the afferent nerves toward the central nervous system. During this phase, the virus cannot be easily detected within the host, and vaccination may still confer cell-mediated immunity to prevent symptomatic rabies. When the virus reaches the brain, it rapidly causes encephalitis, the prodromal phase, which is the beginning of the symptoms. Once the patient becomes symptomatic, treatment is almost never effective and mortality is over 99%. Rabies may also inflame the spinal cord, producing transverse myelitis.

Although it is theoretically possible for rabies-infected humans to transmit it to others by biting or otherwise, no such cases have ever been documented, since infected humans are usually hospitalized and necessary precautions taken. Casual contact, such as touching a person with rabies or contact with non-infectious fluid or tissue (urine, blood, feces) does not constitute an exposure and does not require post-exposure prophylaxis. But as the virus is present in sperm and vaginal secretions, it might be possible for rabies to spread through sex. There are only a handful of recorded cases of human-to-human transmission of rabies, and all occurred through organ transplants from infected donors.

Symptoms

The period between infection and the first symptoms (incubation period) is typically 1–3 months in humans. This period may be as short as four days or longer than six years, depending on the location and severity of the wound and the amount of virus introduced. Initial symptoms of rabies are often nonspecific such as fever and headache. As rabies progresses and causes inflammation of the brain and meninges, symptoms can include slight or partial paralysis, anxiety, insomnia, confusion, agitation, abnormal behavior, paranoia, terror, and hallucinations. The person may also have fear of water.

The symptoms eventually progress to delirium, and coma. Death usually occurs 2 to 10 days after first symptoms. Survival is almost unknown once symptoms have presented, even with intensive care.

Fear of Water
Hydrophobia ("fear of water") is the historic name for rabies. It refers to a set of symptoms in the later stages of an infection in which the person has difficulty swallowing, shows panic when presented with liquids to drink, and cannot quench their thirst. Any mammal infected with the virus may demonstrate hydrophobia. Saliva production is greatly increased, and attempts to drink, or even the intention or suggestion of drinking, may cause excruciatingly painful spasms of the muscles in the throat and larynx. Since the infected individual cannot swallow saliva and water, the virus has a much higher chance of being transmitted, since it multiplies and assimilates in the salivary glands and is transmitted through biting. Hydrophobia is commonly associated with furious rabies, which affects 80% of rabies-infected people. The remaining 20% may experience a paralytic form of rabies that is marked by muscle weakness, loss of sensation, and paralysis; this form of rabies does not usually cause fear of water.

Prevention

Almost all human exposure to rabies was fatal until a vaccine was developed in 1885 by Louis Pasteur and Émile Roux. Their original vaccine was harvested from infected rabbits, from which the virus in the nerve tissue was weakened by allowing it to dry for five to ten days. Similar nerve tissue-derived vaccines are still used in some countries, as they are much cheaper than modern cell culture vaccines.

The human diploid cell rabies vaccine was started in 1967. Less expensive purified chicken embryo cell vaccine and purified vero cell rabies vaccine are now available. A recombinant vaccine called V-RG has been used in Belgium, France, Germany, and the United States to prevent outbreaks of rabies in undomesticated animals. Immunization before exposure has been used in both human and nonhuman populations, where, as in many jurisdictions, domesticated animals are required to be vaccinated.

The Missouri Department of Health and Senior Services Communicable Disease Surveillance 2007 Annual Report states the following can help reduce the risk of contracting rabies:
- Vaccinating dogs, cats, and ferrets against rabies
- Keeping pets under supervision
- Not handling wild animals or strays
- Contacting an animal control officer upon observing a wild animal or a stray, especially if the animal is acting strangely
- If bitten by an animal, washing the wound with soap and water for 10 to 15 minutes and contacting a healthcare provider to determine if post-exposure prophylaxis is required

Treatment

After Exposure
Treatment after exposure can prevent the disease if given within 10 days. The rabies vaccine is 100% effective if given early, and still has a chance of success if delivery is delayed. Every year, more than 15 million people get vaccination after potential exposure. While this works well, the cost is significant. In the US it is recommended people receive one dose of human rabies immunoglobulin (HRIG) and four doses of rabies vaccine over a 14-day period. HRIG is expensive and makes up most of the cost of post exposure treatment, ranging as high as several thousand dollars. As much as possible of this dose should be injected around the bites, with the remainder being given by deep intramuscular injection at a site distant from the vaccination site.

People who have previously been vaccinated against rabies do not need to receive the immunoglobulin, only the postexposure vaccinations on days 0 and 3. The side effects of modern cell-based vaccines are similar to flu shots. The old nerve-tissue-based vaccination required multiple injections into the abdomen with a large needle but is inexpensive. It is being phased out and replaced by affordable World Health Organization intradermal-vaccination regimens.

Intramuscular vaccination should be given into the deltoid, not the gluteal area, which has been associated with vaccination failure due to injection into fat rather than muscle. In children less than a year old, the lateral thigh is recommended. Thoroughly washing the wound as soon as possible with soap and water for approximately five minutes is effective in reducing the number of viral particles. Povidone-iodine or alcohol is then recommended to reduce the virus further.

Awakening to find a bat in the room, or finding a bat in the room of a previously unattended child or mentally disabled or intoxicated person, is an indication for post-exposure prophylaxis (PEP). The recommendation for the precautionary use of PEP in bat encounters where no contact is recognized has been questioned in the medical literature, based on a cost–benefit analysis. However, a 2002 study has supported the protocol of precautionary administering of PEP where a child or mentally compromised individual has been alone with a bat, especially in sleep areas, where a bite or exposure may occur with the victim being unaware.

After Onset
A treatment known as the Milwaukee protocol, which involves putting a person into a chemically induced coma and using antiviral medications, has been proposed but subsequently found not to be useful. It initially came into use in 2003, following Jeanna Giese, a teenager from Wisconsin, becoming the first person known to have survived rabies without preventive treatments before symptom onset. She, however, already had antibodies against rabies when she initially arrived at hospital. While this treatment has been tried multiple times more, there have been no further cases of survival. The protocol has since been assessed as an ineffective treatment with concerns related to the costs and ethics of its use.

25 Rubella (German Measles)

Rubella, also known as German measles or three-day measles, is an infection caused by the rubella virus. This disease is often mild with half of people not realizing that they are infected. A rash may start around two weeks after exposure and last for three days. It usually starts on the face and spreads to the rest of the body. The rash is sometimes itchy and is not as bright as that of measles. Swollen lymph nodes are common and may last a few weeks. A fever, sore throat, and fatigue may also occur. In adults joint pain is common.

Complications may include bleeding problems, testicular swelling, and inflammation of nerves. Infection during early pregnancy may result in a child born with congenital rubella syndrome (CRS) or miscarriage. Symptoms of CRS include problems with the eyes such as cataracts, ears such as deafness, heart, and brain. Problems are rare after the 20th week of pregnancy.

Rubella is usually spread through the air via coughs of people who are infected. People are infectious during the week before and after the appearance of the rash. Babies with CRS may spread the virus for more than a year. Only humans are infected. Insects do not spread the disease. Once recovered, people are immune to future infections. Testing is available that can verify immunity. Diagnosis is confirmed by finding the virus in the blood, throat, or urine. Testing the blood for antibodies may also be useful.

Sources

The disease is caused by rubella virus, a togavirus that is enveloped and has a single-stranded RNA genome. The virus is transmitted by the respiratory route and replicates in the nasopharynx and lymph nodes. The virus is found in the blood 5 to 7 days after infection and spreads throughout the body. The virus has teratogenic properties and is capable of crossing the placenta and infecting the fetus where it stops cells from developing or destroys them. During this incubation period, the patient is contagious typically for about one week before he/she develops a rash and for about one week thereafter.

Increased susceptibility to infection might be inherited as there is some indication that HLA-A1 or factors surrounding A1 on extended haplotypes are involved in virus infection or non-resolution of the disease.

Symptoms

ILLNESS Viral Rubella (German Measles) Symptoms

Rubella has symptoms that are similar to those of flu. However, the primary symptom of rubella virus infection is the appearance of a rash (exanthem) on the face which spreads to the trunk and limbs and usually fades after three days (that is why it is often referred to as three-day measles). The facial rash usually clears as it spreads to other parts of the body. Other symptoms include low grade fever, swollen glands (sub-occipital and posterior cervical lymphadenopathy), joint pains, headache, and conjunctivitis.

The swollen glands or lymph nodes can persist for up to a week and the fever rarely rises above 38 °C (100.4 °F). The rash of rubella is typically pink or light red. The rash causes itching and often lasts for about three days. The rash disappears after a few days with no staining or peeling of the skin. When the rash clears up, the skin might shed in very small flakes where the rash covered it. Forchheimer's sign occurs in 20% of cases, and is characterized by small, red papules on the area of the soft palate.

Rubella can affect anyone of any age. Adult women are particularly prone to arthritis and joint pains.
In children rubella normally causes symptoms which last two days and include:
- Rash beginning on the face which spreads to the rest of the body.
- Low fever of less than 38.3 °C (101 °F).
- Posterior cervical lymphadenopathy.

In older children and adults additional symptoms may be present including:
- Swollen glands
- Coryza (cold-like symptoms)
- Aching joints (especially in young women)

Severe complications of rubella include:
- Brain inflammation (encephalitis)
- Low platelet count
- Ear infection

Prevention

Rubella infections are prevented by active immunisation programs using live attenuated virus vaccines. Two live attenuated virus vaccines, RA 27/3 and Cendehill strains, were effective in the prevention of adult disease. However their use in prepubertal females did not produce a significant fall in the overall incidence rate of CRS in the UK. Reductions were only achieved by immunisation of all children. The vaccine is now usually given as part of the MMR vaccine. The WHO recommends the first dose be given at 12 to 18 months of age with a second dose at 36 months. Pregnant women are usually tested for immunity to rubella early on. Women found to be susceptible are not vaccinated until after the baby is born because the vaccine contains live virus.

The immunisation program has been quite successful. Cuba declared the disease eliminated in the 1990s, and in 2004 the Centers for Disease Control and Prevention announced that both the congenital and acquired forms of rubella had been eliminated from the United States. The World Health Organisation declared Australia rubella free in October 2018. Screening for rubella susceptibility by history of vaccination or by serology is recommended in the United States for all women of childbearing age at their first preconception counseling visit to reduce incidence of congenital rubella syndrome (CRS).

It is recommended that all susceptible non-pregnant women of childbearing age should be offered rubella vaccination. Due to concerns about possible teratogenicity, use of MMR vaccine is not recommended during pregnancy. Instead, susceptible pregnant women should be vaccinated as soon as possible in the postpartum period.

In susceptible people passive immunization, in the form of Polyclonal immunoglobulins appears effective up to the fifth day post-exposure.

Treatment

There is no specific treatment for rubella; however, management is a matter of responding to symptoms to diminish discomfort. Treatment of newborn babies is focused on management of the complications. Congenital heart defects and cataracts can be corrected by direct surgery.

Management for ocular congenital rubella syndrome (CRS) is similar to that for age-related macular degeneration, including counseling, regular monitoring, and the provision of low vision devices, if required.

26 Rift Valley Fever

Rift Valley fever (RVF) is a viral disease that can cause mild to severe symptoms. The mild symptoms may include: fever, muscle pains, and headaches which often last for up to a week. The severe symptoms may include: loss of sight beginning three weeks after the infection, infections of the brain causing severe headaches and confusion, and bleeding together with liver problems which may occur within the first few days. Those who have bleeding have a chance of death as high as 50%.

The disease is caused by the RVF virus, which is of the Phlebovirus type. It is spread by either touching infected animal blood, breathing in the air around an infected animal being butchered, drinking raw milk from an infected animal, or the bite of infected mosquitoes. Animals such as cows, sheep, goats, and camels may be affected. In these animals it is spread mostly by mosquitoes. It does not appear that one person can infect another person. The disease is diagnosed by finding antibodies against the virus or the virus itself in the blood.

Prevention of the disease in humans is accomplished by vaccinating animals against the disease. This must be done before an outbreak occurs because if it is done during an outbreak it may worsen the situation. Stopping the movement of animals during an outbreak may also be useful, as may decreasing mosquito numbers and avoiding their bites. There is a human vaccine; however, as of 2010 it is not widely available. There is no specific treatment and medical efforts are supportive

Sources

The virus is transmitted through mosquito vectors, as well as through contact with the tissue of infected animals. Two species—Culex tritaeniorhynchus and Aedes vexans—are known to transmit the virus. Other potential vectors include Aedes caspius, Aedes mcintosh, Aedes ochraceus, Culex pipiens, Culex antennatus, Culex perexiguus, Culex zombaensis and Culex quinquefasciatus. Contact with infected tissue is considered to be the main source of human infections. The virus has been isolated from two bat species: the Peter's epauletted fruit bat (Micropteropus pusillus) and the aba roundleaf bat (Hipposideros abae), which are believed to be reservoirs for the virus.

Symptoms

ILLNESS | Viral | Rift Valley Fever | Symptoms

In humans, the virus can cause several syndromes. Usually, sufferers have either no symptoms or only a mild illness with fever, headache, muscle pains, and liver abnormalities. In a small percentage of cases (< 2%), the illness can progress to hemorrhagic fever syndrome, meningoencephalitis (inflammation of the brain and tissues lining the brain), or affect the eye. Patients who become ill usually experience fever, generalised weakness, back pain, dizziness, and weight loss at the onset of the illness. Typically, people recover within two to seven days after onset.About 1% of people with the disease die of it. In livestock, the fatality level is significantly higher. Pregnant livestock infected with RVF abort virtually 100% of foetuses. An epizootic (animal disease epidemic) of RVF is usually first indicated by a wave of unexplained abortions.

Other signs in livestock include vomiting and diarrhoea, respiratory disease, fever, lethargy, anorexia and sudden death in young animals.

Prevention

A person's chances of becoming infected can be reduced by taking measures to decrease contact with blood, body fluids, or tissues of infected animals and protection against mosquitoes and other bloodsucking insects. Use of mosquito repellents and bed nets are two effective methods. For persons working with animals in RVF-endemic areas, wearing protective equipment to avoid any exposure to blood or tissues of animals that may potentially be infected is an important protective measure. Potentially, establishing environmental monitoring and case surveillance systems may aid in the prediction and control of future RVF outbreaks.

No vaccines are currently available for humans. While a vaccines have been developed for humans, it has only been used experimentally for scientific personnel in high-risk environments. Trials of a number of vaccines, such as NDBR-103 and TSI-GSD 200, are ongoing. Different types of vaccines for veterinary use are available. The killed vaccines are not practical in routine animal field vaccination because of the need of multiple injections. Live vaccines require a single injection but are known to cause birth defects and abortions in sheep and induce only low-level protection in cattle.

The live-attenuated vaccine, MP-12, has demonstrated promising results in laboratory trials in domesticated animals, but more research is needed before the vaccine can be used in the field. The live-attenuated clone 13 vaccine was recently registered and used in South Africa. Alternative vaccines using molecular recombinant constructs are in development and show promising results. A vaccine has been conditionally approved for use in animals in the US. It has been shown that knockout of the NSs and NSm nonstructural proteins of this virus produces an effective vaccine in sheep as well.

Treatment

There are no FDA-approved treatments for Rift Valley Fever. Because most cases of RVF are mild and self-limiting, a specific treatment for RVF has not been established. Symptoms of mild illness such as fever and body aches can be managed with standard over-the-counter medications.

27 Pappataci Fever (Sandfly Fever)

ILLNESS | Viral | Pappataci Fever (Sandfly Fever) (Phlebotomus Fever)

Pappataci fever (also known as Phlebotomus fever and, somewhat confusingly, sandfly fever and three-day fever) is a vector-borne febrile arboviral infection caused by three serotypes of Phlebovirus. It occurs in subtropical regions of the Eastern Hemisphere. The name, pappataci fever, comes from the Italian word for sandfly, it is the union of the word "pappa" (food) and taci (silent) which distinguishes these insects from blood-feeding mosquitoes, which produce a typical noise while flying.

Sources

Three serotypes of Phlebovirus are known as the causative agents: Naples virus, Sicilian virus and Toscana virus.

Symptoms

A few days after the infective bite, a feeling of lassitude, abdominal distress and chills develop followed by fever of 39 °C to 40 °C, severe frontal headaches, muscle and joint aches, flushing of the face and a fast heart rate. After two days the fever begins to subside and the temperature returns to normal. Fatigue, a slow heart rate and low blood pressure may persist from few days to several weeks but complete recovery is the rule.

Prevention

Prevention of sandfly bites, and control of sandflies and their breeding grounds with insecticides are the principal methods for prevention. Mosquito nets may not be sufficient to prevent sandfly bites.

Treatment

There is no specific treatment for the disease. Pain killers and fluid replacement may be useful.

28 Swine Flu

ILLNESS | Viral | Swine Flu

Swine influenza is an infection caused by any one of several types of swine influenza viruses. Swine influenza virus (SIV) or swine-origin influenza virus (S-OIV) is any strain of the influenza family of viruses that is endemic in pigs. As of 2009, the known SIV strains include influenza C and the subtypes of influenza A known as H1N1, H1N2, H2N1, H3N1, H3N2, and H2N3. The Swine flu was initially seen in humans in Mexico in 2009, where the strain of the particular virus was a mixture from 3 types of strains. Six of the genes are very similar to the H1N2 influenza virus that was found in pigs around 2000. Swine influenza virus is common throughout pig populations worldwide. Transmission of the virus from pigs to humans is not common and does not always lead to human flu, often resulting only in the production of antibodies in the blood. If transmission does cause human flu, it is called zoonotic swine flu. People with regular exposure to pigs are at increased risk of swine flu infection.

Sources

People who work with poultry and swine, especially those with intense exposures, are at increased risk of zoonotic infection with influenza virus endemic in these animals, and constitute a population of human hosts in which zoonosis and reassortment can co-occur. Vaccination of these workers against influenza and surveillance for new influenza strains among this population may therefore be an important public health measure. Transmission of influenza from swine to humans who work with swine was documented in a small surveillance study performed in 2004 at the University of Iowa. This study, among others, forms the basis of a recommendation that people whose jobs involve handling poultry and swine be the focus of increased public health surveillance. Other professions at particular risk of infection are veterinarians and meat processing workers, although the risk of infection for both of these groups is lower than that of farm workers.

Symptoms

Direct transmission of a swine flu virus from pigs to humans is occasionally possible (zoonotic swine flu). In all, 50 cases are known to have occurred since the first report in medical literature in 1958, which have resulted in a total of six deaths. Of these six people, one was pregnant, one had leukemia, one had Hodgkin's lymphoma and two were known to be previously healthy. One of these had unknown whereabouts. Despite these apparently low numbers of infections, the true rate of infection may be higher, since most cases only cause a very mild disease, and will probably never be reported or diagnosed.

According to the United States Centers for Disease Control and Prevention (CDC), in humans the symptoms of the 2009 "swine flu" H1N1 virus are similar to influenza and influenza-like illness in general. Symptoms include fever, cough, sore throat, watery eyes, body aches, shortness of breath, headache, weight loss, chills, sneezing, runny nose, coughing, dizziness, abdominal pain, lack of appetite, and fatigue. The 2009 outbreak showed an increased percentage of patients reporting diarrhea and vomiting as well. The 2009 H1N1 virus is not zoonotic swine flu, as it is not transmitted from pigs to humans, but from person to person through airborne droplets.

Because these symptoms are not specific to swine flu, a differential diagnosis of probable swine flu requires not only symptoms, but also a high likelihood of swine flu due to the person's recent and past medical history. For example, during the 2009 swine flu outbreak in the United States, the CDC advised physicians to "consider swine influenza infection in the differential diagnosis of patients with acute febrile respiratory illness who have either been in contact with persons with confirmed swine flu, or who were in one of the five U.S. states that have reported swine flu cases or in Mexico during the seven days preceding their illness onset." A diagnosis of confirmed swine flu requires laboratory testing of a respiratory sample (a simple nose and throat swab).

The most common cause of death is respiratory failure. Other causes of death are pneumonia (leading to sepsis), high fever (leading to neurological problems), dehydration (from excessive vomiting and diarrhea), electrolyte imbalance and kidney failure. Fatalities are more likely in young children and the elderly.

Prevention

Prevention of swine influenza has three components: prevention in pigs, prevention of transmission to humans, and prevention of its spread among humans. Proper hand washing techniques can prevent the virus from spreading. Avoid touching the eyes, nose, or mouth. Stay away from others who display symptoms of the cold or flu and avoid contact with others when displaying symptoms.

Prevention of Pig-to-Human Transmission
Swine can be infected by both avian and human flu strains of influenza, and therefore are hosts where the antigenic shifts can occur that create new influenza strains.

The transmission from swine to humans is believed to occur mainly in swine farms, where farmers are in close contact with live pigs. Although strains of swine influenza are usually not able to infect humans, it may occasionally happen, so farmers and veterinarians are encouraged to use face masks when dealing with infected animals. The use of vaccines on swine to prevent their infection is a major method of limiting swine-to-human transmission. Risk factors that may contribute to swine-to-human transmission include smoking and, especially, not wearing gloves when working with sick animals, thereby increasing the likelihood of subsequent hand-to-eye, hand-to-nose, or hand-to-mouth transmission.

Prevention of Human-to-Human Transmission
Influenza spreads between humans when infected people cough or sneeze, then other people breathe in the virus or touch something with the virus on it and then touch their own face. "Avoid touching your eyes, nose or mouth. Germs spread this way." Swine flu cannot be spread by pork products, since the virus is not transmitted through food. The swine flu in humans is most contagious during the first five days of the illness, although some people, most commonly children, can remain contagious for up to ten days. Diagnosis can be made by sending a specimen, collected during the first five days, for analysis.

Recommendations to prevent spread of the virus among humans include using standard infection control, which includes frequent washing of hands with soap and water or with alcohol-based hand sanitizers, especially after being out in public. Chance of transmission is also reduced by disinfecting household surfaces, which can be done effectively with a diluted chlorine bleach solution.

Experts agree hand-washing can help prevent viral infections, including ordinary and swine flu infections. Also, avoiding touching one's eyes, nose, or mouth with one's hands helps to prevent the flu. Influenza can spread in coughs or sneezes, but an increasing body of evidence shows small droplets containing the virus can linger on tabletops, telephones, and other surfaces and be transferred via the fingers to the eyes, nose, or mouth. Alcohol-based gel or foam hand sanitizers work well to destroy viruses and bacteria. Anyone with flu-like symptoms, such as a sudden fever, cough, or muscle aches, should stay away from work or public transportation and should contact a doctor for advice.

Social distancing, another tactic, is staying away from other people who might be infected, and can include avoiding large gatherings, spreading out a little at work, or perhaps staying home and lying low if an infection is spreading in a community. Public health and other responsible authorities have action plans which may request or require social distancing actions, depending on the severity of the outbreak.

Treatment

If a person becomes sick with swine flu, antiviral drugs can make the illness milder and make the patient feel better faster. They may also prevent serious flu complications. For treatment, antiviral drugs work best if started soon after getting sick (within two days of symptoms). Beside antivirals, supportive care at home or in a hospital focuses on controlling fevers, relieving pain and maintaining fluid balance, as well as identifying and treating any secondary infections or other medical problems. The U.S. Centers for Disease Control and Prevention recommends the use of oseltamivir (Tamiflu) or zanamivir (Relenza) for the treatment and/or prevention of infection with swine influenza viruses; however, the majority of people infected with the virus make a full recovery without requiring medical attention or antiviral drugs. The virus isolated in the 2009 outbreak have been found resistant to amantadine and rimantadine.

In the U.S., on April 27, 2009, the FDA issued Emergency Use Authorizations to make available Relenza and Tamiflu antiviral drugs to treat the swine influenza virus in cases for which they were currently unapproved. The agency issued these EUAs to allow treatment of patients younger than the current approval allows and to allow the widespread distribution of the drugs, including by volunteers.

29 Tick-Borne Encephalitis

Tick-borne encephalitis (TBE) is a viral infectious disease involving the central nervous system. The disease most often manifests as meningitis, encephalitis, or meningoencephalitis. Long-lasting or permanent neuropsychiatric consequences are observed in 10 to 20% of infected patients. The number of reported cases has been increasing in most countries. TBE is posing a concerning health challenge to Europe, as the number of reported human cases of TBE in all endemic regions of Europe have increased by almost 400% within the last three decades. The tick-borne encephalitis virus is known to infect a range of hosts including ruminants, birds, rodents, carnivores, horses, and humans. The disease can also be spread from animals to humans, with ruminants and dogs providing the principal source of infection for humans.

Sources

TBE is caused by tick-borne encephalitis virus, a member of the genus Flavivirus in the family Flaviviridae. It was first isolated in 1937. Three virus sub-types also exist: European or Western tick-borne encephalitis virus (transmitted by Ixodes ricinus), Siberian tick-borne encephalitis virus (transmitted by I. persulcatus), and Far-Eastern tick-borne encephalitis virus, formerly known as Russian spring summer encephalitis virus (transmitted by I. persulcatus).

Russia and Europe report about 5,000–7,000 human cases annually. The former Soviet Union conducted research on tick-borne diseases, including the TBE viruses.

Symptoms

The disease typically follows a biphasic pattern in 72–87% of patients and the median incubation period is 8 days (range, 4–28 days) after tick bite. Non-specific symptoms of mild fever, malaise, headache, nausea, vomiting and myalgias may be present as first manifestation of the disease and spontaneously resolve within 1 week. After another week the patient may develop neurological symptoms. The virus can result in long neurological symptoms, infecting the brain (encephalitis), the meninges (meningitis) or both (meningoencephalitis). In general, mortality is 1% to 2%, with deaths occurring 5 to 7 days after the onset of neurologic signs.

Prevention

Prevention includes non-specific (tick-bite prevention, tick checks) and specific prophylaxis in the form of a vaccination. Tick-borne encephalitis vaccines are very effective and available in many disease endemic areas and in travel clinics. Trade names are Encepur N and FSME-Immun CC.

Treatment

There is no specific antiviral treatment for TBE. Symptomatic brain damage requires hospitalization and supportive care based on syndrome severity. Anti-inflammatory drugs, such as corticosteroids, may be considered under specific circumstances for symptomatic relief. Tracheal intubation and respiratory support may be necessary.

Notes

In Germany, during the 2010s, there have been a minimum of 95 (2012) and a maximum of 584 cases (2018) of TBE (or FSME as it is known in German). More than half of the reported cases from 2019 had meningitis, encephalitis or myelitis. The risk of infection was noted to be increasing with age, especially in people older than 40 years and it was greater in men than women. Most cases were acquired in Bavaria (46 %) and Baden-Württemberg (37%), much less in Saxonia, Hesse, Niedersachsen and other states. Altogether 164 Landkreise are designated FSME-risk areas, including all of Baden-Württemberg except for the city of Heilbronn.

30 Venezuelan Hemorrhagic Fever

Venezuelan hemorrhagic fever (VHF) is a zoonotic human illness first identified in 1989. The disease is most prevalent in several rural areas of central Venezuela and is caused by Guanarito mammarenavirus (GTOV) which belongs to the Arenaviridae family. The short-tailed cane mouse (Zygodontomys brevicauda) is the main host for GTOV which is spread mostly by inhalation of aerosolized droplets of saliva, respiratory secretions, urine, or blood from infected rodents. Person-to-person spread is possible, but uncommon.

Sources

The short-tailed cane mouse, the main host of GTOV, is native to western Venezuela and resides in large numbers in tall grass, cultivated agricultural fields, human homes, and outbuildings. It is speculated that demographic and ecological changes in the rural areas increased the frequency of contact between humans and infected rodents such that VHF emerged.

Symptoms

VHF has many similarities to Lassa fever and to the arenavirus hemorrhagic fevers that occur in Argentina and Bolivia. It causes fever and malaise followed by hemorrhagic manifestations and convulsions. Some presentations of the virus are also characterized by vascular damage, bleeding diathesis, fever, and multiple organ involvement. Clinical diagnosis of VHF has proven to be difficult based on the nonspecific symptoms. The disease is fatal in 30% of cases and is endemic to Portuguesa state and Barinas state in Venezuela.

Prevention

Treatment and prevention for the VHF virus are limited and there are currently no licensed vaccines available that can act to prevent the disease.

Treatment

Treatment and prevention for the VHF virus are limited and there are currently no licensed vaccines available that can act to prevent the disease. However, once infected, ribavirin, an anti-viral drug given intravenously, is one way to treat VHF.

31 Varicella (Chicken Pox)

Chickenpox, also known as varicella, is a highly contagious disease caused by the initial infection with varicella zoster virus (VZV). The disease results in a characteristic skin rash that forms small, itchy blisters, which eventually scab over. It usually starts on the chest, back, and face. It then spreads to the rest of the body. Other symptoms may include fever, tiredness, and headaches. Symptoms usually last five to seven days. Complications may occasionally include pneumonia, inflammation of the brain, and bacterial skin infections. The disease is often more severe in adults than in children. Symptoms begin 10 to 21 days after exposure to the virus.

Chickenpox is an airborne disease which spreads easily through the coughs and sneezes of an infected person. It may be spread from one to two days before the rash appears until all lesions have crusted over. It may also spread through contact with the blisters. Those with shingles may spread chickenpox to those who are not immune through contact with the blisters. The disease can usually be diagnosed based on the presenting symptom; however, in unusual cases it may be confirmed by polymerase chain reaction (PCR) testing of the blister fluid or scabs. Testing for antibodies may be done to determine if a person is or is not immune. People usually only get chickenpox once. Although reinfections by the virus occur, these reinfections usually do not cause any symptoms.

Sources

Chickenpox is an airborne disease which spreads easily from one person to the next through the coughs and sneezes of an infected person. It may be spread from one to two days before the rash appears until all lesions have crusted over. It may also spread through contact with the blisters. Those with shingles may spread chickenpox to those who are not immune through contact with the blisters.

Symptoms

ILLNESS Viral Varicella (Chicken Pox) Symptoms

The early (prodromal) symptoms in adolescents and adults are nausea, loss of appetite, aching muscles, and headache. This is followed by the characteristic rash or oral sores, malaise, and a low-grade fever that signal the presence of the disease. Oral manifestations of the disease (enanthem) not uncommonly may precede the external rash (exanthem). In children the illness is not usually preceded by prodromal symptoms, and the first sign is the rash or the spots in the oral cavity. The rash begins as small red dots on the face, scalp, torso, upper arms and legs; progressing over 10–12 hours to small bumps, blisters and pustules; followed by umbilication and the formation of scabs.

At the blister stage, intense itching is usually present. Blisters may also occur on the palms, soles, and genital area. Commonly, visible evidence of the disease develops in the oral cavity and tonsil areas in the form of small ulcers which can be painful or itchy or both; this enanthem (internal rash) can precede the exanthem (external rash) by 1 to 3 days or can be concurrent. These symptoms of chickenpox appear 10 to 21 days after exposure to a contagious person. Adults may have a more widespread rash and longer fever, and they are more likely to experience complications, such as varicella pneumonia.

Because watery nasal discharge containing live virus usually precedes both exanthem (external rash) and enanthem (oral ulcers) by 1 to 2 days, the infected person actually becomes contagious one to two days before recognition of the disease. Contagiousness persists until all vesicular lesions have become dry crusts (scabs), which usually entails four or five days, by which time nasal shedding of live virus ceases. The condition usually resolves by itself within a week or two. The rash may, however, last for up to one month.

Chickenpox is rarely fatal, although it is generally more severe in adult men than in women or children. Non-immune pregnant women and those with a suppressed immune system are at highest risk of serious complications. Arterial ischemic stroke (AIS) associated with chickenpox in the previous year accounts for nearly one third of childhood AIS. The most common late complication of chickenpox is shingles (herpes zoster), caused by reactivation of the varicella zoster virus decades after the initial, often childhood, chickenpox infection.

Prevention

ILLNESS Viral Varicella (Chicken Pox) Prevention

Hygiene Measures

The spread of chickenpox can be prevented by isolating affected individuals. Contagion is by exposure to respiratory droplets, or direct contact with lesions, within a period lasting from three days before the onset of the rash, to four days after the onset of the rash. The chickenpox virus is susceptible to disinfectants, notably chlorine bleach (i.e., sodium hypochlorite). Like all enveloped viruses, it is sensitive to drying, heat and detergents.

Vaccine

The varicella vaccine is recommended in many countries. Some countries require the varicella vaccination or an exemption before entering elementary school. A second dose is recommended five years after the initial immunization. A vaccinated person is likely to have a milder case of chickenpox if they become infected. Immunization within three days following household contact reduces infection rates and severity in children.

It is part of the routine immunization schedule in the US. Some European countries include it as part of universal vaccinations in children, but not all countries provide the vaccine. In the UK as of 2014, the vaccine is only recommended in people who are particularly vulnerable to chickenpox. This is to keep the virus in circulation thereby exposing the population to the virus at an early age, when it is less harmful, and to reduce the occurrence of shingles in those who have already had chickenpox by repeated exposure to the virus later in life. In populations that have not been immunized or if immunity is questionable, a clinician may order an enzyme immunoassay. An immunoassay measures the levels of antibodies against the virus that give immunity to a person. If the levels of antibodies are low (low titer) or questionable, reimmunization may be done.

Treatment

ILLNESS Viral Varicella (Chicken Pox) Treatment

Treatment mainly consists of easing the symptoms. As a protective measure, people are usually required to stay at home while they are infectious to avoid spreading the disease to others. Cutting the nails short or wearing gloves may prevent scratching and minimize the risk of secondary infections.

Although there have been no formal clinical studies evaluating the effectiveness of topical application of calamine lotion (a topical barrier preparation containing zinc oxide, and one of the most commonly used interventions), it has an excellent safety profile. It is important to maintain good hygiene and daily cleaning of skin with warm water to avoid secondary bacterial infection. Scratching may also increase the risk of secondary infection.

Paracetamol (acetaminophen) but not aspirin may be used to reduce fever. Aspirin use by someone with chickenpox may cause serious, sometimes fatal disease of the liver and brain, Reye syndrome. People at risk of developing severe complications who have had significant exposure to the virus may be given intra-muscular varicella zoster immune globulin (VZIG), a preparation containing high titres of antibodies to varicella zoster virus, to ward off the disease.

Antivirals are sometimes used.

32 West Nile Fever

ILLNESS Viral West Nile

West Nile fever is an infection by the West Nile virus, which is typically spread by mosquitoes. In about 80% of infections people have few or no symptoms. About 20% of people develop a fever, headache, vomiting, or a rash. In less than 1% of people, encephalitis or meningitis occurs, with associated neck stiffness, confusion, or seizures. Recovery may take weeks to months. The risk of death among those in whom the nervous system is affected is about 10%. West Nile virus (WNV) is usually spread by infected mosquitoes. Mosquitoes become infected when they feed on infected birds, which often carry the disease. Rarely the virus is spread through blood transfusions, organ transplants, or from mother to baby during pregnancy, delivery, or breastfeeding. It otherwise does not spread directly between people.

Risks for severe disease include being over 60 years old and having other health problems. Diagnosis is typically based on symptoms and blood tests. There is no human vaccine. The best way to reduce the risk of infection is to avoid mosquito bites. Mosquito populations may be reduced by eliminating standing pools of water, such as in old tires, buckets, gutters, and swimming pools. When mosquitoes cannot be avoided, mosquito repellent, window screens, and mosquito nets reduce the likelihood of being bitten. There is no specific treatment for the disease; pain medications may reduce symptoms.

Sources

ILLNESS Viral West Nile Fever Sources

The prime method of spread of the West Nile virus (WNV) is the female mosquito. In Europe, cats were identified as being hosts for West Nile virus. The important mosquito vectors vary according to area; in the United States, Culex pipiens (Eastern United States, and urban and residential areas of the United States north of 36–39°N), Culex tarsalis (Midwest and West), and Culex quinquefasciatus (Southeast) are the main vector species.

The mosquito species that are most frequently infected with WNV feed primarily on birds. Different species of mosquitos take a blood meal from different types of vertebrate hosts, Mosquitoes show further selectivity, exhibiting preference for different species of birds. In the United States, WNV mosquito vectors feed preferentially on members of the Corvidae and thrush family. Among the preferred species within these families are the American crow, a corvid, and the American robin (Turdus migratorius).

Some species of birds develop sufficient viral levels (>~104.2 log PFU/ml;) after being infected to transmit the infection to biting mosquitoes that in turn go on to infect other birds. In birds that die from WNV, death usually occurs after 4 to 6 days. In mammals and several species of birds, the virus does not multiply as readily and so does not develop high viremia during infection. Mosquitoes biting such hosts are not believed to ingest sufficient virus to become infected, making them so-called dead-end hosts. As a result of the differential infectiousness of hosts, the feeding patterns of mosquitoes play an important role in WNV transmission, and they are partly genetically controlled, even within a species.

Direct human-to-human transmission initially was believed to be caused only by occupational exposure, such as in a laboratory setting, or conjunctival exposure to infected blood. The US outbreak identified additional transmission methods through blood transfusion, organ transplant, intrauterine exposure, and breast feeding. Since 2003, blood banks in the United States routinely screen for the virus among their donors.

As a precautionary measure, the UK's National Blood Service initially ran a test for this disease in donors who donate within 28 days of a visit to the United States, Canada, or the northeastern provinces of Italy, and the Scottish National Blood Transfusion Service asks prospective donors to wait 28 days after returning from North America or the northeastern provinces of Italy before donating. There also have been reports of possible transmission of the virus from mother to child during pregnancy or breastfeeding or exposure to the virus in a lab, but these are rare cases and not conclusively confirmed.

Recently, the potential for mosquito saliva to affect the course of WNV disease was demonstrated. Mosquitoes inoculate their saliva into the skin while obtaining blood. Mosquito saliva is a pharmacological cocktail of secreted molecules, principally proteins, that can affect vascular constriction, blood coagulation, platelet aggregation, inflammation, and immunity. It clearly alters the immune response in a manner that may be advantageous to a virus. Studies have shown it can specifically modulate the immune response during early virus infection, and mosquito feeding can exacerbate WNV infection, leading to higher viremia and more severe forms of disease.

Symptoms

About 80% of those infected with West Nile virus (WNV) show no symptoms and go unreported. About 20% of infected people develop symptoms. These vary in severity, and begin 3 to 14 days after being bitten. Most people with mild symptoms of WNV recover completely, though fatigue and weakness may last for weeks or months. Symptoms may range from mild, such as fever, to severe, such as paralysis and meningitis. A severe infection can last weeks and can, rarely, cause permanent brain damage. Death may ensue if the central nervous system is affected. Medical conditions such as cancer and diabetes, and age over 60 years, increase the risk of developing severe symptoms.

Headache can be a prominent symptom of WNV fever, meningitis, encephalitis, meningoencephalitis, and it may or may not be present in poliomyelitis-like syndrome. Thus, headache is not a useful indicator of neuroinvasive disease.

- West Nile fever (WNF), which occurs in 20 percent of cases, is a febrile syndrome that causes flu-like symptoms. Most characterizations of WNF describe it as a mild, acute syndrome lasting 3 to 6 days after symptom onset. Systematic follow-up studies of patients with WNF have not been done, so this information is largely anecdotal. Possible symptoms include high fever, headache, chills, excessive sweating, weakness, fatigue, swollen lymph nodes, drowsiness, pain in the joints and flu-like symptoms. There may be gastrointestinal symptoms including nausea, vomiting, loss of appetite, and diarrhea. Fewer than one-third of patients develop a rash.
- West Nile neuroinvasive disease (WNND), which occurs in less than 1 percent of cases, is when the virus infects the central nervous system resulting in meningitis, encephalitis, meningoencephalitis or a poliomyelitis-like syndrome. Many patients with WNND have normal neuroimaging studies, although abnormalities may be present in various cerebral areas including the basal ganglia, thalamus, cerebellum, and brainstem.

- West Nile virus encephalitis (WNE) is the most common neuroinvasive manifestation of WNND. WNE presents with similar symptoms to other viral encephalitis with fever, headaches, and altered mental status. A prominent finding in WNE is muscular weakness (30 to 50 percent of patients with encephalitis), often with lower motor neuron symptoms, flaccid paralysis, and hyporeflexia with no sensory abnormalities.
- West Nile meningitis (WNM) usually involves fever, headache, stiff neck and pleocytosis, an increase of white blood cells in cerebrospinal fluid. Changes in consciousness are not usually seen and are mild when present.
- West Nile meningoencephalitis is inflammation of both the brain (encephalitis) and meninges (meningitis).
- West-Nile reversible paralysis, Like WNP, the weakness or paralysis is asymmetric Reported cases have been noted to have an initial preservation of deep tendon reflexes, which is not expected for a pure anterior horn involvement. Disconnect of upper motor neuron influences on the anterior horn cells possibly by myelitis or glutamate excitotoxicity have been suggested as mechanisms. The prognosis for recovery is excellent.
- Nonneurologic complications of WNV infection that may rarely occur include fulminant hepatitis, pancreatitis, myocarditis, rhabdomyolysis, orchitis, nephritis, optic neuritis and cardiac dysrhythmias and hemorrhagic fever with coagulopathy. Chorioretinitis may also be more common than previously thought.

- West Nile poliomyelitis (WNP), an acute flaccid paralysis syndrome associated with WNV infection, is less common than WNM or WNE. This syndrome is generally characterized by the acute onset of asymmetric limb weakness or paralysis in the absence of sensory loss. Pain sometimes precedes the paralysis. The paralysis can occur in the absence of fever, headache, or other common symptoms associated with WNV infection. Involvement of respiratory muscles, leading to acute respiratory failure, sometimes occurs.
- Skin manifestations, specifically rashes, are common; however, there are few detailed descriptions in case reports, and few images are available. Punctate erythematous, macular, and papular eruptions, most pronounced on the extremities have been observed in WNV cases and in some cases histopathologic findings have shown a sparse superficial perivascular lymphocytic infiltrate, a manifestation commonly seen in viral exanthems. A literature review provides support that this punctate rash is a common cutaneous presentation of WNV infection.

Prevention

Many of the guidelines for preventing occupational West Nile virus exposure are common to all mosquito-borne diseases. Public health measures include taking steps to reduce mosquito populations. Personal recommendations are to reduce the likelihood of being bitten. General measures to avoid bites include:

- Using insect repellent on exposed skin to repel mosquitoes. Repellents include products containing DEET and picaridin. DEET concentrations of 30% to 50% are effective for several hours. Picaridin, available at 7% and 15% concentrations, needs more frequent application. DEET formulations as high as 30% are recommended for children over two months of age. The CDC also recommends the use of: IR3535, oil of lemon eucalyptus, para-menthane-diol, or 2-undecanone. Protect infants less than two months of age by using a carrier draped with mosquito netting with an elastic edge for a tight fit.
- When using sunscreen, apply sunscreen first and then repellent. Repellent should be washed off at the end of the day before going to bed.
- Wear long-sleeve shirts, which should be tucked in, long trousers, socks, and hats to cover exposed skin (although most fabrics do not totally protect against bites). Insect repellents should be applied over top of protective clothing for greater protection. Do not apply insect repellents underneath clothing.

- Repellents containing permethrin (e.g., Permanone) or other insect repellents may be applied to clothing, shoes, tents, mosquito nets, and other gear. (Permethrin is not suitable for use directly on skin.) Most repellent is generally removed from clothing and gear by a single washing, but permethrin-treated clothing is effective for up to five washings.
- Most mosquitoes that transmit disease are most active at dawn and in the evening dusk. A notable exception is the Asian tiger mosquito, which is a daytime feeder and is more apt to be found in, or on the periphery of, shaded areas with heavy vegetation. They are now widespread in the United States, and in Florida they have been found in all 67 counties.
- In an at-risk area, staying in air-conditioned or well-screened room, or sleeping under an insecticide-treated bed net is recommended. Bed nets should be tucked under mattresses, and can be sprayed with a repellent if not already treated with an insecticide.

Treatment

There is no human vaccine. The best way to reduce the risk of infection is to avoid mosquito bites. Mosquito populations may be reduced by eliminating standing pools of water, such as in old tires, buckets, gutters, and swimming pools. When mosquitoes cannot be avoided, mosquito repellent, window screens, and mosquito nets reduce the likelihood of being bitten. There is no specific treatment for the disease; pain medications may reduce symptoms.

33 Yellow Fever

Yellow fever is a viral disease of typically short duration. In most cases, symptoms include fever, chills, loss of appetite, nausea, muscle pains particularly in the back, and headaches. Symptoms typically improve within five days. In about 15% of people, within a day of improving the fever comes back, abdominal pain occurs, and liver damage begins causing yellow skin. If this occurs, the risk of bleeding and kidney problems is increased. The disease is caused by yellow fever virus and is spread by the bite of an infected female mosquito. It infects only humans, other primates, and several types of mosquitoes. In cities, it is spread primarily by Aedes aegypti, a type of mosquito found throughout the tropics and subtropics.

The virus is an RNA virus of the genus Flavivirus. The disease may be difficult to tell apart from other illnesses, especially in the early stages. To confirm a suspected case, blood-sample testing with polymerase chain reaction is required. A safe and effective vaccine against yellow fever exists, and some countries require vaccinations for travelers. Other efforts to prevent infection include reducing the population of the transmitting mosquitoes. In areas where yellow fever is common, early diagnosis of cases and immunization of large parts of the population are important to prevent outbreaks. Once infected, management is symptomatic with no specific measures effective against the virus. Death occurs in up to half of those who get severe disease.

Sources

Yellow fever virus is mainly transmitted through the bite of the yellow fever mosquito Aedes aegypti, but other mostly Aedes mosquitoes such as the tiger mosquito (Aedes albopictus) can also serve as a vector for this virus. Like other arboviruses, which are transmitted by mosquitoes, yellow fever virus is taken up by a female mosquito when it ingests the blood of an infected human or another primate. Viruses reach the stomach of the mosquito, and if the virus concentration is high enough, the virions can infect epithelial cells and replicate there.

Symptoms

Yellow fever begins after an incubation period of three to six days. Most cases only cause a mild infection with fever, headache, chills, back pain, fatigue, loss of appetite, muscle pain, nausea, and vomiting. In these cases, the infection lasts only three to four days. In 15% of cases, though, people enter a second, toxic phase of the disease with recurring fever, this time accompanied by jaundice due to liver damage, as well as abdominal pain. Bleeding in the mouth, nose, the eyes, and the gastrointestinal tract cause vomit containing blood, hence the Spanish name for yellow fever, vómito negro ("black vomit"). There may also be kidney failure, hiccups, and delirium.

Among those who develop jaundice, the fatality rate is 20 to 50%, while the overall fatality rate is about 3 to 7.5%. Severe cases may have a mortality greater than 50%. Surviving the infection provides lifelong immunity, and normally no permanent organ damage results.

Prevention

Personal prevention of yellow fever includes vaccination and avoidance of mosquito bites in areas where yellow fever is endemic. Institutional measures for prevention of yellow fever include vaccination programmes and measures to control mosquitoes. Programmes for distribution of mosquito nets for use in homes produce reductions in cases of both malaria and yellow fever. Use of EPA-registered insect repellent is recommended when outdoors. Exposure for even a short time is enough for a potential mosquito bite. Long-sleeved clothing, long pants, and socks are useful for prevention. The application of larvicides to water-storage containers can help eliminate potential mosquito breeding sites. EPA-registered insecticide spray decreases the transmission of yellow fever.

- Use insect repellent when outdoors such as those containing DEET, picaridin, ethyl butylacetylaminopropionate (IR3535), or oil of lemon eucalyptus on exposed skin.
- Wear proper clothing to reduce mosquito bites. When weather permits, wear long sleeves, long pants, and socks when outdoors. Mosquitoes may bite through thin clothing, so spraying clothes with repellent containing permethrin or another EPA-registered repellent gives extra protection. Clothing treated with permethrin is commercially available. Mosquito repellents containing permethrin are not approved for application directly to the skin.
- The peak biting times for many mosquito species are dusk to dawn. However, A. aegypti, one of the mosquitoes that transmits yellow fever virus, feeds during the daytime. Staying in accommodations with screened or air-conditioned rooms, particularly during peak biting times, also reduces the risk of mosquito bites.

Vaccination is recommended for those traveling to affected areas, because non-native people tend to develop more severe illness when infected. Protection begins by the 10th day after vaccine administration in 95% of people, and had been reported to last for at least 10 years. The World Health Organization (WHO) now states that a single dose of vaccine is sufficient to confer lifelong immunity against yellow fever disease." The attenuated live vaccine stem 17D was developed in 1937 by Max Theiler. The WHO recommends routine vaccination for people living in affected areas between the 9th and 12th month after birth.

Up to one in four people experience fever, aches, and local soreness and redness at the site of injection. In rare cases (less than one in 200,000 to 300,000), the vaccination can cause yellow fever vaccine-associated viscerotropic disease, which is fatal in 60% of cases. It is probably due to the genetic morphology of the immune system. Another possible side effect is an infection of the nervous system, which occurs in one in 200,000 to 300,000 cases, causing yellow fever vaccine-associated neurotropic disease, which can lead to meningoencephalitis and is fatal in less than 5% of cases.

Treatment

As with other Flavivirus infections, no cure is known for yellow fever. Hospitalization is advisable and intensive care may be necessary because of rapid deterioration in some cases. Certain acute treatment methods lack efficacy: passive immunization after the emergence of symptoms is probably without effect; ribavirin and other antiviral drugs, as well as treatment with interferons, are ineffective in yellow fever patients. Symptomatic treatment includes rehydration and pain relief with drugs such as paracetamol. Acetylsalicylic acid (aspirin) should not be given because of its anticoagulant effect, which can be devastating in the case of internal bleeding that may occur with yellow fever.

Notes

Yellow fever is common in tropical and subtropical areas of South America and Africa. Worldwide, about 600 million people live in endemic areas. The WHO estimates that 200,000 cases of disease and 30,000 deaths a year occur, but the number of officially reported cases is far lower.

34 Zika Virus

ILLNESS Viral Zika Virus

Zika virus (ZIKV) is a member of the virus family Flaviviridae. It is spread by daytime-active Aedes mosquitoes, such as A. aegypti and A. albopictus. Its name comes from the Ziika Forest of Uganda, where the virus was first isolated in 1947. Zika virus is related to the dengue, yellow fever, Japanese encephalitis, and West Nile viruses. Since the 1950s, it has been known to occur within a narrow equatorial belt from Africa to Asia. From 2007 to 2016, the virus spread eastward, across the Pacific Ocean to the Americas, leading to the 2015–16 Zika virus epidemic. The infection, known as Zika fever or Zika virus disease, often causes no or only mild symptoms, similar to a very mild form of dengue fever. While there is no specific treatment, paracetamol (acetaminophen) and rest may help with the symptoms. As of 2016, the illness cannot be prevented by medications or vaccines. Zika can spread from a pregnant woman to her baby. This can result in microcephaly, severe brain malformations, and other birth defects. Zika infections in adults may result rarely in Guillain–Barré syndrome.

Sources

Zika is primarily spread by the female Aedes aegypti mosquito, which is active mostly in the daytime. The mosquitos must feed on blood to lay eggs.

Sexual
Zika can be transmitted from men and women to their sexual partners; most known cases involve transmission from symptomatic men to women. As of April 2016, sexual transmission of Zika has been documented in six countries – Argentina, Australia, France, Italy, New Zealand, and the United States – during the 2015 outbreak.

Pregnancy
Zika virus can spread by vertical (or "mother-to-child") transmission, during pregnancy or at delivery. An infection during pregnancy has been linked to changes in neuronal development of the unborn child.

Blood Transfusion
As of April 2016, two cases of Zika transmission through blood transfusions have been reported globally, both from Brazil, after which the US Food and Drug Administration (FDA) recommended screening blood donors and deferring high-risk donors for 4 weeks. A potential risk had been suspected based on a blood-donor screening study during the French Polynesian Zika outbreak, in which 2.8% (42) of donors from November 2013 and February 2014 tested positive for Zika RNA and were all asymptomatic at the time of blood donation. Eleven of the positive donors reported symptoms of Zika fever after their donation, but only three of 34 samples grew in culture.

Symptoms

Zika fever (also known as Zika virus disease) is an illness caused by Zika virus. Most cases have no symptoms, but when present they are usually mild and can resemble dengue fever. Symptoms may include fever, red eyes, joint pain, headache, and a maculopapular rash. Symptoms generally last less than seven days. It has not caused any reported deaths during the initial infection. Infection during pregnancy causes microcephaly and other brain malformations in some babies. Infection in adults has been linked to Guillain–Barré syndrome (GBS) and Zika virus has been shown to infect human Schwann cells.

Prevention

Prevention involves decreasing mosquito bites in areas where the disease occurs, and proper use of condoms. Efforts to prevent bites include the use of insect repellent, covering much of the body with clothing, mosquito nets, and getting rid of standing water where mosquitoes reproduce. There is no vaccine. Health officials recommended that women in areas affected by the 2015–2016 Zika outbreak consider putting off pregnancy and that pregnant women not travel to these areas. While no specific treatment exists, paracetamol (acetaminophen) and rest may help with the symptoms. Admission to a hospital is rarely necessary.

Treatment

While there is no specific treatment, paracetamol (acetaminophen) and rest may help with the symptoms. As of April 2019, no vaccines have been approved for clinical use, however a number of vaccines are currently in clinical trials.

35 Norovirus

Norovirus, sometimes referred to as the winter vomiting bug, is the most common cause of gastroenteritis. Infection is characterized by diarrhea, vomiting, and stomach pain. Blood is not usually present. Fever or headaches may also occur. This usually develops 12 to 48 hours after being exposed. Recovery typically occurs within 1 to 3 days. Complications may include dehydration. The virus is usually spread by the fecal–oral route. This may be by contaminated food or water or person-to-person contact. It may also spread via contaminated surfaces or through the air. Risk factors include unsanitary food preparation and sharing close quarters. Diagnosis is generally based on symptoms. Confirmatory testing may be done for public health purposes. Prevention involves proper hand washing and disinfection of contaminated surfaces. Alcohol-based hand sanitizers are less effective. A vaccine does not exist. There is no specific treatment. Efforts involve supportive care such as drinking sufficient fluids or intravenous fluids. Oral rehydration solutions are the preferred fluids to drink, although other drinks without caffeine or alcohol can help.

Sources

Infected food workers are frequently the source of the outbreaks, often by touching ready-to-eat foods, such as raw fruits and vegetables, with their bare hands before serving them. However, any food served raw or handled after being cooked can get contaminated with norovirus.

Symptoms

The symptoms of the stomach flu include nausea and vomiting, watery diarrhea, and (sometimes severe) abdominal pain, usually within 12 to 48 hours of exposure. Along with this, muscle aches, headache, and fever may be seen. Luckily, life-threatening illness is rare, with dehydration being the main danger in those infected with the virus.

Prevention

After infection, immunity to the same strain of the virus – the genotype – protects against reinfection for between 6 months to 2 years. This immunity does not fully protect against infection with the other diverse genotypes of the virus.

In Canada, norovirus is a notifiable disease. In both the US and the UK it is not notifiable.

Hand Washing and Disinfectants
Hand washing with soap and water is an effective method for reducing the transmission of norovirus pathogens. Alcohol rubs (≥62% isopropyl alcohol) may be used as an adjunct, but are less effective than hand-washing, as norovirus lacks a lipid viral envelope. Surfaces where norovirus particles may be present can be sanitised with a solution of 1.5% to 7.5% of household bleach in water, or other disinfectants effective against norovirus.

Persistence
The norovirus can survive for long periods outside a human host depending on the surface and temperature conditions: it can survive for weeks on hard and soft surfaces, and it can survive for months, maybe even years in contaminated still water. A 2006 study found the virus remained on surfaces used for food preparation seven days after contamination.

Treatment

There is no specific medicine to treat people with norovirus illness. Norovirus infection cannot be treated with antibiotics because it is not a bacterial infection. Treatments aim to avoid complications by measures such as the management of dehydration caused by fluid loss in vomiting and diarrhea, and to mitigate symptoms using antiemetics (Ondansetron (Zofran))and antidiarrheals (loperamide (Imodium)).

Notes

Norovirus is the most common cause of viral gastroenteritis in humans. It was originally called “Norwalk Virus”, after the area where it was first identified in the 1960s. Since then, it’s been blamed for 50% of all gastroenteritis in the U.S. Worldwide, there are more than 200 million cases of norovirus infection a year. It affects people of all ages, but it’s particularly dangerous in the elderly, the very young, and those with weakened immune systems. Winter is the most common time for outbreaks. Norovirus is very contagious (just 5-20 viral particles can cause illness) and is easily transmitted through contaminated food or water, close personal contact, and by air droplets from vomit, contaminated food counters, and even toilet flushes. Infection can be passed from person to person for a time even after apparent recovery. Norovirus is a hardy microbe, and is known to survive for long periods outside a human host. It can live for weeks on countertops and up to twelve days on clothes. It can survive for months in still water. Disinfectants containing chlorine, however, like bleach will quickly eliminate it, as will sufficient heat.

36 Rotavirus

Rotavirus is a genus of double-stranded RNA viruses in the family Reoviridae. Rotaviruses are the most common cause of diarrhoeal disease among infants and young children. Nearly every child in the world is infected with a rotavirus at least once by the age of five. Immunity develops with each infection, so subsequent infections are less severe; adults are rarely affected. There are nine species of the genus, referred to as A, B, C, D, E, F, G, H and I. Rotavirus A, the most common species, causes more than 90% of rotavirus infections in humans. The virus is transmitted by the faecal-oral route. It infects and damages the cells that line the small intestine and causes gastroenteritis (which is often called "stomach flu" despite having no relation to influenza). Although Rotavirus was discovered in 1973 by Ruth Bishop and her colleagues by electron micrograph images and accounts for approximately one third of hospitalisations for severe diarrhoea in infants and children, its importance has historically been underestimated within the public health community, particularly in developing countries. In addition to its impact on human health, rotavirus also infects animals, and is a pathogen of livestock.

Sources

Rotaviruses are transmitted by the fæcal-oral route, via contact with contaminated hands, surfaces and objects, and possibly by the respiratory route. Viral diarrhoea is highly contagious. The faeces of an infected person can contain more than 10 trillion infectious particles per gram; fewer than 100 of these are required to transmit infection to another person.

Rotaviruses are stable in the environment and have been found in estuary samples at levels up to 1–5 infectious particles per US gallon. The viruses survive between 9 and 19 days. Sanitary measures adequate for eliminating bacteria and parasites seem to be ineffective in control of rotavirus, as the incidence of rotavirus infection in countries with high and low health standards is similar.

Symptoms

The main symptoms are vomiting, fever and watery diarrhoea. Symptoms can be mild, but some children, especially those under 2 years, can require hospital treatment for dehydration. Onset is often sudden. The illness mainly affects infants and young children under 3 years of age. The time from contact with the virus to the development of symptoms is usually between 24 and 72 hours. The diarrhoea usually lasts from 2 to 5 days.

Prevention

Rotaviruses are highly contagious and cannot be treated with antibiotics or other drugs. Because improved sanitation does not decrease the prevalence of rotaviral disease, and the rate of hospitalisations remains high despite the use of oral rehydrating medicines, the primary public health intervention is vaccination. In 1998, a rotavirus vaccine was licensed for use in the United States. Clinical trials in the United States, Finland, and Venezuela had found it to be 80 to 100% effective at preventing severe diarrhoea caused by rotavirus A, and researchers had detected no statistically significant serious adverse effects. The manufacturer, however, withdrew it from the market in 1999, after it was discovered that the vaccine may have contributed to an increased risk for intussusception, a type of bowel obstruction, in one of every 12,000 vaccinated infants. The experience provoked intense debate about the relative risks and benefits of a rotavirus vaccine. In 2006, two new vaccines against rotavirus A infection were shown to be safe and effective in children, and in 2009, the WHO recommended that rotavirus vaccine be included in all national immunisation programmes.

Treatment

A child with vomiting and diarrhoea should be taken to the doctor who will advise if treatment is needed. Most rotavirus infections resolve without treatment. It is very important for the child to drink plenty of fluids to avoid dehydration. Rehydration with oral glucose/electrolyte solution is particularly effective. If children refuse this solution, or it is unavailable, diluted fruit juice or soft drinks may be given (1 part juice/soft drink to 3 parts water).

37 CCHF (Crimean-Congo Hemorrhagic Fever)

Crimean–Congo hemorrhagic fever (CCHF) is a viral disease. Symptoms of CCHF may include fever, muscle pains, headache, vomiting, diarrhea, and bleeding into the skin. Onset of symptoms is less than two weeks following exposure. Complications may include liver failure. In those who survive, recovery generally occurs around two weeks after onset. The CCHF virus is typically spread by tick bites or contact with livestock carrying the disease. Those affected are often farmers or work in slaughterhouses. The virus can also spread between people via body fluids. Diagnosis is by detecting antibodies, the virus's RNA, or the virus itself. It is a type of viral hemorrhagic fever. Prevention involves avoiding tick bites. A vaccine is not commercially available. Treatment is typically with supportive care. The medication ribavirin may also help. It occurs in Africa, the Balkans, the Middle East, and Asia. Often it occurs in outbreaks. In 2013 Iran, Russia, Turkey, and Uzbekistan documented more than fifty cases. The risk of death among those affected is between 10 and 40%. It was first detected in the 1940s.

Sources

The CCHF virus is typically spread by tick bites or contact with livestock carrying the disease. Groups that are at high risk of infection are farmers and those who work in slaughterhouses. The virus can also spread between people via body fluids.

Symptoms

Symptoms of CCHF may include fever, muscle pains, headache, vomiting, diarrhea, and bleeding into the skin. Onset of symptoms is less than two weeks following exposure. Complications may include liver failure. In those who survive, recovery generally occurs around two weeks after onset.

Prevention

Prevention involves avoiding tick bites. A vaccine is not commercially available.

Treatment

Treatment is typically with supportive care. The medication ribavirin may also help.

Notes

It occurs in Africa, the Balkans, the Middle East, and Asia. Often it occurs in outbreaks. In 2013 Iran, Russia, Turkey, and Uzbekistan documented more than fifty cases. The risk of death among those affected is between 10 and 40%. It was first detected in the 1940s.

4 Fungal

Fungal infections of the skin are very common and include athlete's foot, jock itch, ringworm, and yeast infections.

Subheadings

		1. Athlete's Foot	**2. Ringworm**	**3. Tinea Capitis**	**4. Onychomycosis**		
		5. Tinea Versicolor	**6. Cutaneous Candidiasis**				

1 Athlete's Foot

Athlete's foot, known medically as tinea pedis, is a common skin infection of the feet caused by fungus. Signs and symptoms often include itching, scaling, cracking and redness. In rare cases the skin may blister. Athlete's foot fungus may infect any part of the foot, but most often grows between the toes. The next most common area is the bottom of the foot. The same fungus may also affect the nails or the hands. It is a member of the group of diseases known as tinea. Athlete's foot is caused by a number of different fungi, including species of Trichophyton, Epidermophyton, and Microsporum.

Sources

The condition is typically acquired by coming into contact with infected skin, or fungus in the environment. Common places where the fungi can survive are around swimming pools and in locker rooms. They may also be spread from other animals. Usually diagnosis is made based on signs and symptoms; however, it can be confirmed either by culture or seeing hyphae using a microscope.

Symptoms

Signs and symptoms often include itching, scaling, and redness. In rare cases the skin may blister. Athlete's foot fungus may infect any part of the foot, but most often grows between the toes. The next most common area is the bottom of the foot.

Prevention

Some methods of prevention include avoiding walking barefoot in public showers, keeping the toenails short, wearing big enough shoes, and changing socks daily.

Treatment

When infected, the feet should be kept dry and clean and wearing sandals may help. Treatment can be either with antifungal medication applied to the skin such as clotrimazole or for persistent infections antifungal medication that are taken by mouth such as terbinafine. The use of the cream is typically recommended for four weeks.

2 Ringworm (Tinea Corporis)

Tinea corporis, also known as ringworm, is a superficial fungal infection (dermatophytosis) of the arms and legs, especially on glabrous skin; however, it may occur on any part of the body. It is similar to other forms of tinea.

Sources

Tinea corporis is caused by a tiny fungus known as dermatophyte. These tiny organisms normally live on the superficial skin surface, and when the opportunity is right, they can induce a rash or infection.

The disease can also be acquired by person-to-person transfer usually via direct skin contact with an infected individual. Animal-to-human transmission is also common. Ringworm commonly occurs on pets (dogs, cats) and the fungus can be acquired while petting or grooming an animal. Ringworm can also be acquired from other animals such as horses, pigs, ferrets and cows. The fungus can also be spread by touching inanimate objects like personal care products, bed linen, combs, athletic gear, or hair brushes contaminated by an affected person.

Individuals at high risk of acquiring ringworm include those who:
● Live in crowded, humid conditions.
● Sweat excessively, as sweat can produce a humid wet environment where the pathogenic fungi can thrive. This is most common in the armpits, groin creases and skin folds of the abdomen.
● Participate in close contact sports like soccer, rugby, or wrestling.
● Wear tight, constrictive clothing with poor aeration.
● Have a weakened immune system (e.g., those infected with HIV or taking immunosuppressive drugs).

Symptoms

ILLNESS Fungal Ringworm (Tinea Corporis) Symptoms

It may have a variety of appearances; most easily identifiable are the enlarging raised red rings with a central area of clearing (ringworm). The same appearances of ringworm may also occur on the scalp (tinea capitis), beard area (tinea barbae) or the groin (tinea cruris, known as jock itch or dhobi itch).

Other classic features of tinea corporis include:
- Itching occurs on infected area.
- The edge of the rash appears elevated and is scaly to touch.
- Sometimes the skin surrounding the rash may be dry and flaky.
- Almost invariably, there will be hair loss in areas of the infection.

Prevention

Because fungi prefer warm, moist environments, preventing ringworm involves keeping skin dry and avoiding contact with infectious material. Basic prevention measures include:
- Washing hands after handling animals, soil, and plants.
- Avoiding touching characteristic lesions on other people.
- Wearing loose-fitting clothing.
- Practicing good hygiene when participating in sports that involve physical contact with other people.

Treatment

Most cases are treated by application of topical antifungal creams to the skin, but in extensive or difficult to treat cases, systemic treatment with oral medication may be required. The over-the-counter options include tolnaftate, as well as ketoconazole (available as Nizoral shampoo that can be applied topically). Among the available prescription drugs, the evidence is best for terbinafine and naftifine, but other agents may also work.

Topical antifungals are applied to the lesion twice a day for at least 3 weeks. The lesion usually resolves within 2 weeks, but therapy should be continued for another week to ensure the fungus is completely eradicated. If there are several ringworm lesions, the lesions are extensive, complications such as secondary infection exist, or the patient is immunocompromised, oral antifungal medications can be used. Oral medications are taken once a day for 7 days and result in higher clinical cure rates. The antifungal medications most commonly used are itraconazole, terbinafine, and ketoconazole.

The benefits of the use of topical steroids in addition to an antifungal is unclear. There might be a greater cure rate but no guidelines currently recommend its addition. The effect of Whitfield's ointment is also unclear.

3 Tinea Capitis

Tinea capitis (also known as "herpes tonsurans", "ringworm of the hair", "ringworm of the scalp", "scalp ringworm", and "tinea tonsurans") is a cutaneous fungal infection (dermatophytosis) of the scalp. The disease is primarily caused by dermatophytes in the genera Trichophyton and Microsporum that invade the hair shaft. The clinical presentation is typically single or multiple patches of hair loss, sometimes with a 'black dot' pattern (often with broken-off hairs), that may be accompanied by inflammation, scaling, pustules, and itching. Uncommon in adults, tinea capitis is predominantly seen in pre-pubertal children, more often boys than girls. At least eight species of dermatophytes are associated with tinea capitis. Cases of Trichophyton infection predominate from Central America to the United States and in parts of Western Europe. Infections from Microsporum species are mainly in South America, Southern and Central Europe, Africa and the Middle East. The disease is infectious and can be transmitted by humans, animals, or objects that harbor the fungus. The fungus can also exist in a carrier state on the scalp, without clinical symptomatology. Treatment of tinea capitis requires an oral antifungal agent; griseofulvin is the most commonly used drug, but other newer antimycotic drugs, such as terbinafine, itraconazole, and fluconazole have started to gain acceptance.

Sources

The disease is primarily caused by dermatophytes in the genera Trichophyton and Microsporum that invade the hair shaft.

Symptoms

It may appear as thickened, scaly, and sometimes boggy swellings, or as expanding raised red rings (ringworm). Common symptoms are severe itching of the scalp, dandruff, and bald patches where the fungus has rooted itself in the skin. It often presents identically to dandruff or seborrheic dermatitis. The highest incidence in the United States of America is in American boys of school age.

There are three type of tinea capitis, microsporosis, trichophytosis, and favus; these are based on the causative microorganism, and the nature of the symptoms. In microsporosis, the lesion is a small red papule around a hair shaft that later becomes scaly; eventually the hairs break off 1–3 mm above the scalp. This disease used to be caused primarily by Microsporum audouinii, but in Europe, M. canis is more frequently the causative fungus. The source of this fungus is typically sick cats and kittens; it may be spread through person to person contact, or by sharing contaminated brushes and combs. In the United States, Trichophytosis is usually caused by Trichophyton tonsurans, while T. violaceum is more common in Eastern Europe, Africa, and India. This fungus causes dry, non-inflammatory patches that tend to be angular in shape.

When the hairs break off at the opening of the follicle, black dots remain. Favus is caused by T. schoenleinii, and is endemic in South Africa and the Middle East. It is characterized by a number of yellowish, circular, cup-shaped crusts (scutula) grouped in patches like a piece of honeycomb, each about the size of a split pea, with a hair projecting in the center. These increase in size and become crusted over, so that the characteristic lesion can only be seen around the edge of the scab.

Prevention

Tinea capitis rarely occurs in adults, so adults in the home, who do not have tinea capitis, do not need to use the shampoo. No one should share towels, combs, hairbrushes, hats or pillowcases with other family members, friends or visitors. Wash the towels in warm, soapy water after each use. Rinse and dry.

Treatment

The treatment of choice by dermatologists is a safe and inexpensive oral medication, griseofulvin, a secondary metabolite of the fungus Penicillium griseofulvin. This compound is fungistatic (inhibiting the growth or reproduction of fungi) and works by affecting the microtubular system of fungi, interfering with the mitotic spindle and cytoplasmic microtubules. The recommended pediatric dosage is 10 mg/kg/day for 6–8 weeks, although this may be increased to 20 mg/kg/d for those infected by T. tonsurans, or those who fail to respond to the initial 6 weeks of treatment. Unlike other fungal skin infections that may be treated with topical therapies like creams applied directly to the afflicted area, griseofulvin must be taken orally to be effective; this allows the drug to penetrate the hair shaft where the fungus lives.

The effective therapy rate of this treatment is generally high, in the range of 88–100%. Other oral antifungal treatments for tinea capitis also frequently reported in the literature include terbinafine, itraconazole, and fluconazole; these drugs have the advantage of shorter treatment durations than griseofulvin. On September 28, 2007, the U.S. Food and Drug Administration stated that Lamisil (Terbinafine hydrochloride, by Novartis AG) is a new treatment approved for use by children aged 4 years and older. The antifungal granules can be sprinkled on a child's food to treat the infection. Lamisil carries hepatotoxic risk, and can cause a metallic taste in the mouth.

4 Onychomycosis

Onychomycosis, also known as tinea unguium, is a fungal infection of the nail. Symptoms may include white or yellow nail discoloration, thickening of the nail, and separation of the nail from the nail bed. Toenails or fingernails may be affected, but it is more common for toenails to be affected. Complications may include cellulitis of the lower leg. A number of different types of fungus can cause onychomycosis including dermatophytes and Fusarium. Risk factors include athlete's foot, other nail diseases, exposure to someone with the condition, peripheral vascular disease, and poor immune function. The diagnosis is generally suspected based on the appearance and confirmed by laboratory testing.

Onychomycosis does not necessarily require treatment. The antifungal medication, terbinafine, taken by mouth appears to be the most effective but is associated with liver problems. Trimming the affected nails when on treatment also appears useful. There is a ciclopirox-containing nail polish, but it does not work as well. The condition returns in up to half of cases following treatment. Not using old shoes after treatment may decrease the risk of recurrence.

Sources

The causative pathogens of onychomycosis are all in the fungus kingdom and include dermatophytes, Candida (yeasts), and nondermatophytic molds. Dermatophytes are the fungi most commonly responsible for onychomycosis in the temperate western countries; while Candida and nondermatophytic molds are more frequently involved in the tropics and subtropics with a hot and humid climate.

Symptoms

The most common symptom of a fungal nail infection is the nail becoming thickened and discoloured: white, black, yellow or green. As the infection progresses the nail can become brittle, with pieces breaking off or coming away from the toe or finger completely. If left untreated, the skin underneath and around the nail can become inflamed and painful. There may also be white or yellow patches on the nailbed or scaly skin next to the nail, and a foul smell. There is usually no pain or other bodily symptoms, unless the disease is severe.

People with onychomycosis may experience significant psychosocial problems due to the appearance of the nail, particularly when fingers – which are always visible – rather than toenails are affected. Dermatophytids are fungus-free skin lesions that sometimes form as a result of a fungus infection in another part of the body. This could take the form of a rash or itch in an area of the body that is not infected with the fungus. Dermatophytids can be thought of as an allergic reaction to the fungus.

Prevention

● Keep your hands and feet clean and dry.
● Clip your fingernails and toenails short and keep them clean.
● Don't walk barefoot in areas like locker rooms or public showers.
● Don't share nail clippers with other people.
● When visiting a nail salon, choose a salon that is clean and licensed by your state's cosmetology board. Make sure the salon sterilizes its instruments (nail clippers, scissors, etc.) after each use, or, you can bring your own.

Treatment

Medications
Most treatments are with antifungal medications either topically or by mouth. Avoiding use of antifungal therapy by mouth (e.g. terbinafine) in persons without a confirmed infection is recommended because of the possible side effects of that treatment.

Topical agents include ciclopirox nail paint, amorolfine, and efinaconazole. Some topical treatments need to be applied daily for prolonged periods (at least 1 year). Topical amorolfine is applied weekly. Topical ciclopirox results in a cure in 6% to 9% of cases; amorolfine might be more effective. Ciclopirox when used with terbinafine appears to be better than either agent alone. In trials, about 17% of people were cured using efinaconazole as opposed to 4% of people using placebo. Although eficonazole, P-3051 (ciclopirox 8% hydrolacquer), and tavaborole are effective at treating fungal infection of toenails, complete cure rates are low.

Medications that may be taken by mouth include terbinafine (76% effective), itraconazole (60% effective) and fluconazole (48% effective). They share characteristics that enhance their effectiveness: prompt penetration of the nail and nail bed, and persistence in the nail for months after discontinuation of therapy. Ketoconazole by mouth is not recommended due to side effects. Oral terbinafine is better tolerated than itraconazole. For superficial white onychomycosis, systemic rather than topical antifungal therapy is advised.

5 Tinea Versicolor

Tinea versicolor is a condition characterized by a skin eruption on the trunk and proximal extremities. The majority of tinea versicolor is caused by the fungus Malassezia globosa, although Malassezia furfur is responsible for a small number of cases. These yeasts are normally found on the human skin and become troublesome only under certain circumstances, such as a warm and humid environment, although the exact conditions that cause initiation of the disease process are poorly understood. The condition pityriasis versicolor was first identified in 1846. Versicolor comes from the Latin, from versāre to turn + color. It is also commonly referred to as Peter Elam's disease in many parts of South Asia.

Sources

The fungus that causes tinea versicolor can be found on healthy skin. It only starts causing problems when the fungus overgrows. A number of factors may trigger this growth, including:
● Hot, humid weather
● Oily skin
● Hormonal changes
● Weakened immune system

Symptoms

ILLNESS Fungal Tinea Versicolor Symptoms

The symptoms of this condition include:
- Occasional fine scaling of the skin producing a very superficial ash-like scale
- Pale, dark tan, or pink in color, with a reddish undertone that can darken when the patient is overheated, such as in a hot shower or during/after exercise. Tanning typically makes the affected areas contrast more starkly with the surrounding skin.
- Sharp border

Pityriasis versicolor is more common in hot, humid climates or in those who sweat heavily, so it may recur each summer. The yeasts can often be seen under the microscope within the lesions and typically have a so-called "spaghetti and meatball appearance" as the round yeasts produce filaments. In people with dark skin tones, pigmentary changes such as hypopigmentation (loss of color) are common, while in those with lighter skin color, hyperpigmentation (increase in skin color) is more common. These discolorations have led to the term "sun fungus".

Prevention

To help prevent tinea versicolor from returning, your doctor can prescribe a skin or oral treatment that you use once or twice a month. You may need to use these just during warm and humid months. Preventive treatments include:
- Selenium sulfide (Selsun) 2.5 percent lotion or shampoo
- Ketoconazole (Ketoconazole, Nizoral, others) cream, gel or shampoo
- Itraconazole (Onmel, Sporanox) tablets, capsules or oral solution
- Fluconazole (Diflucan) tablets or oral solution

Treatment

Treatments for tinea versicolor include:
- Topical antifungal medications containing selenium sulfide are often recommended. Ketoconazole (Nizoral ointment and shampoo) is another treatment. It is normally applied to dry skin and washed off after 10 minutes, repeated daily for two weeks. Ciclopirox (Ciclopirox olamine) is an alternative treatment to ketoconazole, as it suppresses growth of the yeast Malassezia furfur. Initial results show similar efficacy to ketoconazole with a relative increase in subjective symptom relief due to its inherent anti-inflammatory properties. Other topical antifungal agents such as clotrimazole, miconazole, terbinafine, or zinc pyrithione can lessen symptoms in some patients. Additionally, hydrogen peroxide has been known to lessen symptoms and, on certain occasions, remove the problem, although permanent scarring has occurred with this treatment in some sufferers. Clotrimazole is also used combined with selenium sulfide.
- Oral antifungals including ketoconazole or fluconazole in a single dose, or ketoconazole for seven days, or itraconazole can be used. The single-dose regimens, or pulse therapy regimens, can be made more effective by having the patient exercise 1–2 hours after the dose, to induce sweating. The sweat is allowed to evaporate, and showering is delayed for a day, leaving a film of the medication on the skin.

Notes

This skin disease commonly affects adolescents and young adults, especially in warm and humid climates. The yeast is thought to feed on skin oils (lipids), as well as dead skin cells. Infections are more common in people who have seborrheic dermatitis, dandruff, and hyperhidrosis.

6 Cutaneous Candidiasis

Candidiasis is a fungal infection due to any type of Candida (a type of yeast). When it affects the mouth, it is commonly called thrush. Signs and symptoms include white patches on the tongue or other areas of the mouth and throat. Other symptoms may include soreness and problems swallowing. When it affects the vagina, it is commonly called a yeast infection. Signs and symptoms include genital itching, burning, and sometimes a white "cottage cheese-like" discharge from the vagina. Yeast infections of the penis are less common and typically present with an itchy rash. Very rarely, yeast infections may become invasive, spreading to other parts of the body. This may result in fevers along with other symptoms depending on the parts involved. More than 20 types of Candida can cause infection with Candida albicans being the most common.

Infections of the mouth are most common among children less than one month old, the elderly, and those with weak immune systems. Conditions that result in a weak immune system include HIV/AIDS, the medications used after organ transplantation, diabetes, and the use of corticosteroids. Other risks include dentures, following antibiotic therapy, and breastfeeding. Vaginal infections occur more commonly during pregnancy, in those with weak immune systems, and following antibiotic use. Individuals at risk for invasive candidiasis include low birth weight babies, people recovering from surgery, people admitted to an intensive care units, and those with an otherwise compromised immune systems.

Sources

Candida yeasts are generally present in healthy humans, frequently part of the human body's normal oral and intestinal flora, and particularly on the skin; however, their growth is normally limited by the human immune system and by competition of other microorganisms, such as bacteria occupying the same locations in the human body. Candida requires moisture for growth, notably on the skin. For example, wearing wet swimwear for long periods of time is believed to be a risk factor. Additionally, candida can also cause diaper rashes in babies. In extreme cases, superficial infections of the skin or mucous membranes may enter into the bloodstream and cause systemic Candida infections.

Factors that increase the risk of candidiasis include HIV/AIDS, mononucleosis, cancer treatments, steroids, stress, antibiotic usage, diabetes, and nutrient deficiency. Hormone replacement therapy and infertility treatments may also be predisposing factors. Use of inhaled corticosteroids increases risk of candidiasis of the mouth. Inhaled corticosteroids with other risk factors such as antibiotics, oral glucocorticoids, not rinsing mouth after use of inhaled corticosteroids or high dose of inhaled corticosteroids put people at even higher risk.

Treatment with antibiotics can lead to eliminating the yeast's natural competitors for resources in the oral and intestinal flora; thereby increasing the severity of the condition. A weakened or undeveloped immune system or metabolic illnesses are significant predisposing factors of candidiasis. Almost 15% of people with weakened immune systems develop a systemic illness caused by Candida species. Diets high in simple carbohydrates have been found to affect rates of oral candidiases.

Symptoms

Signs and symptoms of candidiasis vary depending on the area affected. Most candidal infections result in minimal complications such as redness, itching, and discomfort, though complications may be severe or even fatal if left untreated in certain populations. In healthy (immunocompetent) persons, candidiasis is usually a localized infection of the skin, fingernails or toenails (onychomycosis), or mucosal membranes, including the oral cavity and pharynx (thrush), esophagus, and the genitalia (vagina, penis, etc.); less commonly in healthy individuals, the gastrointestinal tract, urinary tract, and respiratory tract are sites of candida infection.

In immunocompromised individuals, Candida infections in the esophagus occur more frequently than in healthy individuals and have a higher potential of becoming systemic, causing a much more serious condition, a fungemia called candidemia. Symptoms of esophageal candidiasis include difficulty swallowing, painful swallowing, abdominal pain, nausea, and vomiting.

Mouth
Infection in the mouth is characterized by white discolorations in the tongue, around the mouth, and throat. Irritation may also occur, causing discomfort when swallowing. Thrush is commonly seen in infants. It is not considered abnormal in infants unless it lasts longer than a few weeks.

Genitals
Infection of the vagina or vulva may cause severe itching, burning, soreness, irritation, and a whitish or whitish-gray cottage cheese-like discharge. Symptoms of infection of the male genitalia (balanitis thrush) include red skin around the head of the penis, swelling, irritation, itchiness and soreness of the head of the penis, thick, lumpy discharge under the foreskin, unpleasant odour, difficulty retracting the foreskin (phimosis), and pain when passing urine or during sex.

Skin
Signs and symptoms of candidiasis in the skin include itching, irritation, and chafing or broken skin.

Invasive Infection
Common symptoms of gastrointestinal candidiasis in healthy individuals are anal itching, belching, bloating, indigestion, nausea, diarrhea, gas, intestinal cramps, vomiting, and gastric ulcers. Perianal candidiasis can cause anal itching; the lesion can be red, papular, or ulcerative in appearance, and it is not considered to be a sexually transmissible disease. Abnormal proliferation of the candida in the gut may lead to dysbiosis. While it is not yet clear, this alteration may be the source of symptoms generally described as the irritable bowel syndrome, and other gastrointestinal diseases.

Prevention

A diet that supports the immune system and is not high in simple carbohydrates contributes to a healthy balance of the oral and intestinal flora. While yeast infections are associated with diabetes, the level of blood sugar control may not affect the risk. Wearing cotton underwear may help to reduce the risk of developing skin and vaginal yeast infections, along with not wearing wet clothes for long periods of time. For women who experience recurrent yeast infections, there is limited evidence that oral or intravaginal probiotics help to prevent future infections. This includes either as pills or as yogurt.

Oral hygiene can help prevent oral candidiasis when people have a weakened immune system. For people undergoing cancer treatment, chlorhexidine mouthwash can prevent or reduce thrush. People who use inhaled corticosteroids can reduce the risk of developing oral candidiasis by rinsing the mouth with water or mouthwash after using the inhaler. People with dentures should also disinfect their dentures regularly to prevent oral candidiasis.

Treatment

Candidiasis is treated with antifungal medications; these include clotrimazole, nystatin, fluconazole, voriconazole, amphotericin B, and echinocandins. Intravenous fluconazole or an intravenous echinocandin such as caspofungin are commonly used to treat immunocompromised or critically ill individuals.

The 2016 revision of the clinical practice guideline for the management of candidiasis lists a large number of specific treatment regimens for Candida infections that involve different Candida species, forms of antifungal drug resistance, immune statuses, and infection localization and severity. Gastrointestinal candidiasis in immunocompetent individuals is treated with 100–200 mg fluconazole per day for 2–3 weeks.

Localized Infection
Mouth and throat candidiasis are treated with antifungal medication. Oral candidiasis usually responds to topical treatments; otherwise, systemic antifungal medication may be needed for oral infections. Candidal skin infections in the skin folds (candidal intertrigo) typically respond well to topical antifungal treatments (e.g., nystatin or miconazole). For breastfeeding mothers topical miconazole is the most effective treatment for treating candidiasis on the breasts. Gentian violet can be used for thrush in breastfeeding babies. Systemic treatment with antifungals by mouth is reserved for severe cases or if treatment with topical therapy is unsuccessful. Candida esophagitis may be treated orally or intravenously; for severe or azole-resistant esophageal candidiasis, treatment with amphotericin B may be necessary.

Vaginal yeast infections are typically treated with topical antifungal agents. A one-time dose of fluconazole by mouth is 90% effective in treating a vaginal yeast infection. For severe nonrecurring cases, several doses of fluconazole is recommended.

Local treatment may include vaginal suppositories or medicated douches. Other types of yeast infections require different dosing. C. albicans can develop resistance to fluconazole, this being more of an issue in those with HIV/AIDS who are often treated with multiple courses of fluconazole for recurrent oral infections. For vaginal yeast infection in pregnancy, topical imidazole or triazole antifungals are considered the therapy of choice owing to available safety data. Systemic absorption of these topical formulations is minimal, posing little risk of transplacental transfer. In vaginal yeast infection in pregnancy, treatment with topical azole antifungals is recommended for 7 days instead of a shorter duration.

For vaginal yeast infections, many complementary treatments are proposed, however a number have side effects. No benefit from probiotics has been found for active infections.

Blood Infection
Treatment typically consists of oral or intravenous antifungal medications. In candidal infections of the blood, intravenous fluconazole or an echinocandin such as caspofungin may be used. Amphotericin B is another option.

5 Environmental

These are any illnesses caused by environmental conditions such as altitude sickness.

Acute Radiation Syndrome

Acute radiation syndrome (ARS) is a collection of health effects of radiation that are present within 24 hours of exposure to high amounts. The ionizing radiation causes cellular degradation due to damage to DNA and other key molecular structures within the cells in various tissues. This destruction, particularly because it affects the ability of cells to divide normally, in turn causes the symptoms. The symptoms can begin within one or two hours and may last for several months. The terms refer to acute medical problems rather than ones that develop after a prolonged period. The onset and type of symptoms depends on the radiation exposure. Relatively smaller doses result in gastrointestinal effects, such as nausea and vomiting, and symptoms related to falling blood counts, and predisposition to infection and bleeding. Relatively larger doses can result in neurological effects, including but not limited to seizures, tremors, lethargy, and rapid death. Treatment of acute radiation syndrome is generally supportive with blood transfusions and antibiotics, with some more aggressive treatments, such as bone marrow transfusions, being required in extreme cases.

Symptoms
The onset and type of symptoms depends on the radiation exposure. Relatively smaller doses result in gastrointestinal effects, such as nausea and vomiting, and symptoms related to falling blood counts, and predisposition to infection and bleeding. Relatively larger doses can result in neurological effects, including but not limited to seizures, tremors, lethargy, and rapid death.

Treatment

Treatment of acute radiation syndrome is generally supportive with blood transfusions and antibiotics, with some more aggressive treatments, such as bone marrow transfusions, being required in extreme cases. Similar symptoms may appear months to years after exposure as chronic radiation syndrome when the dose rate is too low to cause the acute form. Radiation exposure can also increase the probability of developing some other diseases, mainly different types of cancers. These diseases are sometimes referred to as radiation sickness, but they are never included in the term acute radiation syndrome.

Gray

The gray (symbol: Gy) is a derived unit of ionizing radiation dose in the International System of Units (SI). It is defined as the absorption of one joule of radiation energy per kilogram of matter.

Radiation Beta Burn

Minor burn: Also known as a Beta burn (though it may be from other particles). Immerse Beta burns in cold water until the pain subsides (usually 5 minutes). If skin starts to blister, char or break; wash it with cold water to remove contaminants, then cover with a sterile compress to prevent infection. Do not break the blisters! If the skin does not blister, char or break; don't cover it, even if it covers a large portion of the body (almost like sunburn). Instead, wash the area and cover it with Vaseline or a solution of baking powder and water if available. But, moist (uncontaminated) earth will do.

Thermal Burn

Comes mostly from the high intensity blast heat, rather than ionizing particles, though it can be from the latter. This can be life threatening; everything becomes a factor: water loss, shock, lung damage, infection, etc. Follow these steps to treat a severe burn. Protect burns from further contamination. If clothing covers the burn area, gently cut and remove the cloth from the burn. DO NOT try to remove cloth which has stuck or fused onto the burn. DO NOT try to pull clothes over the burn. DO NOT put any ointment on the burn.

Or better call the Medical Therapy Unit. Gently wash the burned area with water ONLY. Do NOT apply creams or ointments. Do NOT use a normal sterile medical dressing not specifically intended for burns. As non-adhesive burn dressings (and all other medical supplies) are likely to be in short supply, an expedient alternative is to use plastic wrap (also known as saran wrap, food wrap, and cling film), which is sterile, does not stick to burns, and is readily available.

Prevent shock. Shock is the inadequate flow of blood to the vital tissues and organs. If untreated, it can be fatal. Shock results from excessive blood loss, deep burns, or reactions to the sight of a wound or blood. The signs are restlessness, thirst, pale skin and rapid heartbeat. Sweating may occur even if the skin feels cool and clammy. As it worsens, they breathe short fast gasps, with a vacant stare. To treat: maintain proper heartbeat and respiration by massaging the chest and positioning the person for adequate respiration. Loosen any constrictive clothing and reassure the person. Be firm yet gentle with self confidence.

Absorbed Dose Effect (Gray)

Phase	Symptom	1-2 Gy	2-6 Gy	6-8 Gy	8-30 Gy	>30 Gy
Immediate	Nausea and Vomiting	5–50%	50–100%	75–100%	90–100%	100%

Altitude Sickness

- **Symptoms:** Headache, vomiting, feeling tired, trouble sleeping, dizziness.
- **Complications:** High altitude pulmonary edema (HAPE), High altitude cerebral edema (HACE).
- **Usual Onset:** Within 24 hours.
- **Types:** Acute mountain sickness, high altitude pulmonary edema, high altitude cerebral edema, chronic mountain sickness.
- **Causes:** Low amounts of oxygen at high elevation.
- **Risk Factors:** Prior episode, high degree of activity, rapid increase in elevation.
- **Diagnostic Method:** Based on symptoms.
- **Differential Diagnosis:** Exhaustion, viral infection, hangover, dehydration, carbon monoxide poisoning.
- **Prevention:** Gradual ascent.
- **Treatment:** Descent to lower altitude, sufficient fluids.
- **Medication:** Ibuprofen, acetazolamide, dexamethasone, oxygen therapy.

Altitude sickness, the mildest form being acute mountain sickness (AMS), is the negative health effect of high altitude, caused by rapid exposure to low amounts of oxygen at high elevation. Symptoms may include headaches, vomiting, tiredness, trouble sleeping, and dizziness. Acute mountain sickness can progress to high altitude pulmonary edema (HAPE) with associated shortness of breath or high altitude cerebral edema (HACE) with associated confusion. Chronic mountain sickness may occur after long term exposure to high altitude. Altitude sickness typically occurs only above 2,500 metres (8,000 ft), though some are affected at lower altitudes.

Risk factors include a prior episode of altitude sickness, a high degree of activity, and a rapid increase in elevation. Diagnosis is based on symptoms and is supported in those who have more than a minor reduction in activities. It is recommended that at high-altitude any symptoms of headache, nausea, shortness of breath, or vomiting be assumed to be altitude sickness. Prevention is by gradually increasing elevation by no more than 300 metres (1,000 ft) per day. Being physically fit does not decrease the risk. Treatment is generally by descending to a lower altitude and sufficient fluids. Mild cases may be helped by ibuprofen, acetazolamide, or dexamethasone.

Severe cases may benefit from oxygen therapy and a portable hyperbaric bag may be used if descent is not possible. Treatment efforts, however, have not been well studied. AMS occurs in about 20% of people after rapidly going to 2,500 metres (8,000 ft) and 40% of people going to 3,000 metres (10,000 ft). While AMS and HACE occurs equally frequently in males and females, HAPE occurs more often in males. The earliest description of altitude sickness is attributed to a Chinese text from around 30 BCE which describes "Big Headache Mountains" possibly referring to the Karakoram Mountains around Kilik Pass.

Signs & Symptoms

People have different susceptibilities to altitude sickness; for some otherwise healthy people, acute altitude sickness can begin to appear at around 2,000 metres (6,600 ft) above sea level, such as at many mountain ski resorts, equivalent to a pressure of 80 kilopascals (0.79 atm). This is the most frequent type of altitude sickness encountered. Symptoms often manifest themselves six to ten hours after ascent and generally subside in one to two days, but they occasionally develop into the more serious conditions.

Symptoms include headache, fatigue, stomach illness, dizziness, and sleep disturbance. Exertion aggravates the symptoms. Those individuals with the lowest initial partial pressure of end-tidal pCO2 (the lowest concentration of carbon dioxide at the end of the respiratory cycle, a measure of a higher alveolar ventilation) and corresponding high oxygen saturation levels tend to have a lower incidence of acute mountain sickness than those with high end-tidal pCO2 and low oxygen saturation levels.

Primary Symptoms
Headaches are the primary symptom used to diagnose altitude sickness, although a headache is also a symptom of dehydration. A headache occurring at an altitude above 2,400 metres (7,900 ft) – a pressure of 76 kilopascals (0.75 atm) – combined with any one or more of the following symptoms, may indicate altitude sickness:

Gastrointestinal: Loss of appetite, nausea, or vomiting, excessive flatulation
Nervous: Fatigue or weakness, headache with or without dizziness or lightheadedness, insomnia, "pins and needles" sensation
Locomotory: Peripheral edema (swelling of hands, feet, and face)
Respiratory: Nose bleeding, shortness of breath upon exertion
Cardiovascular: Persistent rapid pulse
Other: General malaise

Severe Symptoms
Pulmonary edema (fluid in the lungs)
● Symptoms similar to bronchitis
● Persistent dry cough
● Fever
● Shortness of breath even when resting

Cerebral edema (swelling of the brain)
● Headache that does not respond to analgesics
● Unsteady gait
● Gradual loss of consciousness
● Increased nausea and vomiting
● Retinal hemorrhage

The most serious symptoms of altitude sickness arise from edema (fluid accumulation in the tissues of the body). At very high altitude, humans can get either high altitude pulmonary edema (HAPE), or high altitude cerebral edema (HACE). The physiological cause of altitude-induced edema is not conclusively established. It is currently believed, however, that HACE is caused by local vasodilation of cerebral blood vessels in response to hypoxia, resulting in greater blood flow and, consequently, greater capillary pressures. On the other hand, HAPE may be due to general vasoconstriction in the pulmonary circulation (normally a response to regional ventilation-perfusion mismatches) which, with constant or increased cardiac output, also leads to increases in capillary pressures.

For those suffering HACE, dexamethasone may provide temporary relief from symptoms in order to keep descending under their own power. HAPE can progress rapidly and is often fatal. Symptoms include fatigue, severe dyspnea at rest, and cough that is initially dry but may progress to produce pink, frothy sputum. Descent to lower altitudes alleviates the symptoms of HAPE. HACE is a life-threatening condition that can lead to coma or death. Symptoms include headache, fatigue, visual impairment, bladder dysfunction, bowel dysfunction, loss of coordination, paralysis on one side of the body, and confusion. Descent to lower altitudes may save those afflicted with HACE.

Cause

Altitude sickness can first occur at 1,500 metres, with the effects becoming severe at extreme altitudes (greater than 5,500 metres). Only brief trips above 6,000 metres are possible and supplemental oxygen is needed to avert sickness. As altitude increases, the available amount of oxygen to sustain mental and physical alertness decreases with the overall air pressure, though the relative percentage of oxygen in air, at about 21%, remains practically unchanged up to 21,000 metres (70,000 ft). The RMS velocities of diatomic nitrogen and oxygen are very similar and thus no change occurs in the ratio of oxygen to nitrogen until stratospheric heights. Dehydration due to the higher rate of water vapor lost from the lungs at higher altitudes may contribute to the symptoms of altitude sickness. The rate of ascent, altitude attained, amount of physical activity at high altitude, as well as individual susceptibility, are contributing factors to the onset and severity of high-altitude illness. Altitude sickness usually occurs following a rapid ascent and can usually be prevented by ascending slowly. In most of these cases, the symptoms are temporary and usually abate as altitude acclimatization occurs. However, in extreme cases, altitude sickness can be fatal.

High Altitude
At high altitude, 1,500 to 3,500 metres (4,900 to 11,500 ft), the onset of physiological effects of diminished inspiratory oxygen pressure (PiO2) includes decreased exercise performance and increased ventilation (lower arterial partial pressure of carbon dioxide: PCO2). While arterial oxygen transport may be only slightly impaired the arterial oxygen saturation (SaO2) generally stays above 90%. Altitude sickness is common between 2,400 and 4,000m because of the large number of people who ascend rapidly to these altitudes.

Very High Altitude
At very high altitude, 3,500 to 5,500 metres (11,500 to 18,000 ft), maximum SaO2 falls below 90% as the arterial PO2 falls below 60mmHg. Extreme hypoxemia may occur during exercise, during sleep, and in the presence of high altitude pulmonary edema or other acute lung conditions. Severe altitude illness occurs most commonly in this range.

Extreme Altitude
Above 5,500 metres (18,000 ft), marked hypoxemia, hypocapnia, and alkalosis are characteristic of extreme altitudes. Progressive deterioration of physiologic function eventually outstrips acclimatization. As a result, no permanent human habitation occurs above 6,000 metres (20,000 ft). A period of acclimatization is necessary when ascending to extreme altitude; abrupt ascent without supplemental oxygen for other than brief exposures invites severe altitude sickness.

Prevention

Ascending slowly is the best way to avoid altitude sickness. Avoiding strenuous activity such as skiing, hiking, etc. in the first 24 hours at high altitude reduces the symptoms of AMS. Alcohol and sleeping pills are respiratory depressants, and thus slow down the acclimatization process and should be avoided. Alcohol also tends to cause dehydration and exacerbates AMS. Thus, avoiding alcohol consumption in the first 24–48 hours at a higher altitude is optimal. Pre-acclimatization is when the body develops tolerance to low oxygen concentrations before ascending to an altitude. It significantly reduces risk because less time has to be spent at altitude to acclimatize in the traditional way. Additionally, because less time has to be spent on the mountain, less food and supplies have to be taken up. Several commercial systems exist that use altitude tents, so called because they mimic altitude by reducing the percentage of oxygen in the air while keeping air pressure constant to the surroundings.

Altitude acclimatization is the process of adjusting to decreasing oxygen levels at higher elevations, in order to avoid altitude sickness. Once above approximately 3,000 metres (10,000 ft) – a pressure of 70 kilopascals (0.69 atm) – most climbers and high-altitude trekkers take the "climb-high, sleep-low" approach. For high-altitude climbers, a typical acclimatization regimen might be to stay a few days at a base camp, climb up to a higher camp (slowly), and then return to base camp. A subsequent climb to the higher camp then includes an overnight stay. This process is then repeated a few times, each time extending the time spent at higher altitudes to let the body adjust to the oxygen level there, a process that involves the production of additional red blood cells. Once the climber has acclimatized to a given altitude, the process is repeated with camps placed at progressively higher elevations. The rule of thumb is to ascend no more than 300 m (1,000 ft) per day to sleep.

That is, one can climb from 3,000 m (9,800 ft) (70 kPa or 0.69 atm) to 4,500 m (15,000 ft) (58 kPa or 0.57 atm) in one day, but one should then descend back to 3,300 m (10,800 ft) (67.5 kPa or 0.666 atm) to sleep. This process cannot safely be rushed, and this is why climbers need to spend days (or even weeks at times) acclimatizing before attempting to climb a high peak. Simulated altitude equipment such as altitude tents provide hypoxic (reduced oxygen) air, and are designed to allow partial pre-acclimation to high altitude, reducing the total time required on the mountain itself. Altitude acclimatization is necessary for some people who move rapidly from lower altitudes to intermediate altitudes (e.g., by aircraft and ground transportation over a few hours), such as from sea level to 8,000 feet (2,400 m) as in many Colorado, USA mountain resorts. Stopping at an intermediate altitude overnight (for example, staying overnight when arriving through Denver, at 5,500 feet (1,700 m), when traveling to the aforementioned Colorado resorts) can alleviate or eliminate occurrences of AMS.

Medications

The drug acetazolamide (trade name Diamox) may help some people making a rapid ascent to sleeping altitude above 2,700 metres (9,000 ft), and it may also be effective if started early in the course of AMS. Acetazolamide can be taken before symptoms appear as a preventive measure at a dose of 125 mg twice daily. The Everest Base Camp Medical Centre cautions against its routine use as a substitute for a reasonable ascent schedule, except where rapid ascent is forced by flying into high altitude locations or due to terrain considerations. The Centre suggests a dosage of 125 mg twice daily for prophylaxis, starting from 24 hours before ascending until a few days at the highest altitude or on descending; with 250 mg twice daily recommended for treatment of AMS.

The Centers for Disease Control and Prevention (CDC) suggest the same dose for prevention of 125 mg acetazolamide every 12 hours. Acetazolamide, a mild diuretic, works by stimulating the kidneys to secrete more bicarbonate in the urine, thereby acidifying the blood. This change in pH stimulates the respiratory center to increase the depth and frequency of respiration, thus speeding the natural acclimatization process. An undesirable side-effect of acetazolamide is a reduction in aerobic endurance performance. Other minor side effects include a tingle-sensation in hands and feet.

Although a sulfonamide; acetazolamide is a non-antibiotic and has not been shown to cause life-threatening allergic cross-reactivity in those with a self-reported sulfonamide allergy. Dosage of 1000 mg/day will produce a 25% decrease in performance, on top of the reduction due to high-altitude exposure.

The CDC advises that Dexamethasone be reserved for treatment of severe AMS and HACE during descents, and notes that Nifedipine may prevent HAPE. Prior to the onset of altitude sickness, ibuprofen is a suggested non-steroidal anti-inflammatory and painkiller that can help alleviate both the headache and nausea associated with AMS. It has not been studied for the prevention of cerebral edema (swelling of the brain) associated with extreme symptoms of AMS. For centuries, indigenous peoples of the Americas such as the Aymaras of the Altiplano, have chewed coca leaves to try to alleviate the symptoms of mild altitude sickness. In Chinese and Tibetan traditional medicine, an extract of the root tissue of Radix rhodiola is often taken in order to prevent the same symptoms, though neither of these therapies has been proven effective in clinical study. Increased water intake may also help in acclimatization to replace the fluids lost through heavier breathing in the thin, dry air found at altitude, although consuming excessive quantities ("over-hydration") has no benefits and may cause dangerous hyponatremia.

In high-altitude conditions, oxygen enrichment can counteract the hypoxia related effects of altitude sickness. A small amount of supplemental oxygen reduces the equivalent altitude in climate-controlled rooms. At 3,400 metres (11,200 ft) (67 kPa or 0.66 atm), raising the oxygen concentration level by 5% via an oxygen concentrator and an existing ventilation system provides an effective altitude of 3,000 m (10,000 ft) (70 kPa or 0.69 atm), which is more tolerable for those unaccustomed to high altitudes. Oxygen from gas bottles or liquid containers can be applied directly via a nasal cannula or mask. Oxygen concentrators based upon pressure swing adsorption (PSA), VSA, or vacuum-pressure swing adsorption (VPSA) can be used to generate the oxygen if electricity is available.

Stationary oxygen concentrators typically use PSA technology, which has performance degradations at the lower barometric pressures at high altitudes. One way to compensate for the performance degradation is to utilize a concentrator with more flow capacity. There are also portable oxygen concentrators that can be used on vehicular DC power or on internal batteries, and at least one system commercially available measures and compensates for the altitude effect on its performance up to 4,000 m (13,000 ft). The application of high-purity oxygen from one of these methods increases the partial pressure of oxygen by raising the FiO2 (fraction of inspired oxygen).

Treatment

The only reliable treatment, and in many cases the only option available, is to descend. Attempts to treat or stabilize the patient in situ (at altitude) are dangerous unless highly controlled and with good medical facilities. However, the following treatments have been used when the patient's location and circumstances permit:

- Oxygen may be used for mild to moderate AMS below 3,700 metres (12,000 ft) and is commonly provided by physicians at mountain resorts. Symptoms abate in 12 to 36 hours without the need to descend.
- For more serious cases of AMS, or where rapid descent is impractical, a Gamow bag, a portable plastic hyperbaric chamber inflated with a foot pump, can be used to reduce the effective altitude by as much as 1,500 m (5,000 ft). A Gamow bag is generally used only as an aid to evacuate severe AMS patients, not to treat them at altitude.
- Acetazolamide 250 mg twice daily dosing assists in AMS treatment by quickening altitude acclimatization. A study by the Denali Medical Research Project concluded: "In established cases of acute mountain sickness, treatment with acetazolamide relieves symptoms, improves arterial oxygenation, and prevents further impairment of pulmonary gas exchange."
- The folk remedy for altitude sickness in Ecuador, Peru and Bolivia is a tea made from the coca plant. See mate de coca.
- Steroids can be used to treat the symptoms of pulmonary or cerebral edema, but do not treat the underlying AMS.

- Two studies in 2012 showed that Ibuprofen 600 milligrams three times daily was effective at decreasing the severity and incidence of AMS; it was not clear if HAPE or HACE was affected.
- Paracetamol (acetaminophen) has also shown to be as good as ibuprofen for altitude sickness when tested on climbers ascending Everest.

Other Poisonings

Shellfish Poisoning

Description	
Sources	Shellfish poisoning is caused by eating shellfish contaminated with bacteria or, more commonly, viruses. Contaminated shellfish include shrimp, crabs, clams, oysters, dried fish, and salted raw fish. Contaminated fish may have a tainted odor or taste.

ILLNESS | Environmental | Other Poisonings | Shellfish Poisoning

Symptoms	Symptoms of shellfish poisoning begin 4-48 hours after eating and include: ● Nausea ● Vomiting ● Diarrhea ● Abdominal pain ● Cramps
Prevention	Avoid eating foul tasting or foul smelling shellfish.
Treatment	Follow these steps for someone with shellfish poisoning: ● Do not induce vomiting. ● Help the person stay well-hydrated. ○ Encourage the person to drink frequent sips of clear fluids. ○ IV fluids may be necessary if nausea and vomiting cannot be controlled. There is no specific cure available for shellfish poisoning, and antibiotics do not shorten the illness. Drugs used to control diarrhea, vomiting, and stomach cramps should not be used except for bismuth (Pepto-Bismol). These drugs are referred to as antimotility drugs since they decrease stomach and intestine motion. Antimotility drugs other than bismuth preparations can worsen or lengthen the illness because the infectious agent is not expelled from the body as rapidly.

Amnesic Shellfish Poisoning (ASP)

ILLNESS | Environmental | Other Poisonings | Amnesic Shellfish Poisoning (ASP)

Description	Amnesic shellfish poisoning (ASP) is an illness caused by consumption of the marine biotoxin called domoic acid. In mammals, including humans, domoic acid acts as a neurotoxin, causing permanent short-term memory loss, brain damage, and death in severe cases. This toxin is produced naturally by marine diatoms belonging to the genus Pseudo-nitzschia and the species Nitzschia navis-varingica. When accumulated in high concentrations by shellfish during filter feeding, domoic acid can then be passed on to birds, marine mammals, and humans by consumption of the contaminated shellfish.
Sources	
Symptoms	In the brain, domoic acid especially damages the hippocampus and amygdaloid nucleus. It damages the neurons by activating AMPA and kainate receptors, causing an influx of calcium. Although calcium flowing into cells is a normal event, the uncontrolled increase of calcium causes the cell to degenerate. Gastrointestinal symptoms can appear 24 hours after ingestion of affected molluscs. They may include vomiting, nausea, diarrhea, abdominal cramps, and haemorrhagic gastritis. In more severe cases, neurological symptoms can take several hours or up to 3 days to develop. These include headache, dizziness, disorientation, vision disturbances, loss of short-term memory, motor weakness, seizures, profuse respiratory secretions, hiccups, unstable blood pressure, abnormal heart rhythms, and coma. People poisoned with very high doses of the toxin or displaying risk factors such as old age and kidney failure can die. Death has occurred in four of 107 confirmed cases. In a few cases, permanent sequelae included short-term memory loss and peripheral polyneuropathy.
Prevention	
Treatment	No antidote for domoic acid is known, so if symptoms fit the description, immediate medical attention is advised. Cooking or freezing affected fish or shellfish tissue does not lessen the toxicity. Domoic acid is a heat-resistant and very stable toxin which can damage kidneys at concentrations that are 1/100th of those that cause neurological effects.

Diarrheal Shellfish Poisoning (DSP)

ILLNESS | Environmental | Other Poisonings | Diarrheal Shellfish Poisoning

Description	Diarrhetic shellfish poisoning (DSP) is one of the four recognized symptom types of shellfish poisoning, the others being paralytic shellfish poisoning, neurotoxic shellfish poisoning and amnesic shellfish poisoning. As the name suggests, this syndrome manifests itself as intense diarrhea and severe abdominal pains. Nausea and vomiting may sometimes occur too.
Sources	
Symptoms	DSP and its symptoms usually set in within about half an hour of ingesting infected shellfish, and last for about one day. A recent case in France, though, with 20 people consuming oysters manifested itself after 36 hours. The causative poison is okadaic acid, which inhibits intestinal cellular de-phosphorylation. This causes the cells to become very permeable to water and causes profuse, intense diarrhea with a high risk of dehydration. As no life-threatening symptoms generally emerge from this, no fatalities from DSP have ever been recorded.
Prevention	
Treatment	

Neurotoxic Shellfish Poisoning (NSP)

ILLNESS | Environmental | Other Poisonings | ... poisoning (NSP)

Description	Neurotoxic shellfish poisoning (NSP) is a term used to describe the disease caused by consumption of brevetoxins, which are marine toxins produced by the dinoflagellate Karenia brevis (among several others). These toxins can produce a series of gastrointestinal and neurological effects. Outbreaks of NSP commonly take place following harmful algal bloom (HAB) events, commonly referred to as "Florida red tide" (given that blooms are more commonplace along the coasts of Florida and Texas, especially during late summer and early fall).
Sources	Humans are typically exposed to these potent natural toxins via filter-feeding mollusks (i.e., shellfish), because shellfish accumulate biotoxins in their flesh due to the way that they feed. Human exposure seems to be most common via consumption of commonly harvested shellfish such as clams, oysters, and mussels, although it has been proposed that exposure to lower levels of brevetoxins can take place following the consumption of certain planktivorous fish. Toxins will typically be found in the flesh of shellfish for up to 2–8 weeks following a HAB event, however there have been reports of toxin retention for nearly one year post-bloom. Notably, brevetoxins are tasteless and odorless and cannot be eradicated by rinsing, cleaning, cooking, freezing, or application of acid. To date, there is no reasonable means of preventing the uptake of toxins by shellfish, nor of removing the toxins from shellfish after harvest.

Symptoms	Diagnosis of NSP is made based on clinical presentation as well as history findings including recent consumption of shellfish. On average, symptoms begin 3-4 hours after consumption, but can begin anywhere from several minutes to 18 hours afterward. Symptoms typically include neurologic and gastrointestinal issues including: ● Nausea ● Vomiting ● Diarrhea ● Numbness and tingling in the lips, mouth, face, and extremities The latter has been described as “nerves being on fire” or “ants crawling and biting all over”.

Other less common symptoms can include:
● Ataxia
● Loss of coordination
● Limb paralysis
● Reversal of hot and cold sensations
● Slurred speech
● Headache
● Pupil dilation
● Generalized fatigue

Patients may be thought to be disoriented or intoxicated. Rarely, patients may experience respiratory distress requiring ventilatory support. Despite this seemingly severe constellation of symptoms, there have been no documented deaths due to NSP. NSP can present similar to other disorders such as:
● Common food poisoning
● Seafood allergy
● Paralytic shellfish poisoning
● Ciguatera fish poisoning
● Pesticide poisoning
● Alcohol intoxication
● Certain psychiatric disorders.
Due to the extensive list of disorders with similar symptoms, a detailed food history is necessary to make the diagnosis.

Prevention	
Treatment	Treatment for NSP is mostly supportive with monitoring and symptom management. Intravenous fluids and observation of respiratory function are the mainstay of treatment along with pain control. Activated charcoal can be given if the patient presents within four hours of consumption to decontaminate the gastrointestinal tract. Currently, there is no specific antidote for brevetoxins, however there may be a role for mannitol (the primary treatment for ciguatoxin, a dinoflagellate-produced toxin found in some species of fish) or brevatal, a natural antagonist of brevetoxin produced by K. brevis.

Paralytic Shellfish Poisoning (PSP)

Description	Paralytic shellfish poisoning (PSP) is one of the four recognized syndromes of shellfish poisoning, which share some common features and are primarily associated with bivalve mollusks (such as mussels, clams, oysters and scallops). These shellfish are filter feeders and accumulate neurotoxins, chiefly saxitoxin, produced by microscopic algae, such as dinoflagellates, diatoms, and cyanobacteria. Some pufferfish, including the chamaeleon puffer, contain saxitoxin, making their consumption hazardous.
Sources	
Symptoms	
Prevention	
Treatment	
Notes	The toxins responsible for most shellfish poisonings are water insoluble, heat and acid-stable, and ordinary cooking methods do not eliminate the toxins. The principal toxin responsible for PSP is saxitoxin. Some shellfish can store this toxin for several weeks after a harmful algal bloom passes, but others, such as butter clams, are known to store the toxin for up to two years. Additional toxins are found, such as neosaxitoxin and gonyautoxins I to IV. All of them act primarily on the nervous system. PSP can be fatal in extreme cases, particularly in immunocompromised individuals. Children are more susceptible. PSP affects those who come into contact with the affected shellfish by ingestion. Symptoms can appear ten to 30 minutes after ingestion, and include nausea, vomiting, diarrhea, abdominal pain, tingling or burning lips, gums, tongue, face, neck, arms, legs, and toes. Shortness of breath, dry mouth, a choking feeling, confused or slurred speech, and loss of coordination are also possible.

Scombroid Poisoning

Description	Scombroid food poisoning, also known as simple scombroid, is a foodborne illness that typically results from eating spoiled fish. Symptoms may include flushed skin, headache, itchiness, blurred vision, abdominal cramps, and diarrhea. Onset of symptoms is typically 10 to 60 minutes after eating and can last for up to two days. Rarely, breathing problems or an irregular heartbeat may occur.
Sources	Scombroid occurs from eating fish high in histamine due to inappropriate storage or processing. Fish commonly implicated include tuna, mackerel, mahi mahi, sardine, anchovy, herring, bluefish, amberjack, and marlin. These fish naturally have high levels of histidine, which is converted to histamine when bacterial growth occurs during improper storage. Subsequent cooking, smoking, or freezing does not eliminate the histamine. Diagnosis is typically based on the symptoms and may be supported by a normal blood tryptase. If a number of people who eat the same fish develop symptoms, the diagnosis is more likely. Unlike many types of food poisoning, scombroid form is not brought about by ingestion of a pathogen. Histidine is an amino acid that exists naturally in many types of food, including fish. At temperatures above 16 °C (60 °F), histidine is converted to the biogenic amine histamine via the enzyme histidine decarboxylase produced by symbiotic bacteria such as Morganella morganii (this is one reason why fish should be stored in the freezer).

Histamine is not destroyed by normal cooking temperatures, so even properly cooked fish can still result in poisoning. Histamine is the main natural chemical responsible for true allergic reactions, so the symptoms produced are almost identical to a food allergy. Rarely cheese may be involved.

ILLNESS | Environmental | Other Poisonings | Scombroid Poisoning

Symptoms	Symptoms typically occur within 10–30 minutes of ingesting the fish and generally are self-limited. People with asthma are more vulnerable to respiratory problems such as wheezing or bronchospasms. However, symptoms may show over two hours after eating a spoiled dish. They usually last for about 10 to 14 hours, and rarely exceed one to two days.

Initial The first signs of poisoning suggest an allergic reaction with these symptoms: ● Facial flushing/sweating ● Burning-peppery taste sensations in the mouth and throat ● Dizziness ● Nausea ● Headache ● Tachycardia ● Cold-like symptoms	**Additional Symptoms** The above symptoms can advance to: ● Facial rash (intense itching may accompany the rash) ● Torso or body rash: The rash associated with scombroid poisoning is a form of urticaria, but most commonly does not include wheals (patchy areas of skin-swelling also known as hives) that may be seen in true allergies. ● Edema (generalized if it occurs at all) ● Short-term diarrhea ● Abdominal cramps	**Severe** In the worst cases, the poisoning may cause: ● Blurred vision ● Respiratory distress ● Swelling of the tongue In rare cases, the poisoning may result in death.

Prevention	Prevention is by refrigerating or freezing fish right after it is caught. Treatment is generally with antihistamines such as diphenhydramine and ranitidine. Epinephrine may be used for severe symptoms. Along with ciguatera fish poisoning, it is one of the most common type of seafood poisoning. It occurs globally in both temperate and tropical waters. Only one death has been reported. The condition was first described in 1799.
Treatment	Treatment is in the form of supportive care. If light-headedness occurs, a person should lie with feet partly elevated. Antihistamines such as diphenhydramine (H1 blockade) and ranitidine (H2 blockade) together with intravenous fluids may help with mild to moderate symptoms. Epinephrine combined with a steroid may be used for severe symptoms.

Shellfish Toxin (Ciguatera)

Description	Ciguatera fish poisoning (CFP), also known simply as ciguatera, is a foodborne illness caused by eating reef fish whose flesh is contaminated with certain toxins. Such individual fish are said to be ciguatoxic. Symptoms may include diarrhea, vomiting, numbness, itchiness, sensitivity to hot and cold, dizziness, and weakness. The onset of symptoms varies with the amount of toxin eaten from half an hour to up to two days. The diarrhea may last for up to four days. Some symptoms typically remain for a few weeks to months. Heart difficulties such as slow heart rate and low blood pressure may also occur.
Sources	The specific toxins involved are ciguatoxin and maitotoxin. They are originally made by a small marine organism, Gambierdiscus toxicus, that grows on and around coral reefs in tropical and subtropical waters. These are eaten by herbivorous fish which in turn are eaten by larger carnivorous fish. The toxins become more concentrated as they move up the food chain. The fish most often implicated include barracuda, grouper, moray eel, amberjack, sea bass, and sturgeon.
Symptoms	Hallmark symptoms of ciguatera in humans include gastrointestinal, cardiovascular, and neurological effects. Gastrointestinal symptoms include nausea, vomiting, and diarrhea, usually followed by neurological symptoms such as headaches, muscle aches, paresthesia, numbness of extremities, mouth and lips, reversal of hot and cold sensation, ataxia, vertigo, and hallucinations. Severe cases of ciguatera can also result in cold allodynia, which is a burning sensation on contact with cold. Neurological symptoms can persist and ciguatera poisoning is occasionally misdiagnosed as multiple sclerosis. Cardiovascular symptoms include bradycardia, tachycardia, hypotension, hypertension, orthostatic tachycardia, exercise intolerance, and rhythm disorders. Death from the condition can occur, but is very rare. Dyspareunia and other ciguatera symptoms have developed in otherwise healthy males and females following sexual intercourse with partners suffering ciguatera poisoning, signifying that the toxin may be sexually transmitted. Diarrhea and facial rashes have been reported in breastfed infants of poisoned mothers, suggesting that ciguatera toxins migrate into breast milk. The symptoms can last from weeks to years, and in extreme cases as long as 20 years, often leading to long-term disability. Most people do recover slowly over time.
Prevention	Preventive efforts include not eating reef fish, not eating high-risk fish such as barracuda, and not eating fish liver, roe, or fish heads. Ciguatoxin has no taste or smell, and cannot be destroyed by conventional cooking. There is no specific treatment for ciguatera fish poisoning once it occurs. Mannitol may be considered, but the evidence supporting its use is not very strong. Gabapentin or amitriptyline may be used to treat some of the symptoms.
Treatment	There is no effective treatment or antidote for ciguatera poisoning. The mainstay of treatment is supportive care. There is some evidence that calcium channel blockers like nifedipine and verapamil are effective in treating some of the symptoms that remain after the initial sickness passes, such as poor circulation and shooting pains through the chest. These symptoms are due to vasoconstriction caused by maitotoxin. Ciguatoxin lowers the threshold for opening voltage-gated sodium channels in synapses of the nervous system. Opening a sodium channel causes depolarization, which could sequentially cause paralysis, heart contraction, and changing the senses of hot and cold. Some medications such as amitriptyline may reduce some symptoms, such as fatigue and paresthesia, although benefit does not occur in every case.

Hemlock Poisoning (Conium Maculatum)

Description	Conium maculatum, the hemlock or poison hemlock, is a highly poisonous biennial herbaceous flowering plant in the carrot family Apiaceae, native to Europe and North Africa. A hardy plant capable of living in a variety of environments, hemlock is widely naturalized in locations outside its native range, such as parts of North and South America, Australia and West Asia, to which it has been introduced.

Conium maculatum is a herbaceous biennial flowering plant that grows to 1.5–2.5 m (5–8 ft) tall, with a smooth, green, hollow stem, usually spotted or streaked with red or purple on the lower half of the stem. All parts of the plant are hairless (glabrous); the leaves are two- to four-pinnate, finely divided and lacy, overall triangular in shape, up to 50 cm (20 in) long and 40 cm (16 in) broad. Hemlock's flower is small and white; they are loosely clustered and each flower has five petals. The plant looks like the wild carrot plant (Daucus carota). One can distinguish the two from each other by hemlock's smooth texture, mid-green, quite vivid, color and typical height of large clumps being least 1.5 metres, twice the maximum of wild carrot. Carrots have hairy stems that lack the purple blotches. It can be confused with harmless cow parsley (Anthriscus sylvestris).

The hemlock plant is native to Europe and the Mediterranean region. It exists in some woodland (and elsewhere) in most British Isles counties; in Ulster these are particularly Down, Antrim and Londonderry. It has become naturalised in Asia, North America, Australia and New Zealand. It is introduced in 12 U.S. states. It is sometimes encountered around rivers in southeast Australia and Tasmania.

Sources	

Symptoms	A short time after ingestion, the alkaloids produce potentially fatal neuromuscular dysfunction due to failure of the respiratory muscles. Acute toxicity, if not lethal, may resolve in spontaneous recovery, provided further exposure is avoided. Since no specific antidote is available, prevention is the only way to deal with the production losses caused by the plant. It is a common myth that C. maculatum alkaloids can enter the human food chain via milk and fowl, but scientific studies have disproven these claims.
Prevention	Control with herbicides and grazing with less-susceptible animals (such as sheep) have been suggested.
Treatment	No antidote is available.
Notes	The plant is often found in poorly drained soil, particularly near streams, ditches and other watery surfaces. It also appears on roadsides, edges of cultivated fields and waste areas Conium maculatum grows in quite damp soil, but also on drier rough grassland, roadsides and disturbed ground. It is used as a food plant by the larvae of some lepidoptera, including silver-ground carpet moths and particularly the poison hemlock moth (Agonopterix alstroemeriana). The latter has been widely used as a biological control agent for the plant. Poison hemlock grows in the spring, when much undergrowth is not in flower and may not be in leaf. All plant parts are poisonous.

Ingesting less than a tenth of a gram of coniine, approximately equivalent to six to eight hemlock leaves, can be fatal for adult humans. The seeds and roots are also toxic, more so than the leaves. While hemlock toxicity primarily results from consumption, poisoning can also result from inhalation, and from skin contact. Farmers also need to be careful that the hay fed to animals does not contain hemlock. Poison hemlock is most poisonous in the spring when the concentration of γ-coniceine (the precursor to other toxins) is at its peak.

Poison hemlock grows quite tall, reaching heights of up to twelve feet (3.6 meters). The stalk of hemlock is green with purple spots and completely lacks hair. A biennial plant, hemlock produces leaves at its base the first year but no flowers. In its second year it produces white flowers in umbrella shaped clusters. Hemlock can be confused with the wild carrot plant; however, this plant has a hairy stem without purple markings, grows less than three feet tall, and does not have clustered flowers.

Mushroom Poisoning

Description	Mushroom poisoning refers to harmful effects from ingestion of toxic substances present in a mushroom. These symptoms can vary from slight gastrointestinal discomfort to death in about 10 days. The toxins present are secondary metabolites produced by the fungus. Mushroom poisoning is usually the result of ingestion of wild mushrooms after misidentification of a toxic mushroom as an edible species. The most common reason for this misidentification is close resemblance in terms of colour and general morphology of the toxic mushrooms species with edible species. To prevent mushroom poisoning, mushroom gatherers familiarize themselves with the mushrooms they intend to collect, as well as with any similar-looking toxic species. The safety of eating wild mushrooms may depend on methods of preparation for cooking.
Sources	Mushrooms.
Symptoms	Poisonous mushrooms contain a variety of different toxins that can differ markedly in toxicity. Symptoms of mushroom poisoning may vary from gastric upset to organ failure resulting in death. Serious symptoms do not always occur immediately after eating, often not until the toxin attacks the kidney or liver, sometimes days or weeks later. The most common consequence of mushroom poisoning is simply gastrointestinal upset. Most "poisonous" mushrooms contain gastrointestinal irritants that cause vomiting and diarrhea (sometimes requiring hospitalization), but usually no long-term damage. However, there are a number of recognized mushroom toxins with specific, and sometimes deadly, effects:

Toxin	Toxicity	Effects
Alpha-amanitin	Deadly	Causes often fatal liver damage 1–3 days after ingestion. Principal toxin in the death cap.
Phallotoxin	Non-lethal	Causes extreme gastrointestinal upset. Found in various mushrooms.
Orellanine	Deadly	Redox cycler similar to paraquat. Causes kidney failure within three weeks after ingestion. Principal toxin in genus Cortinarius.
Muscarine	Potentially deadly	Causes SLUDGE syndrome. Found in various mushrooms. Antidote is atropine.
Monomethylhydrazine (MMH)	Deadly	Causes brain damage, seizures, gastrointestinal upset, and hemolysis. Metabolic poison. Principal toxin in genus Gyromitra. Antidote is large doses of intravenous pyridoxine hydrochloride
Coprine	Non-lethal	Causes illness when consumed with alcohol. Principal toxin in genus Coprinus.
Ibotenic acid	Potentially deadly	Excitotoxin. Principal toxin in Amanita muscaria, A. pantherina, and A. gemmata.
Muscimol	Potentially deadly	Causes CNS depression and hallucinations. Principal toxin in Amanita muscaria, A. pantherina, and A. gemmata.
Arabitol	Non-lethal	Causes diarrhea in some people.
Bolesatine	Non-lethal	Causes gastrointestinal irritation, vomiting, nausea.
Ergotamine	Deadly	Affects the vascular system and can lead to loss of limbs and/or cardiac arrest. Found in genus Claviceps.

Prevention	Avoid eating mushrooms.
Treatment	Some mushrooms contain less toxic compounds and, therefore, are not severely poisonous. Poisonings by these mushrooms may respond well to treatment. However, certain types of mushrooms contain very potent toxins and are very poisonous; so even if symptoms are treated promptly, mortality is high. With some toxins, death can occur in a week or a few days. Although a liver or kidney transplant may save some patients with complete organ failure, in many cases there are no organs available. Patients hospitalized and given aggressive support therapy almost immediately after ingestion of amanitin-containing mushrooms have a mortality rate of only 10%, whereas those admitted 60 or more hours after ingestion have a 50–90% mortality rate.
Notes	New species of fungi are continuing to be discovered, with an estimated number of 800 new species registered annually. This, added to the fact that many investigations have recently reclassified some species of mushrooms from edible to poisonous has made older classifications insufficient at describing what now is known about the different species of fungi that are harmful to humans. Thus, contrary to what older registers state, it is now thought that of the approximately 100,000 known fungi species found worldwide, about 100 of them are poisonous to humans. However, by far the majority of mushroom poisonings are not fatal, and the majority of fatal poisonings are attributable to the Amanita phalloides mushroom.

A majority of these cases are due to mistaken identity. This is a common occurrence with A. phalloides in particular, due to its resemblance to the Asian paddy-straw mushroom, Volvariella volvacea. Both are light-colored and covered with a universal veil when young. Amanitas can be mistaken for other species, as well, in particular when immature. On at least one occasion they have been mistaken for Coprinus comatus. In this case, the victim had some limited experience in identifying mushrooms, but did not take the time to correctly identify these particular mushrooms until after he began to experience symptoms of mushroom poisoning.

The author of Mushrooms Demystified, David Arora cautions puffball-hunters to beware of Amanita "eggs", which are Amanitas still entirely encased in their universal veil. Amanitas at this stage are difficult to distinguish from puffballs. Foragers are encouraged to always cut the fruiting bodies of suspected puffballs in half, as this will reveal the outline of a developing Amanita should it be present within the structure. A majority of mushroom poisonings in general are the result of small children, especially toddlers in the "grazing" stage, ingesting mushrooms found in the lawn. While this can happen with any mushroom, Chlorophyllum molybdites is often implicated due to its preference for growing in lawns. C. molybdites causes severe gastrointestinal upset but is not considered deadly poisonous.

A few poisonings are the result of misidentification while attempting to collect hallucinogenic mushrooms for recreational use. In 1981, one fatality and two hospitalizations occurred following consumption of Galerina marginata, mistaken for a Psilocybe species. Galerina and Psilocybe species are both small, brown, and sticky, and can be found growing together. However, Galerina contains amatoxins, the same poison found in the deadly Amanita species. Another case reports kidney failure following ingestion of Cortinarius orellanus, a mushroom containing orellanine.

It is natural that accidental ingestion of hallucinogenic species also occurs, but is rarely harmful when ingested in small quantities. Cases of serious toxicity have been reported in small children. Amanita pantherina, while containing the same hallucinogens as Amanita muscaria (e.g., ibotenic acid and muscimol), has been more commonly associated with severe gastrointestinal upset than its better-known counterpart.

6 Chemical

A chemical weapon (CW) is a specialized munition that uses chemicals formulated to inflict death or harm on humans. The term chemical weapon may also be applied to any toxic chemical or its precursor that can cause death, injury, temporary incapacitation or sensory irritation through its chemical action. Chemical weapons are classified as weapons of mass destruction (WMDs), though they are distinct from nuclear weapons, biological weapons, and radiological weapons.

All may be used in warfare and are known by the military acronym NBC (for nuclear, biological, and chemical warfare). Weapons of mass destruction are distinct from conventional weapons, which are primarily effective due to their explosive, kinetic, or incendiary potential. Chemical weapons can be widely dispersed in gas, liquid and solid forms, and may easily afflict others than the intended targets. Nerve gas, tear gas and pepper spray are three modern examples of chemical weapons.

Subheadings

1. Blood Agent	2. Blister Agent	3. Nerve Agent	4. Nettle Agent
5. Choking Agent	6. Vomiting Agent	7. Incapacitating Agent	8. Riot Control Agent

1 Blood Agent

A blood agent is a toxic chemical agent that affects the body by being absorbed into the blood. Blood agents are fast-acting, potentially lethal poisons that typically manifest at room temperature as volatile colorless gases with a faint odor. They are either cyanide- or arsenic-based.

Sources	Blood agents work through inhalation or ingestion. As chemical weapons, blood agents are typically disseminated as aerosols and take effect through inhalation. Due to their volatility, they are more toxic in confined areas than in open areas.
Symptoms	Cyanide-based blood agents irritate the eyes and the respiratory tract, while arsine is nonirritating. Exposure to small amounts of cyanide has no effect. Higher concentrations cause dizziness, weakness and nausea, which cease with the exposure, but long-time exposure can cause mild symptoms followed by permanent brain damage and muscle paralysis. Moderate exposure causes stronger and longer-lasting symptoms, including headache, that can be followed by convulsions and coma. Stronger or longer exposure will also lead to convulsions and coma. Very strong exposure causes severe toxic effects within seconds, and rapid death. The blood of people killed by blood agents is bright red, because the agents inhibit the use of the oxygen in it by the body's cells. Cyanide poisoning can be detected by the presence of thiocyanate or cyanide in the blood, a smell of bitter almonds, or respiratory tract inflammations and congestions in the case of cyanogen chloride poisoning. There is no specific test for arsine poisoning, but it may leave a garlic smell on the victim's breath.
Effects	At sufficient concentrations, blood agents can quickly saturate the blood and cause death in a matter of minutes or seconds. They cause powerful gasping for breath, violent convulsions and a painful death that can take several minutes. The immediate cause of death is usually respiratory failure. Blood agents work at the cellular level by preventing the exchange of oxygen and carbon dioxide between the blood and the body's cells. This causes the cells to suffocate from lack of oxygen. Cyanide-based agents do so by interrupting the electron transport chain in the inner membranes of mitochondria. Arsine damages the red blood cells which deliver oxygen throughout the body.
Detection	Chemical detection methods, in the form of kits or testing strips, exist for hydrogen cyanide.
Prevention	Ordinary clothing provides some protection, but proper protective clothing and masks are recommended. Mask filters containing only charcoal are ineffective, and effective filters are quickly saturated.
Treatment	Due to their high volatility, cyanide agents generally need no decontamination. In enclosed areas, fire extinguishers spraying sodium carbonate can decontaminate hydrogen cyanide, but the resulting metal salts remain poisonous on contact. Liquid hydrogen cyanide can be flushed with water. Cyanide poisoning can be treated with antidotes; see the corresponding article.

Blood Agents

Hydrogen Cyanide	• Effectiveness - 10 • Persistence Open - 2 • Persistance Enclosed - 9 • Field Stability - 10 • Storage Stability - 8 • Toxicity - 10	Colorless gas or liquid, faint almond odor, burns with a bluish flame.

ILLNESS | Chemical | Blood Agent | Blood Agents

Cyanogen	• Effectiveness - 9 • Persistence Open - 2 • Persistance Enclosed - 9 • Field Stability - 8 • Storage Stability - 7 • Toxicity - 9	Colorless gas, almond odor, burns with a pinkish flame having a blue border.
Cyanogen Chloride	• Effectiveness - 8 • Persistence Open - 3 • Persistance Enclosed - 9 • Field Stability - 9 • Storage Stability - 9 • Toxicity - 8	Colorless gas or liquid, pungent and biting odor, soluble in water and alcohol.
Cyanogen Bromide	• Effectiveness - 9 • Persistence Open - 5 • Persistance Enclosed - 8 • Field Stability - 5 • Storage Stability - 6 • Toxicity - 8	Colorless needle-shaped or cubic crystals, tending to volatize on standing, hence of limited usefulness as a weapon.
Arsine	• Effectiveness - 9 • Persistence Open - 3 • Persistance Enclosed - 8 • Field Stability - 5 • Storage Stability - 9 • Toxicity - 9	Colorless gas, garlic-like odor, slightly soluble in water.
Vinyl Arsine	• Effectiveness - 7 • Persistence Open - 7 • Persistance Enclosed - 9 • Field Stability - 8 • Storage Stability - 9 • Toxicity - 6	Colorless liquid, irritating and bitter odor, slightly soluble in water, also acts as a blister agent.
Phosgene	• Effectiveness - 10 • Persistence Open - 6 • Persistance Enclosed - 9 • Field Stability - 5 • Storage Stability - 8 • Toxicity - 6	Colorless gas and slightly yellow liquid, moldy hay odor, slightly soluble in water and soluble in most solvents, also acts as a choking agent.

2 Blister Agent

ILLNESS | Chemical | Blister Agent

A blister agent, or vesicant, is a chemical compound that causes severe skin, eye and mucosal pain and irritation. They are named for their ability to cause severe chemical burns, resulting in painful water blisters on the bodies of those affected.

Types
- Sulfur mustards – A family of sulfur-based agents, including mustard gas.
- Nitrogen mustards – A family of agents similar to the sulfur mustards, but based on nitrogen instead of sulfur.
- Lewisite – An early blister agent that was developed, but not used, during World War I. It was effectively rendered obsolete with the development of British anti-Lewisite in the 1940s.

Sources	
Symptoms	• Severe skin, eye and mucosal pain and irritation • Skin erythema with large fluid blisters that heal slowly and may become infected • Tearing, conjunctivitis, corneal damage • Mild respiratory distress to marked airway damage
Prevention	Avoid exposure to blister agents.
Treatment	
Natural Remedy	

ILLNESS | Chemical | Blister Agent | Blister

Blister Agents

Sulfur Mustards	A family of sulfur-based agents, including mustard gas.
Nitrogen Mustards	A family of agents similar to the sulfur mustards, but based on nitrogen instead of sulfur.
Lewisite	An early blister agent that was developed, but not used, during World War I. It was effectively rendered obsolete with the development of British anti-Lewisite in the 1940s.

3 Nerve Agent

ILLNESS | Chemical | Nerve Agent

Nerve agents are a class of organic chemicals that disrupt the mechanisms by which nerves transfer messages to organs. The disruption is caused by the blocking of acetylcholinesterase, an enzyme that catalyzes the breakdown of acetylcholine, a neurotransmitter.

Sources	Chemical compound created for military use. Nerve Agents can be aerosolised, liquified or grains/powder. Some countries known to possess VX are the United States, the United Kingdom, Russia, North Korea, Israel, and Syria.
Symptoms	Poisoning by a nerve agent leads to contraction of pupils, profuse salivation, convulsions, and involuntary urination and defecation, with the first symptoms appearing in seconds after exposure. Death by asphyxiation or cardiac arrest may follow in minutes due to the loss of the body's control over respiratory and other muscles.

ILLNESS Chemical Nerve Agent

Symptoms of Exposure	Early symptoms of percutaneous exposure (skin contact) include local sweating and muscular twitching at the area of exposure, followed by nausea or vomiting. Early symptoms of exposure to VX vapor include rhinorrhea (runny nose) and/or tightness in the chest with shortness of breath (bronchial constriction). Miosis (pinpointing of the pupils) may be an early sign of agent exposure, but is not usually used as the only indicator of exposure.
Prevention	Nerve agents can also be absorbed through the skin, requiring that those likely to be subjected to such agents wear a full body suit in addition to a respirator. Butyrylcholinesterase is a prophylactic countermeasure against organophosphate nerve agents. It binds nerve agent in the bloodstream before it can exert effects in the nervous system. Because it is a biological scavenger (and universal target), it is currently the only therapeutic agent effective in providing complete stoichiometric protection against the entire spectrum of organophosphate nerve agents.
Treatment	Atropine and related anticholinergic drugs act as antidotes to nerve agent poisoning because they block acetylcholine receptors, but they are poisonous in their own right. Some synthetic anticholinergics, such as biperiden, may counteract the central symptoms of nerve agent poisoning better than atropine, since they pass the blood–brain barrier better than atropine. While these drugs will save the life of a person affected by nerve agents, that person may be incapacitated briefly or for an extended period, depending on the extent of exposure. The endpoint of atropine administration is the clearing of bronchial secretions. Atropine for field use by military personnel is often loaded in an autoinjector, for ease of use in stressful conditions. Pralidoxime chloride, also known as 2-PAM chloride, is also used as an antidote. Rather than counteracting the initial effects of the nerve agent on the nervous system as does atropine, pralidoxime chloride reactivates the poisoned enzyme (acetylcholinesterase) by scavenging the phosphoryl group attached on the functional hydroxyl group of the enzyme. Though safer to use than atropine, it takes longer to act.
Spreading	● Uncontrolled aerosol munitions ● Smoke generation ● Explosive dissemination ● Atomizers, humidifiers and foggers
Exposure	On such exposure, these agents severely disrupt the body's signaling between the nervous and muscular systems, leading to a prolonged neuromuscular blockade, flaccid paralysis of all the muscles in the body including the diaphragm, and death by asphyxiation.

Nerve Agent G Series

The G-series is thus named because German scientists first synthesized them. G series agents are known as non-persistent, while the V series are persistent. All of the compounds in this class were discovered and synthesized during or prior to World War II.

Tabun (GA)	Extremely toxic chemical substance. Tabun or GA is an extremely toxic chemical substance. It is a clear, colorless, and tasteless liquid with a faint fruity odor. Tabun can be destroyed with bleaching powder (calcium hypochlorite), though the poisonous gas cyanogen chloride is produced.
Sarin (GB)	Highly toxic synthetic compound. Exposure is lethal even at very low concentrations, where death can occur within one to ten minutes after direct inhalation of a lethal dose. Death will usually occur as a result of asphyxia due to the inability to control the muscles.
Soman (GD)	It is a volatile, corrosive, and colorless liquid with a faint odor when pure. More commonly, it is a yellow to brown color and has a strong odor described as similar to camphor. t is both more lethal and more persistent than sarin or tabun, but less so than cyclosarin.
Cyclosarin (GF)	The original agent, tabun, was discovered in Germany in 1936 in the process of work on insecticides. Next came sarin, soman and finally the most toxic, cyclosarin. At room temperature, cyclosarin is a colorless liquid whose odor has been variously described as sweet and musty, or resembling peaches or shellac.
GV	It is a potent acetylcholinesterase inhibitor with properties similar to other nerve agents, being a highly poisonous vapour. Treatment for poisoning with GV involves drugs such as atropine, benactyzine, obidoxime, and HI-6.

Nerve Agent V Series

The V-series is the second family of nerve agents and contains five well known members: VE, VG, VM, VR, and VX, along with several more obscure analogues. This class of compounds is also sometimes known as Tammelin's esters

VE	They have similar lethal dose levels to VX (between 10–50 mg) and have similar symptoms and method of action to other nerve agents that act on cholinesterase, and treatment remains the same, but the window for effectively treating second generation V series seizures is shorter. In addition to the standard seizures, some of the second generation V series agents are known to cause comas.
VG	With a toxicity of about 1/10 that of VX, i.e. similar to that of sarin. It is thought that North Korea may have military stockpiles of this chemical.
VM	Little is known about this chemical compound other than its chemical formula. They have similar lethal dose levels to VX (between 10 and 50 mg) and have similar symptoms and method of action to other nerve agents that act on cholinesterase. The treatment remains the same, but the window for effectively treating second generation V series seizures is shorter.
VR	VR has similar lethal dose levels to VX (between 10–50 mg) and has similar symptoms and method of action to other nerve agents that act on cholinesterase, and treatment remains the same. However, the window for effectively treating second generation V series seizures is shorter, as they rapidly denature the acetylcholinesterase protein in a similar manner to soman, making treatment with the standard nerve gas antidote pralidoxime ineffective unless it is given very soon after exposure. Pre-treatment with pyridostigmine prior to exposure, and treatment with other drugs such as atropine and diazepam after exposure, will reduce symptoms of nerve agent toxicity but may not be sufficient to prevent death if a large dose of nerve agent has been absorbed. In addition to the standard seizures, some of the second generation V series agents are known to cause comas.
VX **(Venomous Agent X)**	Because of its low volatility, VX persists in environments where it is dispersed. VX fatalities occur with exposure to tens of milligram quantities via inhalation or absorption through skin; VX is thus more potent than sarin, another nerve agent with a similar mechanism of action.

4 Nettle Agent

Nettle agents (named after stinging nettles) or urticants are a variety of chemical warfare agents that produce corrosive skin and tissue injury upon contact, resulting in erythema, urticaria, intense itching, and a hive-like rash. Most nettle agents, such as the best known and studied nettle agent, phosgene oxime, are often grouped with the vesicant (blister agent) chemical agents. However, because nettle agents do not cause blisters, they are not true vesicants.

5 Choking Agent (Pulmonary Agent)

A pulmonary agent, or choking agent, is a chemical weapon agent designed to impede a victim's ability to breathe. They operate by causing a build-up of fluids in the lungs, which then leads to suffocation. Exposure to the eyes and skin tends to be corrosive, causing blurred vision and severe deep burns. Inhalation of these agents cause burning of the throat, coughing, vomiting, headache, pain in chest, tightness in chest, and respiratory and circulatory failure.

Chlorine Gas

Chlorine is a toxic gas that attacks the respiratory system, eyes, and skin. Because it is denser than air, it tends to accumulate at the bottom of poorly ventilated spaces. Chlorine gas is a strong oxidizer, which may react with flammable materials.

Chlorine is detectable with measuring devices in concentrations as low as 0.2 parts per million (ppm), and by smell at 3 ppm. Coughing and vomiting may occur at 30 ppm and lung damage at 60 ppm. About 1000 ppm can be fatal after a few deep breaths of the gas. The IDLH (immediately dangerous to life and health) concentration is 10 ppm. Breathing lower concentrations can aggravate the respiratory system and exposure to the gas can irritate the eyes. The toxicity of chlorine comes from its oxidizing power. When chlorine is inhaled at concentrations greater than 30 ppm, it reacts with water and cellular fluid, producing hydrochloric acid (HCl) and hypochlorous acid (HClO).

Signs and Symptoms
Chlorine gas, also known as bertholite, was first used as a weapon in World War I by Germany on April 22, 1915, in the Second Battle of Ypres. As described by the soldiers, it had the distinctive smell of a mixture of pepper and pineapple. It also tasted metallic and stung the back of the throat and chest. Chlorine reacts with water in the mucosa of the lungs to form hydrochloric acid, destructive to living tissue and potentially lethal. Human respiratory systems can be protected from chlorine gas by gas masks with activated charcoal or other filters, which makes chlorine gas much less lethal than other chemical weapons. It was pioneered by a German scientist later to be a Nobel laureate, Fritz Haber of the Kaiser Wilhelm Institute in Berlin, in collaboration with the German chemical conglomerate IG Farben, which developed methods for discharging chlorine gas against an entrenched enemy. After its first use, both sides in the conflict used chlorine as a chemical weapon, but it was soon replaced by the more deadly phosgene and mustard gas.

Treatment
There is no antidote for chlorine poisoning; management is supportive after evacuating people from the site of exposure and flushing exposed tissues. For lung damage caused by inhalation, oxygen and bronchodilators may be administered. There is no way to predict outcomes. Most people with mild to moderate exposure generally recover fully in three to five days, but some develop chronic problems such as reactive airway disease. Smoking or pre-existing lung conditions like asthma appear to increase the risk of long term complications.

Chloropicrin (PS)

Chloropicrin, also known as PS and nitrochloroform, is a chemical compound currently used as a broad-spectrum antimicrobial, fungicide, herbicide, insecticide, and nematicide. Chloropicrin is harmful to humans. It can be absorbed systemically through inhalation, ingestion, and the skin. At high concentrations it is severely irritating to the lungs, eyes, and skin. In World War I German forces used concentrated chloropicrin against Allied forces as a tear gas. While not as lethal as other chemical weapons, it caused vomiting and forced Allied soldiers to remove their masks to vomit, exposing them to other, more toxic chemical gases used as weapons during the war. Smells like 'flypaper'.

Diphosgene (DP)

Diphosgene was originally developed as a pulmonary agent for chemical warfare, a few months after the first use of phosgene. It was used as a poison gas in artillery shells by Germany during World War I. The first recorded battlefield use was in May 1916. Diphosgene was developed because the vapors could destroy the filters in gas masks in use at the time.

Phosgene (CG)

It is very poisonous and was used as a chemical weapon during World War I, when it was responsible for 85,000 deaths. Although less toxic than many other chemical weapons such as sarin, phosgene is still regarded as a viable chemical warfare agent because of its simpler manufacturing requirements when compared to that of more technically advanced chemical weapons such as the first-generation nerve agent tabun.

Phosgene was first deployed as a chemical weapon by the French in 1915 in World War I. It was also used in a mixture with an equal volume of chlorine, with the chlorine helping to spread the denser phosgene. Phosgene was more potent than chlorine, though some symptoms took 24 hours or more to manifest. Following the extensive use of phosgene during World War I, it was stockpiled by various countries. Smells like 'musty hay'.

Disulfur Decafluoride

S_2F_{10} was considered a potential chemical warfare pulmonary agent in World War II because it does not produce lacrimation or skin irritation, thus providing little warning of exposure. Disulfur decafluoride is a colorless gas or liquid with a SO_2-like odor. It is about 4 times as poisonous as phosgene. Its toxicity is thought to be caused by its disproportionation in the lungs into SF_6, which is inert, and SF_4, which reacts with moisture to form sulfurous acid and hydrofluoric acid. Disulfur decafluoride itself is not toxic due to hydrolysis products, since it is hardly hydrolysed by water and most aqueous solutions. It is a colorless liquid with a burnt match smell similar to sulfur dioxide.

Perfluoroisobutene

An alkene, it is a colorless gas that it is notable as a highly toxic perfluoroalkene.

Acrolein

Acrolein is toxic and is a strong irritant for the skin, eyes, and nasal passages. The main metabolic pathway for acrolein is the alkylation of glutathione. The WHO suggests a "tolerable oral acrolein intake" of 7.5 μg per day per kg of body weight.

Diphenylcyanoarsine

ILLNESS Chemical

Diphenylcyanoarsine, also called Clark 2 (Chlor-Arsen-Kampfstoff 2, being the successor of Clark 1) by the Germans, was discovered in 1918 by Sturniolo and Bellinzoni and shortly thereafter used like the related Clark 1 gas by the Germans for chemical warfare in the First World War. The substance causes nausea, vomiting and headaches. It can subsequently lead to e.g. pulmonary edema (fluid in the lungs).

6 Vomiting Agent

Vomiting agents are chemical weapon agents causing vomiting. Prolonged exposure can be lethal. They were used for the first time during WWI.

ILLNESS Chemical Incapacitating Agent

7 Incapacitating Agent

The term incapacitating agent is defined by the U.S. Department of Defense as:
"An agent that produces temporary physiological or mental effects, or both, which will render individuals incapable of concerted effort in the performance of their assigned duties." It describes an agent which renders a person unable to harm themselves or others, regardless of consciousness.
Lethal agents are primarily intended to kill, but incapacitating agents can also kill if administered in a potent enough dose, or in certain scenarios.

The term "incapacitation," when used in a general sense, is not equivalent to the term "disability" as used in occupational medicine and denotes the inability to perform a task because of a quantifiable physical or mental impairment. In this sense, any of the chemical warfare agents may incapacitate a victim; however, by the military definition of this type of agent, incapacitation refers to impairments that are temporary and nonlethal. Thus, riot-control agents are incapacitating because they cause temporary loss of vision due to blepharospasm, but they are not considered military incapacitants because the loss of vision does not last long. Although incapacitation may result from physiological changes such as mucous membrane irritation, diarrhea, or hyperthermia, the term "incapacitating agent" as militarily defined refers to a compound that produces temporary and nonlethal impairment of military performance by virtue of its psychobehavioral or CNS effects.

In biological warfare, a distinction is also made between bio-agents as Lethal Agents (e.g., Bacillus anthracis, Francisella tularensis, Botulinum toxin) or Incapacitating Agents (e.g., Brucella suis, Coxiella burnetii, Venezuelan equine encephalitis virus, Staphylococcal enterotoxin B).

ILLNESS Chemical Riot Control Agent

8 Riot Control Agent (RCA)

Riot control agents (sometimes called RCAs) are non-lethal lachrymatory agents used for riot control. Most commonly used riot control agents are pepper spray and various kinds of tear gas. These chemicals disperse a crowd that could be protesting or rioting, or to clear a building. They can rapidly produce sensory irritation or disabling physical effects which usually disappear within 15 minutes (for tear gas) and up to 2 hours (for pepper spray) following termination of exposure. They can also be used for chemical warfare defense training, although their use in warfare itself is a violation of Article I.5 of the Chemical Weapons Convention. Article II.9 of the CWC specifically authorizes their use for civilian law enforcement.

Pepper Spray

Pepper Spray

The active ingredient in pepper-spray is capsaicin, which is a chemical derived from the fruit of plants in the Capsicum genus, including chilies. A synthetic analogue of capsaicin, pelargonic acid vanillylamide (desmethyldihydrocapsaicin), is used in another version of pepper spray known as PAVA spray which is used in the United Kingdom. Another synthetic counterpart of pepper spray, pelargonic acid morpholide, was developed and is widely used in Russia. Its effectiveness compared to natural pepper spray is uncertain and it reportedly has caused some injuries. When undesirables threaten an area, such as a riot after a soccer game, riot police are called in to subdue them. In these situations, the police may use pepper spray, or water cannons to neutralize the threat.

Pepper spray typically comes in canisters, which are often small enough to be carried or concealed in a pocket or purse. Pepper spray can also be bought concealed in items such as rings. There are also pepper spray projectiles available, which can be fired from a paintball gun. Having been used for years against demonstrators, it is increasingly being used by police in routine interventions.

ILLNESS Chemical Riot Control Agent Tear Gas

Tear Gas

Tear gas is a non-specific term for any chemical that is used to temporarily incapacitate through irritation of eyes and/or respiratory system. It is used as a hand-held spray or can be fired in canisters that heat up spewing out an aerosol cloud at a steady rate. Whilst the use of tear gas in warfare is prohibited by various international treaties that most states have signed, police and private self-defense use is not banned in the same manner.

Popular tear gases include the eye irritants ortho-chlorobenzylidene-malononitrile (CS gas), chloroacetophenone (CN gas), and dibenz (b,f)-1,4-oxazepine (CR gas). Among a long list of substances, these three have become of greater importance than the others because of their effectiveness and low risks when used. Today, CS has largely replaced CN as the most widely used tear gas internationally.

Decontamination
At room temperature, tear gases are white solids. They are stable when heated and have low vapor pressure. Consequently, they are usually dispersed as aerosols. All of them have low solubility in water but can be dissolved in several organic solvents. Hydrolysis of CN is very slow in a water solution, especially if alkali is added. CS is rapidly hydrolyzed in water solution (half-life at pH 7 is about 15 min. at room temperature) and extremely rapid when alkali is added (half-life at pH 9 is about 1 min.). CR is hydrolyzed only to a negligible extent in water solution.

CN and CR are, thus, difficult to decompose under practical conditions, whereas CS can easily be inactivated by means of a water solution. Skin is suitably decontaminated of CS and CN gas by thorough washing with soap and water. CS is then decomposed, whereas CN is only removed via soap and water. The effects of CR gas are greatly increased by water, causing any attempt to DECON CR via soap and water to increase the severity and duration of the effects. When decontamination of CR is attempted with soap and water the effects of CR can last up to 48 hours

Chemical Riot Control Agent Tear Gas

Decontamination of material after contamination with CR gas is not possible for up to 45 days. CS can be decontaminated l with a 5–10 percent soda solution or 2 percent alkaline solution. If this type of decontamination cannot be accomplished (e.g., contaminated rooms and furniture), then the only other means is by intensive air exchange—preferably with hot air.

Exposed streets and sidewalks will have toxic and irritating CS powder that will be stirred into the air by traffic and pedestrians long after the cloud has dissipated, and should be washed away with water. In contrast to human beings, domesticated animals generally have lower sensitivity to tear gases. Dogs and horses can therefore be used by police for riot control even when tear gas is used.

ILLNESS

7 Biological

ILLNESS Biological

A biological agent (also called bio-agent, biological threat agent, biological warfare agent, biological weapon, or bioweapon) is a bacterium, virus, protozoan, parasite, or fungus that can be used purposefully as a weapon in bioterrorism or biological warfare (BW). In addition to these living or replicating pathogens, toxins and biotoxins are also included among the bio-agents. More than 1,200 different kinds of potentially weaponizable bio-agents have been described and studied to date.

Biological agents have the ability to adversely affect human health in a variety of ways, ranging from relatively mild allergic reactions to serious medical conditions, including serious injury, as well as serious or permanent disability or even death. Many of these organisms are ubiquitous in the natural environment where they are found in water, soil, plants, or animals. Bio-agents may be amenable to "weaponization" to render them easier to deploy or disseminate. Genetic modification may enhance their incapacitating or lethal properties, or render them impervious to conventional treatments or preventives. Since many bio-agents reproduce rapidly and require minimal resources for propagation, they are also a potential danger in a wide variety of occupational settings.

Biological warfare (BW)—also known as germ warfare—is the use of biological toxins or infectious agents such as bacteria, viruses, insects, and fungi with the intent to kill, harm or incapacitate humans, animals or plants as an act of war. Biological weapons (often termed "bio-weapons", "biological threat agents", or "bio-agents") are living organisms or replicating entities (i.e. viruses, which are not universally considered "alive"). Entomological (insect) warfare is a subtype of BW.

Offensive biological warfare is prohibited under customary international humanitarian law and several international treaties. In particular, the 1972 Biological Weapons Convention (BWC) bans the development, production, acquisition, transfer, stockpiling and use of biological weapons. Therefore, the use of biological agents in armed conflict is a war crime. In contrast, defensive biological research for prophylactic, protective or other peaceful purposes is not prohibited by the BWC.

Biological warfare is distinct from warfare involving other types of weapons of mass destruction (WMD), including nuclear warfare, chemical warfare, and radiological warfare. None of these are considered conventional weapons, which are deployed primarily for their explosive, kinetic, or incendiary potential. Biological weapons may be employed in various ways to gain a strategic or tactical advantage over the enemy, either by threats or by actual deployments. Like some chemical weapons, biological weapons may also be useful as area denial weapons. These agents may be lethal or non-lethal, and may be targeted against a single individual, a group of people, or even an entire population. They may be developed, acquired, stockpiled or deployed by nation states or by non-national groups. In the latter case, or if a nation-state uses it clandestinely, it may also be considered bioterrorism.

Biological warfare and chemical warfare overlap to an extent, as the use of toxins produced by some living organisms is considered under the provisions of both the BWC and the Chemical Weapons Convention. Toxins and psychochemical weapons are often referred to as midspectrum agents. Unlike bioweapons, these midspectrum agents do not reproduce in their host and are typically characterized by shorter incubation periods.

Biological Agents

Bacterial Bio-Agents

Disease	Causative Agent
Anthrax	Bacillus anthracis (N or TR)
Brucellosis (bovine)	Brucella abortus
Brucellosis (caprine)	Brucella melitensis (AM or BX)
Brucellosis (porcine)	Brucella suis (US, AB or NX)
Cholera	Vibrio cholerae (HO)
Diphtheria	Corynebacterium diphtheriae (DK)
Dysentery (bacterial)	Shigella dysenteriae, some species of Escherichia coli (Y)
Glanders	Burkholderia mallei (LA)
Listeriosis	Listeria monocytogenes (TQ)
Melioidosis	Burkholderia pseudomallei (HI)
Plague	Yersinia pestis (LE)
Tularemia	Francisella tularensis (SR or JT)

Chlamydial Bio-Agents

Disease	Causative Agent
Psittacosis	Chlamydophila psittaci (SI)

Rickettsial Bio-Agents

Disease	Causative Agent
Q Fever	Coxiella burnetii (OU)
Rocky Mountain spotted fever	Rickettsia rickettsii (RI or UY)
Typhus (human)	Rickettsia prowazekii (YE)
Typhus (murine)	Rickettsia typhi (AV)

Viral Bio-Agents

Disease	Causative Agent
Equine Encephalitis (Eastern)	Eastern equine encephalitis virus (ZX)
Equine Encephalitis (Venezuelan)	Venezuelan Equine Encephalomyelitis virus (FX)
Equine Encephalitis (Western)	Western equine encephalitis virus (EV)
Japanese B encephalitis	Japanese encephalitis virus (AN)
Marburg Hemorrhagic Fever (Marburg HF)	Marburg Virus (MARV)
Rift Valley fever	Rift Valley fever virus (FA)
Smallpox	Variola virus (ZL)
Yellow fever	Yellow fever virus (OJ or LU)

Mycotic Bio-Agents

Disease	Causative Agent
Coccidiomycosis	Coccidioides immitis (OC)

Biological Toxins

Disease	Causative Agent

ILLNESS	Biological	Biological Agents	Biological To[xins]	
			Abrin	Rosary pea (Abrus precatorius)
			Botulinum toxins (A through G)	Clostridium botulinum bacteria or spores, and several other Clostridial species. (X or XR)
			Ricin	Castor bean (Ricinus communis) (W or WA)
			Saxitoxin	Various marine and brackish cyanobacteria, such as Anabaena, Aphanizomenon, Lyngbya, and Cylindrospermopsis (TZ)
			Staphyloccocal enterotoxin B	Staphylococcus aureus (UC or PG)
			Tetrodotoxin	Various marine bacteria, including Vibrio alginolyticus, Pseudoalteromonas tetraodonis (PP)
			Trichothecene mycotoxins	Various species of fungi, including Fusarium, Trichoderma, and Stachybotrys

Biological Vectors

Disease	Causative Agent
Mosquito (Aedes aegypti) (AP)	Malaria, Dengue fever, Chikungunya, Yellow fever, other Arboviruses
Oriental rat flea (Xenopsylla cheopis)	Plague, Murine typhus

Injury

Common types of injuries and how to treat them

"An injury is not just a process of recovery it's a process of discovery."
Conor McGregor

Introduction

This category lists any injuries that can be sustained to the body and how to remedy them.

Purpose	The aim of INJURY is to inform the reader on the causes, symptoms, prevention techniques and treatments of the most likely injuries you'll sustain in a disaster.
Lost?	***** **QUICK TRIAGE (If you're injured or sick and looking for the correct section)** ***** ● **Sections under ILLNESS:** Radiation Sickness, Parasitic Infections, Bacterial Infections, Viral Infections, Fungal Infections, Altitude Sickness, Poisoning, Chemical Agents, Biological Agents. ● **Sections under INJURY:** Surface Wound & Bruises, Internal Injuries (Back Pain, Cerebral Hemorrhage, Bone Fractures, Dislocation, Concussion) Open Wounds, Avulsion, Burns, Environmental (Anaphylaxis, Heat Stroke, Hypothermia, Hyperthermia, Motion Sickness, Aero-otitis Media), Atmosphere (Asphyxiation, Drowning, Choking, Hypoxia, Carbon Monoxide Poisoning), Animal & Plant (Bites and Stings), Childbirth, Toothaches. ● **Sections under EMOTIONAL:** Depression, Anxiety, Stress, Confidence, Relaxation, Memory & Dementia, Grief & Loss, Postnatal Depression, New Parents, Body Image, Family & Friends and Healthy Living.

● For medications and recommended doses, see the MEDICATION section.
● For curing ailments naturally and herbal remedies, see the NATURAL REMEDIES section.
● For eating disorders, see the HEALTH > Nutrients section.

Contents

1 Surface Wound & Bruise

Where the skin membrane has been removed or marked or scraped.

Subheadings

		1. Friction Burn	2. Blisters	3. Bruises			

1 Friction Burn

A friction burn is a form of abrasion caused by the friction of skin rubbing against a surface. A friction burn may also be referred to as skinning, chafing, or a term named for the surface causing the burn such as rope burn, carpet burn or rug burn. Because friction generates heat, extreme cases of chafing may result in genuine burning of the outer layers of skin. The dermal papillae may be exposed after top layers of the dermis (stratum corneum, stratum granulosum, stratum spinosum and stratum basale) have been removed. This is often uncomfortable and even painful, but rarely results in bleeding. A person's own skin (or the skin of another person) may be sufficient to act as an abrasive surface to cause friction burn.

More commonly, friction with abrasive surfaces, including clothing, carpet, or rope, can lead to a friction burn. Common places at which skin-to-skin chafing can occur are between the thighs and under the armpits. Friction burns are very common with clothing such as trousers on the knees caused by playing sport or sliding on wooden surfaces. Less dangerous friction burns can occur frequently on sensitive skin surfaces such as the genitals, such as during sexual intercourse or masturbation. The risks of a friction burn include infection and temporary or permanent scarring.

Treatment
Most minor cases of a friction burn require little to no treatment; as a specific case of allergy might aggravate. Treatments for friction burns usually involve application of an anti-inflammatory cream. Pain relieving medication may also be taken.

2 Blisters

A blister is a small pocket of body fluid within the upper layers of the skin, typically caused by forceful rubbing (friction), burning, freezing, chemical exposure or infection. Most blisters are filled with a clear fluid, either serum or plasma. However, blisters can be filled with blood (known as "blood blisters") or with pus (for instance, if they become infected). To heal properly, a blister should not be popped unless medically necessary. If popped, the excess skin should not be removed because the skin underneath needs that top layer to heal properly. A blister may form when the skin has been damaged by friction or rubbing, heat, cold or chemical exposure. Fluid collects between the upper layers of Skin (the epidermis) and the layers below (the dermis). This fluid cushions the tissue underneath, protecting it from further damage and allowing it to heal.

Friction & Rubbing
Intense rubbing can cause a blister, as can any friction on the skin if continued long enough. This kind of blister is most common after walking long distances or by wearing old or poorly fitting shoes. Blisters are most common on the hands and feet, as these extremities are susceptible while walking, running, or performing repetitive motions, such as joystick manipulation whilst playing certain video games, digging with a shovel, playing guitar, etc. Blisters form more easily on damp skin than on dry or soaked skin, and are more common in warm conditions. Less-aggressive rubbing over long periods of time may cause calluses to form rather than a blister. Both blisters and calluses can lead to more serious complications, such as foot ulceration and infection, particularly when sensation or circulation is impaired, as in the case of diabetes, neuropathy or peripheral artery disease (PAD).

Friction blisters are caused by excess shear stress between the surface of the skin and the body. The strata of skin around the Stratum spinosum are most susceptible to shear. As the Stratum spinosum tears away from the connecting tissues below, plasma from the cells diffuses out. This plasma solution helps new cells divide and grow into new connective tissues and epidermal layers. The clear fluid will be reabsorbed as new cells develop and the swollen appearance will subside. Painful blisters located on hands (palmar surface) and feet (plantar surface) are due to tissue shearing deeper in the epidermis, near nerve endings. Lower tissues are more susceptible to infection.

Extreme Temperature
This type of blistering is one of the tools used to determine the degree of burns sustained. First and second degree burns may result in blistered skin; however, it is characteristic of second degree burns to blister immediately, whereas first degree burns can have blisters after a couple of days. Blisters can also form on the hands and feet as a result of tissue damage incurred by frostbite.

Chemical Exposure
Sometimes, the skin will blister when it comes into contact with a cosmetic, detergent, solvent, or other chemical such as nickel sulphate, Balsam of Peru, or urushiol (poison ivy, poison oak, poison sumac). This is known as contact dermatitis. Blisters can also develop as a result of an allergic reaction to an insect bite or sting. Some chemical warfare agents, known as blister agents or vesicants, cause large, painful blisters wherever they contact skin; an example is mustard gas.

Crushing / Pinching
A blood blister usually forms when a minute blood vessel close to the surface of the skin ruptures (breaks), and blood leaks into a tear between the layers of skin. This can happen if the skin is crushed, pinched or aggressively squeezed.

Medical Conditions
There are also a number of medical conditions that cause blisters. The most common are chickenpox, herpes, impetigo, and a form of eczema called dyshidrosis. Other, much rarer conditions that cause blisters include:

- Bullous Pemphigoid: a skin disease that causes large, tightly filled blisters to develop, usually affecting people over the age of 60.
- Pemphigus: a serious skin disease in which blisters develop if pressure is applied to the skin; the blisters burst easily, leaving raw areas that can become infected.
- Dermatitis Herpetiformis: a skin disease that causes intensely itchy blisters, usually on the elbows, knees, back and buttocks. The blisters usually develop in patches of the same shape and size on both sides of the body.
- Chronic Bullous Dermatosis: a disease that causes clusters of blisters on the face, mouth or genitals.
- Cutaneous Radiation Syndrome
- Epidermolysis Bullosa

Prevention
Friction blisters, caused by rubbing against the skin, can be prevented by reducing the friction to a level where blisters will not form. This can be accomplished in a variety of ways. Blisters on the feet can be prevented by wearing comfortable, well-fitting shoes and clean socks. Inherently ill-fitting or stiffer shoes, such as high heels and dress shoes, present a larger risk of blistering. Blisters are more likely to develop on skin that is moist, so socks that manage moisture or frequent sock changes will aid those with particularly sweaty feet. While exercising or playing sports, special sports socks can help keep feet drier and reduce the chance of blisters.

Before going for a long walk, it is also important to ensure that shoes or hiking boots have been properly broken in. Even before a "hot" or irritated area on the foot is felt, taping a protective layer of padding or a friction-reducing interface between the affected area and the footwear can prevent the formation of a blister. Bandages, moleskin and tapes generally must be applied to the foot daily, and most have a very high coefficient of friction (COF), but a friction-management patch applied to the shoe will remain in place much longer, throughout many changes of socks and insoles.
This type of intervention may be used with footwear that is worn daily, with specialty shoes and boots like hockey skates, ice skates, inline skates, ski boots and cleats, or even with orthotic braces and splints. For periods of sustained use such as hiking and trail running, especially where water ingress or moisture build up in the shoe or boot can occur, moisture wicking liner socks can provide the required friction protection.

To avoid friction blisters on the hands, gloves should be worn when using tools such as a shovel or pickaxe, doing manual work such as gardening, or using sports equipment like golf clubs or baseball bats. Oars used for competitive rowing are known for causing frequent blisters on the hands of oarsmen. Weightlifters are also prone to blisters as are gymnasts from the friction developed by the rubbing against the bars. To further reduce the occurrence one can tape the hands, and there are also a number of products on the market that claim to reduce the occurrence of blisters.

These are all intended to be worn as a liner underneath a glove. The majority of these offerings simply add padding and create a layer that reduces the coefficient of friction between the skin and the glove. A lubricant, typically talcum powder, can be used to reduce friction between skin and apparel in the short term. People put talcum powder inside gloves or shoes for this purpose, although this type of lubricant will increase the friction in the long term, as it absorbs moisture. Increased friction makes blisters more likely.

Sunscreen and protective clothing should also be used during the hottest part of the day to avoid blisters from sunburn. Avoiding sunlight during midday is the best way to avoid blisters from sunburn. Protective gloves should be worn when handling detergents, cleaning products, solvents and other chemicals.

3 Bruises

A contusion, commonly known as a bruise, is a type of hematoma of tissue in which capillaries and sometimes venules are damaged by trauma, allowing blood to seep, haemorrhage, or extravasate into the surrounding interstitial tissues. Most bruises are not very deep under the skin so that the bleeding causes a visible discoloration. The bruise then remains visible until the blood is either absorbed by tissues or cleared by immune system action. Bruises, which do not blanch under pressure, can involve capillaries at the level of skin, subcutaneous tissue, muscle, or bone.

Bruises are not to be confused with other similar-looking lesions primarily distinguished by their diameter or causation. These lesions include petechia (< 3 mm result from numerous and diverse etiologies such as adverse reactions from medications such as warfarin, straining, asphyxiation, platelet disorders and diseases such as cytomegalovirus), purpura (3 mm to 1 cm, classified as palpable purpura or non-palpable purpura and indicates various pathologic conditions such as thrombocytopenia), and ecchymosis (>1 cm caused by blood dissecting through tissue planes and settled in an area remote from the site of trauma or pathology such as periorbital ecchymosis, e.g., "raccoon eyes", arising from a basilar skull fracture or from a neuroblastoma). As a type of hematoma, a bruise is always caused by internal bleeding into the interstitial tissues which does not break through the skin, usually initiated by blunt trauma, which causes damage through physical compression and deceleration forces. Trauma sufficient to cause bruising can occur from a wide variety of situations including accidents, falls, and surgeries.

Disease states such as insufficient or malfunctioning platelets, other coagulation deficiencies, or vascular disorders, such as venous blockage associated with severe allergies can lead to the formation of purpura which is not to be confused with trauma-related bruising/contusion. If the trauma is sufficient to break the skin and allow blood to escape the interstitial tissues, the injury is not a bruise but bleeding, a different variety of haemorrhage. Such injuries may be accompanied by bruising elsewhere. Bruises often induce pain immediately after the trauma that results in their formation, but small bruises are not normally dangerous alone. Sometimes bruises can be serious, leading to other more life-threatening forms of hematoma, such as when associated with serious injuries, including fractures and more severe internal bleeding. The likelihood and severity of bruising depends on many factors, including type and healthiness of affected tissues. Minor bruises may be easily recognized in people with light skin colour by characteristic blue or purple appearance in the days following the injury.

Cause
The presence of bruises may be seen in patients with platelet or coagulation disorders, or those who are being treated with an anticoagulant. Unexplained bruising may be a warning sign of child abuse, domestic abuse, or serious medical problems such as leukaemia or meningococcal infection. Unexplained bruising can also indicate internal bleeding or certain types of cancer. Long-term glucocorticoid therapy can cause easy bruising. Bruising present around the navel (belly button) with severe abdominal pain suggests acute pancreatitis. Connective tissue disorders such as Ehlers-Danlos syndrome may cause relatively easy or spontaneous bruising depending on the severity. During an autopsy, bruises accompanying abrasions indicate the abrasions occurred while the individual was alive, as opposed to damage incurred post mortem.

Size / Shape
Bruise shapes may correspond directly to the instrument of injury or be modified by additional factors. Bruises often become more prominent as time lapses, resulting in additional size and swelling, and may grow to a large size over the course of the hours after the injury that caused the bruise was inflicted. As stated above, bruising present in a different location than the site of impact is called ecchymosis and generally occurs when the tissue at the site of injury is loose, allowing blood to travel under the skin to another location due to gravity or other forces, such as in a black eye.

Size / Shape
● Condition and type of tissue: In soft tissues, a larger area is bruised than would be in firmer tissue due to ease of blood to invade tissue.
● Age: elderly skin and other tissues are often thinner and less elastic and thus more prone to bruising.
● Gender: More bruising occurs in females due to increased subcutaneous fat.
● Skin tone: Discoloration caused by bruises is more prominent in lighter complexions.
● Diseases: Coagulation, platelet and blood vessel diseases or deficiencies can increase bruising due to more bleeding.
● Location: More extensive vascularity causes more bleeding. Areas such as the arms, knees, shins and the facial area are especially common bruise sites.
● Forces: Greater striking forces cause greater bruising.
● Genes: Despite having completely normal coagulation factors, natural redheads have been shown to bruise more, although this may just be due to greater visibility on commonly associated lighter complexion.

Severity
Bruises can be scored on a scale from 0-5 to categorize the severity and danger of the injury.

	0	1	2	3	4	5
Severity	Light Bruise	Mild Bruise	Moderate Bruise	Serious Bruise	Extremely Serious Bruise	Critical Bruise
Effects	No Damage	Damage	Some Damage	Dangerous	Dangerous	Risk of Death

The harm score is determined by the extent and severity of the injuries to the organs and tissues causing the bruising, in turn depending on multiple factors. For example, a contracted muscle will bruise more severely, as will tissues crushed against underlying bone. Capillaries vary in strength, stiffness and toughness, which can also vary by age and medical conditions. Low levels of damaging forces produce small bruises and generally cause the individual to feel minor pain straight away.

Repeated impacts worsen bruises, increasing the harm level. Normally, light bruises heal nearly completely within two weeks, although duration is affected by variation in severity and individual healing processes; generally, more severe or deeper bruises take somewhat longer. Severe bruising (harm score 2–3) may be dangerous or cause serious complications. Further bleeding and excess fluid may accumulate causing a hard, fluctuating lump or swelling hematoma. This has the potential to cause compartment syndrome in which the swelling cuts off blood flow to the tissues.

The trauma that induced the bruise may also have caused other severe and potentially fatal harm to internal organs. For example, impacts to the head can cause traumatic brain injury: bleeding, bruising and massive swelling of the brain with the potential to cause concussion, coma and death. Treatment for brain bruising may involve emergency surgery to relieve the pressure on the brain.

Damage that causes bruising can also cause bones to be broken, tendons or muscles to be strained, ligaments to be sprained, or other tissue to be damaged. The symptoms and signs of these injuries may initially appear to be those of simple bruising. Abdominal bruising or severe injuries that cause difficulty in moving a limb or the feeling of liquid under the skin may indicate life-threatening injury and require the attention of a physician.

Treatment

Treatment for light bruises is minimal and may include RICE (rest, immobilize, cold, elevate), painkillers (particularly NSAIDs) and, later in recovery, light stretching exercises. Particularly, immediate application of ice while elevating the area may reduce or completely prevent swelling by restricting blood flow to the area and preventing internal bleeding. Rest and preventing re-injury is essential for rapid recovery. Very gently massaging the area and applying heat may encourage blood flow and relieve pain according to the gate control theory of pain, although causing additional pain may indicate the massage is exacerbating the injury.

As for most injuries, these techniques should not be applied until at least three days following the initial damage to ensure all internal bleeding has stopped, because although increasing blood flow will allow more healing factors into the area and encourage drainage, if the injury is still bleeding this will allow more blood to seep out of the wound and cause the bruise to become worse. In most cases hematomas spontaneously revert, but in cases of large hematomas or those localized in certain organs (e.g., the brain), the physician may perform a puncture of the hematoma to allow blood to exit.

2 Internal Injury

Injuries which are inside the body such as cramps and dislocation.

Subheadings

1 Back Pain

Back pain is pain felt in the back. It is divided into neck pain (cervical), middle back pain (thoracic), lower back pain (lumbar) or coccydynia (tailbone or sacral pain) based on the segment affected. The lumbar area is the most common area for pain, as it supports most of the weight in the upper body. Episodes of back pain may be acute, sub-acute, or chronic depending on the duration.

The pain may be characterized as a dull ache, shooting or piercing pain, or a burning sensation. Discomfort can radiate into the arms and hands as well as the legs or feet, and may include numbness, or weakness in the legs and arms. Back pain typically originates from degenerative or traumatic changes to the disks and facets joints, which can then cause secondary pain in the muscles, and nerves, and referred pain to the bones, joints and extremities.

Diseases and inflammation of the gallbladder, pancreas, aorta, and kidneys may also cause referred pain in the back. Tumours of the verteba, neural tissues and adjacent structures can also manifest as back pain. Back pain is common, with about nine out of ten adults experiencing it at some point in their life, and five out of ten working adults having it every year. Some estimate up to 95% of Americans will experience back pain at some point in their lifetime. It is the most common cause of chronic pain, and is a major contributor of missed work and disability.

However, it is rare for back pain to be permanently disabling. In most cases of herniated disks and stenosis, rest, injections or surgery have similar general pain resolution outcomes on average after one year. In the United States, acute low back pain is the fifth most common reason for physician visits and causes 40% of missed days off work. Additionally, it is the single leading cause of disability worldwide.

Causes

There are many causes of back pain, including blood vessels, internal organs, infections, mechanical, and autoimmune causes. The spinal cord, nerve roots, vertebral column, can all be sources of back pain, but primary muscle problems are rarely the cause. The anterior ligaments of the intervertebral disc are extremely sensitive, and even the slightest injury can cause significant pain. In osteoporosis, the bones become weaker and can develop small cracks, or fractures, in the bones, resulting in pain.

Arthritis in the joints of the back can also result in discomfort. The synovial joints of the spine (e.g. zygapophysial joints/facet joints) have been identified as the primary source of the pain in approximately one third of people with chronic low back pain, and in most people with neck pain following whiplash. Approximately 98 percent of people with back pain are diagnosed with nonspecific acute back pain in which there is no serious underlying pathology. Less than 2 percent are attributed to secondary factors, with metastatic cancers and serious infections, such as spinal osteomyelitis and epidural abscesses, accounting for around 1 percent. Back pain can be divided into non-radicular pain and radiculopathy.

Radiculopathy occurs when there is irritation in the nerve root, causing neurologic symptoms, such as numbness and tingling. Disk herniation and foraminal stenosis are the most common causes of radiculopathy. Non-radicular back pain is most commonly caused by injury to the spinal muscles or ligaments, degenerative spinal disease, or a herniated disk. Spondylosis, or spinal degeneration, occurs when the intervertebral disc undergoes degenerative changes, causing the disc to fail at cushioning the vertebrae. There is an association between intervertebral disc space narrowing and lumbar spine pain.

The space between the vertebrae becomes more narrow, resulting in compression and irritation of the nerves. There is a weak association between low back pain and facet osteoarthritis, which has been considered as a primary reason for compression of spine nerve roots as they exit the intervertebral foramen. Back pain can also be due to referred pain from another source. Referred pain occurs when pain is felt at a location different from the source of the pain.

An abdominal aortic aneurysm and ureteral colic can both result in pain felt in the back. Another possible cause of chronic back pain in people with otherwise normal scans is central sensitization, where an initial injury or infection causes a longer-lasting state of heightened sensitivity to pain. This persistent state maintains pain even after the initial injury has healed. Treatment of sensitization typically involves low doses of anti-depressants. Obesity, sedentary lifestyle, and lack of exercise can increase a person's risk of back pain.

People who smoke are more likely to experience back pain than others. Poor posture and weight gain in pregnancy are also risk factors for back pain. In general, fatigue can worsen pain. A few studies suggest that psychosocial factors such as on-the-job stress and dysfunctional family relationships may correlate more closely with back pain than structural abnormalities revealed in X-rays and other medical imaging scans.

Management

INJURY Internal Injury Back Pain Management

The management goals when treating back pain are to achieve maximal reduction in pain intensity as rapidly as possible, to restore the individual's ability to function in everyday activities, to help the patient cope with residual pain, to assess for side-effects of therapy, and to facilitate the patient's passage through the legal and socioeconomic impediments to recovery. For many, the goal is to keep the pain to a manageable level to progress with rehabilitation, which then can lead to long-term pain relief.

Also, for some people the goal is to use non-surgical therapies to manage the pain and avoid major surgery, while for others surgery may be the quickest way to feel better. Not all treatments work for all conditions or for all individuals with the same condition, and many find that they need to try several treatment options to determine what works best for them. The present stage of the condition (acute or chronic) is also a determining factor in the choice of treatment. Only a minority of people with back pain (most estimates are 1% - 10%) require surgery.

Management (Non Medical)
Back pain is generally treated with non-pharmacological therapy first, as it typically resolves without the use of medication. Superficial heat and massage, acupuncture, and spinal manipulation therapy may be recommended.

- Heat therapy is useful for back spasms or other conditions. A review concluded that heat therapy can reduce symptoms of acute and sub-acute low-back pain.
- Regular activity and gentle stretching exercises is encouraged in uncomplicated back pain, and is associated with better long-term outcomes. Physical therapy to strengthen the muscles in the abdomen and around the spine may also be recommended. These exercises are associated with better patient satisfaction, although it has not been shown to provide functional improvement. However, one study found that exercise is effective for chronic back pain, but not for acute pain. If used, they should be performed under supervision of a licensed health professional.
- Massage therapy may give short-term pain relief, but not functional improvement, for those with acute lower back pain. It may also give short-term pain relief and functional improvement for those with long-term (chronic) and sub-acute lower pack pain, but this benefit does not appear to be sustained after 6 months of treatment. There does not appear to be any serious adverse effects associated with massage.
- Acupuncture may provide some relief for back pain. However, further research with stronger evidence needs to be done.
- Spinal manipulation is a widely-used method of treating back pain. Immediate benefits can be significant, but long-term benefits can be variable.
- "Back school" is an intervention that consists of both education and physical exercises. A 2016 Cochrane review found the evidence concerning back school to be very low quality and was not able to make generalizations as to whether back school is effective or not.

Management(Medication)
If non-pharmacological measures are not effective, medications may be tried.
- Non-steroidal anti-inflammatory drugs (NSAIDs) are typically tried first. NSAIDs have been shown to be more effective than placebo, and are usually more effective than paracetamol (acetaminophen).
- Long-term use of opioids has not been tested in order to determine if it is effective or safe for treating chronic lower back pain. For severe back pain not relieved by NSAIDs or acetaminophen, opioids may be used. Opioids may not be better than NSAIDs or antidepressants for chronic back pain with regards to pain relief and gain of function.
- Skeletal muscle relaxers may also be used. Their short term use has been shown to be effective in the relief of acute back pain. However, the evidence of this effect has been disputed, and these medications do have negative side-effects.
- In people with nerve root pain and acute radiculopathy, there is evidence that a single dose of steroids, such as dexamethasone, may provide pain relief.
- Epidural corticosteroid injection (ESI) is a procedure in which steroid medications are injected into the epidural space. The steroid medications reduce inflammation and thus decrease pain and improve function. ESI has long been used to both diagnose and treat back pain, although recent studies have shown a lack of efficacy in treating low back pain.

Pregnancy

About 50% of women experience low back pain during pregnancy. Some studies have suggested women who have experienced back pain before pregnancy are at a higher risk of having back pain during pregnancy. It may be severe enough to cause significant pain and disability in up to a third of pregnant women. Back pain typically begins at around 18 weeks gestation, and peaks between 24 and 36 weeks gestation. Approximately 16% of women who experienced back pain during pregnancy report continued back pain years after pregnancy, indicating those with significant back pain are at greater risk of back pain following pregnancy.

Biomechanical factors of pregnancy shown to be associated with back pain include increased curvature of the lower back, or lumbar lordosis, to support the added weight on the abdomen. Also, a hormone called relaxin is released during pregnancy that softens the structural tissues in the pelvis and lower back to prepare for vaginal delivery. This softening and increased flexibility of the ligaments and joints in the lower back can result in pain. Back pain in pregnancy is often accompanied by radicular symptoms, suggested to be caused by the fetus pressing on the sacral plexus and lumbar plexus in the pelvis.

Typical factors aggravating the back pain of pregnancy include standing, sitting, forward bending, lifting, and walking. Back pain in pregnancy may also be characterized by pain radiating into the thigh and buttocks, night-time pain severe enough to wake the patient, pain that is increased during the night-time, or pain that is increased during the day-time. Local heat, acetaminophen (paracetamol), and massage can be used to help relieve the pain. Avoiding standing for prolonged periods of time is also suggested.

2 Ankle Sprain

A sprained ankle, also known as a twisted ankle or rolled ankle, is a common injury where sprain occurs on one or more ligaments of the ankle.

3 Intercranial Injury (Traumatic Brain Injury)

INJURY Internal Injury Intercranial Injuries

Traumatic injuries to the cranium or skull and the structures within. Traumatic brain injury (TBI), also known as intracranial injury, occurs when an external force injures the brain. TBI can be classified based on severity, mechanism (closed or penetrating head injury), or other features (e.g., occurring in a specific location or over a widespread area). Head injury is a broader category that may involve damage to other structures such as the scalp and skull. TBI can result in physical, cognitive, social, emotional, and behavioural symptoms, and outcome can range from complete recovery to permanent disability or death.

Causes include falls, vehicle collisions, and violence. Brain trauma occurs as a consequence of a sudden acceleration or deceleration within the cranium or by a complex combination of both movement and sudden impact. In addition to the damage caused at the moment of injury, a variety of events following the injury may result in further injury. These processes include alterations in cerebral blood flow and the pressure within the skull. Some of the imaging techniques used for diagnosis include computed tomography and magnetic resonance imaging (MRIs).

Prevention measures include use of protective technology in vehicles, such as seat belts and sports or motorcycle helmets, as well as efforts to reduce the number of collisions, such as safety education programs and enforcement of traffic laws. Depending on the injury, treatment required may be minimal or may include interventions such as medications, emergency surgery or surgery years later. Physical therapy, speech therapy, recreation therapy, occupational therapy and vision therapy may be employed for rehabilitation.

Classification
Traumatic brain injury is defined as damage to the brain resulting from external mechanical force, such as rapid acceleration or deceleration, impact, blast waves, or penetration by a projectile. Brain function is temporarily or permanently impaired and structural damage may or may not be detectable with current technology. TBI is one of two subsets of acquired brain injury (brain damage that occur after birth); the other subset is non-traumatic brain injury, which does not involve external mechanical force (examples include stroke and infection). All traumatic brain injuries are head injuries, but the latter term may also refer to injury to other parts of the head. However, the terms head injury and brain injury are often used interchangeably. Similarly, brain injuries fall under the classification of central nervous system injuries and neurotrauma. In neuropsychology research literature, in general the term "traumatic brain injury" is used to refer to non-penetrating traumatic brain injuries. TBI is usually classified based on severity, anatomical features of the injury, and the mechanism (the causative forces). Mechanism-related classification divides TBI into closed and penetrating head injury. A closed (also called nonpenetrating, or blunt) injury occurs when the brain is not exposed. A penetrating, or open, head injury occurs when an object pierces the skull and breaches the dura mater, the outermost membrane surrounding the brain.

Severity

Brain injuries can be classified into mild, moderate, and severe categories. The Glasgow Coma Scale (GCS), the most commonly used system for classifying TBI severity, grades a person's level of consciousness on a scale of 3–15 based on verbal, motor, and eye-opening reactions to stimuli. In general, it is agreed that a TBI with a GCS of 13 or above is mild, 9–12 is moderate, and 8 or below is severe. Similar systems exist for young children. However, the GCS grading system has limited ability to predict outcomes. Because of this, other classification systems such as the one shown in the table are also used to help determine severity. A current model developed by the Department of Defence and Department of Veterans Affairs uses all three criteria of GCS after resuscitation, duration of post-traumatic amnesia (PTA), and loss of consciousness (LOC). It also has been proposed to use changes that are visible on neuroimaging, such as swelling, focal lesions, or diffuse injury as method of classification. Grading scales also exist to classify the severity of mild TBI, commonly called concussion; these use duration of LOC, PTA, and other concussion symptoms.

Severity	GCS	PTA	LOC
Mild	13-15	< 1 Day	0-30 Minutes
Moderate	9-12	1-7 Days	30 Mins - 24 Hours
Severe	3-8	Over 7 Days	Over 24 Hours

Glasgow Coma Scale (GCS)
The Glasgow Coma Scale (GCS) is a neurological scale which aims to give a reliable and objective way of recording the conscious state of a person for initial as well as subsequent assessment. A patient is assessed against the criteria of the scale, and the resulting points give a patient score between 3 (indicating deep unconsciousness) and either 14 (original scale) or 15 (more widely used modified or revised scale). GCS was initially used to assess a patient's level of consciousness after a head injury, and the scale is now used by first responders, EMS, nurses, and doctors as being applicable to all acute medical and trauma patients. In hospitals it is also used in monitoring chronic patients in intensive care.

Post-Traumatic Amnesia (PTA)
Post-traumatic amnesia (PTA) is a state of confusion that occurs immediately following a traumatic brain injury (TBI) in which the injured person is disoriented and unable to remember events that occur after the injury. The person may be unable to state their name, where they are, and what time it is. When continuous memory returns, PTA is considered to have resolved. While PTA lasts, new events cannot be stored in the memory. About a third of patients with mild head injury are reported to have "islands of memory", in which the patient can recall only some events. During PTA, the patient's consciousness is "clouded". Because PTA involves confusion in addition to the memory loss typical of amnesia, the term "post-traumatic confusional state" has been proposed as an alternative. There are two types of amnesia: retrograde amnesia (loss of memories that were formed shortly before the injury) and anterograde amnesia (problems with creating new memories after the injury has taken place). Both retrograde and anterograde forms may be referred to as PTA, or the term may be used to refer only to anterograde amnesia. A common example in sports concussion is the quarterback who was able to conduct the complicated mental tasks of leading a football team after a concussion, but has no recollection the next day of the part of the game that took place after the injury. Retrograde amnesia sufferers may partially regain memory later, but memories are not regained with anterograde amnesia because they were not encoded properly.

Loss of Consciousness (LOC)
Unconsciousness is a state which occurs when the ability to maintain an awareness of self and environment is lost. It involves a complete or near-complete lack of responsiveness to people and other environmental stimuli. Loss of consciousness should not be confused with the notion of the psychoanalytic unconscious or cognitive processes (e.g., implicit cognition) that take place outside awareness, and with altered states of consciousness, such as delirium (when the person is confused and only partially responsive to the environment), normal sleep, hypnosis, and other altered states in which the person responds to stimuli. Unconsciousness may occur as the result of traumatic brain injury, brain hypoxia (e.g., due to a brain infarction or cardiac arrest), severe poisoning with drugs that depress the activity of the central nervous system (e.g., alcohol and other hypnotic or sedative drugs), severe fatigue, anaesthesia, and other causes.

Signs and Symptoms

Symptoms are dependent on the type of TBI (diffuse or focal) and the part of the brain that is affected. Unconsciousness tends to last longer for people with injuries on the left side of the brain than for those with injuries on the right. Symptoms are also dependent on the injury's severity. With mild TBI, the patient may remain conscious or may lose consciousness for a few seconds or minutes. Other symptoms of mild TBI include headache, vomiting, nausea, lack of motor coordination, dizziness, difficulty balancing, lightheadedness, blurred vision or tired eyes, ringing in the ears, bad taste in the mouth, fatigue or lethargy, and changes in sleep patterns. Cognitive and emotional symptoms include behavioural or mood changes, confusion, and trouble with memory, concentration, attention, or thinking. Mild TBI symptoms may also be present in moderate and severe injuries. A person with a moderate or severe TBI may have a headache that does not go away, repeated vomiting or nausea, convulsions, an inability to awaken, dilation of one or both pupils, slurred speech, aphasia (word-finding difficulties), dysarthria (muscle weakness that causes disordered speech), weakness or numbness in the limbs, loss of coordination, confusion, restlessness, or agitation. Common long-term symptoms of moderate to severe TBI are changes in appropriate social behaviour, deficits in social judgment, and cognitive changes, especially problems with sustained attention, processing speed, and executive functioning. Alexithymia, a deficiency in identifying, understanding, processing, and describing emotions occurs in 60.9% of individuals with TBI.

Cognitive and social deficits have long-term consequences for the daily lives of people with moderate to severe TBI, but can be improved with appropriate rehabilitation. When the pressure within the skull (intracranial pressure, abbreviated ICP) rises too high, it can be deadly. Signs of increased ICP include decreasing level of consciousness, paralysis or weakness on one side of the body, and a blown pupil, one that fails to constrict in response to light or is slow to do so. Cushing's triad, a slow heart rate with high blood pressure and respiratory depression is a classic manifestation of significantly raised ICP. Anisocoria, unequal pupil size, is another sign of serious TBI. Abnormal posturing, a characteristic positioning of the limbs caused by severe diffuse injury or high ICP, is an ominous sign. Small children with moderate to severe TBI may have some of these symptoms but have difficulty communicating them. Other signs seen in young children include persistent crying, inability to be consoled, listlessness, refusal to nurse or eat, and irritability.

Causes
The most common causes of TBI in the U.S. include violence, transportation accidents, construction, and sports. Motor bikes are major causes, increasing in significance in developing countries as other causes reduce. The estimates that between 1.6 and 3.8 million traumatic brain injuries each year are a result of sports and recreation activities in the US. In children aged two to four, falls are the most common cause of TBI, while in older children traffic accidents compete with falls for this position. TBI is the third most common injury to result from child abuse. Abuse causes 19% of cases of paediatric brain trauma, and the death rate is higher among these cases. Although men are twice as likely to have a TBI. Domestic violence is another cause of TBI, as are work-related and industrial accidents. Firearms and blast injuries from explosions are other causes of TBI, which is the leading cause of death and disability in war zones. According to Representative Bill Pascrell (Democrat, NJ), TBI is "the signature injury of the wars in Iraq and Afghanistan." There is a promising technology called activation database-guided EEG biofeedback, which has been documented to return a TBI's auditory memory ability to above the control group's performance.

Treatment

It is important to begin emergency treatment within the so-called "golden hour" following the injury. People with moderate to severe injuries are likely to receive treatment in an intensive care unit followed by a neurosurgical ward. Treatment depends on the recovery stage of the patient. In the acute stage the primary aim of the medical personnel is to stabilize the patient and focus on preventing further injury because little can be done to reverse the initial damage caused by trauma. Rehabilitation is the main treatment for the subacute and chronic stages of recovery. International clinical guidelines have been proposed with the aim of guiding decisions in TBI treatment, as defined by an authoritative examination of current evidence.

Treatment Acute Stage

Certain facilities are equipped to handle TBI better than others; initial measures include transporting patients to an appropriate treatment centre. Both during transport and in hospital the primary concerns are ensuring proper oxygen supply, maintaining adequate blood flow to the brain, and controlling raised intracranial pressure (ICP), since high ICP deprives the brain of badly needed blood flow and can cause deadly brain herniation. Other methods to prevent damage include management of other injuries and prevention of seizures.

Some data supports the use of hyperbaric oxygen therapy to improve outcomes. Neuroimaging is helpful but not flawless in detecting raised ICP. A more accurate way to measure ICP is to place a catheter into a ventricle of the brain, which has the added benefit of allowing cerebrospinal fluid to drain, releasing pressure in the skull. Treatment of raised ICP may be as simple as tilting the person's bed and straightening the head to promote blood flow through the veins of the neck.

Sedatives, analgesics and paralytic agents are often used. Hypertonic saline can improve ICP by reducing the amount of cerebral water (swelling), though it is used with caution to avoid electrolyte imbalances or heart failure. Mannitol, an osmotic diuretic, appears to be equally effective at reducing ICP. Some concerns; however, have been raised regarding some of the studies performed.

Diuretics, drugs that increase urine output to reduce excessive fluid in the system, may be used to treat high intracranial pressures, but may cause hypovolemia (insufficient blood volume). Hyperventilation (larger and/or faster breaths) reduces carbon dioxide levels and causes blood vessels to constrict; this decreases blood flow to the brain and reduces ICP, but it potentially causes ischemia and is, therefore, used only in the short term. Giving corticosteroids is associated with an increased risk of death, and so their routine use is not recommended.

Endotracheal intubation and mechanical ventilation may be used to ensure proper oxygen supply and provide a secure airway. Hypotension (low blood pressure), which has a devastating outcome in TBI, can be prevented by giving intravenous fluids to maintain a normal blood pressure. Failing to maintain blood pressure can result in inadequate blood flow to the brain.

Blood pressure may be kept at an artificially high level under controlled conditions by infusion of norepinephrine or similar drugs; this helps maintain cerebral perfusion. Body temperature is carefully regulated because increased temperature raises the brain's metabolic needs, potentially depriving it of nutrients. Seizures are common. While they can be treated with benzodiazepines, these drugs are used carefully because they can depress breathing and lower blood pressure.

People with TBI are more susceptible to side effects and may react adversely or be inordinately sensitive to some pharmacological agents. During treatment monitoring continues for signs of deterioration such as a decreasing level of consciousness. Traumatic brain injury may cause a range of serious coincidental complications that include cardiac arrhythmias and neurogenic pulmonary edema. These conditions must be adequately treated and stabilised as part of the core care.

Chronic Stage

Once medically stable, people may be transferred to a subacute rehabilitation unit of the medical centre or to an independent rehabilitation hospital. Rehabilitation aims to improve independent function at home and in society and to help adapt to disabilities and has demonstrated its general effectiveness, when conducted by a team of health professionals who specialise in head trauma. As for any person with neurologic deficits, a multidisciplinary approach is key to optimising outcome. Physiatrists or neurologists are likely to be the key medical staff involved, but depending on the person, doctors of other medical specialties may also be helpful.

Allied health professions such as physiotherapy, speech and language therapy, cognitive rehabilitation therapy, and occupational therapy will be essential to assess function and design the rehabilitation activities for each person. Treatment of neuropsychiatric symptoms such as emotional distress and clinical depression may involve mental health professionals such as therapists, psychologists, and psychiatrists, while neuropsychologists can help to evaluate and manage cognitive deficits. After discharge from the inpatient rehabilitation treatment unit, care may be given on an outpatient basis. Community-based rehabilitation will be required for a high proportion of people, including vocational rehabilitation; this supportive employment matches job demands to the worker's abilities.

People with TBI who cannot live independently or with family may require care in supported living facilities such as group homes. Respite care, including day centres and leisure facilities for the disabled, offers time off for caregivers, and activities for people with TBI. Pharmacological treatment can help to manage psychiatric or behavioural problems. Medication is also used to control post-traumatic epilepsy; however the preventive use of anti-epileptics is not recommended. In those cases where the person is bedridden due to a reduction of consciousness, has to remain in a wheelchair because of mobility problems, or has any other problem heavily impacting self-caring capacities, caregiving and nursing are critical.

The most effective research documented intervention approach is the activation database guided EEG biofeedback approach, which has shown significant improvements in memory abilities of the TBI subject that are far superior than traditional approaches (strategies, computers, medication intervention). Gains of 2.61 standard deviations have been documented. The TBI's auditory memory ability was superior to the control group after the treatment.

Prognosis

Prognosis worsens with the severity of injury. Most TBIs are mild and do not cause permanent or long-term disability; however, all severity levels of TBI have the potential to cause significant, long-lasting disability. Permanent disability is thought to occur in 10% of mild injuries, 66% of moderate injuries, and 100% of severe injuries. Most mild TBI is completely resolved within three weeks, and almost all people with mild TBI are able to live independently and return to the jobs they had before the injury, although a portion have mild cognitive and social impairments. Over 90% of people with moderate TBI are able to live independently, although a portion require assistance in areas such as physical abilities, employment, and financial managing.

Most people with severe closed head injury either die or recover enough to live independently; middle ground is less common. Coma, as it is closely related to severity, is a strong predictor of poor outcome. Prognosis differs depending on the severity and location of the lesion, and access to immediate, specialised acute management. Subarachnoid haemorrhage approximately doubles mortality. Subdural hematoma is associated with worse outcome and increased mortality, while people with epidural hematoma are expected to have a good outcome if they receive surgery quickly. Diffuse axonal injury may be associated with coma when severe, and poor outcome.

Following the acute stage, prognosis is strongly influenced by the patient's involvement in activity that promote recovery, which for most patients requires access to a specialised, intensive rehabilitation service. The Functional Independence Measure is a way to track progress and degree of independence throughout rehabilitation. Medical complications are associated with a bad prognosis. Examples are hypotension (low blood pressure), hypoxia (low blood oxygen saturation), lower cerebral perfusion pressures and longer times spent with high intracranial pressures. Patient characteristics also influence prognosis.

Factors thought to worsen it include abuse of substances such as illicit drugs and alcohol and age over sixty or under two years (in children, younger age at time of injury may be associated with a slower recovery of some abilities). Other influences that may affect recovery include pre-injury intellectual ability, coping strategies, personality traits, family environment, social support systems and financial circumstances. Life satisfaction has been known to decrease for individuals with TBI immediately following the trauma, but evidence has shown that life roles, age, and depressive symptoms influence the trajectory of life satisfaction as time passes.

Complications

INJURY Internal Injury Intercranial Injuries Complications

Improvement of neurological function usually occurs for two or more years after the trauma. For many years it was believed that recovery was fastest during the first six months, but there is no evidence to support this. It may be related to services commonly being withdrawn after this period, rather than any physiological limitation to further progress. Children recover better in the immediate time frame and improve for longer periods. Complications are distinct medical problems that may arise as a result of the TBI. The results of traumatic brain injury vary widely in type and duration; they include physical, cognitive, emotional, and behavioural complications. TBI can cause prolonged or permanent effects on consciousness, such as coma, brain death, persistent vegetative state (in which patients are unable to achieve a state of alertness to interact with their surroundings), and minimally conscious state (in which patients show minimal signs of being aware of self or environment).

Lying still for long periods can cause complications including pressure sores, pneumonia or other infections, progressive multiple organ failure, and deep venous thrombosis, which can cause pulmonary embolism. Infections that can follow skull fractures and penetrating injuries include meningitis and abscesses. Complications involving the blood vessels include vasospasm, in which vessels constrict and restrict blood flow, the formation of aneurysms, in which the side of a vessel weakens and balloons out, and stroke.
Movement disorders that may develop after TBI include tremor, ataxia (uncoordinated muscle movements), myoclonus (shock-like contractions of muscles), and loss of movement range and control (in particular with a loss of movement repertoire). The risk of post-traumatic seizures increases with severity of trauma (image at right) and is particularly elevated with certain types of brain trauma such as cerebral contusions or hematomas.

People with early seizures, those occurring within a week of injury, have an increased risk of post-traumatic epilepsy (recurrent seizures occurring more than a week after the initial trauma). People may lose or experience altered vision, hearing, or smell. Hormonal disturbances may occur secondary to hypopituitarism, occurring immediately or years after injury in 10 to 15% of TBI patients. Development of diabetes insipidus or an electrolyte abnormality acutely after injury indicate need for endocrinologic work up.

Signs and symptoms of hypopituitarism may develop and be screened for in adults with moderate TBI and in mild TBI with imaging abnormalities. Children with moderate to severe head injury may also develop hypopituitarism. Screening should take place 3 to 6 months, and 12 months after injury, but problems may occur more remotely.

Cognitive deficits that can follow TBI include impaired attention; disrupted insight, judgement, and thought; reduced processing speed; distractibility; and deficits in executive functions such as abstract reasoning, planning, problem-solving, and multitasking. Memory loss, the most common cognitive impairment among head-injured people, occurs in 20–79% of people with closed head trauma, depending on severity.

People who have suffered TBI may also have difficulty with understanding or producing spoken or written language, or with more subtle aspects of communication such as body language. Post-concussion syndrome, a set of lasting symptoms experienced after mild TBI, can include physical, cognitive, emotional and behavioral problems such as headaches, dizziness, difficulty concentrating, and depression. Multiple TBIs may have a cumulative effect.

A young person who receives a second concussion before symptoms from another one have healed may be at risk for developing a very rare but deadly condition called second-impact syndrome, in which the brain swells catastrophically after even a mild blow, with debilitating or deadly results. About one in five career boxers is affected by chronic traumatic brain injury (CTBI), which causes cognitive, behavioral, and physical impairments. Dementia pugilistica, the severe form of CTBI, affects primarily career boxers years after a boxing career. It commonly manifests as dementia, memory problems, and parkinsonism (tremors and lack of coordination).

TBI may cause emotional, social, or behavioral problems and changes in personality. These may include emotional instability, depression, anxiety, hypomania, mania, apathy, irritability, problems with social judgment, and impaired conversational skills. TBI appears to predispose survivors to psychiatric disorders including obsessive compulsive disorder, substance abuse, dysthymia, clinical depression, bipolar disorder, and anxiety disorders. In patients who have depression after TBI, suicidal ideation is not uncommon; the suicide rate among these persons is increased 2- to 3-fold.

Social and behavioral symptoms that can follow TBI include disinhibition, inability to control anger, impulsiveness, lack of initiative, inappropriate sexual activity, asociality and social withdrawal, and changes in personality. TBI also has a substantial impact on the functioning of family systems Caregiving family members and TBI survivors often significantly alter their familial roles and responsibilities following injury, creating significant change and strain on a family system.

Typical challenges identified by families recovering from TBI include: frustration and impatience with one another, loss of former lives and relationships, difficulty setting reasonable goals, inability to effectively solve problems as a family, increased level of stress and household tension, changes in emotional dynamics, and overwhelming desire to return to pre-injury status. In addition, families may exhibit less effective functioning in areas including coping, problem solving and communication. Psychoeducation and counseling models have been demonstrated to be effective in minimizing family disruption.

INJURY Internal Injury Cerebral Hemorrhage

4 Cerebral Hemorrhage

Intracerebral hemorrhage (ICH), also known as cerebral bleed, is a type of intracranial bleed that occurs within the brain tissue or ventricles. Symptoms can include headache, one-sided weakness, vomiting, seizures, decreased level of consciousness, and neck stiffness. Often symptoms get worse over time. Fever is also common. In many cases bleeding is present in both the brain tissue and the ventricles. Causes include brain trauma, aneurysms, arteriovenous malformations, and brain tumors.

The largest risk factors for spontaneous bleeding are high blood pressure and amyloidosis. Other risk factors include alcoholism, low cholesterol, blood thinners, and cocaine use. Diagnosis is typically by CT scan. Other conditions that may present similarly include ischemic stroke. Treatment should typically be carried out in an intensive care unit. Guidelines recommended decreasing the blood pressure to a systolic of 140 mmHg. Blood thinners should be reversed if possible and blood sugar kept in the normal range Surgery to place a ventricular drain may be used to treat hydrocephalus but corticosteroids should not be used.

Signs & Symptoms
People with intracerebral bleeding have symptoms that correspond to the functions controlled by the area of the brain that is damaged by the bleed. Other symptoms include those that indicate a rise in intracranial pressure caused by a large mass putting pressure on the brain. Intracerebral bleeds are often misdiagnosed as subarachnoid hemorrhages due to the similarity in symptoms and signs. A severe headache followed by vomiting is one of the more common symptoms of intracerebral hemorrhage. Another common symptom is a patient can collapse. Some people may experience continuous bleeding from the ear. Some patients may also go into a coma before the bleed is noticed.

Causes
Intracerebral bleeds are the second most common cause of stroke, accounting for 10% of hospital admissions for stroke. High blood pressure raises the risks of spontaneous intracerebral hemorrhage by two to six times. More common in adults than in children, intraparenchymal bleeds are usually due to penetrating head trauma, but can also be due to depressed skull fractures. Acceleration-deceleration trauma, rupture of an aneurysm or arteriovenous malformation (AVM), and bleeding within a tumor are additional causes. Amyloid angiopathy is a not uncommon cause of intracerebral hemorrhage in patients over the age of 55. A very small proportion is due to cerebral venous sinus thrombosis. Traumautic intracerebral hematomas are divided into acute and delayed. Acute intracerebral hematomas occur at the time of the injury while delayed intracerebral hematomas have been reported from as early as 6 hours post injury to as long as several weeks.

Risk factors for ICH
- Hypertension (high blood pressure)
- Diabetes mellitus
- Menopause
- Cigarette smoking
- Excessive alcohol consumption
- Severe migraine

Treatment Treatment depends substantially on the type of ICH. Rapid CT scan and other diagnostic measures are used to determine proper treatment, which may include both medication and surgery.	● Tracheal intubation is indicated in people with decreased level of consciousness or other risk of airway obstruction. ● IV fluids are given to maintain fluid balance, using isotonic rather than hypotonic fluids. ● Frozen plasma, vitamin K, protamine, or platelet transfusions may be given in case of a coagulopathy. Platelets however appear to worsen outcomes in those with spontaneous intracerebral bleeding on antiplatelet medication.	Surgery is required if the hematoma is greater than 3 cm (1 in), if there is a structural vascular lesion or lobar hemorrhage in a young patient.	● A catheter may be passed into the brain vasculature to close off or dilate blood vessels, avoiding invasive surgical procedures. ● A craniectomy may take place, where part of the skull is removed to allow a swelling brain room to expand without being squeezed.

Prognosis
The risk of death from an intraparenchymal bleed in traumatic brain injury is especially high when the injury occurs in the brain stem. Intraparenchymal bleeds within the medulla oblongata are almost always fatal, because they cause damage to cranial nerve X, the vagus nerve, which plays an important role in blood circulation and breathing. This kind of hemorrhage can also occur in the cortex or subcortical areas, usually in the frontal or temporal lobes when due to head injury, and sometimes in the cerebellum. For spontaneous ICH seen on CT scan, the death rate (mortality) is 34–50% by 30 days after the insult, and half of the deaths occur in the first 2 days. Even though the majority of deaths occurs in the first days after ICH, survivors have a long term excess mortality of 27% compared to the general population.

5 Spinal Cord Injury

A spinal cord injury (SCI) is damage to the spinal cord that causes temporary or permanent changes in its function. Symptoms may include loss of muscle function, sensation, or autonomic function in the parts of the body served by the spinal cord below the level of the injury. Injury can occur at any level of the spinal cord and can be complete injury, with a total loss of sensation and muscle function, or incomplete, meaning some nervous signals are able to travel past the injured area of the cord. Depending on the location and severity of damage, the symptoms vary, from numbness to paralysis to incontinence. Long term outcomes also range widely, from full recovery to permanent tetraplegia (also called quadriplegia) or paraplegia. Complications can include muscle atrophy, pressure sores, infections, and breathing problems.

In the majority of cases the damage results from physical trauma such as car accidents, gunshot wounds, falls, or sports injuries, but it can also result from nontraumatic causes such as infection, insufficient blood flow, and tumors. Just over half of injuries affect the cervical spine, while 15% occur in each of the thoracic spine, border between the thoracic and lumbar spine, and lumbar spine alone. Diagnosis is typically based on symptoms and medical imaging.

Efforts to prevent SCI include individual measures such as using safety equipment, societal measures such as safety regulations in sports and traffic, and improvements to equipment. Treatment starts with restricting further motion of the spine and maintaining adequate blood pressure. Corticosteroids have not been found to be useful. Other interventions vary depending on the location and extent of the injury, from bed rest to surgery. In many cases, spinal cord injuries require long-term physical and occupational therapy, especially if it interferes with activities of daily living.

Types

Spinal cord injury can be traumatic or nontraumatic, and can be classified into three types based on cause: mechanical forces, toxic, and ischemic (from lack of blood flow). The damage can also be divided into primary and secondary injury: the cell death that occurs immediately in the original injury, and biochemical cascades that are initiated by the original insult and cause further tissue damage. These secondary injury pathways include the ischemic cascade, inflammation, swelling, cell suicide, and neurotransmitter imbalances. They can take place for minutes or weeks following the injury.

At each level of the spinal column, spinal nerves branch off from either side of the spinal cord and exit between a pair of vertebrae, to innervate a specific part of the body. The area of skin innervated by a specific spinal nerve is called a dermatome, and the group of muscles innervated by a single spinal nerve is called a myotome. The part of the spinal cord that was damaged corresponds to the spinal nerves at that level and below. Injuries can be cervical 1–8 (C1–C8), thoracic 1–12 (T1–T12), lumbar 1–5 (L1–L5), or sacral (S1–S5). A person's level of injury is defined as the lowest level of full sensation and function. Paraplegia occurs when the legs are affected by the spinal cord damage (in thoracic, lumbar, or sacral injuries), and tetraplegia occurs when all four limbs are affected (cervical damage).

Muscle Strength		ASIA Impairment Scale for classifying spinal cord injury	
Grade	**Muscle function**	**Grade**	**Description**
0	No muscle contraction	**A**	**Complete injury.** No motor or sensory function is preserved in the sacral segments S4 or S5.
1	Muscle flickers	**B**	**Sensory incomplete.** Sensory but not motor function is preserved below the level of injury, including the sacral segments.
2	Full range of motion, gravity eliminated	**C**	**Motor incomplete.** Motor function is preserved below the level of injury, and more than half of muscles tested below the level of injury have a muscle grade less than 3 (see muscle strength scores, left).
3	Full range of motion, against gravity	**D**	**Motor incomplete.** Motor function is preserved below the level of injury and at least half of the key muscles below the neurological level have a muscle grade of 3 or more.
4	Full range of motion against resistance	**E**	**Normal.** No motor or sensory deficits, but deficits existed in the past.
5	Normal strength		

Complete and Incomplete Injuries
In a "complete" spinal injury, all functions below the injured area are lost, whether or not the spinal cord is severed. An "incomplete" spinal cord injury involves preservation of motor or sensory function below the level of injury in the spinal cord. To be classed as incomplete, there must be some preservation of sensation or motion in the areas innervated by S4 to S5, e.g. voluntary external anal sphincter contraction. The nerves in this area are connected to the very lowest region of the spinal cord, and retaining sensation and function in these parts of the body indicates that the spinal cord is only partially damaged.

Incomplete injury by definition includes a phenomenon known as sacral sparing: some degree of sensation is preserved in the sacral dermatomes, even though sensation may be more impaired in other, higher dermatomes below the level of the lesion. Sacral sparing has been attributed to the fact that the sacral spinal pathways are not as likely as the other spinal pathways to become compressed after injury due to the lamination of fibers within the spinal cord.

Signs & Symptoms

Signs (observed by a clinician) and symptoms (experienced by a patient) vary depending on where the spine is injured and the extent of the injury. A section of skin innervated through a specific part of the spine is called a dermatome, and injury to that part of the spine can cause pain, numbness, or a loss of sensation in the related areas. Paraesthesia, a tingling or burning sensation in affected areas of the skin, is another symptom. A person with a lowered level of consciousness may show a response to a painful stimulus above a certain point but not below it. A group of muscles innervated through a specific part of the spine is called a myotome, and injury to that part of the spinal cord can cause problems with movements that involve those muscles. The muscles may contract uncontrollably (spasticity), become weak, or be completely paralysed. Spinal shock, loss of neural activity including reflexes below the level of injury, occurs shortly after the injury and usually goes away within a day. Priapism, an erection of the penis may be a sign of acute spinal cord injury.

The specific parts of the body affected by loss of function are determined by the level of injury. Some signs, such as bowel and bladder dysfunction can occur at any level. Neurogenic bladder involves a compromised ability to empty the bladder and is a common symptom of spinal cord injury. This can lead to high pressures in the bladder that can damage the kidneys.

Actions of the Spinal Nerves

Level	Motor Function
C1-C6	Neck flexors
C1-T1	Neck extensors
C3, C4, C5	Supply diaphragm (mostly C4)
C5, C6	Move shoulder, raise arm (deltoid); flex elbow (biceps)
C6	Externally rotate (supinate) the arm
C6, C7	Extend elbow and wrist (triceps and wrist extensors); pronate wrist
C7, T1	Flex wrist; supply small muscles of the hand
T1-T6	Intercostals and trunk above the waist
T7-L1	Abdominal muscles
L1-L4	Flex thigh
L2, L3, L4	Adduct thigh; Extend leg at the knee (quadriceps femoris)
L4, L5, S1	Abduct thigh; Flex leg at the knee (hamstrings); Dorsiflex foot (tibialis anterior); Extend toes
L5, S1, S2	Extend leg at the hip (gluteus maximus); Plantar flex foot and flex toes

Lumbosacral
The effects of injuries at or above the lumbar or sacral regions of the spinal cord (lower back and pelvis) include decreased control of the legs and hips, genitourinary system, and anus. People injured below level L2 may still have use of their hip flexor and knee extensor muscles. Bowel and bladder function are regulated by the sacral region. It is common to experience sexual dysfunction after injury, as well as dysfunction of the bowel and bladder, including fecal and urinary incontinence.

Thoracic
In addition to the problems found in lower-level injuries, thoracic (chest height) spinal lesions can affect the muscles in the trunk. Injuries at the level of T1 to T8 result in inability to control the abdominal muscles. Trunk stability may be affected; even more so in higher level injuries. The lower the level of injury, the less extensive its effects. Injuries from T9 to T12 result in partial loss of trunk and abdominal muscle control. Thoracic spinal injuries result in paraplegia, but function of the hands, arms, and neck are not affected.

One condition that occurs typically in lesions above the T6 level is autonomic dysreflexia (AD), in which the blood pressure increases to dangerous levels, high enough to cause potentially deadly stroke. It results from an overreaction of the system to a stimulus such as pain below the level of injury, because inhibitory signals from the brain cannot pass the lesion to dampen the excitatory sympathetic nervous system response. Signs and symptoms of AD include anxiety, headache, nausea, ringing in the ears, blurred vision, flushed skin, and nasal congestion. It can occur shortly after the injury or not until years later.

Other autonomic functions may also be disrupted. For example, problems with body temperature regulation mostly occur in injuries at T8 and above. Another serious complication that can result from lesions above T6 is neurogenic shock, which results from an interruption in output from the sympathetic nervous system responsible for maintaining muscle tone in the blood vessels. Without the sympathetic input, the vessels relax and dilate. Neurogenic shock presents with dangerously low blood pressure, low heart rate, and blood pooling in the limbs—which results in insufficient blood flow to the spinal cord and potentially further damage to it.

Cervical
Spinal cord injuries at the cervical (neck) level result in full or partial tetraplegia (also called quadriplegia). Depending on the specific location and severity of trauma, limited function may be retained. Additional symptoms of cervical injuries include low heart rate, low blood pressure, problems regulating body temperature, and breathing dysfunction. If the injury is high enough in the neck to impair the muscles involved in breathing, the person may not be able to breathe without the help of an endotracheal tube and mechanical ventilator.

Function after Complete Cervical Spinal Cord Injury

Level	Motor Function	Respiratory Function
C1-C4	Full paralysis of the limbs	Cannot breathe without mechanical ventilation
C5	Paralysis of the wrists, hands, and triceps	Difficulty coughing, may need help clearing secretions
C6	Paralysis of the wrist flexors, triceps, and hands	Difficulty coughing, may need help clearing secretions
C7-C8	Some hand muscle weakness, difficulty grasping and releasing	Difficulty coughing, may need help clearing secretions

Complications of spinal cord injuries include pulmonary edema, respiratory failure, neurogenic shock, and paralysis below the injury site. In the long term, the loss of muscle function can have additional effects from disuse, including atrophy of the muscle. Immobility can lead to pressure sores, particularly in bony areas, requiring precautions such as extra cushioning and turning in bed every two hours (in the acute setting) to relieve pressure.

In the long term, people in wheelchairs must shift periodically to relieve pressure. Another complication is pain, including nociceptive pain (indication of potential or actual tissue damage) and neuropathic pain, when nerves affected by damage convey erroneous pain signals in the absence of noxious stimuli.

Spasticity, the uncontrollable tensing of muscles below the level of injury, occurs in 65–78% of chronic SCI. It results from lack of input from the brain that quells muscle responses to stretch reflexes. It can be treated with drugs and physical therapy. Spasticity increases the risk of contractures (shortening of muscles, tendons, or ligaments that result from lack of use of a limb); this problem can be prevented by moving the limb through its full range of motion multiple times a day.

Another problem lack of mobility can cause is loss of bone density and changes in bone structure. Loss of bone density (bone demineralization), thought to be due to lack of input from weakened or paralysed muscles, can increase the risk of fractures. Conversely, a poorly understood phenomenon is the overgrowth of bone tissue in soft tissue areas, called heterotopic ossification. It occurs below the level of injury, possibly as a result of inflammation, and happens to a clinically significant extent in 27% of people.

Causes

Spinal cord injuries are most often caused by physical trauma. Forces involved can be hyperflexion (forward movement of the head); hyperextension (backward movement); lateral stress (sideways movement); rotation (twisting of the head); compression (force along the axis of the spine downward from the head or upward from the pelvis); or distraction (pulling apart of the vertebrae). Traumatic SCI can result in contusion, compression, or stretch injury. It is a major risk of many types of vertebral fracture. Pre-existing asymptomatic congenital anomalies can cause major neurological deficits, such as hemiparesis, to result from otherwise minor trauma.

In the US, Motor vehicle accidents are the most common cause of SCIs; second are falls, then violence such as gunshot wounds, then sports injuries. In some countries falls are more common, even surpassing vehicle crashes as the leading cause of SCI. The rates of violence-related SCI depend heavily on place and time. Of all sports-related SCIs, shallow water dives are the most common cause; winter sports and water sports have been increasing as causes while association football and trampoline injuries have been declining. Hanging can cause injury to the cervical spine, as may occur in attempted suicide. Military conflicts are another cause, and when they occur they are associated with increased rates of SCI. Another potential cause of SCI is iatrogenic injury, caused by an improperly done medical procedure such as an injection into the spinal column.

SCI can also be of a nontraumatic origin. Nontraumatic lesions cause anywhere from 30 to 80% of all SCI; the percentage varies by locale, influenced by efforts to prevent trauma. Developed countries have higher percentages of SCI due to degenerative conditions and tumors than developing countries. In developed countries, the most common cause of nontraumatic SCI is degenerative diseases, followed by tumors; in many developing countries the leading cause is infection such as HIV and tuberculosis. SCI may occur in intervertebral disc disease, and spinal cord vascular disease. Spontaneous bleeding can occur within or outside of the protective membranes that line the cord, and intervertebral disks can herniate.

Damage can result from dysfunction of the blood vessels, as in arteriovenous malformation, or when a blood clot becomes lodged in a blood vessel and cuts off blood supply to the cord. When systemic blood pressure drops, blood flow to the spinal cord may be reduced, potentially causing a loss of sensation and voluntary movement in the areas supplied by the affected level of the spinal cord. Congenital conditions and tumors that compress the cord can also cause SCI, as can vertebral spondylosis and ischemia. Multiple sclerosis is a disease that can damage the spinal cord, as can infectious or inflammatory conditions such as tuberculosis, herpes zoster or herpes simplex, meningitis, myelitis, and syphilis.

Management

Prehospital Treatment
The first stage in the management of a suspected spinal cord injury is geared toward basic life support and preventing further injury: maintaining airway, breathing, and circulation and restricting further motion of the spine. In the emergency setting, most people who has been subjected to forces strong enough to cause SCI are treated as though they have instability in the spinal column and have spinal motion restricted to prevent damage to the spinal cord. Injuries or fractures in the head, neck, or pelvis as well as penetrating trauma near the spine and falls from heights are assumed to be associated with an unstable spinal column until it is ruled out in the hospital. High-speed vehicle crashes, sports injuries involving the head or neck, and diving injuries are other mechanisms that indicate a high SCI risk. Since head and spinal trauma frequently coexist, anyone who is unconscious or has a lowered level of consciousness as a result of a head injury is spinal motion restricted.

A rigid cervical collar is applied to the neck, and the head is held with blocks on either side and the person is strapped to a backboard. Extrication devices are used to move people without excessively moving the spine if they are still inside a vehicle or other confined space. The use of a cervical collar has been shown to increase mortality in people with penetrating trauma and is thus not routinely recommended in this group.

Modern trauma care includes a step called clearing the cervical spine, ruling out spinal cord injury if the patient is fully conscious and not under the influence of drugs or alcohol, displays no neurological deficits, has no pain in the middle of the neck and no other painful injuries that could distract from neck pain. If these are all absent, no spinal motion restriction is necessary.

If an unstable spinal column injury is moved, damage may occur to the spinal cord. Between 3 and 25% of SCIs occur not at the time of the initial trauma but later during treatment or transport. While some of this is due to the nature of the injury itself, particularly in the case of multiple or massive trauma, some of it reflects the failure to adequately restrict motion of the spine. SCI can impair the body's ability to keep warm, so warming blankets may be needed.

Early Hospital Treatment
Initial care in the hospital, as in the prehospital setting, aims to ensure adequate airway, breathing, cardiovascular function, and spinal motion restriction. Imaging of the spine to determine the presence of a SCI may need to wait if emergency surgery is needed to stabilize other life-threatening injuries. Acute SCI merits treatment in an intensive care unit, especially injuries to the cervical spinal cord. People with SCI need repeated neurological assessments and treatment by neurosurgeons. People should be removed from the spine board as rapidly as possible to prevent complications from its use.

If the systolic blood pressure falls below 90 mmHg within days of the injury, blood supply to the spinal cord may be reduced, resulting in further damage. Thus it is important to maintain the blood pressure which may be done using intravenous fluids and vasopressors. Vasopressors used include phenylephrine, dopamine, or norepinephrine. Mean arterial blood pressure is measured and kept at 85 to 90 mmHg for seven days after injury. The treatment for shock from blood loss is different from that for neurogenic shock, and could harm people with the latter type, so it is necessary to determine why someone is in shock.

However it is also possible for both causes to exist at the same time. Another important aspect of care is prevention of insufficient oxygen in the bloodstream, which could deprive the spinal cord of oxygen. People with cervical or high thoracic injuries may experience a dangerously slowed heart rate; treatment to speed it may include atropine.

The corticosteroid medication methylprednisolone has been studied for use in SCI with the hope of limiting swelling and secondary injury. As there does not appear to be long term benefits and the medication is associated with risks such as gastrointestinal bleeding and infection its use is not recommended as of 2018. Its use in traumatic brain injury is also not recommended.

Surgery may be necessary, e.g. to relieve excess pressure on the cord, to stabilize the spine, or to put vertebrae back in their proper place. In cases involving instability or compression, failing to operate can lead to worsening of the condition. Surgery is also necessary when something is pressing on the cord, such as bone fragments, blood, material from ligaments or intervertebral discs, or a lodged object from a penetrating injury.

Although the ideal timing of surgery is still debated, studies have found that earlier surgical intervention (within 24 hours of injury) is associated with better outcomes. Sometimes a patient has too many other injuries to be a surgical candidate this early. Surgery is controversial because it has potential complications (such as infection), so in cases where it is not clearly needed (e.g. the cord is being compressed), doctors must decide whether to perform surgery based on aspects of the patient's condition and their own beliefs about its risks and benefits.

In cases where a more conservative approach is chosen, bed rest, cervical collars, motion restriction devices, and optionally traction are used. Surgeons may opt to put traction on the spine to remove pressure from the spinal cord by putting dislocated vertebrae back into alignment, but herniation of intervertebral disks may prevent this technique from relieving pressure.

Prognosis

Spinal cord injuries generally result in at least some incurable impairment even with the best possible treatment. The best predictor of prognosis is the level and completeness of injury, as measured by the ASIA impairment scale. The neurological score at the initial evaluation done 72 hours after injury is the best predictor of how much function will return. Most people with ASIA scores of A (complete injuries) do not have functional motor recovery, but improvement can occur. Most patients with incomplete injuries recover at least some function. Chances of recovering the ability to walk improve with each AIS grade found at the initial examination; e.g. an ASIA D score confers a better chance of walking than a score of C. The symptoms of incomplete injuries can vary and it is difficult to make an accurate prediction of the outcome. A person with a mild, incomplete injury at the T5 vertebra will have a much better chance of using his or her legs than a person with a severe, complete injury at exactly the same place. Of the incomplete SCI syndromes, Brown-Séquard and central cord syndromes have the best prognosis for recovery and anterior cord syndrome has the worst.

People with nontraumatic causes of SCI have been found to be less likely to suffer complete injuries and some complications such as pressure sores and deep vein thrombosis, and to have shorter hospital stays. Their scores on functional tests were better than those of people with traumatic SCI upon hospital admission, but when they were tested upon discharge, those with traumatic SCI had improved such that both groups' results were the same. In addition to the completeness and level of the injury, age and concurrent health problems affect the extent to which a person with SCI will be able to live independently and to walk. However, in general people with injuries to L3 or below will likely be able to walk functionally, T10 and below to walk around the house with bracing, and C7 and below to live independently. New therapies are beginning to provide hope for better outcomes in patients with SCI, but most are in the experimental/translational stage.

One important predictor of motor recovery in an area is presence of sensation there, particularly pain perception. Most motor recovery occurs in the first year post-injury, but modest improvements can continue for years; sensory recovery is more limited. Recovery is typically quickest during the first six months. Spinal shock, in which reflexes are suppressed, occurs immediately after the injury and resolves largely within three months but continues resolving gradually for another 15.

Sexual dysfunction after spinal injury is common. Problems that can occur include erectile dysfunction, loss of ability to ejaculate, insufficient lubrication of the vagina, and reduced sensation and impaired ability to orgasm. Despite this, many people learn ways to adapt their sexual practices so they can lead satisfying sex lives.

Although life expectancy has improved with better care options, it is still not as good as the uninjured population. The higher the level of injury, and the more complete the injury, the greater the reduction in life expectancy. Mortality is very elevated within a year of injury.

6 Nerve Injury (Except Spinal)

Nerve injury is injury to nervous tissue. There is no single classification system that can describe all the many variations of nerve injury.

Types

Neurapraxia
Neurapraxia is the least severe form of nerve injury, with complete recovery. In this case, the axon remains intact, but there is myelin damage causing an interruption in conduction of the impulse down the nerve fiber. Most commonly, this involves compression of the nerve or disruption to the blood supply (ischemia). There is a temporary loss of function which is reversible within hours to months of the injury (the average is 6–8 weeks). Wallerian degeneration does not occur, so recovery does not involve actual regeneration. There is frequently greater involvement of motor than sensory function with autonomic function being retained. In electrodiagnostic testing with nerve conduction studies, there is a normal compound motor action potential amplitude distal to the lesion at day 10, and this indicates a diagnosis of mild neurapraxia instead of axonotmesis or neurotmesis.

Axonotmesis
This is a more severe nerve injury with disruption of the neuronal axon, but with maintenance of the epineurium. This type of nerve damage may cause paralysis of the motor, sensory, and autonomic. Mainly seen in crush injury. If the force creating the nerve damage is removed in a timely fashion, the axon may regenerate, leading to recovery. Electrically, the nerve shows rapid and complete degeneration, with loss of voluntary motor units. Regeneration of the motor end plates will occur, as long as the endoneural tubules are intact.

Axonotmesis involves the interruption of the axon and its covering of myelin but preservation of the connective tissue framework of the nerve (the encapsulating tissue, the epineurium and perineurium, are preserved). Because axonal continuity is lost, Wallerian degeneration occurs. Electromyography (EMG) performed 2 to 4 weeks later shows fibrillations and denervation potentials in musculature distal to the injury site. Loss in both motor and sensory spines is more complete with axonotmesis than with neurapraxia, and recovery occurs only through regenerations of the axons, a process requiring time. Axonotmesis is usually the result of a more severe crush or contusion than neurapraxia, but can also occur when the nerve is stretched (without damage to the epineurium).

There is usually an element of retrograde proximal degeneration of the axon, and for regeneration to occur, this loss must first be overcome. The regeneration fibers must cross the injury site and regeneration through the proximal or retrograde area of degeneration may require several weeks. Then the neuritis tip progresses down the distal site, such as the wrist or hand. Proximal lesion may grow distally as fast as 2 to 3 mm per day and distal lesion as slowly as 1.5 mm per day. Regeneration occurs over weeks to years.

Neurotmesis
Neurotmesis is the most severe lesion with no potential of full recovery. It occurs on severe contusion, stretch, or laceration. The axon and encapsulating connective tissue lose their continuity. The last (extreme) degree of neurotmesis is transsection, but most neurotmetic injuries do not produce gross loss of continuity of the nerve but rather internal disruption of the architecture of the nerve sufficient to involve perineurium and endoneurium as well as axons and their covering. Denervation changes recorded by EMG are the same as those seen with axonotmetic injury. There is a complete loss of motor, sensory and autonomic function. If the nerve has been completely divided, axonal regeneration causes a neuroma to form in the proximal stump. For neurotmesis, it is better to use a new more complete classification called the Sunderland System.

7 Traumatic Injury

Traumatic Injury to Muscle, Tendons, Ligaments, Joints

8 Bone Fracture

A bone fracture (sometimes abbreviated FRX or Fx, Fx, or #) is a medical condition in which there is a partial or complete break in the continuity of the bone. In more severe cases, the bone may be broken into several pieces. A bone fracture may be the result of high force impact or stress, or a minimal trauma injury as a result of certain medical conditions that weaken the bones, such as osteoporosis, osteopenia, bone cancer, or osteogenesis imperfecta, where the fracture is then properly termed a pathologic fracture.

Signs & Symptoms

Although bone tissue itself contains no nociceptors, bone fracture is painful for several reasons:
- Breaking in the continuity of the periosteum, with or without similar discontinuity in endosteum, as both contain multiple pain receptors.
- Edema and hematoma of nearby soft tissues caused by ruptured bone marrow evokes pressure pain.
- Involuntary muscle spasms trying to hold bone fragments in place.

Damage to adjacent structures such as nerves, muscles or blood vessels, spinal cord, and nerve roots (for spine fractures), or cranial contents (for skull fractures) may cause other specific signs and symptoms.

INJURY | Internal Injury | Bone Fracture | Signs & Symptoms

Complications
Some fractures may lead to serious complications including a condition known as compartment syndrome. If not treated, eventually, compartment syndrome may require amputation of the affected limb. Other complications may include non-union, where the fractured bone fails to heal or mal-union, where the fractured bone heals in a deformed manner. One form of malunion is the malrotation of a bone, which is especially common after femoral and tibial fractures.

Complications of fractures may be classified into three broad groups, depending upon their time of occurrence. These are as follows –
1. Immediate complications – occurs at the time of the fracture.
2. Early complications – occurring in the initial few days after the fracture.
3. Late complications – occurring a long time after the fracture.

Immediate complications	Early complications	Late complications
Systemic ● Hypovolaemic shock	**Systemic** ● Hypovolaemic shock ● ARDS – Adult respiratory distress syndrome ● Fat embolism syndrome ● Deep vein thrombosis ● Pulmonary syndrome ● Aseptic traumatic fever ● Sepsis (in open fracture) ● Crush syndrome	**Imperfect union of the fracture** ● Delayed union ● Non union ● Mal union ● Cross union
Local ● Injury to major vessels ● Injury to muscles and tendons ● Injury to joints ● Injury to viscera	**Local** ● Infection ● Compartment syndrome	**Others** ● Avascular necrosis ● Shortening ● Joint stiffness ● Sudeck's dystrophy ● Osteomyelitis ● Ischaemic contracture ● Myositis ossificans ● Osteoarthritis

Pathophysiology

The natural process of healing a fracture starts when the injured bone and surrounding tissues bleed, forming a fracture hematoma. The blood coagulates to form a blood clot situated between the broken fragments. Within a few days, blood vessels grow into the jelly-like matrix of the blood clot. The new blood vessels bring phagocytes to the area, which gradually removes the non-viable material. The blood vessels also bring fibroblasts in the walls of the vessels and these multiply and produce collagen fibres. In this way, the blood clot is replaced by a matrix of collagen. Collagen's rubbery consistency allows bone fragments to move only a small amount unless severe or persistent force is applied.

At this stage, some of the fibroblasts begin to lay down bone matrix in the form of collagen monomers. These monomers spontaneously assemble to form the bone matrix, for which bone crystals (calcium hydroxyapatite) are deposited in amongst, in the form of insoluble crystals. This mineralization of the collagen matrix stiffens it and transforms it into bone. In fact, bone is a mineralized collagen matrix; if the mineral is dissolved out of bone, it becomes rubbery. Healing bone callus on average is sufficiently mineralized to show up on X-ray within 6 weeks in adults and less in children. This initial "woven" bone does not have the strong mechanical properties of mature bone. By a process of remodelling, the woven bone is replaced by mature "lamellar" bone. The whole process may take up to 18 months, but in adults, the strength of the healing bone is usually 80% of normal by 3 months after the injury.
Several factors may help or hinder the bone healing process. For example, tobacco smoking hinders the process of bone healing, and adequate nutrition (including calcium intake) will help the bone healing process. Weight-bearing stress on bone, after the bone has healed sufficiently to bear the weight, also builds bone strength.

Although there are theoretical concerns about NSAIDs slowing the rate of healing, there is not enough evidence to warrant withholding the use of this type analgesic in simple fractures.

Smokers generally have lower bone density than non-smokers, so they have a much higher risk of fractures. There is also evidence that smoking delays bone healing.

Classification

A bone fracture may be diagnosed based on the history given and the physical examination performed. Radiographic imaging often is performed to confirm the diagnosis. Under certain circumstances, radiographic examination of the nearby joints is indicated in order to exclude dislocations and fracture-dislocations. In situations where projectional radiography alone is insufficient, Computed Tomography (CT) or Magnetic Resonance Imaging (MRI) may be indicated.

In orthopedic medicine, fractures are classified in various ways. Historically they are named after the physician who first described the fracture conditions, however, there are more systematic classifications as well.

They may be divided into stable versus unstable depending on the likelihood that they may shift further.

Mechanism
● Traumatic fracture – a fracture due to sustained trauma. e.g., fractures caused by a fall, road traffic accident, fight, etc.
● Pathologic fracture – a fracture through a bone that has been made weak by some underlying disease is called pathological fracture. e.g., a fracture through a bone weakened by metastasis. Osteoporosis is the most common cause of pathological fracture.
● Periprosthetic fracture – a fracture at the point of mechanical weakness at the end of an implant

Soft-tissue Involvement
● Closed fractures are those in which the overlying skin is intact
● Open/compound fractures involve wounds that communicate with the fracture, or where fracture hematoma is exposed, and may thus expose bone to contamination. Open injuries carry a higher risk of infection.
  ○ Clean fracture
  ○ Contaminated fracture

Displacement
● Non-displaced
● Displaced
  ○ Translated, or ad latus, with sideways displacement.
  ○ Angulated
  ○ Rotated
  ○ Shortened, a reduction in overall bone length when displaced fracture fragments overlap

Fracture Pattern
- Linear fracture: a fracture that is parallel to the bone's long axis
- Transverse fracture: a fracture that is at a right angle to the bone's long axis
- Oblique fracture: a fracture that is diagonal to a bone's long axis (more than 30°)
- Spiral fracture: a fracture where at least one part of the bone has been twisted
- Compression fracture/wedge fracture: usually occurs in the vertebrae, for example when the front portion of a vertebra in the spine collapses due to osteoporosis (a medical condition which causes bones to become brittle and susceptible to fracture, with or without trauma)
- Impacted fracture: a fracture caused when bone fragments are driven into each other
- Avulsion fracture: a fracture where a fragment of bone is separated from the main mass

Fragments
- Incomplete fracture: a fracture in which the bone fragments are still partially joined, in such cases, there is a crack in the osseous tissue that does not completely traverse the width of the bone.
- Complete fracture: a fracture in which bone fragments separate completely.
- Comminuted fracture: a fracture in which the bone has broken into several pieces.

Anatomical Location

An anatomical classification may begin with specifying the involved body part, such as the head or arm, followed with more specific localization. Fractures that have additional definition criteria than merely localization often may be classified as subtypes of fractures, such as a Holstein-Lewis fracture being a subtype of a humerus fracture. Most typical examples in an orthopaedic classification given in the previous section cannot be classified appropriately into any specific part of an anatomical classification, however, as they may apply to multiple anatomical fracture sites.

- Skull fracture
    - Basilar skull fracture
    - Blowout fracture – a fracture of the walls or floor of the orbit
    - Mandibular fracture
    - Nasal fracture
    - Le Fort fracture of skull – facial fractures involving the maxillary bone and surrounding structures in a usually bilateral and either horizontal, pyramidal, or transverse way.

- Spinal fracture
    - Cervical fracture
        - Fracture of C1, including Jefferson fracture
        - Fracture of C2, including Hangman's fracture
        - Flexion teardrop fracture – a fracture of the anteroinferior aspect of a cervical vertebral
    - Clay-shoveler fracture – fracture through the spinous process of a vertebra occurring at any of the lower cervical or upper thoracic vertebrae
    - Burst fracture – in which a vertebra breaks from a high-energy axial load
    - Compression fracture – a collapse of a vertebra, often in the form of wedge fractures due to larger compression anteriorly
    - Chance fracture – compression injury to the anterior portion of a vertebral body with concomitant distraction injury to posterior elements
    - Holdsworth fracture – an unstable fracture dislocation of the thoracolumbar junction of the spine

- Rib fracture
- Sternal fracture
- Shoulder fracture
    - Clavicle fracture
    - Scapular fracture

- Arm fracture
    - Humerus fracture (fracture of upper arm)
        - Supracondylar fracture
        - Holstein-Lewis fracture – a fracture of the distal third of the humerus resulting in entrapment of the radial nerve
    - Forearm fracture
        - Ulnar fracture
            - Monteggia fracture – a fracture of the proximal third of the ulna with the dislocation of the head of the radius
            - Hume fracture – a fracture of the olecranon with an associated anterior dislocation of the radial head

        - Radius fracture
            - Essex-Lopresti fracture – a fracture of the radial head with concomitant dislocation of the distal radio-ulnar joint
            - Distal radius fracture
                - Galeazzi fracture – a fracture of the radius with dislocation of the distal radioulnar joint
                - Colles' fracture – a distal fracture of the radius with dorsal (posterior) displacement of the wrist and hand
                - Smith's fracture – a distal fracture of the radius with volar (ventral) displacement of the wrist and hand
                - Barton's fracture – an intra-articular fracture of the distal radius with dislocation of the radiocarpal joint

- Hand fracture
    - Scaphoid fracture
    - Rolando fracture – a comminuted intra-articular fracture through the base of the first metacarpal bone
    - Bennett's fracture – a fracture of the base of the first metacarpal bone which extends into the carpometacarpal (CMC) joint
    - Boxer's fracture – a fracture at the neck of a metacarpal
- Pelvic fracture
    - Fracture of the hip bone
    - Duverney fracture – an isolated pelvic fracture involving only the iliac wing
- Femoral fracture
    - Hip fracture (anatomically a fracture of the femur bone and not the hip bone)
- Patella fracture
- Crus fracture (A crus fracture is a fracture of the lower legs bones meaning either or both of the tibia and fibula)
    - Tibia fracture
        - Pilon fracture
        - Tibial plateau fracture
        - Bumper fracture – a fracture of the lateral tibial plateau caused by a forced valgus applied to the knee
        - Segond fracture – an avulsion fracture of the lateral tibial condyle
        - Gosselin fracture – a fractures of the tibial plafond into anterior and posterior fragments
        - Toddler's fracture – an undisplaced and spiral fracture of the distal third to distal half of the tibia
    - Fibular fracture
        - Maisonneuve fracture
        - Le Fort fracture of ankle – a vertical fracture of the antero-medial part of the distal fibula with avulsion of the anterior tibiofibular ligament
        - Bosworth fracture – a fracture with an associated fixed posterior dislocation of the distal fibular fragment that becomes trapped

- Combined tibia and fibula fracture
    - Trimalleolar fracture – involving the lateral malleolus, medial malleolus, and the distal posterior aspect of the tibia
    - Bimalleolar fracture – involving the lateral malleolus and the medial malleolus
    - Pott's fracture

- Foot fracture
  - Lisfranc fracture – in which one or all of the metatarsals are displaced from the tarsus
  - Jones fracture – a fracture of the proximal end of the fifth metatarsal
  - March fracture – a fracture of the distal third of one of the metatarsals occurring because of recurrent stress
  - Calcaneal fracture - a fracture of the calcaneus (heel bone)

Prevention

Both high- and low-force trauma can cause bone fracture injuries. Preventive efforts to reduce motor vehicle crashes, the most common cause of high-force trauma, include reducing distractions while driving. Common distractions are driving under the influence and texting or calling while driving, both of which lead to an approximate 6-fold increase in crashes. Wearing a seatbelt can also reduce the likelihood of injury in a collision.

A common cause of low-force trauma is an at-home fall. When considering preventative efforts, the National Institute of Health (NIH) examines ways to reduce the likelihood of falling, the force of the fall, and bone fragility. To prevent at-home falls they suggest keeping cords out of high-traffic areas where someone could trip, installing handrails and keeping stairways well-lit, and installing an assistive bar near the bathtub in the washroom for support. To reduce the impact of a fall the NIH recommends to try falling straight down on your buttocks or onto your hands. Finally, taking calcium vitamin D supplements can help strengthen your bones.

Treatment

Treatment of bone fractures are broadly classified as surgical or conservative, the latter basically referring to any non-surgical procedure, such as pain management, immobilization or other non-surgical stabilization. A similar classification is open versus closed treatment, in which open treatment refers to any treatment in which the fracture site is opened surgically, regardless of whether the fracture is an open or closed fracture.

Pain Management
In arm fractures in children, ibuprofen has been found to be as effective as a combination of acetaminophen and codeine.

Immobilization
Since bone healing is a natural process that will occur most often, fracture treatment aims to ensure the best possible function of the injured part after healing. Bone fractures typically are treated by restoring the fractured pieces of bone to their natural positions (if necessary), and maintaining those positions while the bone heals. Often, aligning the bone, called reduction, in a good position and verifying the improved alignment with an X-ray is all that is needed. This process is extremely painful without anaesthesia, about as painful as breaking the bone itself.

To this end, a fractured limb usually is immobilized with a plaster or fibreglass cast or splint that holds the bones in position and immobilizes the joints above and below the fracture. When the initial post-fracture oedema or swelling goes down, the fracture may be placed in a removable brace or orthosis. If being treated with surgery, surgical nails, screws, plates, and wires are used to hold the fractured bone together more directly. Alternatively, fractured bones may be treated by the Ilizarov method which is a form of an external fixator.

Occasionally smaller bones, such as phalanges of the toes and fingers, may be treated without the cast, by buddy wrapping them, which serves a similar function to making a cast. A device called a Suzuki frame may be used in cases of deep, complex intra-articular digit fractures. By allowing only limited movement, immobilization helps preserve anatomical alignment while enabling callus formation, toward the target of achieving union.

Splinting results in the same outcome as casting in children who have a distal radius fracture with little shifting.

Surgery
Surgical methods of treating fractures have their own risks and benefits, but usually surgery is performed only if conservative treatment has failed, is very likely to fail, or likely to result in a poor functional outcome. With some fractures such as hip fractures (usually caused by osteoporosis), surgery is offered routinely because non-operative treatment results in prolonged immobilisation, which commonly results in complications including chest infections, pressure sores, deconditioning, deep vein thrombosis (DVT), and pulmonary embolism, which are more dangerous than surgery. When a joint surface is damaged by a fracture, surgery is also commonly recommended to make an accurate anatomical reduction and restore the smoothness of the joint.

Infection is especially dangerous in bones, due to the recrudescent nature of bone infections. Bone tissue is predominantly extracellular matrix, rather than living cells, and the few blood vessels needed to support this low metabolism are only able to bring a limited number of immune cells to an injury to fight infection. For this reason, open fractures and osteotomies call for very careful antiseptic procedures and prophylactic use of antibiotics. Occasionally, bone grafting is used to treat a fracture. Sometimes bones are reinforced with metal. These implants must be designed and installed with care. Stress shielding occurs when plates or screws carry too large of a portion of the bone's load, causing atrophy.

This problem is reduced, but not eliminated, by the use of low-modulus materials, including titanium and its alloys. The heat generated by the friction of installing hardware can accumulate easily and damage bone tissue, reducing the strength of the connections. If dissimilar metals are installed in contact with one another (i.e., a titanium plate with cobalt-chromium alloy or stainless steel screws), galvanic corrosion will result. The metal ions produced can damage the bone locally and may cause systemic effects as well.

9 Cramp

A cramp is a sudden, involuntary muscle contraction or over-shortening; while generally temporary and non-damaging, they can cause significant pain, and a paralysis-like immobility of the affected muscle. Onset is usually sudden, and it resolves on its own over a period of several seconds, minutes or hours. Cramps may occur in a skeletal muscle or smooth muscle. Skeletal muscle cramps may be caused by muscle fatigue or a lack of electrolytes such as low sodium, low potassium or low magnesium. Cramps of smooth muscle may be due to menstruation or gastroenteritis.

Differential Diagnosis

Causes of cramping include hyperflexion, hypoxia, exposure to large changes in temperature, dehydration, or low blood salt. Muscle cramps can also be a symptom or complication of pregnancy; kidney disease; thyroid disease; hypokalemia, hypomagnesemia, or hypocalcaemia (as conditions); restless legs syndrome; varicose veins; and multiple sclerosis. As early as 1965, researchers observed that leg cramps and restless legs syndrome can result from excess insulin, sometimes called hyperinsulinemia.

Skeletal Muscle Cramps
Under normal circumstances, skeletal muscles can be voluntarily controlled. Skeletal muscles that cramp the most often are the calves, thighs, and arches of the foot, and are sometimes called a "Charley horse" or a "corky". Such cramping is associated with strenuous physical activity and can be intensely painful; however, they can even occur while inactive and relaxed. Around 40% of people who experience skeletal cramps are likely to endure extreme muscle pain, and may be unable to use the entire limb that contains the "locked-up" muscle group. It may take up to seven days for the muscle to return to a pain-free state.

INJURY Internal Injury Cramps Differential Diagnosis

Nocturnal Leg Cramps
Nocturnal leg cramps are involuntary muscle contractions that occur in the calves, soles of the feet, or other muscles in the body during the night or (less commonly) while resting. The duration of nocturnal leg cramps is variable, with cramps lasting anywhere from a few seconds to several minutes. Muscle soreness may remain after the cramp itself ends. These cramps are more common in older people. They happen quite frequently in teenagers and in some people while exercising at night. Besides being painful, a nocturnal leg cramp can cause much distress and anxiety. The precise cause of these cramps is unclear. Potential contributing factors include dehydration, low levels of certain minerals (magnesium, potassium, calcium, and sodium, although the evidence has been mixed), and reduced blood flow through muscles attendant in prolonged sitting or lying down. Nocturnal leg cramps (almost exclusively calf cramps) are considered "normal" during the late stages of pregnancy. They can, however, vary in intensity from mild to extremely painful.

Nocturnal Leg Cramps
A lactic acid buildup around muscles can trigger cramps; however, these happen during anaerobic respiration when a person is exercising or engaging in an activity where the heartbeat speeds up. Medical conditions associated with leg cramps are cardiovascular disease, hemodialysis, cirrhosis, pregnancy, and lumbar canal stenosis. Differential diagnoses include restless legs syndrome, claudication, myositis, peripheral neuropathy. All of these can be differentiated through careful history and physical examination. Gentle stretching and massage, putting some pressure on the affected leg by walking or standing, or taking a warm bath or shower may help to end the cramp. If the cramp is in the calf muscle, pulling the big toe gently backwards will stretch the muscle and, in some cases, cause almost immediate relief. There is limited evidence supporting the use of magnesium, calcium channel blockers, carisoprodol, and vitamin B12. Quinine is no longer recommended for treatment of nocturnal leg cramps due to potential fatal hypersensitivity reactions and thrombocytopenia. Arrhythmias, cinchonism, hemolytic uremic syndrome can also occur at higher dosages.

Smooth Muscle Cramps
Smooth muscle contractions may be symptomatic of endometriosis or other health problems. Menstrual cramps may also occur during a menstrual cycle.

INJURY Internal Injury Cramps

Treatment
Stretching, massage and drinking plenty of liquids, such as water, may be helpful in treating simple muscle cramps. With exertional heat cramps due to electrolyte abnormalities (primarily sodium loss and not calcium, magnesium, and potassium), appropriate fluids and sufficient salt improves symptoms.

Prevention
Adequate conditioning, stretching, mental preparation, hydration, and electrolyte balance are likely helpful in preventing muscle cramps.

10 Dislocation

INJURY Internal Injury Dislocation

A joint dislocation, also called luxation, occurs when there is an abnormal separation in the joint, where two or more bones meet. A partial dislocation is referred to as a subluxation. Dislocations are often caused by sudden trauma on the joint like an impact or fall. A joint dislocation can cause damage to the surrounding ligaments, tendons, muscles, and nerves. Dislocations can occur in any joint major (shoulder, knees, etc.) or minor (toes, fingers, etc.). The most common joint dislocation is a shoulder dislocation. Treatment for joint dislocation is usually by closed reduction, that is, skilled manipulation to return the bones to their normal position. Reduction should only be performed by trained medical professionals, because it can cause injury to soft tissue and/or the nerves and vascular structures around the dislocation.

Signs & Symptoms

INJURY Internal Injury Dislocation Signs &

- Intense pain
- Joint instability
- Deformity of the joint area
- Reduced muscle strength
- Bruising or redness of joint area
- Difficulty moving joint
- Stiffness

Causes

Causes

Joint dislocations are caused by trauma to the joint or when an individual falls on a specific joint. Great and sudden force applied, by either a blow or fall, to the joint can cause the bones in the joint to be displaced or dislocated from normal position. With each dislocation, the ligaments keeping the bones fixed in the correct position can be damaged or loosened, making it easier for the joint to be dislocated in the future. Some individuals are prone to dislocations due to congenital conditions, such as hypermobility syndrome and Ehlers-Danlos Syndrome. Hypermobility syndrome is genetically inherited disorder that is thought to affect the encoding of the connective tissue protein's collagen in the ligament of joints. The loosened or stretched ligaments in the joint provide little stability and allow for the joint to be easily dislocated.

Diagnosis

INJURY Internal Injury Dislocation

Initial evaluation of a suspected joint dislocation should begin with a thorough patient history, including mechanism of injury, and physical examination. Special attention should be focused on the neurovascular exam both before and after reduction, as injury to these structures may occur during the injury or during the reduction process. Subsequent imaging studies are frequently obtained to assist with diagnosis.

Treatment

INJURY Internal Injury Dislocation Treatment

A dislocated joint usually can be successfully reduced into its normal position only by a trained medical professional. Trying to reduce a joint without any training could substantially worsen the injury. X-rays are usually taken to confirm a diagnosis and detect any fractures which may also have occurred at the time of dislocation. A dislocation is easily seen on an X-ray. Once a diagnosis is confirmed, the joint is usually manipulated back into position. This can be a very painful process, therefore this is typically done either in the emergency department under sedation or in an operating room under a general anaesthetic.

It is important the joint is reduced as soon as possible, as in the state of dislocation, the blood supply to the joint (or distal anatomy) may be compromised. This is especially true in the case of a dislocated ankle, due to the anatomy of the blood supply to the foot. Shoulder injuries can also be surgically stabilized, depending on the severity, using arthroscopic surgery. The most common treatment method for a dislocation of the Glenohumeral Joint (GH Joint/Shoulder Joint) is exercise based management. Another method of treatment is to place the injured arm in a sling or in another immobilizing device in order to keep the joint stable.

Some joints are more at risk of becoming dislocated again after an initial injury. This is due to the weakening of the muscles and ligaments which hold the joint in place. The shoulder is a prime example of this. Any shoulder dislocation should be followed up with thorough physiotherapy. On field reduction is crucial for joint dislocations. As they are extremely common in sports events, managing them correctly at the game at the time of injury, can reduce long term issues. They require prompt evaluation, diagnosis, reduction, and postreduction management before the person can be evaluated at a medical facility.

INJURY Internal Injury Dislocation Treatment

After Care
After a dislocation, injured joints are usually held in place by a splint (for straight joints like fingers and toes) or a bandage (for complex joints like shoulders). Additionally, the joint muscles, tendons and ligaments must also be strengthened. This is usually done through a course of physiotherapy, which will also help reduce the chances of repeated dislocations of the same joint. For glenohumeral instability, the therapeutic program depends on specific characteristics of the instability pattern, severity, recurrence and direction with adaptations made based on the needs of the patient. In general, the therapeutic program should focus on restoration of strength, normalization of range of motion and optimization of flexibility and muscular performance. Throughout all stages of the rehabilitation program, it is important to take all related joints and structures into consideration.

Epidemiology

Each joint in the body can be dislocated, however, there are common sites where most dislocations occur. The following structures are the most common sites of joint dislocations:

Shoulder
Shoulder dislocations account for 45% of all dislocation visits to the emergency room. Anterior shoulder dislocation, the most common type of shoulder dislocation (96-98% of the time) occurs when the arm is in external rotation and abduction (away from the body) produces a force that displaces the humeral head anteriorly and downwardly. Vessel and nerve injuries during a shoulder dislocation is rare, but can cause many impairments and requires a longer recovery process. There is a 39% average rate of recurrence of anterior shoulder dislocation, with age, sex, hyperlaxity and greater tuberosity fractures being the key risk factors.

Knee (Patellar Dislocation)
Many different knee injuries can happen. Three percent of knee injuries are acute traumatic patellar dislocations. Because dislocations make the knee unstable, 15% of patellas will re-dislocate. Patellar dislocations occur when the knee is in full extension and sustains a trauma from the lateral to medial side.

Elbow (Posterior Dislocation)
90% of all elbow dislocations.

Wrist
Lunate and Perilunate dislocation most common.

Finger
Interphalangeal (IP) or metacarpophalangeal (MCP) joint dislocations. In the United States, men are most likely to sustain a finger dislocation with an incidence rate of 17.8 per 100,000 person-years. Women have an incidence rate of 4.65 per 100,000 person-years. The average age group that sustain a finger dislocation are between 15 and 19 years old.

Hip
Posterior and Anterior Dislocation of Hip. Anterior dislocations are less common than posterior dislocations. 10% of all dislocations are anterior and this is broken down into superior and inferior types. Superior dislocations account for 10% of all anterior dislocations, and inferior dislocations account for 90%. 16-40 year old males are more likely to receive dislocations due to a car accident. When an individual receives a hip dislocation, there is an incidence rate of 95% that they will receive an injury to another part of their body as well. 46–84% of hip dislocations occur secondary to traffic accidents, the remaining percentage is due based on falls, industrial accidents or sporting injury.

Foot & Ankle
Lisfranc injury is a dislocation or fracture-dislocation injury at the tarsometatarsal joints. Subtalar dislocation, or talocalcaneonavicular dislocation, is a simultaneous dislocation of the talar joints at the talocalcaneal and talonavicular levels. Subtalar dislocations without associated fractures represent about 1% of all traumatic injuries of the foot and 1-2 % of all dislocations, and they are associated with high energy trauma. Early closed reduction is recommended, otherwise open reduction without further delay. Total talar dislocation is very rare and has very high rates of complications. Ankle Sprains primarily occur as a result of tearing the ATFL (anterior talofibular ligament) in the Talocrural Joint. The ATFL tears most easily when the foot is in plantarflexion and inversion. Ankle dislocation without fracture is rare.

11 Concussion

Concussion, also known as mild traumatic brain injury (mTBI), is typically defined as a head injury that temporarily affects brain functioning. Symptoms may include headaches, trouble with thinking, memory or concentration, nausea, blurry vision, sleep disturbances or mood changes. Some symptoms may begin immediately, while others may appear days after the injury. Fewer than 10% of sports-related concussions among children are associated with loss of consciousness. It is not unusual for symptoms to last up to four weeks. Common causes include motor vehicle collisions, falls, sports injuries and bicycle accidents.

Risk factors include drinking alcohol. The mechanism may involve either a direct blow to the head or forces elsewhere on the body that are transmitted to the head. This is believed to result in neuron dysfunction, as there is increased glucose requirements but insufficient blood supply. Diagnosis requires less than 30 minutes of loss of consciousness, memory loss of less than 24 hours and a Glasgow Coma Scale score of 13 to 15. Otherwise, it is considered a moderate or severe traumatic brain injury. Efforts to prevent the condition includes the use of helmets when bicycling or motorbiking. Treatment generally involves physical and cognitive rest for a day or two, with a gradual return to activities. Prolonged periods of rest may worsen outcomes. Paracetamol (acetaminophen) or NSAIDs may be recommended. Physiotherapy may be useful for persistent balance problems while cognitive behavioral therapy may be useful for mood changes. Evidence to support the use of hyperbaric oxygen therapy and chiropractic therapy is lacking. Concussions are estimated to affect more than 6 per 1,000 people a year. It is the most common type of traumatic brain injury. Males and young adults are most commonly affected. Outcomes are generally good. Another concussion before the symptoms of a prior concussion have resolved is associated with worse outcomes. Repeated concussions may also increase the risk in later life of chronic traumatic encephalopathy, Parkinson's disease or depression.

Signs & Symptoms

Signs & Symptoms
Concussions are associated with a variety of symptoms, which typically occur rapidly after the injury. Early symptoms usually subside within days or weeks. The number and type of symptoms any one individual suffer varies widely. Headaches are the most common mTBI symptom. Others include dizziness, vomiting, nausea, lack of motor coordination, difficulty balancing, or other problems with movement or sensation. Visual symptoms include light sensitivity, seeing bright lights, blurred vision, and double vision. Tinnitus, or a ringing in the ears, is also commonly reported. In one in about seventy concussions, concussive convulsions occur, but seizures that take place during or immediately after a concussion are not "post-traumatic seizures", and, unlike post-traumatic seizures, are not predictive of post-traumatic epilepsy, which requires some form of structural brain damage, not just a momentary disruption in normal brain functioning. Concussive convulsions are thought to result from temporary loss or inhibition of motor function and are not associated either with epilepsy or with more serious structural damage. They are not associated with any particular sequelae and have the same high rate of favorable outcomes as concussions without convulsions.

Cognitive symptoms include confusion, disorientation, and difficulty focusing attention. Loss of consciousness may occur, but is not necessarily correlated with the severity of the concussion if it is brief. Post-traumatic amnesia, in which events following the injury cannot be recalled, is a hallmark of concussions. Confusion, another concussion hallmark, may be present immediately or may develop over several minutes. A person may repeat the same questions, be slow to respond to questions or directions, have a vacant stare, or have slurred or incoherent speech. Other MTBI symptoms include changes in sleeping patterns and difficulty with reasoning, concentrating, and performing everyday activities. A concussion can result in changes in mood including crankiness, loss of interest in favorite activities or items, tearfulness, and displays of emotion that are inappropriate to the situation. Common symptoms in concussed children include restlessness, lethargy, and irritability.

Mechanism
The brain is surrounded by cerebrospinal fluid, which protects it from light trauma. More severe impacts, or the forces associated with rapid acceleration, may not be absorbed by this cushion. Concussion may be caused by impact forces, in which the head strikes or is struck by something, or impulsive forces, in which the head moves without itself being subject to blunt trauma (for example, when the chest hits something and the head snaps forward). Forces may cause linear, rotational, or angular movement of the brain or a combination of them. In rotational movement, the head turns around its center of gravity and in angular movement, it turns on an axis, not through its center of gravity. The amount of rotational force is thought to be the major component in concussion and its severity. Studies with athletes have shown that the amount of force and the location of the impact are not necessarily correlated with the severity of the concussion or its symptoms, and have called into question the threshold for concussion previously thought to exist at around 70–75 g. The parts of the brain most affected by rotational forces are the midbrain and diencephalon. It is thought that the forces from the injury disrupt the normal cellular activities in the reticular activating system located in these areas and that this disruption produces the loss of consciousness often seen in concussion. Other areas of the brain that may be affected include the upper part of the brain stem, the fornix, the corpus callosum, the temporal lobe, and the frontal lobe. Angular accelerations of 4600, 5900, or 7900 rad/s2 are estimated to have 25, 50, or 80% risk of MTBI respectively.

Diagnosis

Head trauma recipients are initially assessed to exclude a more severe emergency such as an intracranial hemorrhage. This includes the "ABCs" (airway, breathing, circulation) and stabilization of the cervical spine which is assumed to be injured in any athlete who is found to be unconscious after head or neck injury. Indications that screening for more serious injury is needed include worsening of symptoms such as headaches, persistent vomiting, increasing disorientation or a deteriorating level of consciousness, seizures, and unequal pupil size. Those with such symptoms, or those who are at higher risk of a more serious brain injury, may undergo brain imaging to detect lesions and are frequently observed for 24–48 hours. A brain CT or brain MRI should be avoided unless there are progressive neurological symptoms, focal neurological findings or concern of skull fracture on exam. Diagnosis of MTBI is based on physical and neurological examination findings, duration of unconsciousness (usually less than 30 minutes) and post-traumatic amnesia (PTA; usually less than 24 hours), and the Glasgow Coma Scale (MTBI sufferers have scores of 13 to 15). Neuropsychological tests exist to measure cognitive function and the international consensus meeting in Zurich recommended the use of the SCAT2 test. Such tests may be administered hours, days, or weeks after the injury, or at different times to demonstrate any trend. Increasingly, athletes are also being tested pre-season to provide a baseline for comparison in the event of an injury, though this may not reduce risk or affect return to play.

If the Glasgow Coma Scale is less than 15 at two hours or less than 14 at any time, a CT is recommended. In addition, a CT scan is more likely to be performed if observation after discharge is not assured or intoxication is present, there is suspected increased risk for bleeding, age greater than 60, or less than 16. Most concussions, without complication, cannot be detected with MRI or CT scans. However, changes have been reported on MRI and SPECT imaging in those with concussion and normal CT scans, and post-concussion syndrome may be associated with abnormalities visible on SPECT and PET scans. Mild head injury may or may not produce abnormal EEG readings. A blood test known as the Brain Trauma Indicator was approved in the United States in 2018 and may be able to rule out the risk of intracranial bleeding and thus the need for a CT scan. Concussion may be under-diagnosed because of the lack of the highly noticeable signs and symptoms while athletes may minimize their injuries to remain in the competition. A retrospective survey in 2005 suggested that more than 88% of concussions are unrecognized. Diagnosis can be complex because concussion shares symptoms with other conditions. For example, post-concussion symptoms such as cognitive problems may be misattributed to brain injury when, in fact, due to post-traumatic stress disorder (PTSD).

Grading Systems

Three grading systems have been most widely followed: by Robert Cantu, the Colorado Medical Society, and the American Academy of Neurology. Each employs three grades, as summarized in the following table:

Guidelines	Grade I	Grade II	Grade III
Cantu	Post-traumatic amnesia <30 minutes, no loss of consciousness	Loss of consciousness <5 minutes or amnesia lasting 30 minutes–24 hours	Loss of consciousness >5 minutes or amnesia >24 hours
Colorado Medical Society	Confusion, no loss of consciousness	Confusion, post-traumatic amnesia, no loss of consciousness	Any loss of consciousness
American Academy of Neurology	Confusion, symptoms last <15 minutes, no loss of consciousness	Symptoms last >15 minutes, no loss of consciousness	Loss of consciousness (IIIa, coma lasts seconds, IIIb for minutes)

Prevention

Prevention of MTBI involves general measures such as wearing seat belts and using airbags in cars. Older people are encouraged to reduce fall risk by keeping floors free of clutter and wearing thin, flat, shoes with hard soles that do not interfere with balance. Protective equipment such as headgear has been found to reduce the number of concussions in athletes and improvements in the design of helmets may decrease the number and severity further. New "Head Impact Telemetry System" technology is being placed in helmets to study injury mechanisms and may generate knowledge that will potentially help reduce the risk of concussions among American Football players. Self-reported concussion rates among U-20 and elite rugby union players in Ireland are 45–48%. Half of these injuries go unreported. Changes to the rules or enforcing existing rules in sports, such as those against "head-down tackling", or "spearing", which is associated with a high injury rate, may also prevent concussions.

Treatment

After exclusion of neck injury, observation should be continued for several hours. If repeated vomiting, worsening headache, dizziness, seizure activity, excessive drowsiness, double vision, slurred speech, unsteady walk, or weakness or numbness in arms or legs, or signs of basilar skull fracture develop, immediate assessment in an emergency department is warranted. After this initial period has passed, there is debate as to whether it is necessary to awaken the person several times during the first night, as has traditionally been done, or whether there is more benefit from uninterrupted sleep.

Physical and cognitive rest should be continued until all symptoms have resolved with most (80–90%) concussions resolving in seven to ten days, although the recovery time may be longer in children and adolescents. Cognitive rest includes reducing activities which require concentration and attention such as school work, video games, and text messaging.

It has been suggested that even leisure reading can commonly worsen symptoms in children and adolescents and proposals include time off from school and attending partial days. Since students may appear 'normal', continuing education of relevant school personnel may be needed. Those with concussion are generally prescribed rest, including adequate nighttime sleep as well as daytime rest. Rest includes both physical and cognitive rest until symptoms clear and a gradual return to normal activities at a pace that does not cause symptoms to worsen is recommended. Education about symptoms, their management, and their normal time course, can lead to an improved outcome.

For persons participating in athletics, the 2008 Zurich Consensus Statement on Concussion in Sport recommends that participants be symptom-free before restarting and then progress through a series of graded steps. These steps include:	● Complete physical and cognitive rest ● Light aerobic activity (less than 70% of maximum heart rate) ● Sport-specific activities such as running drills and skating drills ● Non-contact training drills (exercise, coordination, and cognitive load) ● Full-contact practice ● Full-contact games.	Only when symptom-free for 24 hours, should progression to the next step occur. If symptoms occur, the person should drop back to the previous asymptomatic level for at least another 24 hours. The emphasis is on remaining symptom-free and taking it in medium steps, not on the steps themselves.

Medications may be prescribed to treat sleep problems and depression. Analgesics such as ibuprofen can be taken for headaches, but paracetamol (acetaminophen) is preferred to minimize the risk of intracranial hemorrhage. Concussed individuals are advised not to use alcohol or other drugs that have not been approved by a doctor as they can impede healing. Activation database-guided EEG biofeedback has been shown to return the memory abilities of the concussed individual to levels better than the control group. About one percent of people who receive treatment for MTBI need surgery for a brain injury. Observation to monitor for worsening condition is an important part of treatment.

Health care providers recommend that those suffering from concussion return for further medical care and evaluation 24 to 72 hours after the concussive event if the symptoms worsen. Athletes, especially intercollegiate or professional, are typically followed closely by team athletic trainers during this period but others may not have access to this level of health care and may be sent home with minimal monitoring. People may be released after assessment from hospital or emergency room to the care of a trusted person with instructions to return if they display worsening symptoms or those that might indicate an emergent condition such as change in consciousness, convulsions, severe headache, extremity weakness, vomiting, new bleeding or deafness in either or both ears.

Prognosis

People who have had a concussion seem more susceptible to another one, particularly if the new injury occurs before symptoms from the previous concussion have completely gone away. It is also a negative process if smaller impacts cause the same symptom severity. Repeated concussions may increase a person's risk in later life for dementia, Parkinson's disease, and depression. MTBI has a mortality rate of almost zero. The symptoms of most concussions resolve within weeks, but problems may persist. These are seldom permanent, and the outcome is usually excellent. About 75% of children recover within three months. The overall prognosis for recovery may be influenced by a variety of factors that include age at the time of injury, intellectual abilities, family environment, social support system, occupational status, coping strategies, and financial circumstances. People over age 55 may take longer to heal from MTBI or may heal incompletely. Similarly, factors such as a previous head injury or a coexisting medical condition have been found to predict longer-lasting post-concussion symptoms.

Other factors that may lengthen recovery time after MTBI include psychological problems such as substance abuse or clinical depression, poor health before the injury or additional injuries sustained during it, and life stress. Longer periods of amnesia or loss of consciousness immediately after the injury may indicate longer recovery times from residual symptoms. For unknown reasons, having had one concussion significantly increases a person's risk of having another. Having previously sustained a sports concussion has been found to be a strong factor increasing the likelihood of a concussion in the future. Other strong factors include participation in a contact sport and body mass size. The prognosis may differ between concussed adults and children; little research has been done on concussion in the pediatric population, but concern exists that severe concussions could interfere with brain development in children. A 2009 study found that individuals with a history of concussions might demonstrate a decline in both physical and mental performance for longer than 30 years. Compared to their peers with no history of brain trauma, sufferers of concussion exhibited effects including loss of episodic memory and reduced muscle speed.

Post-Concussion Syndrome

In post-concussion syndrome, symptoms do not resolve for weeks, months, or years after a concussion, and may occasionally be permanent. About 10% to 20% of people have post-concussion syndrome for more than a month. Symptoms may include headaches, dizziness, fatigue, anxiety, memory and attention problems, sleep problems, and irritability. There is no established treatment, and rest, a recommended recovery technique, has limited effectiveness. Symptoms usually go away on their own within months but may last for years. The question of whether the syndrome is due to structural damage or other factors such as psychological ones, or a combination of these, has long been the subject of debate.

3 Open Wound

A wound which is exposed to the outside world such as a cut or laceration. Gunshot wounds can be found under "Foreign Bodies".

Subheadings

1. Minor Cuts	2. Open Wound	3. Multiple Open Wounds	4. Avulsion
5. Enucleations	6. Amputation		

1 Minor Cuts

Minor cuts are small breaks in the skin such as a shallow cut with a knife or other sharp object. Minor cuts don't require stitches and are easily treatable yourself. This is the most common type of injury, therefore it's recommended that you have a lot of small bandages, Band-Aids and sterilizing wipes in your BOB.

Treatment

Sterilize the wound and apply a bangade or Band-Aid ensuring the enture wound is covered. All minor injuries should be taken care of immediately before they become infected. Some alcoholic beverages can sterilize wounds if theey are 40% alcohol content or more and 60% for Surgical Alcohol for use during an operation. Use isopropyl, hydrogen peroxide and iodine to clean the wound. Only hydrogen peroxide can be used inside the wound.

2 Open Wound

Open wounds are much more severe than minor cuts and typically require more attention and equipment such as a staple gun or stitches. You may also be able to see parts of bone showing in the wound, however the bones aren't broken damaged in an open wound.

Treatment

If the wound is over 2.5cm (1in) Sterilize and attempt to close the wound with tight wrappings or duct tape if a suture kit isn't available.

3 Multiple Open Wounds

The same type of open wounds mentioned above but multiple skin breaks around the location instead of just one.

INJURY Open Wound Avulsions

4 Avulsion

The ripping or tearing away of a body part or nerve without bone loss. The term most commonly refers to a surface trauma where all layers of the skin have been torn away, exposing the underlying structures (i.e., subcutaneous tissue, muscle, tendons, or bone). This is similar to an abrasion but more severe, as body parts such as an eyelid or an ear can be partially or fully detached from the body.

Skin Avulsions	The most common avulsion injury, skin avulsions usually occur during motor vehicle collisions. The severity of avulsion ranges from skin flaps (minor) to degloving (moderate) and amputation of a finger or limb (severe). Suprafascial avulsions are those in which the depth of the removed skin reaches the subcutaneous tissue layer, while subfascial avulsions extend deeper than the subcutaneous layer. Small suprafascial avulsions can be repaired by suturing, but most avulsions require skin grafts or reconstructive surgery.
Ear Avulsions	The ear is particularly vulnerable to avulsion injuries because of its position on the side of the head. The most common cause of ear avulsions is human bites, followed by falls, motor vehicle collisions, and dog bites. A partially avulsed ear can be reattached through suturing or microvascular surgery, depending on the severity of the injury. Microvascular surgery can also be used to reattach a completely avulsed ear, but its success rate is lower because of the need for venous drainage. The ear can also be reconstructed with cartilage and skin grafts or an external ear prosthesis can be made by an anaplastologist.
Eyelid Avulsions	Eyelid avulsions are uncommon, but can be caused by motor vehicle collisions, dog bites, or human bites. Eyelid avulsions are repaired by suturing after a CT scan is performed to determine where damage to the muscles, nerves, and blood vessels of the eyelid has occurred. More severe injuries require reconstruction, however, this usually results in some loss of function and subsequent surgeries may be necessary to improve structure and function. Microvascular surgery is another method of repair but is rarely used to treat eye avulsions. Sometimes botulinum toxin is injected into the eyelid to paralyze the muscles while the eyelid heals.
Nail Avulsions	Trauma to the nail can cause the nail plate to be torn from the nail bed. Unlike other types of avulsion, when a nail is lost, it is not typically reattached. Following the loss of the nail, the nail bed forms a germinal layer which hardens as the cells acquire keratin and becomes a new nail. Until this layer has formed, the exposed nail bed is highly sensitive, and is typically covered with a non-adherent dressing, as an ordinary dressing will stick to the nail bed and cause pain upon removal. In the average person, fingernails require 3 to 6 months to regrow completely, while toenails require 12 to 18 months.
Brachial Plexus Avulsions	In brachial plexus avulsions, the brachial plexus (a bundle of nerves that communicates signals between the spine and the arms, shoulders, and hands) is torn from its attachment to the spinal cord. One common cause of brachial plexus avulsions is when a baby's shoulders rotate in the birth canal during delivery, which causes the brachial plexus to stretch and tear. It occurs in 1-2 out of every 1,000 births. Shoulder trauma during motor vehicle collisions is another common cause of brachial plexus avulsions. Detachment of the nerves can cause pain and loss of function in the arms, shoulders, and hands. Neuropathic pain can be treated with medication, but it is only through surgical reattachment or nerve grafts that function can be restored. For intractable pain, a procedure called dorsal root entry zone (DREZ) lesioning can be effective.
Tooth Avulsions	During a tooth avulsion, a tooth is completely or partially (such that the dental pulp is exposed) detached from its socket. Secondary (permanent) teeth can be replaced and stabilised by a dentist. Primary (baby) teeth are not replaced because they tend to become infected and to interfere with the growth of the secondary teeth. A completely avulsed tooth that is replaced within one hour of the injury can be permanently retained. The long-term retention rate decreases as the time that the tooth is detached increases, and eventually root resorption makes replacement of the tooth impossible. To minimize damage to the root, the tooth should be kept in milk or sterile saline while it is outside the mouth.

5 Enucleations

A enucleation is the traumatic removal of an organ such as en eyeball in it's entirety.

INJURY Open Wound Amputations

6 Amputation

Amputation is the removal of a limb by trauma, medical illness, or surgery. As a surgical measure, it is used to control pain or a disease process in the affected limb, such as malignancy or gangrene. In some cases, it is carried out on individuals as a preventative surgery for such problems. A special case is that of congenital amputation, a congenital disorder, where fetal limbs have been cut off by constrictive bands. In some countries, amputation of the hands, feet or other body parts is or was used as a form of punishment for people who committed crimes.

Amputation has also been used as a tactic in war and acts of terrorism; it may also occur as a war injury. In some cultures and religions, minor amputations or mutilations are considered a ritual accomplishment. When done by a person, the person executing the amputation is an amputator. The amputated person is called an amputee.

Leg	Lower limb, or leg, amputations can be divided into two broad categories - minor amputations and major amputations, Minor amputations generally refers to the amputation of digits. Major amputations are commonly referred to as below-knee amputation, above-knee amputation and so forth. To avoid ambiguity the correct terminology for major amputations is:	● Partial foot amputation - amputation of the lower limb distal to the ankle joint. ● Ankle disarticulation - amputation of the lower limb at the ankle joint. ● Trans-tibial amputation - amputation of the lower limb between the knee joint and the ankle joint, commonly referred to as a below-knee amputation. ● Knee disarticulation - amputation of the lower limb at the knee joint. ● Trans-femoral amputation - amputation of the lower limb between the hip joint and the knee joint, commonly referred to an above-knee amputation. ● Hip disarticulation - amputation of the lower limb at the hip joint. ● Trans-pelvic disarticulation- amputation of the whole lower limb together with all or part of the pelvis. This is also known as a hemipelvectomy or hindquarter amputation.	
Arm	The correct terminology for arm, or upper-limb amputations is also described in ISO 8549-2:1989, these being:	● Partial hand amputation ● Wrist disarticulation ● Trans-radial amputation, commonly referred to as below-elbow or forearm amputation ● Elbow disarticulation ● Trans-humeral amputation, commonly referred to as above-elbow amputation ● Shoulder disarticulation ● Forequarter amputation	A variant of the trans-radial amputation is the Krukenberg procedure in which the radius and ulna are used to create a stump capable of a pincer action.

Other	**Face** Many of these facial disfigurings were and still are done in some parts of the world as punishment for some crimes, and as individual shame and population terror practices. ● Amputation of the ears ● Amputation of the nose (rhinotomy) ● Amputation of the tongue (glossectomy). ● Amputation of the eyes (enucleation). ● Amputation of the teeth. Removal of teeth, mainly incisors.	**Breasts & Genitals** ● Amputation of the breasts (mastectomy). ● Amputation of the testicles (castration). ● Amputation of the penis (penectomy). ● Amputation of the foreskin (circumcision). ● Amputation of the clitoris (clitoridectomy).	Hemicorporectomy, or amputation at the waist, and decapitation, or amputation at the neck, are the most radical amputations. Genital modification and mutilation may involve amputating tissue, although not necessarily as a result of injury or disease.

Self-Amputation
In some rare cases when a person has become trapped in a deserted place, with no means of communication or hope of rescue, the victim has amputated his or her own limb. The most notable case of this is Aron Ralston, a hiker who amputated his own right forearm after it was pinned by a boulder in a hiking accident and he was unable to free himself for over five days. Body integrity identity disorder is a psychological condition in which an individual feels compelled to remove one or more of their body parts, usually a limb. In some cases, that individual may take drastic measures to remove the offending appendages, either by causing irreparable damage to the limb so that medical intervention cannot save the limb, or by causing the limb to be severed.

Athletic Performance Sometimes professional athletes may choose to have a non-essential digit amputated to relieve chronic pain and impaired performance.	**Legal Punishment** ● Amputation is used as a legal punishment in a number of countries, among them Saudi Arabia, Yemen, United Arab Emirates, and Iran.

Surgery
The first step is ligating the supplying artery and vein, to prevent hemorrhage (bleeding). The muscles are transected, and finally, the bone is sawed through with an oscillating saw. Sharp and rough edges of the bone(s) are filed down, skin and muscle flaps are then transposed over the stump, occasionally with the insertion of elements to attach a prosthesis. Distal stabilisation of muscles is recommended. This allows effective muscle contraction which reduces atrophy, allows functional use of the stump and maintains soft tissue coverage of the remnant bone. The preferred stabilisation technique is myodesis where the muscle is attached to the bone or its periostium. In joint disarticulation amputations tenodesis may be used where the muscle tendon is attached to the bone. Muscles should be attached under similar tension to normal physiological conditions.

Post-Operative Management
The use of rigid removable dressings (RRD's) in trans-tibial (below knee) amputations, rather than soft bandaging has been shown to improve healing time, reduce edema, prevent knee flexion contractures and reduce complications, including further amputation, from external trauma such as falls onto the stump and should be considered standard practice. Post-operative management, in addition to wound healing, should consider maintenance of limb strength, joint range, edema management, preservation of the intact limb (if applicable) and stump desensitisation.

Trauma
Traumatic amputation is the partial or total avulsion of a part of a body during a serious accident, like traffic, labor, or combat. Traumatic amputation of a human limb, either partial or total, creates the immediate danger of death from blood loss. Orthopedic surgeons often assess the severity of different injuries using the Mangled Extremity Severity Score. Given different clinical and situational factors, they can predict the likelihood of amputation. This is especially useful for emergency physicians to quickly evaluate patients and decide on consultations.

Causes Traumatic amputation is uncommon in humans (1 per 20,804 population per year). Loss of limb usually happens immediately during the accident, but sometimes a few days later after medical complications. Statistically the most common causes of traumatic amputations are:	● Traffic accidents (cars, motorcycles, bicycles, trains, etc.) ● Labor accidents (equipment, instruments, cylinders, chainsaws, press machines, meat machines, wood machines, etc.) ● Agricultural accidents, with machines and mower equipment ● Electric shock hazards ● Firearms, bladed weapons, explosives ● Violent rupture of ship rope or industry wire rope ● Ring traction (ring amputation, de-gloving injuries) ● Building doors and car doors ● Gas cylinder explosions ● Other rare accidents

Circulatory Disorders ● Diabetic foot infection or gangrene (the most frequent reason for infection-related amputations) ● Sepsis with peripheral necrosis	**Neoplasm** ● Cancerous bone or soft tissue tumors (e.g. osteosarcoma, chondrosarcoma, fibrosarcoma, epithelioid sarcoma, Ewing's sarcoma, synovial sarcoma, sacrococcygeal teratoma, liposarcoma) ● Melanoma	**Infection** ● Bone infection (osteomyelitis) ● Diabetes ● Frostbite	**Deformities** ● Deformities of digits and/or limbs (e.g., proximal femoral focal deficiency, Fibular hemimelia) ● Extra digits and/or limbs (e.g., polydactyly)	**Trauma** ● Severe limb injuries in which the limb cannot be saved or efforts to save the limb fail. ● Traumatic amputation (an unexpected amputation that occurs at the scene of an accident, where the limb is partially or entirely severed as a direct result of the accident, for example, a finger that is severed from the blade of a table saw)

Treatment The development of the science of microsurgery over last 40 years has provided several treatment options for a traumatic amputation, depending on the patient's specific trauma and clinical situation:	**1st Choice** Surgical amputation - break - prosthesis	**2nd Choice** Surgical amputation - transplantation of other tissue - plastic reconstruction.	**3rd Choice** Replantation - reconnection - revascularisation of amputated limb, by microscope (after 1969)	**4th Choice** Transplantation of cadaveric hand (after 2000)

Prognosis
The individual may experience psychological trauma and emotional discomfort. The stump will remain an area of reduced mechanical stability. Limb loss can present significant or even drastic practical limitations. A large proportion of amputees (50–80%) experience the phenomenon of phantom limbs; they feel body parts that are no longer there. These limbs can itch, ache, burn, feel tense, dry or wet, locked in or trapped or they can feel as if they are moving. Some scientists believe it has to do with a kind of neural map that the brain has of the body, which sends information to the rest of the brain about limbs regardless of their existence. Phantom sensations and phantom pain may also occur after the removal of body parts other than the limbs, e.g. after amputation of the breast, extraction of a tooth (phantom tooth pain) or removal of an eye (phantom eye syndrome). A similar phenomenon is unexplained sensation in a body part unrelated to the amputated limb.

It has been hypothesized that the portion of the brain responsible for processing stimulation from amputated limbs, being deprived of input, expands into the surrounding brain, (Phantoms in the Brain: V.S. Ramachandran and Sandra Blakeslee) such that an individual who has had an arm amputated will experience unexplained pressure or movement on his face or head. In many cases, the phantom limb aids in adaptation to a prosthesis, as it permits the person to experience proprioception of the prosthetic limb. To support improved resistance or usability, comfort or healing, some type of stump socks may be worn instead of or as part of wearing a prosthesis.

Another side effect can be heterotopic ossification, especially when a bone injury is combined with a head injury. The brain signals the bone to grow instead of scar tissue to form, and nodules and other growth can interfere with prosthetics and sometimes require further operations. This type of injury has been especially common among soldiers wounded by improvised explosive devices in the Iraq War. Nearly half of the individuals who have an amputation due to vascular disease will die within 5 years. This is higher than the five year mortality rates for breast cancer, colon cancer, and prostate cancer. Of persons with diabetes who have a lower extremity amputation, up to 55% will require amputation of the second leg within two to three years.

4 Burns

A burn is a type of injury to skin, or other tissues, caused by heat, cold, electricity, chemicals, friction, or radiation. Most burns are due to heat from hot liquids, solids, or fire.

The characteristics of a burn depend upon its depth. Superficial burns cause pain lasting two or three days, followed by peeling of the skin over the next few days. Individuals suffering from more severe burns may indicate discomfort or complain of feeling pressure rather than pain. Full-thickness burns may be entirely insensitive to light touch or puncture. While superficial burns are typically red in color, severe burns may be pink, white or black. Burns around the mouth or singed hair inside the nose may indicate that burns to the airways have occurred, but these findings are not definitive. More worrisome signs include: shortness of breath, hoarseness, and stridor or wheezing. Itchiness is common during the healing process, occurring in up to 90% of adults and nearly all children. Numbness or tingling may persist for a prolonged period of time after an electrical injury. Burns may also produce emotional and psychological distress.

Type	Layers Involved	Appearance	Texture	Sensation	Healing Time	Prognosis
Superficial (first-degree)	Epidermis	Red without blisters	Dry	Painful	5–10 days	Heals well. Repeated sunburns increase the risk of skin cancer later in life.
Superficial partial thickness (second-degree)	Extends into superficial (papillary) dermis	Redness with clear blister. Blanches with pressure.	Moist	Very painful	2–3 weeks	Local infection (cellulitis) but no scarring typically
Deep partial thickness (second-degree)	Extends into deep (reticular) dermis	Yellow or white. Less blanching. May be blistering.	Fairly dry	Pressure and discomfort	3–8 weeks	Scarring, contractures (may require excision and skin grafting)
Full thickness (third-degree)	Extends through entire dermis	Stiff and white/brown. No blanching.	Leathery	Painless	Prolonged (months) and incomplete	Scarring, contractures, amputation (early excision recommended)
Fourth-degree	Extends through entire skin, and into underlying fat, muscle and bone	Black; charred with eschar	Dry	Painless	Requires excision	Amputation, significant functional impairment and in some cases, death.

Cause

Burns are caused by a variety of external sources classified as thermal (heat-related), chemical, electrical, and radiation. In the United States, the most common causes of burns are: fire or flame (44%), scalds (33%), hot objects (9%), electricity (4%), and chemicals (3%). Most (69%) burn injuries occur at home or at work (9%), and most are accidental, with 2% due to assault by another, and 1–2% resulting from a suicide attempt. These sources can cause inhalation injury to the airway and/or lungs, occurring in about 6%.

Burn injuries occur more commonly among the poor. Smoking and alcoholism are other risk factors. Fire-related burns are generally more common in colder climates. Specific risk factors in the developing world include cooking with open fires or on the floor as well as developmental disabilities in children and chronic diseases in adults.

Subheadings

1. Sunburn	**2. Minor Burn**	**3. Major Burn**	**4. Chemical Burn**
5. Electrical Burn	**6. Heat Burns & Scald**		

1 Sunburn

Sunburn is a form of radiation burn that affects living tissue, such as skin, that results from an overexposure to ultraviolet (UV) radiation, commonly from the sun. Common symptoms in humans and other animals include red or reddish skin that is hot to the touch, pain, general fatigue, and mild dizziness. An excess of UV radiation can be life-threatening in extreme cases. Excessive UV radiation is the leading cause of primarily non-malignant skin tumors. Sunburn is an inflammatory response in the skin triggered by direct DNA damage by UV radiation. When the skin cells' DNA is overly damaged by UV radiation, type I cell-death is triggered and the skin is replaced. Sun protective measures including sunscreen and sun protective clothing are widely accepted to prevent sunburn and some types of skin cancer. Special populations including children are especially susceptible to sunburn and protective measures should be used.

Signs & Symptoms

Typically, there is initial redness (erythema), followed by varying degrees of pain, proportional in severity to both the duration and intensity of exposure. Other symptoms can include blistering, swelling (edema), pruritus (itching), peeling skin, rash, nausea, fever, chills, and fainting (syncope). Also, a small amount of heat is given off from the burn, caused by the concentration of blood in the healing process, giving a warm feeling to the affected area. Sunburns may be classified as superficial, or partial thickness burns. Blistering is a sign of second degree sunburn.

Variations	Minor sunburns typically cause nothing more than slight redness and tenderness to the affected areas. In more serious cases, blistering can occur. Extreme sunburns can be painful to the point of debilitation and may require hospital care.
Duration	Sunburn can occur in less than 15 minutes, and in seconds when exposed to non-shielded welding arcs or other sources of intense ultraviolet light. Nevertheless, the inflicted harm is often not immediately obvious. After the exposure, skin may turn red in as little as 30 minutes but most often takes 2 to 6 hours. Pain is usually strongest 6 to 48 hours after exposure. The burn continues to develop for 1 to 3 days, occasionally followed by peeling skin in 3 to 8 days. Some peeling and itching may continue for several weeks.
Skin Cancer	Ultraviolet radiation causes sunburns and increases the risk of three types of skin cancer: melanoma, basal-cell carcinoma and squamous-cell carcinoma. Of greatest concern is that the melanoma risk increases in a dose-dependent manner with the number of a person's lifetime cumulative episodes of sunburn. It has been estimated that over 1/3 of melanomas in the United States and Australia could be prevented with regular sunscreen use.

Biological	Sunburn is caused by UV radiation, either from the sun or from artificial sources, such as tanning lamps, welding arcs, or ultraviolet germicidal irradiation. It is a reaction of the body to direct DNA damage from UVB light. This damage is mainly the formation of a thymine dimer. The damage is recognized by the body, which then triggers several defense mechanisms, including DNA repair to revert the damage, apoptosis and peeling to remove irreparably damaged skin cells, and increased melanin production to prevent future damage. Melanin readily absorbs UV wavelength light, acting as a photoprotectant. By preventing UV photons from disrupting chemical bonds, melanin inhibits both the direct alteration of DNA and the generation of free radicals, thus indirect DNA damage. Sunburn causes an inflammation process, including production of prostanoids and bradykinin. These chemical compounds increase sensitivity to heat by reducing the threshold of heat receptor (TRPV1) activation from 109 °F (43 °C) to 85 °F (29 °C). The pain may be caused by overproduction of a protein called CXCL5, which activates nerve fibres. Skin type determines the ease of sunburn. In general, people with lighter skin tone and limited capacity to develop a tan after UV radiation exposure have a greater risk of sunburn. The Fitzpatrick's Skin phototypes classification describes the normal variations of skin responses to UV radiation. Persons with type I skin have the greatest capacity to sunburn and type VI have the least capacity to burn. However, all skin types can develop sunburn.

Fitzpatrick's Skin Phototypes
- Type I: Pale white skin, burns easily, does not tan
- Type II: White skin, burns easily, tans with difficulty
- Type III: White skin, may burn but tans easily
- Type IV: Light brown/olive skin, hardly burns, tans easily
- Type V: Brown skin, usually does not burn, tans easily
- Type VI: Black skin, very unlikely to burn, becomes darker with UV radiation exposure

UV Intensity The UV Index indicates the risk of getting a sunburn at a given time and location. Contributing factors include:	1. The time of day. In most locations, the sun's rays are strongest between approximately 10am and 4pm daylight saving time. 2. Cloud cover. UV is partially blocked by clouds; but even on an overcast day, a significant percentage of the sun's damaging UV radiation can pass through clouds. 3. Proximity to reflective surfaces, such as water, sand, concrete, snow, and ice. All of these reflect the sun's rays and can cause sunburns. 4. The season of the year. The position of the sun in late spring and early summer can cause a more-severe sunburn. 5. Altitude. At a higher altitude it is easier to become burnt, because there is less of the earth's atmosphere to block the sunlight. UV exposure increases about 4% for every 1000 ft (305 m) gain in elevation. 6. Proximity to the equator (latitude). Between the polar and tropical regions, the closer to the equator, the more direct sunlight passes through the atmosphere over the course of a year. For example, the southern United States gets fifty percent more sunlight than the northern United States.

Because of variations in the intensity of UV radiation passing through the atmosphere, the risk of sunburn increases with proximity to the tropic latitudes, located between 23.5° north and south latitude. All else being equal (e.g., cloud cover, ozone layer, terrain, etc.), over the course of a full year, each location within the tropic or polar regions receives approximately the same amount of UV radiation. In the temperate zones between 23.5° and 66.5°, UV radiation varies substantially by latitude and season. The higher the latitude, the lower the intensity of the UV rays. Intensity in the northern hemisphere is greatest during the months of May, June and July — and in the southern hemisphere, November, December and January. On a minute-by-minute basis, the amount of UV radiation is dependent on the angle of the sun. This is easily determined by the height ratio of any object to the size of its shadow. The greatest risk is at solar noon, when shadows are at their minimum and the sun's radiation passes most directly through the atmosphere. Regardless of one's latitude (assuming no other variables), equal shadow lengths mean equal amounts of UV radiation.

Diagnosis

Diagnosis
The differential diagnosis of sunburn includes other skin pathology induced by UV radiation including photoallergic reactions, phototoxic reactions to topical or systemic medications, and other dermatologic disorders that are aggravated by exposure to sunlight. Considerations for diagnosis include duration and intensity of UV exposure, use of topical or systemic medications, history of dermatologic disease, and nutritional status.

- Phototoxic reactions: Non-immunological response to sunlight interacting with certain drugs and chemicals in the skin which resembles an exaggerated sunburn. Common drugs that may cause a phototoxic reaction include amiodarone, dacarbazine, fluoroquinolones, 5-fluorouracil, furosemide, nalidixic acid, phenothiazines, psoralens, retinoids, sulfonamides, sulfonylureas, tetracyclines, thiazides, and vinblastine.
- Photoallergic reactions: Uncommon immunological response to sunlight interacting with certain drugs and chemicals in the skin. When in excited state by UVR, these drugs and chemicals form free radicals that react to form functional antigens and induce a Type IV hypersensitivity reaction. These drugs include 6-methylcoumarin, aminobenzoic acid and esters, chlorpromazine, promethazine, diclofenac, sulfonamides, and sulfonylureas. Unlike phototoxic reactions which resemble exaggerated sunburns, photoallergic reactions can cause intense itching and can lead to thickening of the skin.
- Phytophotodermatitis: UV radiation induces inflammation of the skin after contact with certain plants (including limes, celery, and meadow grass). Causes pain, redness, and blistering of the skin in the distribution of plant exposure.
- Polymorphic light eruption: Recurrent abnormal reaction to UVR. It can present in various ways including pink-to-red bumps, blisters, plaques and urticaria.

- Solar urticaria: UVR-induced wheals that occurs within minutes of exposure and fades within hours.
- Other skin diseases exacerbated by sunlight: Several dermatologic conditions can increase in severity with exposure to UVR. These include systemic lupus erythematosus (SLE), dermatomyositis, acne, atopic dermatitis, and rosacea.

Prevention

Skin	The most effective way to prevent sunburn is to reduce the amount of UV radiation reaching the skin. The World Health Organization, American Academy of Dermatology, and Skin Cancer Foundation recommend the following measures to prevent excessive UV exposure and skin cancer.	● Limit sun exposure between the hours of 10am and 4pm, when UV rays are the strongest ● Seek shade when UV rays are most intense ● Wear sun-protective clothing including a wide brim hat, sunglasses, and tightly-woven, loose-fitting clothing ● Use sunscreen ● Avoid tanning beds and artificial UV exposure
UV Intensity	The strength of sunlight is published in many locations as a UV Index. Sunlight is generally strongest when the sun is close to the highest point in the sky. Due to time zones and daylight saving time, this is not necessarily at 12 noon, but often one to two hours later. Seeking shade including using umbrellas and canopies can reduce the amount of UV exposure, but does not block all UV rays. The WHO recommends following the shadow rule: "Watch your shadow – Short shadow, seek shade!"	

INJURY Burns Sunburns Prevention

Sunscreen	Commercial preparations are available that block UV light, known as sunscreens or sunblocks. They have a sun protection factor (SPF) rating, based on the sunblock's ability to suppress sunburn: The higher the SPF rating, the lower the amount of direct DNA damage. The stated protection factors are correct only if 2 mg of sunscreen is applied per square cm of exposed skin. This translates into about 28 mL (1 oz) to cover the whole body of an adult male, which is much more than many people use in practice. Sunscreens function as chemicals such as oxybenzone and dioxybenzone that absorb UV radiation (chemical sunscreens) or opaque materials such as zinc oxide or titanium oxide to physically block UV radiation (physical sunscreens). Chemical and mineral sunscreens vary in the wavelengths of UV radiation blocked. Broad-spectrum sunscreens contain filters that protect against UVA radiation as well as UVB. Although UVA radiation does not primarily cause sunburn, it does contribute to skin aging and an increased risk of skin cancer. Sunscreen is effective and thus recommended for preventing melanoma and squamous cell carcinoma. There is little evidence that it is effective in preventing basal cell carcinoma. Typical use of sunscreen does not usually result in vitamin D deficiency, but extensive usage may. Research has shown that the best sunscreen protection is achieved by application 15 to 30 minutes before exposure, followed by one reapplication 15 to 30 minutes after exposure begins. Further reapplication is necessary only after activities such as swimming, sweating, and rubbing.	
Sunscreen	This varies based on the indications and protection shown on the label — from as little as 80 minutes in water to a few hours, depending on the product selected. The American Academy of Dermatology recommends the following criteria in selecting a sunscreen:	• Broad spectrum: protects against both UVA and UVB rays • SPF 30 or higher • Water resistant: sunscreens are classified as water resistant based on time, either 40 minutes, 80 minutes, or not water resistant
Eyes	The eyes are also sensitive to sun exposure at about the same UV wavelengths as skin; snow blindness is essentially sunburn of the cornea. Wrap-around sunglasses or the use by spectacle-wearers of glasses that block UV light reduce the harmful radiation. UV light has been implicated in the development of age-related macular degeneration, pterygium and cataract. Concentrated clusters of melanin, commonly known as freckles, are often found within the iris.	
Diet	Dietary factors influence susceptibility to sunburn, recovery from sunburn, and risk of secondary complications from sunburn. Several dietary antioxidants, including essential vitamins, have been shown to have some effectiveness for protecting against sunburn and skin damage associated with ultraviolet radiation, in both human and animal studies. Supplementation with Vitamin C and Vitamin E was shown in one study to reduce the amount of sunburn after a controlled amount of UV exposure. A review of scientific literature through 2007 found that beta carotene (Vitamin A) supplementation had a protective effect against sunburn, but that the effects were only evident in the long-term, with studies of supplementation for periods less than 10 weeks in duration failing to show any effects. There is also evidence that common foods may have some protective ability against sunburn if taken for a period before the exposure.	
Protecting Children	Babies and children are particularly susceptible to UV damage which increases their risk of both melanoma and non-melanoma skin cancers later in life. Children should not sunburn at any age and protective measures can ensure their future risk of skin cancer is reduced.	• Infants 0-6 months: Children under 6mo generally have skin too sensitive for sunscreen and protective measures should focus on avoiding excessive UV exposure by using window mesh covers, wide brim hats, loose clothing that covers skin, and reducing UV exposure between the hours of 10am and 4pm. • Infants 6-12 months: Sunscreen can safely be used on infants this age. It is recommended to apply a broad-spectrum, water-resistant SPF 30+ sunscreen to exposed areas as well as avoid excessive UV exposure by using wide-brim hats and protective clothing. • Toddlers and Preschool-aged children: Apply a broad-spectrum, water-resistant SPF 30+ sunscreen to exposed areas, use wide-brim hats and sunglasses, avoid peak UV intensity hours of 10am-4pm and seek shade. Sun protective clothing with a SPF rating can also provide additional protection.

Treatment

INJURY Burns Sunburns Treatment

The primary measure is avoiding further exposure to the sun. The best treatment for most sunburns is time. Most sunburns heal completely within a few weeks. The American Academy of Dermatology recommends the following for treatment of sunburn:	• For pain relief, take cool baths or showers frequently. • Use soothing moisturizers that contain aloe vera or soy. Hydrocortisone creams that can be purchased over-the-counter can also be used on areas that are painful, however avoid creams that end in "caine" as these can be more irritating. • Anti-inflammatory medications such as ibuprofen or aspirin can help with pain. • Keep hydrated and drink extra water. • Do not pop blisters on a sunburn. Instead, let them heal on their own. • Protect sunburned skin with loose clothing when going outside to prevent further damage.

Non-steroidal anti-inflammatory drugs (such as ibuprofen or naproxen), and aspirin may decrease redness and pain. Local anesthetics such as benzocaine, however, are contraindicated. Schwellnus et al. states that topical steroids (such as hydrocortisone cream) do not help with sunburns, although the American Academy of Dermatology says they can be used on especially sore areas. While lidocaine cream is often used as a sunburn treatment, there is little evidence for the effectiveness of such use. Home treatments that may help the discomfort include using cool and wet cloths on the sunburned areas. Applying soothing lotions that contain aloe vera to the sunburn areas was supported by one review. Others have found aloe vera to have no effect. Aloe vera has no ability to protect people from sunburns. Another treatment includes using a moisturizer that contains soy. A sunburn draws fluid to the skin's surface and away from the rest of the body. Drinking extra water is recommended to help prevent dehydration.

2 Minor Burn

INJURY Burns Minor Burns

A minor burn is considered to be a first-degree or second-degree burn. If you are unfamiliar with the degrees see the main Burns heading above.

Treatment

Treatment

Early cooling (within 30 minutes of the burn) reduces burn depth and pain, but care must be taken as over-cooling can result in hypothermia. It should be performed with cool water 10–25 °C (50.0–77.0 °F) and not ice water as the latter can cause further injury. Cleaning with soap and water, removal of dead tissue, and application of dressings are important aspects of wound care. If intact blisters are present, it is not clear what should be done with them. Some tentative evidence supports leaving them intact. Second-degree burns should be re-evaluated after two days.

In the management of first and second-degree burns, little quality evidence exists to determine which dressing type to use. It is reasonable to manage first-degree burns without dressings. While topical antibiotics are often recommended, there is little evidence to support their use. Silver sulfadiazine (a type of antibiotic) is not recommended as it potentially prolongs healing time. There is insufficient evidence to support the use of dressings containing silver or negative-pressure wound therapy. Silver sulfadiazine does not appear to differ from silver containing foam dressings with respect to healing.

Medication
Burns can be very painful and a number of different options may be used for pain management. These include simple analgesics (such as ibuprofen and acetaminophen) and opioids such as morphine. Benzodiazepines may be used in addition to analgesics to help with anxiety. During the healing process, antihistamines, massage, or transcutaneous nerve stimulation may be used to aid with itching. Antihistamines, however, are only effective for this purpose in 20% of people. There is tentative evidence supporting the use of gabapentin and its use may be reasonable in those who do not improve with antihistamines. Intravenous lidocaine requires more study before it can be recommended for pain.

INJURY Burns Minor Burns Treatment

Intravenous antibiotics are recommended before surgery for those with extensive burns (>60% TBSA). As of 2008, guidelines do not recommend their general use due to concerns regarding antibiotic resistance and the increased risk of fungal infections. Tentative evidence, however, shows that they may improve survival rates in those with large and severe burns. Erythropoietin has not been found effective to prevent or treat anemia in burn cases. In burns caused by hydrofluoric acid, calcium gluconate is a specific antidote and may be used intravenously and/or topically. Recombinant human growth hormone (rhGH) in those with burns that involve more than 40% of their body appears to speed healing without affecting the risk of death. The use of steroids is of unclear evidence.

Alternative Medicine
Honey has been used since ancient times to aid wound healing and may be beneficial in first- and second-degree burns. There is moderate evidence that honey helps heal partial thickness burns. The evidence for aloe vera is of poor quality. While it might be beneficial in reducing pain, and a review from 2007 found tentative evidence of improved healing times, a subsequent review from 2012 did not find improved healing over silver sulfadiazine. There were only three randomized controlled trials for the use of plants for burns, two for aloe vera and one for oatmeal.

There is little evidence that vitamin E helps with keloids or scarring. Butter is not recommended. In low income countries, burns are treated up to one-third of the time with traditional medicine, which may include applications of eggs, mud, leaves or cow dung. Surgical management is limited in some cases due to insufficient financial resources and availability. There are a number of other methods that may be used in addition to medications to reduce procedural pain and anxiety including: virtual reality therapy, hypnosis, and behavioral approaches such as distraction techniques.

3 Major Burn

A major burn is considered to be a third-degree or fourth-degree burn. If you are unfamiliar with the degrees see the main Burns heading above.

Treatment

Early cooling (within 30 minutes of the burn) reduces burn depth and pain, but care must be taken as over-cooling can result in hypothermia. It should be performed with cool water 10–25 °C (50.0–77.0 °F) and not ice water as the latter can cause further injury. Cleaning with soap and water, removal of dead tissue, and application of dressings are important aspects of wound care. If intact blisters are present, it is not clear what should be done with them. Some tentative evidence supports leaving them intact. Second-degree burns should be re-evaluated after two days.

In the management of first and second-degree burns, little quality evidence exists to determine which dressing type to use. It is reasonable to manage first-degree burns without dressings. While topical antibiotics are often recommended, there is little evidence to support their use. Silver sulfadiazine (a type of antibiotic) is not recommended as it potentially prolongs healing time. There is insufficient evidence to support the use of dressings containing silver or negative-pressure wound therapy. Silver sulfadiazine does not appear to differ from silver containing foam dressings with respect to healing.

Medication
Burns can be very painful and a number of different options may be used for pain management. These include simple analgesics (such as ibuprofen and acetaminophen) and opioids such as morphine. Benzodiazepines may be used in addition to analgesics to help with anxiety. During the healing process, antihistamines, massage, or transcutaneous nerve stimulation may be used to aid with itching. Antihistamines, however, are only effective for this purpose in 20% of people. There is tentative evidence supporting the use of gabapentin and its use may be reasonable in those who do not improve with antihistamines. Intravenous lidocaine requires more study before it can be recommended for pain.

Intravenous antibiotics are recommended before surgery for those with extensive burns (>60% TBSA). As of 2008, guidelines do not recommend their general use due to concerns regarding antibiotic resistance and the increased risk of fungal infections. Tentative evidence, however, shows that they may improve survival rates in those with large and severe burns. Erythropoietin has not been found effective to prevent or treat anemia in burn cases. In burns caused by hydrofluoric acid, calcium gluconate is a specific antidote and may be used intravenously and/or topically. Recombinant human growth hormone (rhGH) in those with burns that involve more than 40% of their body appears to speed healing without affecting the risk of death. The use of steroids is of unclear evidence.

Surgery
Wounds requiring surgical closure with skin grafts or flaps (typically anything more than a small full thickness burn) should be dealt with as early as possible. Circumferential burns of the limbs or chest may need urgent surgical release of the skin, known as an escharotomy. This is done to treat or prevent problems with distal circulation, or ventilation. It is uncertain if it is useful for neck or digit burns. Fasciotomies may be required for electrical burns.

Skin grafts can involve temporary skin substitute, derived from animal (human donor or pig) skin or synthesized. They are used to cover the wound as a dressing, preventing infection and fluid loss, but will eventually need to be removed. Alternatively, human skin can be treated to be left on permanently without rejection.

Prognosis

The prognosis is worse in those with larger burns, those who are older, and those who are females. The presence of a smoke inhalation injury, other significant injuries such as long bone fractures, and serious co-morbidities (e.g. heart disease, diabetes, psychiatric illness, and suicidal intent) also influence prognosis. On average, of those admitted to United States burn centers, 4% die, with the outcome for individuals dependent on the extent of the burn injury. For example, admittees with burn areas less than 10% TBSA had a mortality rate of less than 1%, while admittees with over 90% TBSA had a mortality rate of 85%. In Afghanistan, people with more than 60% TBSA burns rarely survive. The Baux score has historically been used to determine prognosis of major burns. However, with improved care, it is no longer very accurate. The score is determined by adding the size of the burn (% TBSA) to the age of the person, and taking that to be more or less equal to the risk of death. Burns in 2013 resulted in 1.2 million years lived with disability and 12.3 million disability adjusted life years.

Complications
A number of complications may occur, with infections being the most common. In order of frequency, potential complications include: pneumonia, cellulitis, urinary tract infections and respiratory failure. Risk factors for infection include: burns of more than 30% TBSA, full-thickness burns, extremes of age (young or old), or burns involving the legs or perineum. Pneumonia occurs particularly commonly in those with inhalation injuries.

Anemia secondary to full thickness burns of greater than 10% TBSA is common. Electrical burns may lead to compartment syndrome or rhabdomyolysis due to muscle breakdown. Blood clotting in the veins of the legs is estimated to occur in 6 to 25% of people. The hypermetabolic state that may persist for years after a major burn can result in a decrease in bone density and a loss of muscle mass. Keloids may form subsequent to a burn, particularly in those who are young and dark skinned. Following a burn, children may have significant psychological trauma and experience post-traumatic stress disorder. Scarring may also result in a disturbance in body image. In the developing world, significant burns may result in social isolation, extreme poverty and child abandonment.

4 Chemical Burn

5 Electrical Burn

An electrical burn is a burn that results from electricity passing through the body causing rapid injury. Electrical burns differ from thermal or chemical burns in that they cause much more subdermal damage. They can exclusively cause surface damage, but more often tissues deeper underneath the skin have been severely damaged. As a result, electrical burns are difficult to accurately diagnose, and many people underestimate the severity of their burn. In extreme cases, electricity can cause shock to the brain, strain to the heart, and injury to other organs. For a burn to be classified as electrical, electricity must be the direct cause.

For example, burning a finger on a hot electric steam iron would be thermal, not electrical. According to Joule's first law: electricity passing through resistance creates heat, so there is no current entering the body in this type of burn. Likewise, a fire that is ruled to be "electrical" in origin, does not necessarily mean that any injuries or deaths are due to electrical burns. Unless someone was injured at the exact moment that the fire began, it is unlikely that any electrical burns would occur.

Causes

Causes

Electrical burns can be caused by a variety of ways such as touching or grasping electrically live objects, short-circuiting, inserting fingers into electrical sockets, and falling into electrified water. Lightning strikes are also a cause of electrical burns, but this is a less common event. With the advances in technology, electrical injuries are becoming more common and are the fourth leading cause of work-related traumatic death. One third of all electrical traumas and most high-voltage injuries are job related, and more than 50% of these injuries result from power line contact.

Categorization

Electrical burns can be classified into six categories, and any combination of these categories may be present on an electrical burn victim:
- **Low Voltage Burn:** A burn produced by contact with a power source of 500 volts or less is classified as a low-voltage burn. The current at this voltage is not enough to cause tissue damage along its path except at the contact site. This type of burn may be mild, superficial, or severe depending on the contact time.
- **High Voltage Burn:** This burn is very severe as the victim makes direct contact with the high voltage supply and the damage runs its course throughout the body. Exterior injuries are misleading as most of the damage occurs underneath the skin. In this case, subdermal tissues are severely damaged.
- **Arc Burn:** This type of burn occurs when electrical energy passes from a high-resistance area to a low-resistance area. No contact is required with an arc burn as the electricity ionizes air particles to complete the circuit. The heat generated can be as high as 4,000°C - hot enough to vaporize metal and ignite a victim's clothing. A form of explosion dissipates excess energy from the arc. In addition, a high-current arc can produce a pressure wave blast in excess of 1000 pounds per square inch of pressure. This can throw the victim and cause severe injuries.

- **Flash Burn:** Flash burns are caused by electrical arcs that pass over the skin. The intense heat and light of an arc flash can cause severe burns in a fraction of a second. Although the burns on the skin are largely superficial and cover a large area, tissues beneath the skin are generally undamaged and unaffected. This typically occurs when the frequency of the AC current is significantly higher than the 50 or 60 Hz used in land-based electrical distribution systems (such as in aircraft).
- **Flame Burn:** Flame burns are caused by contact to objects that were ignited by an electrical source when associated with flash and arc burns.
- **Oral Burn:** This is caused by biting or sucking on electrical cords, and it most commonly happens to children. Electric current typically passes from one side of the child's mouth to the other, possibly causing deformity.

Pathophysiology

Four electrical factors determine the severity of the damage caused by electrical burns: voltage, current, resistance, and frequency. The severity of the burn also depends on the pathway the current takes through the body. Generally, the pathway of the current will follow the course of the least resistant tissues: firstly blood vessels, nerves, and muscle, then skin, tendon, fat, and bone. Most commonly, electric injuries primarily damage the outer limbs, but more critical portions of the body may be affected as well causing severe complications. As the body comes into contact with an electrical source, it becomes part of the electrical circuit. As such, the current has a point of entry and an exit at two different points on the body. The point of entry tends to be depressed and leathery whereas the exit wound is typically more extensive and explosive. It is hard to accurately diagnose an electrical burn because only the entry and exit wounds are visible and the internal damage is not.

Prevention

The following are some examples of unsafe practices which could lead to electric injury (cannot cover every possible scenario):

- Using electrical appliances while wet (showering, bathing, etc.) as plumbing is often connected to electrical ground, and wet skin loses much of its resistance. Exception for newer quality appliances intended for the bathroom when not simultaneously showering, bathing, being in a path of water going to plumbing, or touching bare concrete or sheet metal. Standing on a dry carpet or rug is ideal.
- All power mains outlets should have a wall cover to avoid accidentally touching the electrified sides between the wall and outlet. This is especially important for children, as their small fingers can easily reach into this gap along the sides.
- Using AC electrical appliances around bathtubs, swimming pools, hot tubs, etc. with the risk that the appliance may fall into the water and cause electrocution. Only battery-operated devices are safe.
- Adjusting prongs of an electrical cord that are too wide or narrow them with your fingertips while simultaneously plugging the cord into the power mains. The power plug used in the UK and some Commonwealth countries provides limited protection (Type G, with the lower half of the live prongs insulated), but all others do not.

- Failure to use child safety plugs in all outlets, and keeping children away from electrical cords.
- Not following manufacturer safety instructions for electrical appliances. This includes not using and immediately unplugging any appliance with a damaged electrical cord. If this cannot be done safely (i.e. damage is too close to the plug), the circuit breaker should be turned off beforehand.
- Touching metallic areas of an AC electrical appliance while also simultaneously touching faucets, water pipes, another metallic AC appliance, or being even partly immersed in water (including wet feet). This could ground the body through metal or water, with the risk that a faulty appliance is electrically "hot" on its outside cover or chassis.
- Not installing Ground Fault Circuit Interrupter (GFCI) outlets or circuit breakers in all areas with plumbing, bare concrete flooring, exposed to the elements, or outdoors by a qualified electrician. (Many newer homes already have these devices pre-installed.) Running an extension cord from non-GFCI areas such as bedrooms and hallways defeats this safety feature. Oral burns (above) cannot be prevented by GFCI.
- At poolside, not having a non-metallic fiberglass pole or net on hand to pull someone to safety in case the pool water is electrified, and the victim is still conscious. Furthermore, to not know where the circuit breakers for the pool are located.

- Using an ordinary vacuum cleaner in wet or damp areas. Only a "wet vac" is suitable for this purpose. Overfilling its collection container is also unsafe.
- Going near or under a downed power line, even if there's no direct contact with the wire. Also, not remaining inside your vehicle and waiting for rescue should a power line fall on it.
- Not double checking polarity before doing a jump start, or attempting a jump on a frozen battery. Although 12-volt batteries used in vehicles are at a safe voltage, a short circuit can still cause various types of burns and an explosion.
- Failure to replace high-risk appliances of decades past with new ones (hand-held corded electric drills, blow dryers, etc.)

Treatment

First Aid
An electrically burned patient should not be touched or treated until the source of electricity has been removed. Electrical injuries often extend beyond burns and include cardiac arrhythmia, such as ventricular fibrillation. First aid treatments include assessment of consciousness of the victim, evaluation of pulse and circulation, and treatment of burns.

These injuries must be treated in addition to the burns themselves. In very rare instances, a high voltage electric shock can cause cataracts in the lens of the eyes, and detachment of the retina. This may be delayed for some days or weeks after the initial injury.

Hospitalization
Typically, an electrical burn patient has a lower affected body surface area than other burn patients, yet complication risks are much higher due to internal injury. Often, the damaged internal tissue demands hospitalization. If not treated, this damaged tissue can cause complications (such as gaseous gangrene from dead tissue or loss of blood flow to limbs) and the damaged body parts may need to be amputated. Repeated removal of the damaged tissue and extensive rehabilitation are common while limb amputation rates for victims who experience direct electrical contact can be as high as 75%. Burn treatment for severe wounds may require skin grafting, debridement, excision of dead tissue, and repair of damaged organs.

Rehabilitation Electrical burning has an effect on most vital body functions and is accompanied by several other electrical related injuries:	● Damage to the veins and arteries which can cause ischaemic necrosis. ● Involuntary contraction of muscles due to electrical interference which can cause bone fractures and dislocations. ● Interference with the electrical conductivity of organs such as the heart and nerves. This can lead to seizures, lung injury due to severe central nervous system damage, and cardiac arrest. ● Forceful propulsion of the body, producing such injuries as spinal and limb fractures.	These injuries must be treated in addition to the burns themselves. In very rare instances, a high voltage electric shock can cause cataracts in the lens of the eyes, and detachment of the retina. This may be delayed for some days or weeks after the initial injury.

6 Heat Burns & Scald

5 Environmental

Any injury you can get from environmental factors such as the sun or water but excluding air injuries such as suffocation.

Subheadings

1. Anaphylaxis	**2. Heatstroke**	**3. Heat Syncope**	**4. Heat Fatigue**

9. Trench Foot	**10. Seasickness**	**11. Aero-otitis Media**	**12. Aerosinusitis**

1 Anaphylaxis

Anaphylaxis is a serious allergic reaction that is rapid in onset and may cause death. It typically causes more than one of the following: an itchy rash, throat or tongue swelling, shortness of breath, vomiting, lightheadedness, and low blood pressure. These symptoms typically come on over minutes to hours.

Common causes include insect bites and stings, foods, and medications. Other causes include latex exposure and exercise. Additionally, cases may occur without an obvious reason. The mechanism involves the release of mediators from certain types of white blood cells triggered by either immunologic or non-immunologic mechanisms. Diagnosis is based on the presenting symptoms and signs after exposure to a potential allergen.

The primary treatment of anaphylaxis is epinephrine injection into a muscle, intravenous fluids, and positioning the person flat. Additional doses of epinephrine may be required. Other measures, such as antihistamines and steroids, are complementary. Carrying an epinephrine autoinjector and identification regarding the condition is recommended in people with a history of anaphylaxis.

Worldwide, 0.05–2% of the population is estimated to experience anaphylaxis at some point in life. Rates appear to be increasing. It occurs most often in young people and females. Of people who go to a hospital with anaphylaxis in the United States about 99.7% survive.

There are three main classifications of anaphylaxis. Anaphylactic shock is associated with systemic vasodilation that causes low blood pressure which is by definition 30% lower than the person's baseline or below standard values. Biphasic anaphylaxis is the recurrence of symptoms within 1–72 hours with no further exposure to the allergen. Reports of incidence vary, with some studies claiming as many as 20% of cases. The recurrence typically occurs within 8 hours. It is managed in the same manner as anaphylaxis. Pseudoanaphylaxis or anaphylactoid reactions are a type of anaphylaxis that does not involve an allergic reaction but is due to direct mast cell degranulation. Non-immune anaphylaxis is the current term used by the World Allergy Organization with some recommending that the old terminology no longer be used.

Signs & Symptoms

Anaphylaxis typically presents many different symptoms over minutes or hours with an average onset of 5 to 30 minutes if exposure is intravenous and 2 hours if from eating food. The most common areas affected include: skin (80–90%), respiratory (70%), gastrointestinal (30–45%), heart and vasculature (10–45%), and central nervous system (10–15%) with usually two or more being involved.

Skin	Symptoms typically include generalized hives, itchiness, flushing, or swelling (angioedema) of the afflicted tissues. Those with angioedema may describe a burning sensation of the skin rather than itchiness. Swelling of the tongue or throat occurs in up to about 20% of cases. Other features may include a runny nose and swelling of the conjunctiva. The skin may also be blue tinged because of lack of oxygen.
Respiratory	Respiratory symptoms and signs that may be present include shortness of breath, wheezes, or stridor. The wheezing is typically caused by spasms of the bronchial muscles while stridor is related to upper airway obstruction secondary to swelling. Hoarseness, pain with swallowing, or a cough may also occur.

Cardiovascular	While a fast heart rate caused by low blood pressure is more common, a Bezold–Jarisch reflex has been described in 10% of people, where a slow heart rate is associated with low blood pressure. A drop in blood pressure or shock (either distributive or cardiogenic) may cause the feeling of lightheadedness or loss of consciousness. Rarely very low blood pressure may be the only sign of anaphylaxis. Coronary artery spasm may occur with subsequent myocardial infarction, dysrhythmia, or cardiac arrest. Those with underlying coronary disease are at greater risk of cardiac effects from anaphylaxis. The coronary spasm is related to the presence of histamine-releasing cells in the heart.
Other	Gastrointestinal symptoms may include crampy abdominal pain, diarrhea, and vomiting. There may be confusion, a loss of bladder control or pelvic pain similar to that of uterine cramps. Dilation of blood vessels around the brain may cause headaches. A feeling of anxiety or of "impending doom" has also been described.

Causes

Anaphylaxis can occur in response to almost any foreign substance. Common triggers include venom from insect bites or stings, foods, and medication. Foods are the most common trigger in children and young adults while medications and insect bites and stings are more common in older adults. Less common causes include: physical factors, biological agents such as semen, latex, hormonal changes, food additives such as monosodium glutamate and food colors, and topical medications. Physical factors such as exercise (known as exercise-induced anaphylaxis) or temperature (either hot or cold) may also act as triggers through their direct effects on mast cells.

Events caused by exercise are frequently associated with the ingestion of certain foods. During anesthesia, neuromuscular blocking agents, antibiotics, and latex are the most common causes. The cause remains unknown in 32–50% of cases, referred to as "idiopathic anaphylaxis." Six vaccines (MMR, varicella, influenza, hepatitis B, tetanus, meningococcal) are recognized as a cause for anaphylaxis, and HPV may cause anaphylaxis as well. Physical exercise is an uncommon cause of anaphylaxis; in about a third of such cases there is a co-factor like taking an NSAID or eating a specific food prior to exercising.

Food	Many foods can trigger anaphylaxis; this may occur upon the first known ingestion. Common triggering foods vary around the world. In Western cultures, ingestion of or exposure to peanuts, wheat, nuts, certain types of seafood like shellfish, milk, and eggs are the most prevalent causes. Sesame is common in the Middle East, while rice and chickpeas are frequently encountered as sources of anaphylaxis in Asia. Severe cases are usually caused by ingesting the allergen, but some people experience a severe reaction upon contact. Children can outgrow their allergies. By age 16, 80% of children with anaphylaxis to milk or eggs and 20% who experience isolated anaphylaxis to peanuts can tolerate these foods.
Medication	Any medication may potentially trigger anaphylaxis. The most common are β-lactam antibiotics (such as penicillin) followed by aspirin and NSAIDs. Other antibiotics are implicated less frequently. Anaphylactic reactions to NSAIDs are either agent specific or occur among those that are structurally similar meaning that those who are allergic to one NSAID can typically tolerate a different one or different group of NSAIDs. Other relatively common causes include chemotherapy, vaccines, protamine and herbal preparations. Some medications (vancomycin, morphine, x-ray contrast among others) cause anaphylaxis by directly triggering mast cell degranulation. The frequency of a reaction to an agent partly depends on the frequency of its use and partly on its intrinsic properties. Anaphylaxis to penicillin or cephalosporins occurs only after it binds to proteins inside the body with some agents binding more easily than others. Anaphylaxis to penicillin occurs once in every 2,000 to 10,000 courses of treatment, with death occurring in fewer than one in every 50,000 courses of treatment. Anaphylaxis to aspirin and NSAIDs occurs in about one in every 50,000 persons. If someone has a reaction to penicillins, his or her risk of a reaction to cephalosporins is greater but still less than one in 1,000.
Venom	Venom from stinging or biting insects such as Hymenoptera (ants, bees, and wasps) or Triatominae (kissing bugs) may cause anaphylaxis in susceptible people. Previous reactions, that are anything more than a local reaction around the site of the sting, are a risk factor for future anaphylaxis; however, half of fatalities have had no previous systemic reaction.
Risk Factors	People with atopic diseases such as asthma, eczema, or allergic rhinitis are at high risk of anaphylaxis from food, latex, and radiocontrast agents but not from injectable medications or stings. One study in children found that 60% had a history of previous atopic diseases, and of children who die from anaphylaxis, more than 90% have asthma. Those with mastocytosis or of a higher socioeconomic status are at increased risk. The longer the time since the last exposure to the agent in question, the lower the risk.

Prevention

Avoidance of the trigger of anaphylaxis is recommended. In cases where this may not be possible, desensitization may be an option. Immunotherapy with Hymenoptera venoms is effective at desensitizing 80–90% of adults and 98% of children against allergies to bees, wasps, hornets, yellowjackets, and fire ants. Oral immunotherapy may be effective at desensitizing some people to certain food including milk, eggs, nuts and peanuts; however, adverse effects are common. For example, many people develop an itchy throat, cough, or lip swelling during immunotherapy. Desensitization is also possible for many medications, however it is advised that most people simply avoid the agent in question. In those who react to latex it may be important to avoid cross-reactive foods such as avocados, bananas, and potatoes among others.

Management

Anaphylaxis is a medical emergency that may require resuscitation measures such as airway management, supplemental oxygen, large volumes of intravenous fluids, and close monitoring. Passive leg raise may also be helpful in the emergency management.

Administration of epinephrine is the treatment of choice with antihistamines and steroids (for example, dexamethasone) often used as adjuncts. A period of in-hospital observation for between 2 and 24 hours is recommended for people once they have returned to normal due to concerns of biphasic anaphylaxis.

Epinephrine	Epinephrine (adrenaline) is the primary treatment for anaphylaxis with no absolute contraindication to its use. It is recommended that an epinephrine solution be given intramuscularly into the mid anterolateral thigh as soon as the diagnosis is suspected. The injection may be repeated every 5 to 15 minutes if there is insufficient response. A second dose is needed in 16–35% of episodes with more than two doses rarely required. The intramuscular route is preferred over subcutaneous administration because the latter may have delayed absorption. Minor adverse effects from epinephrine include tremors, anxiety, headaches, and palpitations. People on β-blockers may be resistant to the effects of epinephrine. In this situation if epinephrine is not effective intravenous glucagon can be administered which has a mechanism of action independent of β-receptors. If necessary, it can also be given intravenously using a dilute epinephrine solution. Intravenous epinephrine, however, has been associated both with dysrhythmia and myocardial infarction. Epinephrine autoinjectors used for self-administration typically come in two doses, one for adults or children who weigh more than 25 kg and one for children who weigh 10 to 25 kg.

Adjuncts	Antihistamines (both H1 and H2), while commonly used and assumed effective based on theoretical reasoning, are poorly supported by evidence. A 2007 Cochrane review did not find any good-quality studies upon which to base recommendations and they are not believed to have an effect on airway edema or spasm. Corticosteroids are unlikely to make a difference in the current episode of anaphylaxis, but may be used in the hope of decreasing the risk of biphasic anaphylaxis. Their prophylactic effectiveness in these situations is uncertain. Nebulized salbutamol may be effective for bronchospasm that does not resolve with epinephrine. Methylene blue has been used in those not responsive to other measures due to its presumed effect of relaxing smooth muscle.
Preparedness	People prone to anaphylaxis are advised to have an "allergy action plan." Parents are advised to inform schools of their children's allergies and what to do in case of an anaphylactic emergency. The action plan usually includes use of epinephrine autoinjectors, the recommendation to wear a medical alert bracelet, and counseling on avoidance of triggers. Immunotherapy is available for certain triggers to prevent future episodes of anaphylaxis. A multi-year course of subcutaneous desensitization has been found effective against stinging insects, while oral desensitization is effective for many foods.

Prognosis

In those in whom the cause is known and prompt treatment is available, the prognosis is good. Even if the cause is unknown, if appropriate preventative medication is available, the prognosis is generally good. If death occurs, it is usually due to either respiratory (typically asphyxia) or cardiovascular causes (shock), with 0.7–20% of cases causing death. There have been cases of death occurring within minutes. Outcomes in those with exercise-induced anaphylaxis are typically good, with fewer and less severe episodes as people get older.

2 Heatstroke

Heat stroke, also known as sun stroke, is a type of severe heat illness that results in a body temperature greater than 40.0 °C (104.0 °F) and confusion. Other symptoms include red skin, headache, and dizziness. There is generally a lack of sweating in classic heat stroke while sweating is generally present in exertional heatstroke. Onset can be sudden or gradual. Complications may include seizures, rhabdomyolysis, or kidney failure.

Heat stroke occurs because of high external temperatures or physical exertion. Risk factors include heat waves, high humidity, certain drugs such as diuretics, beta blockers, or alcohol, heart disease, and skin disorders. Cases not associated with physical exertion typically occur in those at the extremes of age or with long term health problems. Diagnosis is based on symptoms. It is a type of hyperthermia. It is distinct from a fever, where there is a physiological increase in the temperature set point.

Preventive measures include drinking sufficient fluids and avoiding excessive heat. Treatment is by rapid physical cooling of the body and supportive care. Recommended methods include spraying the person with water and using a fan, putting the person in ice water, or giving cold intravenous fluids. While it is reasonable to add ice packs around a person, this by itself is not routinely recommended.

Signs & Symptoms

Heat stroke generally presents with a hyperthermia of greater than 40.6 °C (105.1 °F) in combination with disorientation. There is generally a lack of sweating in classic heatstroke, while sweating is generally present in exertional heatstroke.

Before a heat stroke occurs, people show signs of heat exhaustion such as dizziness, mental confusion, headaches, and weakness; if a heat stroke occurs when the person is asleep, symptoms may be harder to notice. However, in exertional heat stroke, the affected person may sweat excessively. Young children, in particular, may have seizures. Eventually, unconsciousness, organ failure, and death will result.

Causes

Heat stroke occurs when thermoregulation is overwhelmed by a combination of excessive metabolic production of heat (exertion), excessive environmental heat, and insufficient or impaired heat loss, resulting in an abnormally high body temperature. Substances that inhibit cooling and cause dehydration such as alcohol, stimulants, medications, and age-related physiological changes predispose to so-called "classic" or non-exertional heat stroke (NEHS), most often in elderly and infirm individuals in summer situations with insufficient ventilation. Exertional heat stroke (EHS) can happen in young people without health problems or medications – most often in athletes, outdoor laborers, or military personnel engaged in strenuous hot-weather activity or in certified first responders wearing heavy personal protective equipment. In environments that are not only hot but also humid, it is important to recognize that humidity reduces the degree to which the body can cool itself by perspiration and evaporation. For humans and other warm-blooded animals, excessive body temperature can disrupt enzymes regulating biochemical reactions that are essential for cellular respiration and the functioning of major organs.

Cars	When the outside temperature is 21 °C (70 °F), the temperature inside a car parked in direct sunlight can quickly exceed 49 °C (120 °F). Young children or elderly adults left alone in a vehicle are at particular risk of succumbing to heat stroke. "Heat stroke in children and in the elderly can occur within minutes, even if a car window is opened slightly." As these groups of individuals may not be able to open car doors or to express discomfort verbally (or audibly, inside a closed car), their plight may not be immediately noticed by others in the vicinity. Dogs are even more susceptible than humans to heat stroke in cars, as they cannot produce whole-body sweat to cool themselves. Leaving the dog at home with plenty of water on hot days is recommended instead, or, if a dog must be brought along, it can be tied up in the shade outside the destination and provided with a full water bowl.

Prevention

The risk of heat stroke can be reduced by observing precautions to avoid overheating and dehydration. Light, loose-fitting clothes will allow perspiration to evaporate and cool the body. Wide-brimmed hats in light colors help prevent the sun from warming the head and neck. Vents on a hat will help cool the head, as will sweatbands wetted with cool water. Strenuous exercise should be avoided during hot weather, especially in the sun peak hours as well as avoiding confined spaces (such as automobiles) without air-conditioning or adequate ventilation.

In hot weather, people need to drink plenty of cool liquids and mineral salts to replace fluids lost from sweating. Thirst is not a reliable sign that a person needs fluids. A better indicator is the color of urine. A dark yellow color may indicate dehydration.

The Occupational Safety and Health Administration in the United States publishes a QuickCard with a checklist designed to help protect workers from heat stress:

- Know signs/symptoms of heat-related illnesses.
- Block out direct sun and other heat sources.
- Drink fluids often, and before you are thirsty.
- Wear lightweight, light-colored, loose-fitting clothes.
- Avoid beverages containing alcohol or caffeine.

Treatment

Treatment of heat stroke involves rapid mechanical cooling along with standard resuscitation measures. The body temperature must be lowered quickly. The person should be moved to a cool area (indoors, or at least in the shade) and clothing removed to promote heat loss (passive cooling). Active cooling methods should also be used, if possible: The person is bathed in cold water, or a hyperthermia vest can be applied. (However, wrapping the person in wet towels or clothes can actually act as insulation and increase the body temperature.) Cold compresses to the torso, head, neck, and groin will help cool the victim. A fan or dehumidifying air-conditioning unit may be used to aid in evaporation of the water (evaporative method).

Immersing a person into a tub of cold water (immersion method) is a widely recognized method of cooling. This method may require the effort of several people and the person should be monitored carefully during the treatment process. Immersion should be avoided for an unconscious person, but if there is no alternative, the person's head must be held above water.

Immersion in very cold water was once thought to be counterproductive by reducing blood flow to the skin and thereby preventing heat from escaping the body core. However, this hypothesis has been challenged in experimental studies, as well as by systematic reviews of the clinical data, indicating that cutaneous vasoconstriction and shivering thermogenesis do not play a dominant role in the decrease in core body temperature brought on by cold water immersion.

This can be seen in the effect of submersion hypothermia, where the body temperature decrease is directly related to environmental temperature, and though bodily defenses slow the decrease in temperature for a time, they ultimately fail to maintain endothermic homeostasis. Dantrolene, a direct-acting paralytic which abolishes shuddering and is effective in many other forms of hyperthermia, including centrally-, peripherally- and cellularly-mediated thermogenesis, has no individual or additive effects to cooling in the context of heat stroke, showing a lack of endogenous thermogenic response to cold water immersion. Thus, aggressive ice-water immersion remains the gold standard for life-threatening heat stroke.

Hydration is important in cooling the person. In mild cases of concomitant dehydration, this can be achieved by drinking water, or commercial isotonic sports drinks may be used as a substitute. In either exercise- or heat-induced dehydration, electrolyte imbalance can result, and can be worsened by excess consumption of water. Hyponatremia can be corrected by intake of hypertonic fluids. Absorption is rapid and complete in most people but if the person is confused, unconscious, or unable to tolerate oral fluid, then an intravenous drip may be necessary for rehydration and electrolyte replacement.

Heatstroke is also covered in the SURVIVAL section.

3 Heat Syncope

Heat syncope is fainting or dizziness as a result of overheating (syncope is the medical term for fainting). It is a type of heat illness. The basic symptom of heat syncope is fainting, with or without mental confusion. Heat syncope is caused by peripheral vessel dilation, resulting in diminished blood flow to the heart and dehydration.

Causes

Heat syncope occurs in a warm environment when blood pressure is lowered as the body dilates (widens) arterioles (small blood vessels) in the skin to radiate heat. This condition occurs within five days of heat acclimatization, before the blood volume expands. The result is less blood to the brain, causing light-headedness and fainting when a person stands up quickly or stands for a long period of time. Those who perform strenuous work outside in warm climates are at particular risk.

Signs & Symptoms

Faintness, dizziness, headache, increased pulse, restlessness, nausea, vomiting, and brief loss of consciousness.

Diagnosis

The diagnosis of heat syncope is done during a physical examination. During the physical exam the practitioner will test the blood pressure of the patient, and the pulse. If the patient is experiencing heat syncope the blood pressure will be low, and the pulse will be elevated. Observation of excess sweating will also be a key sign. Finally, the practitioner will ask questions figuring out the history of the patient's symptoms. If the patient developed symptoms while engaging in physical activity and high temperatures it will then be a true case of heat syncope.

Treatment

The basic treatment for heat syncope is like that for other types of fainting: the patient is positioned in a seating or supine position with legs raised. Water containing salt, or another drink containing electrolytes, is administered slowly, and the patient is moved to a cooler area, such as the shade. The affected person should rest and recover, because heat syncope can lead to heat stroke or heat exhaustion.

Prevention

Physical activity in extremely hot weather should be avoided. If a person starts to experience over heating, and symptoms of heat syncope, they should move or be moved to a shaded or cool area. It is also recommended to avoid alcoholic beverages in hot weather, because they cause dehydration which may worsen symptoms. Finally, drinking plenty of water with electrolytes is imperative when engaging in physical activity in hot weather.

Heat Syncope is also covered in the SURVIVAL section.

4 Heat Fatigue (Heat Exhaustion)

Heat exhaustion is a severe form of heat illness. It is a medical emergency. Heat exhaustion is caused by the loss of water and electrolytes through sweating.

Causes

Common causes of heat exhaustion include:
- Hot, sunny, humid weather
- Physical exertion, especially in hot, humid weather
- Due to impaired thermoregulation, elderly people and infants can get serious heat illness even at rest, if the weather outside is hot and humid, and they are not getting enough cool air.
- Some drugs, such as diuretics, antihistamines, beta-blockers, alcohol, ecstasy, and amphetamines can cause an increase in the risk of heat exhaustion.

Especially during physical exertion, risk factors for heat exhaustion include:
- Wearing dark, padded, or insulated clothing; hats; and/or helmets (for example, football pads or turnout gear)
- Having a higher percentage of body fat
- Dehydration
- Fever
- Some medications, like beta blockers and antipsychotic medicines

Signs & Symptoms

Symptoms of heat exhaustion include nausea, dizziness, irritability, headache, thirst, weakness, high body temperature, excessive sweating, and decreased urine output.

Treatment

INJURY Environmental Heat Fatigue Treatment

First aid for heat exhaustion includes:
- Moving the person to a cool place
- Having the patient take off extra layers of clothes
- Cooling the patient down by fanning them and putting wet towels on their body
- Having them lie down and put their feet up if they are feeling dizzy
- Having them drink water or sports drinks – but only if they are awake, not confused nor vomiting
- Turning the person on their side if they are vomiting

Emergency Medical Treatment
If a person with heat exhaustion gets medical treatment, Emergency Medical Technicians (EMTs) or doctors and/or nurses may also:
- Give them supplemental oxygen
- Give them intravenous fluids and electrolytes if they are too confused to drink and/or are vomiting

Heat Fatigue is also covered in the SURVIVAL section.

5 Heat Edema

Heat edema is a cutaneous condition characterized by dependent edema from vasodilatory pooling. Heat causes the blood vessels to expand (dilate), so body fluid moves into the hands or legs by gravity. The balance of salt in the body is also a risk factor for heat edema. If salt loss is less than normal, the increased salt level draws fluid into the hands and legs. Older adults have an increased risk of heat edema, especially if they have other medical conditions that affect their circulation. People visiting hot climates from colder climates may also have an increased risk of heat edema.

Heat Edema is also covered in the SURVIVAL section.

6 Frostbite

Frostbite occurs when exposure to low temperatures causes freezing of the skin or other tissues. The initial symptom is typically numbness. This may be followed by clumsiness with a white or bluish color to the skin. Swelling or blistering may occur following treatment. The hands, feet, and face are most commonly affected. Complications may include hypothermia or compartment syndrome. People who are exposed to low temperatures for prolonged periods, such as winter sports enthusiasts, military personnel, and homeless individuals, are at greatest risk.

Other risk factors include drinking alcohol, smoking, mental health problems, certain medications, and prior injuries due to cold. The underlying mechanism involves injury from ice crystals and blood clots in small blood vessels following thawing. Diagnosis is based on symptoms. Severity may be divided into superficial (1st and 2nd degree) or deep (3rd and 4th degree).

A bone scan or MRI may help in determining the extent of injury. Prevention is through wearing proper clothing, maintaining hydration and nutrition, avoiding low temperatures, and staying active without becoming exhausted. Treatment is by rewarming. This should be done only when refreezing is not a concern. Rubbing or applying snow to the affected part is not recommended. The use of ibuprofen and tetanus toxoid is typically recommended. For severe injuries iloprost or thrombolytics may be used. Surgery is sometimes necessary. Amputation, however, should generally be delayed for a few months to allow determination of the extent of injury.

Signs & Symptoms

Areas that are usually affected include cheeks, ears, nose and fingers and toes. Frostbite is often preceded by frostnip. The symptoms of frostbite progress with prolonged exposure to cold. Historically, frostbite has been classified by degrees according to skin and sensation changes, similar to burn classifications. However, the degrees do not correspond to the amount of long term damage. A simplification of this system of classification is superficial (first or second degree) or deep injury (third or fourth degree).

First Degree	• First degree frostbite is superficial, surface skin damage that is usually not permanent. • Early on, the primary symptom is loss of feeling in the skin. In the affected areas, the skin is numb, and possibly swollen, with a reddened border. • In the weeks after injury, the skin's surface may slough off.
Second Degree	• In second degree frostbite, the skin develops clear blisters early on, and the skin's surface hardens. • In the weeks after injury, this hardened, blistered skin dries, blackens, and peels. • At this stage, lasting cold sensitivity and numbness can develop.
Third Degree	• In third degree frostbite, the layers of tissue below the skin freeze. • Symptoms include blood blisters and "blue-grey discoloration of the skin". • In the weeks after injury, pain persists and a blackened crust (eschar) develops. • There can be longterm ulceration and damage to growth plates.
Fourth Degree	• In fourth degree frostbite, structures below the skins are involved like muscles, tendon, and bone. • Early symptoms include a colorless appearance of the skin, a hard texture, and painless rewarming. • Later, the skin becomes black and mummified. The amount of permanent damage can take one month or more to determine. Autoamputation can occur after two months.

Causes

The major risk factor for frostbite is exposure to cold through geography, occupation and/or recreation. Inadequate clothing and shelter are major risk factors. Frostbite is more likely when the body's ability to produce or retain heat is impaired. Physical, behavioral, and environmental factors can all contribute to the development of frostbite. Immobility and physical stress (such as malnutrition or dehydration) are also risk factors. Disorders and substances that impair circulation contribute, including diabetes, Raynaud's phenomenon, tobacco and alcohol use. Homeless individuals and individuals with some mental illnesses may be at higher risk.

Mechanism

Freezing
In frostbite, cooling of the body causes narrowing of the blood vessels (vasoconstriction). Temperatures below −4 °C are required to form ice crystals in the tissues. The process of freezing causes ice crystals to form in the tissue, which in turn causes damage at the cellular level. Ice crystals can damage cell membranes directly. In addition, ice crystals can damage small blood vessels at the site of injury. Scar tissue forms when fibroblasts replace the dead cells.

Rewarming
Rewarming causes tissue damage through reperfusion injury, which involves vasodilation, swelling (edema), and poor blood flow (stasis). Platelet aggregation is another possible mechanism of injury. Blisters and spasm of blood vessels (vasospasm) can develop after rewarming.

Non-Freezing Cold Injury
The process of frostbite differs from the process of non-freezing cold injury (NFCI). In NFCI, temperature in the tissue decreases gradually. This slower temperature decrease allows the body to try to compensate through alternating cycles of closing and opening blood vessels (vasoconstriction and vasodilation). If this process continues, inflammatory mast cells act in the area. Small clots (microthrombi) form and can cut off blood to the affected area (known as ischemia) and damage nerve fibers. Rewarming causes a series of inflammatory chemicals such as prostaglandins to increase localized clotting.

Pathophysiology The pathological mechanism by which frostbite causes body tissue injury can be characterized by four stages: Prefreeze, freeze-thaw, vascular stasis, and the late ischemic stage.	1. Prefreeze phase: involves the cooling of tissues without ice crystal formation. 2. Freeze-thaw phase: ice-crystals form, resulting in cellular damage and death. 3. Vascular stasis phase: marked by blood coagulation or the leaking of blood out of the vessels. 4. Late ischemic phase: characterized by inflammatory events, ischemia and tissue death.

Diagnosis

Frostbite is diagnosed based on signs and symptoms as described above, and by patient history. Other conditions that can have a similar appearance or occur at the same time include:	● Frostnip is similar to frostbite, but without ice crystal formation in the skin. Whitening of the skin and numbness reverse quickly after rewarming. ● Trench foot is damage to nerves and blood vessels that results exposure to wet, cold (non-freezing) conditions. This is reversible if treated early. ● Pernio or chillbains are inflammation of the skin from exposure to wet, cold (non-freezing) conditions. They can appear as various types of ulcers and blisters. ● Bullous pemphigoid is a condition that causes itchy blisters over the body that can mimic frostbite. It does not require exposure to cold to develop. ● Levamisole toxicity is a vasculitis that can appear similar to frostbite. It is caused by contamination of cocaine by levamisole. Skin lesions can look similar those of frostbite, but do not require cold exposure to occur.	People who have hypothermia often have frostbite as well. Since hypothermia is life-threatening this should be treated first. Technetium-99 or MR scans are not required for diagnosis, but might be useful for prognostic purposes.

Prevention

The Wilderness Medical Society recommends covering the skin and scalp, taking in adequate nutrition, avoiding constrictive footwear and clothing, and remaining active without causing exhaustion. Supplemental oxygen might also be of use at high elevations. Repeated exposure to cold water makes people more susceptible to frostbite. Additional measures to prevention frostbite include:	● Avoiding temperatures below −15 °C ● Avoiding moisture, including in the form of sweat and/or skin emollients ● Avoiding alcohol and drugs that impair circulation or natural protective responses ● Layering clothing ● Using chemical or electric warming devices ● Recognizing early signs of frostnip and frostbite

Treatment

Individuals with frostbite or potential frostbite should go to a protected environment and get warm fluids. If there is no risk of re-freezing, the extremity can be exposed and warmed in the groin or underarm of a companion. If the area is allowed to refreeze, there can be worse tissue damage. If the area cannot be reliably kept warm, the person should be brought to a medical facility without rewarming the area. Rubbing the affected area can also increase tissue damage.

Aspirin and ibuprofen can be given in the field to prevent clotting and inflammation. Ibuprofen is often preferred to aspirin because aspirin may block a subset of prostaglandins that are important in injury repair. The first priority in people with frostbite should be to assess for hypothermia and other life-threatening complications of cold exposure. Before treating frostbite, the core temperature should be raised above 35C. Oral or intravenous (IV) fluids should be given.

Other considerations for standard hospital management include:
● Wound care: blisters can be drained by needle aspiration, unless they are bloody (hemorrhagic). Aloe vera gel can be applied before breathable, protective dressings or bandages are put on.
● Antibiotics: if there is trauma, skin infection (cellulitis) or severe injury
● Tetanus toxoid: should be administered according to local guidelines. Uncomplicated frostbite wounds are not known to encourage tetanus.
● Pain control: NSAIDs or opioids are recommended during the painful rewarming process.

Rewarming
If the area is still partially or fully frozen, it should be rewarmed in the hospital with a warm bath with povidone iodine or chlorhexidine antiseptic. Active rewarming seeks to warm the injured tissue as quickly as possible without burning. The faster tissue is thawed, the less tissue damage occurs. According to Handford and colleagues, "The Wilderness Medical Society and State of Alaska Cold Injury Guidelines recommend a temperature of 37–39 °C, which decreases the pain experienced by the patient whilst only slightly slowing rewarming time." Warming takes 15 minutes to 1 hour. Rewarming can be very painful, so pain management is important.

Medications
People with potential for large amputations and who present within 24 hours of injury can be given TPA with heparin. These medications should be withheld if there are any contraindications. Bone scans or CT angiography can be done to assess damage. Blood vessel dilating medications such as iloprost may prevent blood vessel blockage. This treatment might be appropriate in grades 2–4 frostbite, when people get treatment within 48 hours. In addition to vasodilators, sympatholytic drugs can be used to counteract the detrimental peripheral vasoconstriction that occurs during frostbite.

Surgery
Various types of surgery might be indicated in frostbite injury, depending on the type and extent of damage. Debridement or amputation of necrotic tissue is usually delayed unless there is gangrene or systemic infection (sepsis). This has led to the adage "Frozen in January, amputate in July". If symptoms of compartment syndrome develop, fasciotomy can be done to attempt to preserve blood flow.

Prognosis
Tissue loss and autoamputation are potential consequences of frostbite. Permanent nerve damage including loss of feeling can occur. It can take several weeks to know what parts of the tissue will survive. Time of exposure to cold is more predictive of lasting injury than temperature the individual was exposed to. The classification system of grades, based on the tissue response to initial rewarming and other factors is designed to predict degree of longterm recovery. A number of long term sequelae can occur after frostbite. These include transient or permanent changes in sensation, paresthesia, increased sweating, cancers, and bone destruction/arthritis in the area affected.

● **Grade 1:** If there is no initial lesion on the area, no amputation or lasting effects are expected.
● **Grade 2:** If there is a lesion on the distal body part, tissue and fingernails can be destroyed.
● **Grade 3:** If there is a lesion on the intermediate or near body part, autoamputation and loss of function can occur.
● **Grade 4:** If there is a lesion very near the body (such as the carpals of the hand), the limb can be lost. Sepsis and/or other systemic problems are expected.

7 Hypothermia

Drink a lot of water, the heat generation system uses water to run. The basic principles of rewarming a hypothermic victim are to conserve the heat they have and replace the body fuel they are burning up to generate that heat. If a person is shivering, they have the ability to rewarm themselves at a rate of 2°C per hour.

Treatment

Treatment - Mild

INJURY Environmental Hypothermia Treatment

1. Reduce Heat Loss
- Additional layers of clothing
- Dry clothing
- Increased physical activity
- Shelter

2. Add Fuel & Fluids
It is essential to keep a hypothermic person adequately hydrated and fueled.

Food Types
- Carbohydrates - 5 calories/gram - quickly released into blood stream for sudden brief heat surge - these are the best to use for quick energy intake especially for mild cases of hypothermia
- Proteins - 5 calories/gram - slowly released - heat given off over a longer period
- Fats - 9 calories/gram - slowly released but are good because they release heat over a long period, however, it takes more energy to break fats down into glucose - also takes more water to break down fats leading to increased fluid loss

Food Intake ● Hot liquids - calories plus heat source ● Sugars (kindling) ● GORP - has both carbohydrates (sticks) and proteins/fats (logs)	**Things to Avoid** ● Alcohol - a vasodilator - increases peripheral heat loss ● Caffeine - a diuretic - causes water loss increasing dehydration ● Tobacco/nicotine - a vasoconstrictor, increases risk of frostbite	**Add Heat** ● Fire or other external heat source ● Body to body contact. Get into a sleeping back, in dry clothing with a normothermic person in lightweight dry clothing

Treatment - Severe

Reduce Heat Loss
Hypothermia Wrap: The idea is to provide a shell of total insulation for the patient. No matter how cold, patients can still internally rewarm themselves much more efficiently than any external rewarming. Make sure the patient is dry, and has a polypropylene layer to minimize sweating on the skin. The person must be protected from any moisture in the environment. Use multiple sleeping bags, wool blankets, wool clothing, Ensolite pads to create a minimum of 4" of insulation all the way around the patient, especially between the patient and the ground. Include an aluminum "space" blanket to help prevent radiant heat loss, and wrap the entire ensemble in plastic to protect from wind and water. If someone is truly hypothermic, don't put him/her naked in a sleeping bag with another person.

Add Fuel & Fluids
Warm Sugar Water - for people in severe hypothermia, the stomach has shut down and will not digest solid food but can absorb water and sugars. Give a dilute mixture of warm water with sugar every 15 minutes. Dilute Jello works best since it is part sugar and part protein. This will be absorbed directly into the blood stream providing the necessary calories to allow the person to rewarm themselves. One box of Jello = 500 Kilocalories of heat energy. Do not give full strength Jello even in liquid form, it is too concentrated and will not be absorbed. Urination - people will have to urinate from cold diuresis. Vasoconstriction creates greater volume pressure in the blood stream. The kidneys pull off excess fluid to reduce the pressure. A full bladder results in body heat being used to keep urine warm rather than vital organs. Once the person has urinated, it precious body heat will be used to maintain the temperature of vital organs. So in the end urinating will help conserve heat. You will need to help the person urinate. Open up the Hypothermia Wrap enough to do this and then cover them back up. You will need to keep them hydrated with the dilute Jello solution described above.

Add Heat
Heat can be applied to transfer heat to major arteries - at the neck for the carotid, at the armpits for the brachial, at the groin for the femoral, at the palms of the hands for the arterial arch.

- Chemical heat packs such as the Heat Wave™ provides 110°F for 6-10 hours.
- Hot water bottles, warm rocks, towels, compresses
- For a severely hypothermic person, rescue breathing can increase oxygen and provide internal heat.

Afterdrop
Is a situation in which the core temperature actually decreases during rewarming. This is caused by peripheral vessels in the arms and legs dilating if they are rewarmed. This dilation sends this very cold, stagnate blood from the periphery to the core further decreasing core temperature which can lead to death. In addition, this blood also is very acetic which may lead to cardiac arrythmias and death. Afterdrop can best be avoided by not rewarming the periphery. Rewarm the core only! Do not expose a severely hypothermic victim to extremes of heat.

CPR & Hypothermia
When a person is in severe hypothermia they may demonstrate all the accepted clinical signs of death:
- Cold
- Blue skin
- Fixed and dilated pupils
- No discernable pulse
- No discernable breathing
- Comatose & unresponsive to any stimuli
- Rigid muscles

But they still may be alive in a "metabolic icebox" and can be revived. You job as a rescuer is to rewarm the person and do CPR if indicated. A hypothermia victim is never cold and dead only warm and dead. During severe hypothermia the heart is hyperexcitable and mechanical stimulation (such as CPR, moving them or Afterdrop) may result in fibrillation leading to death.

As a result CPR may be contraindicated for some hypothermia situations:
1. Make sure you do a complete assessment of heart rate before beginning CPR. Remember, the heart rate may be 2-3/minute and the breathing rate 1/30 seconds. Instituting cardiac compressions at this point may lead to life-threatening arrythmias. Check the carotid pulse for a longer time period (up to a minute) to ascertain if there is some slow heartbeat. Also, even though the heart is beating very slowly, it is filling completely and distributing blood fairly effectively. External cardiac compressions only are 20-30% effective. Thus, with its severely decreased demands, the body may be able to satisfy its circulatory needs with only 2-3 beats per minute. Be sure the pulse is absent before beginning CPR. You will need to continue to do CPR as you rewarm the person.

2. Ventilation may have stopped but respiration may continue - the oxygen demands for the body have been so diminished with hypothermia that the body may be able to survive for some time using only the oxygen that is already in the body. If ventilation has stopped, artificial ventilation may be started to increase available oxygen. In addition, blowing warm air into the persons lungs may assist in internal rewarming.

3. CPR Procedures
- Check radial pulse, between 33-30°C (91.4-86°F) this pulse disappears
- Check for carotid pulse - wait at least a full minute to check for very slow heartbeat
- If pulse but not breathing or slow breathing, give rescue breathing (also adds heat).
- If no discernible heartbeat begin CPR and be prepared to continue - persons with hypothermia have been given CPR for up to 3.5 hours and have recovered with no neurological damage
- Begin active rewarming

Cold Injuries

Tissue temperature in cold weather is regulated by two factors, the external temperature and the internal heat flow. All cold injuries described below are intimately connected with the degree of peripheral circulation. As peripheral circulation is reduced to prevent heat loss to the core these conditions are more likely to occur.

1

Factors influencing cold injuries
- Low ambient temperature
- Wind chill - increases rate of freezing dramatically
- Moisture - wet skin freezes at a higher temp than dry
- Insulation
- Contact with metal or supercooled liquids (white gas)
- Exposed skin
- Vasodilation
- Vasoconstriction
- Previous cold injuries
- Constricting garments
- Local pressure
- Cramped position
- Body type
- Dehydration
- Women do better in cold than men (greater subcutaneous body fat)
- Caloric intake
- Diabetes, some medications
- Alcohol
- Caffeine, nicotine

2

Cold-induced Vasodilation
When a hand or foot is cooled to 59°F, maximal vasoconstriction and minimal blood flow occur. If cooling continues to 50°F, vasoconstriction is interrupted by periods of vasodilation with an increase in blood and heat flow. This "hunting" response recurs in 5-10 minute cycles to provide some protection from cold. Prolonged, repeated exposure increases this response and offers some degree of acclimatization. Ex. Eskimos have a strong response with short intervals in between.

3

Pathophysiology of Tissue Freezing
As tissue begins to freeze, ice crystals are formed within the cells. As intracellular fluids freeze, extracellular fluid enters the cell and there is an increase in the levels of extracellular salts due to the water transfer. Cells may rupture due to the increased water and/or from tearing by the ice crystals. Do not rub tissue; it causes cell tearing from the ice crystals. As the ice melts there is an influx of salts into the tissue further damaging the cell membranes. Cell destruction results in tissue death and loss of tissue. Tissue can't freeze if the temperature is above 32°F. It has to be below 28°F because of the salt content in body fluids. Distal areas of the body and areas with a high surface to volume ratio are the most susceptible (e.g ears, nose, fingers and toes - this little rhyme should help remind you what to watch out for in yourself and others).

- Surface frostbite generally involves destruction of skin layers resulting in blistering and minor tissue loss. Blisters are formed from the cellular fluid released when cells rupture.
- Deep frostbite can involve muscle and bone

Visual Cold Table	Cold Response	Mild Frostnip	Superficial Frostbite	Deep Frostbite
Sensation	Painful	Possible Sensation	Numb	Numb
Feels	Normal	Normal	Soft	Hard
Color	Red	White	White	White

4

Cold Response
- Circulation is reduce to the are to prevent heat loss.
- The area may be pale, cold.
- It may have sensation or be numb.

5

Frostnip
- Freezing of top layers of skin tissue
- It is generally reversible
- White, waxy skin, top layer feels hard, rubbery but deeper tissue is still soft
- Numbness
- Most typically seen on cheeks, earlobes, fingers, and toes

Treatment
- Rewarm the area gently, generally by blowing warm air on it or placing the area against a warm body part (partner's stomach or armpit)
- Do not rub the area - this can damage the affected tissue by having ice crystals tear the cell

6

Frostbite
- Skin is white and "wooden" feel all the way through
- Superficial frostbite includes all layers of skin
- Numbness, possible anesthesia
- Deep frostbite can include freezing of muscle and/or bone, it is very difficult to rewarm the appendage without some damage occurring

Treatment
Superficial frostbite may be rewarmed as frostnip if only a small area is involved
If deep frostbite, see below for rewarming technique

7

Rewarming of Frostbite
- Rewarming is accomplished by immersion of the effected part into a water bath of 105-110°F. No hotter or additional damage will result. This is the temperature which is warm to your skin. Monitor the temperature carefully with a thermometer. Remove constricting clothing. Place the appendage in the water and continue to monitor the water temperature. This temperature will drop so that additional warm water will need to be added to maintain the 105-110°F. Do not add this warm water directly to the injury. The water will need to be circulated fairly constantly to maintain even temperature. The effected appendage should be immersed for 25 - 40 minutes. Thawing is complete when the part is pliable and color and sensation has returned. Once the area is rewarmed, there can be significant pain. Discontinue the warm water bath when thawing is complete.
- Do not use dry heat to rewarm. It cannot be effectively maintained at 105-110°F and can cause burns further damaging the tissues.
- Once rewarming is complete the injured area should be wrapped in sterile gauze and protected from movement and further cold.

- Once a body part has been rewarmed it cannot be used for anything. Also it is essential that the part can be kept from refreezing. Refreezing after rewarming causes extensive tissue damage and may result in loss of tissue. If you cannot guarantee that the tissue will stay warm, do not rewarm it.
- Mountaineers have walked out on frozen feet to have them rewarmed after getting out with no tissue loss. Once the tissue is frozen the major harm has been done. Keeping it frozen will not cause significant additional damage.

8

Special Considerations for Frostbite
- If the person is hypothermic and frostbitten, the first concern is core rewarming. Do not rewarm the frostbitten areas until the core temp approaches 96°F.
- No alcohol - vasodilation may increase fluid buildup
- No smoking - nicotine as a vasoconstrictor may increase chances for developing frostbite
- Liquids such as white gas can "supercool" in the winter (drop below their freezing point but not freeze). White gas also evaporates quickly into the air. Spilling supercooled white gas on exposed skin leads to instant frostbite from evaporative cooling. Always were gloves when handling fuel.
- Touching metal with bare skin can cause the moisture on your skin to freeze to the metal. (In really cold conditions, metal glasses frames can be a problem). When you pull away, you may leave a layer of skin behind. Don't touch metal with bare skin.

INJURY Environmental Hypothermia Cold Injuries

9	**Trench Foot - Immersion Foot** Trench foot is a process similar to chilblains. It is caused by prolonged exposure of the feet to cool, wet conditions. This can occur at temperatures as high as 60°F if the feet are constantly wet. This can happen with wet feet in winter conditions or wet feet in much warmed conditions (ex. sea kayaking). The mechanism of injury is as follows: wet feet lose heat 25x faster than dry, therefore the body uses vasoconstriction to shut down peripheral circulation in the foot to prevent heat loss. Skin tissue begins to die because of lack of oxygen and nutrients and due to buildup of toxic products. The skin is initially reddened with numbness, tingling pain, and itching then becomes pale and mottled and finally dark purple, gray or blue. The effected tissue generally dies and sluffs off. In severe cases trench foot can involve the toes, heels, or the entire foot. If circulation is impaired for > 6 hours there will be permanent damage to tissue. If circulation is impaired for > 24 hours the victim may lose the entire foot. Trench Foot causes permanent damage to the circulatory system making the person more prone to cold related injuries in that area. A similar phenomenon can occur when hands are kept wet for long periods of time such as kayaking with wet gloves or pogies. The damage to the circulatory system is known as Reynaud's Phenomenon.

Treatment and Prevention of Trench foot

● Includes careful washing and drying of the feet, gentle rewarming and slight elevation. Since the tissue is not frozen as in severe frostbite it is more susceptible to damage by walking on it. Cases of trench foot should not walk out; they should be evacuated by litter. Pain and itching are common complaints. Give Ibuprofen or other pain medication.

Prevention is the best approach to dealing with trench foot. Keep feet dry by wearing appropriate footwear. Check your feet regularly to see if they are wet. If your feet get wet (through sweating or immersion), stop and dry your feet and put on dry socks. Periodic air drying, elevation, and massage will also help. Change socks at least once a day and do not sleep with wet socks. Be careful of tight socks which can further impair peripheral circulation. Foot powder with aluminum hydroxide can help. High altitude mountaineers will put antiperspirant on their feet for a week before the trip. The active ingredient, aluminum hydroxide will keep your feet from sweating for up to a month and their are no confirmed contraindications for wearing antiperspirant.

Vapor barrier socks may increase the possibility of trench foot. When you are active and you are wearing a vapor barrier sock, you must carefully monitor how you sweat. If you are someone who sweats a lot with activity, your foot and polypropylene liner sock may be totally soaked before the body shuts down sweating. Having this liquid water next to the skin is going to lead to increased heat loss. If you don't sweat much, your body may shut down perspiration at the foot before it gets actually wet. This is when the vapor barrier system is working. You must experiment to determine if vapor barrier systems will work for you.

10	**Chilblains** ● Caused by repeated exposure of bare skin to temperatures below 15.5°C (60°F) ● Redness and itching of the effected area ● Particularly found on cheeks and ears, fingers and toes ● Women and young children are the most susceptible ● The cold exposure causes damage to the peripheral capillary beds, this damage is permanent and the redness and itching will return with exposure		
11	**Avoiding Frostbite and Cold related Injuries** ● "Buddy system" - keep a regular watch on each other's faces, cheeks, ears for signs of frostnip/frostbite ● Keep a regular "self check" for cold areas, wet feet, numbness or anesthesia ● If at any time you discover a cold injury, stop and rewarm the area (unless doing so places you at greater risk).		
12	**Eye Injuries** **a. Freezing of Cornea** ● Caused by forcing the eyes open during strong winds without goggles ● Treatment is very controlled, rapid rewarming e.g. placing a warm hand or compress over the closed eye. After rewarming the eyes must be completely covered with patches for 24 - 48 hours.	**b. Eyelashes freezing together** ● Put hand over eye until ice melts, then you can open the eye.	**c. Snowblindness** ● Sunburn of the eyes ● Prevention by wearing good sunglasses with side shields or goggles. Eye protection from sun is just as necessary on cloudy or overcast days as it is in full sunlight when you are on snow. Snow blindness can even occur during a snow storm if the cloud cover is thin.

Symptoms ● Occur 8-12 hours after exposure ● Eyes feel dry and irritated, then feel as if they are full of sand, moving or blinking becomes extremely painful, exposure to light hurts the eyes, eyelids may swell, eye redness, and excessive tearing	**Treatment** ● Cold compresses and dark environment ● Do not rub eyes

Hypothermia is also touched on in the SURVIVAL section.

8 Hyperthermia

INJURY Environmental Hyperthermia

Hyperthermia is elevated body temperature due to failed thermoregulation that occurs when a body produces or absorbs more heat than it dissipates. Extreme temperature elevation then becomes a medical emergency requiring immediate treatment to prevent disability or death. The most common causes include heat stroke and adverse reactions to drugs. The former is an acute temperature elevation caused by exposure to excessive heat, or combination of heat and humidity, that overwhelms the heat-regulating mechanisms. The latter is a relatively rare side effect of many drugs, particularly those that affect the central nervous system. Malignant hyperthermia is a rare complication of some types of general anesthesia. Hyperthermia differs from fever in that the body's temperature set point remains unchanged. The opposite is hypothermia, which occurs when the temperature drops below that required to maintain normal metabolism.

Classification

In humans, hyperthermia is defined as a temperature greater than 37.5–38.3 °C (99.5–100.9 °F), depending on the reference used, that occurs without a change in the body's temperature set point. The normal human body temperature can be as high as 37.7 °C (99.9 °F) in the late afternoon. Hyperthermia requires an elevation from the temperature that would otherwise be expected. Such elevations range from mild to extreme; body temperatures above 40 °C (104 °F) can be life-threatening.

Signs & Symptoms

An early stage of hyperthermia can be "heat exhaustion" (or "heat prostration" or "heat stress"), whose symptoms include heavy sweating, rapid breathing and a fast, weak pulse. If the condition progresses to heat stroke, then hot, dry skin is typical as blood vessels dilate in an attempt to increase heat loss. An inability to cool the body through perspiration may cause the skin to feel dry. Other signs and symptoms vary. Accompanying dehydration can produce nausea, vomiting, headaches, and low blood pressure and the latter can lead to fainting or dizziness, especially if the standing position is assumed quickly. In severe heat stroke, there may be confused, hostile, or seemingly intoxicated behavior. Heart rate and respiration rate will increase (tachycardia and tachypnea) as blood pressure drops and the heart attempts to maintain adequate circulation. The decrease in blood pressure can then cause blood vessels to contract reflexively, resulting in a pale or bluish skin color in advanced cases. Young children, in particular, may have seizures. Eventually, organ failure, unconsciousness and death will result.

Causes

Heat stroke occurs when thermoregulation is overwhelmed by a combination of excessive metabolic production of heat (exertion), excessive environmental heat, and insufficient or impaired heat loss, resulting in an abnormally high body temperature. In severe cases, temperatures can exceed 40 °C (104 °F). Heat stroke may be non-exertional (classic) or exertional.

Exertional	Significant physical exertion in hot conditions can generate heat beyond the ability to cool, because, in addition to the heat, humidity of the environment may reduce the efficiency of the body's normal cooling mechanisms. Human heat-loss mechanisms are limited primarily to sweating (which dissipates heat by evaporation, assuming sufficiently low humidity) and vasodilation of skin vessels (which dissipates heat by convection proportional to the temperature difference between the body and its surroundings, according to Newton's law of cooling). Other factors, such as insufficient water intake, consuming alcohol, or lack of air conditioning, can worsen the problem. The increase in body temperature that results from a breakdown in thermoregulation affects the body biochemically. Enzymes involved in metabolic pathways within the body such as cellular respiration fail to work effectively at higher temperatures, and further increases can lead them to denature, reducing their ability to catalyse essential chemical reactions. This loss of enzymatic control affects the functioning of major organs with high energy demands such as the heart and brain.
Situational	Situational heat stroke occurs in the absence of exertion. It mostly affects the young and elderly. In the elderly in particular, it can be precipitated by medications that reduce vasodilation and sweating, such as anticholinergic drugs, antihistamines, and diuretics. In this situation, the body's tolerance for high environmental temperature may be insufficient, even at rest. Heat waves are often followed by a rise in the death rate, and these 'classical hyperthermia' deaths typically involve the elderly and infirm. This is partly because thermoregulation involves cardiovascular, respiratory and renal systems which may be inadequate for the additional stress because of the existing burden of aging and disease, further compromised by medications. During the July 1995 heat wave in Chicago, there were at least 700 heat-related deaths. The strongest risk factors were being confined to bed, and living alone, while the risk was reduced for those with working air conditioners and those with access to transportation. Even then, reported deaths may be underestimates as diagnosis can be misclassified as stroke or heart attack.
