● Keep wasps around; they're beneficial insects which feed on hornworms and act as a biological control. You may see hormworms with parasitic wasp larvae attached, which look like grains of rice. These attacked hornworms will continue to feed for a little while, but will soon succumb to their hitchhikers, so it's wise to leave them alone and let the wasps carry out their life cycle. Alternatively, remove infected hornworms and place them far away from your garden. This way, the wasps will still do their job, but the hornworm won't continue to damage your crops.

Japanese Beetles

Japanese beetles are small bugs that carry a big threat. They do not discriminate on what types of plants they feed on. In fact, they are classified as a pest to hundreds of different species. They are one of the major insect pests in the Eastern and Midwestern United States, causing monumental damage to crops each year.

Identification

Japanese Beetles are ½ inch in length with metallic blue-green heads, copper backs, tan wings, and small white hairs lining each side of the abdomen. Japanese beetles usually feed in small groups. They lay eggs in the soil during June, which develop into tiny white grubs with brown heads and six legs that are up to ¾ inch in length. These grubs will remain under wraps for about 10 months, overwintering and growing in the soil.

They emerge from the soil as adult beetles and begin feeding in June. They usually attack plants in groups, which is why damage is so severe. Although the lifecycle of the adult Japanese beetle is barely 40 days, it can cover a lot of ground. Even if you succeed in controlling your Japanese beetle population, your neighbour's Japanese beetles might come on over.

Japanese beetles eat a wide variety of flowers and crops (the adult beetles attack more than 300 different kinds of plants), but they are especially common on roses, as well as beans, grapes, and raspberries.
They can devour most of the foliage on favoured plants like roses. Look for leaves that are "skeletonised" (only have veins remaining). This is a tell-tale sign of Japanese Beetles. Mexican Bean Beetles can also leave foliage skeletonised, though, so be sure to identify them by their appearance as well.

Prevention

● Row Covers: Protect your plants from Japanese beetles with row covers during the 6- to 8-week feeding period.
● Hand Pick: Unfortunately, the most effective way of getting rid of Japanese beetles is to hand pick them. It's time consuming, but it works, especially if you are diligent. When you pick them off, put them in a solution of 1 tablespoon of liquid dishwashing detergent and water, which will cause them to drown.
● Neem Oil: Neem oil and sprays containing potassium bicarbonate are somewhat effective, especially on roses. The adults ingest a chemical in the neem oil and pass it on in their eggs, and the resulting larvae die before they become adults. Neem can be harmful to fish and should be reapplied after rainstorms.
● Use a Dropcloth: Put down a dropcloth and, in the early morning when they're most active, shake them off and dump them into a bucket of soapy water.
● Insecticides: If you wish to spray or dust with insecticides, speak to your local cooperative extension or garden centre about approved insecticides in your area.

Or, try this safe homemade solution: Mix 1 teaspoon of liquid dishwashing detergent with 1 cup of vegetable oil and shake well; then add it to 1 quart of water. Add 1 cup of rubbing alcohol and shake vigorously to emulsify. Pour this mixture into a spray bottle and use it at ten-day intervals on pests. Homemade sprays can run more of a risk of damaging plant leaves, so be careful. Apply sprays in the morning, never in full sun or at temperatures above 90ºF. If your plants start to wilt, rinse the leaves immediately with clean water.

● Traps: Japanese beetle traps can be helpful in controlling large numbers of beetles, but they also might attract beetles from beyond your yard. Eugenol and geraniol, aromatic chemicals extracted from plants, are attractive to adult Japanese beetles as well as to other insects. Unfortunately, the traps do not effectively suppress adults and might even result in a higher localized population. If you want to try them, be sure to place traps far away from plants so that the beetles do not land on your favoured plants on their way to the traps.
● Fruit Cocktail: You can buy Japanese beetle traps of all sorts, but most are no more effective than a can of fruit cocktail. Open the can and let it sit in the sun for a week to ferment. Then place it on top of bricks or wood blocks in a light-coloured pail, and fill the pail with water to just below the top of the can. Place the pail about 25 feet from the plants you want to protect. The beetles will head for the sweet bait, fall into the water, and drown. If rain dilutes the bait, start over.
● Geraniums: Japanese beetles are attracted to geraniums. They eat the blossoms, promptly get dizzy, fall down, and permit you to dispose of them conveniently with a dustpan and brush. Plant geraniums close to more valuable plants which you wish to save from the ravages of Japanese beetles.

Squirrels

GARDENING Plant Pests & Diseases Pests Squirrels

With a fondness for fresh fruits, vegetables, and flowers, the common squirrel has long spelled trouble for home gardeners. From Maine to Montana, these wily critters yank geraniums from window boxes, pluck cherry tomatoes from their vines, and strip apple trees like professional pickers. Though their foraging forays can happen at any time of year, a squirrel's raid in autumn can drive a gardener nuts.

Squirrels are especially active in autumn as they stock up for winter. They do not hibernate (although they may "lie low" during cold spells), so their underground pantries are vitally important winter warehouses. They have a major instinct for hoarding food, which helps them to survive. Gray squirrels stash food by burying it in a scattered fashion around their territory.

The average squirrel gathers acorns, pinecones, nuts, bark, fruit, berries, fungi, and insects, but is not above stealing bird eggs and bulbs. Sometimes they will even ruin your flowers just for the fun of it! Keep an eye out for these pesky visitors and try some of our tips below.

Identification	Weighing an average of 16 to 24 ounces, the type of squirrel that is probably causing damage in your garden is the common gray squirrel. Its color varies from gray, tan, or light brown to dark brown and black. Its belly is light, from white to gray. Its body is 8 to 11 inches in length, and its tail measures 8 to 10 inches. Its vocal call is a rapid CRRK CRRK or QUACK QUACK, similar to a duck. The famous feature of the gray squirrel is its bushy tail, a luxurious puff of fur used for warmth, communication, and balance. Squirrels have a very keen sense of smell, which most gardeners blame for their bulb pilfering. The nose of these expert foragers is a tiny but powerful tool in the search for hidden nuts and berries. Gardeners aren't sure whether the squirrels do actively seek out the spring bulbs or not, but the problem of bulb snatching is real and widespread. ● Spring bulbs snacked on? You're probably dealing with squirrels or chipmunks. Squirrels love to dig up spring bulbs during their autumn foraging—both to eat the bulbs and to use the ready-made holes to store their nuts. ● Squirrels will not only attack your gardens, but your bird feeders as well. If you notice your bird food disappearing rather quickly, you may have a squirrel problem.
Prevention	Is your yard covered in nuts, berries, and acorns from trees? If so, your place is squirrel heaven! Be sure to rake and remove their food so you're not party central. Also, make sure you have tight-fitting trash cans and never leave food sitting out. Consider protecting your garden with a wire fence and make sure it is buried about a foot into the ground, so the squirrels can't dig under it.

● There are many natural repellents on the market. Some are made with the urine of squirrels' predators. These are meant to be sprayed around gardens to keep squirrels away.
● Try sprinkling cayenne pepper, pepper flakes, and/or garlic pepper on and around your plants when they are ready to bloom. Squirrels won't eat anything with cayenne—which you can often buy in bulk. Birds don't mind the taste.
● One reader claims blood meal sprinkled around the garden soil works.
● For edibles, you may wish to invest in some netting and put that over your plants—just as you would invest in bird netting for berry bushes.
● A dog or cat is a great squirrel chaser if that's an option.
● Pots are easy to protect with a layer of netting across the top of the pot.
● Or, here's an expensive pantry solution: Lay aluminum foil across the top of vegetable pots; poke holes for water. The squirrels do not like the shiny reflection.

● Scatter dog or human hair around your garden. One readers shares, "I used to have a problem with squirrels digging up my bulbs. Now, once in the spring and once in the fall, I ask my hairdresser to save a big bag of hair for me. I lightly dig this into the soil. Squirrels can not stand the smell of humans, so they leave the gardens alone."
● Plant nasturtiums, marigolds, and mustard as a border around your vegetable garden; these plants have an unpleasant aroma.
● Don't trap and relocate squirrels. This is a losing battle, since the population of squirrels is extremely high. Also, if the animal is a female, there is a high likelihood that you will remove her from babies that depend on her for survival.
● Some readers will feed the squirrels in a different part of the yard so that they don't eat their garden vegetables or plants. We've never tried this approach!
● If you're really going crazy, explore the idea of a raptor perch and owl nest box for natural predators who will eat them in no time.

Protecting Bulbs from Squirrels
● To protect spring bulbs, cover the surface of the bed with black plastic netting, which is invisible and inexpensive.
● Or, you can line the planting hole itself with wire mesh "hardware cloth." Some gardeners have found that planting the bulbs in a handful of sharp, crushed gravel discourages the squirrels. This might help provide better drainage as well.
● If squirrels are especially challenging, try chicken wire. Plant beds with one inch chicken wire and place more wire on top of the bulbs. The plants can grow through the wires, but the squirrels can't get to the bulbs. Also, consider planting bulbs that squirrels don't like such as daffodils, ornamental onions (Allium), snowdrops (Galanthus), and grape hyacinths (Muscari). Plus, check out our list of rodent-proof bulbs.
● Don't advertise your newly dug bulbs by leaving papery bits of bulb debris in or on the soil. Clean up your act, or better still, try not to lay your bulbs on the ground while you dig the holes to plant them—squirrels will smell their favorite and scamper over.
● If all else fails, just grow tulips in pots as squirrels aren't attracted to tulips.

Suggestions
● Try motion-activated sprinklers, primarily designed to keep cats and rabbits out of gardens, may help scare away squirrels, especially in small yards or at corners of front yards where damage is most likely to occur. However, the presence of numerous squirrels, stray animals, or children may result in overwatering and high water bills if they continually trigger this device.
● Get some mousetraps. Anchor them solidly to the ground in the area where the squirrels have been digging. Cover them with newspaper, and sprinkle a little dirt on top. When a squirrel comes to dig, it will set off the traps. As the mechanism snaps, it will scare and throw dirt at the squirrel. Once it's scared enough times, it will find another digging area. Be sure to anchor the traps just in case the wind blows the newspaper off of them. If the trap is anchored, the squirrel will not get hurt.

Rabbits

GARDENING Plant Pests & Diseases Pests Rabbits

Anyone who tills the soil regards the rabbit as more than a cute threat to the carrot patch. This long-eared animal possesses a voracious appetite for all kinds of fresh vegetation—woody plants, perennials, annuals, vegetables, and berries. In fact, a menu of rabbit favorites is so ridiculously long that it's easier to list the few plants they don't enjoy.

Rabbits also have an extremely high reproductive potential, which is why keeping them around might quickly cause a total garden infestation. They reach up to three litters of six babies each per year in the north, and up to six litters of three babies each per year in the south. The first litter appears in March in the north, year-round elsewhere. The gestation period is 29 days.

Your backyard bunny's primary concern is to eat without being eaten, a difficult task given that rabbits are relished by more than two dozen species of predators. Nibbling your petunias is therefore not a carefree picnic but a danger-fraught mission. However, if your neighborhood bunny can squeeze through a hole in your garden fence, it will be able to munch in safety.

Identification

Of the nine species of North American cottontail rabbits, it's the eastern cottontail (Sylvilagus floridanus) that is our most abundant and annoying. Ranging from Boston to Boulder and south into Mexico, this bunny-about-town is rarely found in forests; preferring instead brushy fence rows, field edges, brush piles, and—you guessed it—landscaped backyards. Its fondness for flowers, vegetables, bark, and bulbs often results in pruned peppers and clipped cosmos.

Even though its nicknames are adorable (among them bunny, bunny rabbit, and cottontail), and you'll probably want to befriend it once you see its cute ears, the eastern cottontail can be a bothersome pest. It is gray or brownish, with a short tail and big ears. It can weigh 2 to 4 pounds, be 15 to 19 inches in length, and live for 12 to 15 months. Its vocal call is almost silent, but it will emit a scream when threatened. Its famous features include a short white tail resembling a cotton ball and long, tapered ears.

For an eastern cottontail, security is a pile of brush, leaves, or another animal's abandoned burrow. Unlike their European cousins, these rabbits do not dig intricate burrows or warrens but make due with what they find. Rabbits rarely leave their shelters in broad daylight, preferring instead early morning or evening. Like most animals, they are sensitive to the change in day length as spring approaches. For rabbits, the longer days signal the start of two things: breeding season and spring dining.

Damage

Rabbits are voracious eaters and leave clean-cut damage. Check the leaves and stems of your plants for cleanly cut damage; insects and other pests usually leave jagged edges on damaged plants. This clean-cut damage often happens at ground level, as rabbits tend to eat the yummy green shoots of tulips and other plants.

These low mowers graze close to the ground and sniff out the first tender young shoots and crop them short. They love to munch on flowers, clover, peas, lettuce, beans, and more. Many of these plants are also the favorites of woodchucks or groundhogs, so check for burrows before deciding you have rabbit damage. Once your plants have passed the seedling stage, they are usually safe from rabbit damage.

Although bunny nibbling occurs in every season, it's especially discouraging in the early spring when rabbits mercilessly munch the tender green shoots of plants. As a Connecticut gardener remembers, "My tulips were just poking through the snow when suddenly it looked like they'd been weed-whacked. Cut clean off! I blame the bunnies—their little paw prints were everywhere."

Prevention

● As their twitching noses indicate, rabbits sniff a lot. Try sprinkling dried sulfur around or on your plants. Rabbits also dislike the smell of onions, so try planting these around your garden to further deter the furry creatures.
● To discourage pesky rabbits, try dusting your plants with plain talcum powder.
● Since rabbits are great sniffers, powdered red pepper sprinkled around the garden or on targeted plants may keep them out.
● Irish Spring soap shavings placed in little drawstring bags around the garden will also help to keep rabbits away.
● Make a bad-tasting rabbit cocktail by grinding together three hot peppers, three large onions, and one whole bunch of garlic. Add water to cover, and place into a covered container overnight. Strain, and then add enough additional water to make a gallon of the mixture. Spray onto plants, repeating after rainfall. Commercial products using pungent garlic oil are also worth a try.
● Spray your plants with a mixture of 1 teaspoon Lysol and 1 gallon of water.
● Some people protect plants with individual "collars" of tin cans or screening so that the plants may reach a less vulnerable size. Put the collar around each stem for protection.

● Use cylinders of ¼-inch mesh hardware cloth to keep rabbits from nibbling on young fruit and landscape trees. The cylinders should extend higher than a rabbit's reach while the rabbit is standing on the expected depth of snow, and they should stand one to two inches out from the tree trunk.
● Some of the deer techniques related to odor are also said to work against rabbits. Deter rabbits with commercially-available deer repellents that contain a mixture of dried bovine blood, sulfured eggs, and garlic.
● Legend has it that rabbits are terrified of their own reflection, so try an old-time rabbit remedy and place large, clear glass jars of water throughout the garden. Garden centers sell ready-made reflectors, as well as other devices—crouching cats, fake snakes, menacing owls—designed to frighten bunnies away from your plants.
● Sometimes, humane traps are the best solution. If you don't want to buy a trap, consider building one. Place the trap where you've seen the rabbits feeding or resting, and cover it with a piece of canvas. Apples, carrots, cabbage, and other fresh green veggies make excellent bait. Check it often, and release bunnies in rural areas several miles away.

● It's best to keep rabbits from crossing into the garden to begin with, and many old-time remedies rely on spreading various products around the perimeter of the garden such as dried blood or dried blood meal or human hair. Sprinkle dried blood on the surface around all your plants as early in the season as you can, and repeat after a heavy rain. Note: If you have dogs, don't try this method because they might be attracted to the scent and start digging up your garden.
● Do not rely on repellents alone. The most effective way of keeping out rabbits is chicken wire fencing. Install a fence that is 4 feet high and bury it 6 inches deep. Bend the top foot of the fence away from the garden like a security fence, so that they can't climb or jump over it. For new bulbs, try a dome or cage of chicken wire secured over the bed.
● Rabbits don't like to leave their shelters, so try to reduce the possible rabbit homes around your yard. Brush away piles of brush and leaves, and fill in abandoned burrows. If a rabbit doesn't have a place to live, hopefully it won't stay and munch. Rabbits will also breed much more if they have a good habitat available—all the more reason to have no vacancy!

Disliked Plants

According to bunny experts, rabbits have plant preferences based on taste, nutritive value, the presence of poison or prickles, and ease of availability. Their tastes in food can also vary by region and season, so not all plants work for all rabbits. Be tricky and tend plants that rabbits don't find very appetizing.

Rabbits tend to avoid some of the same plants as deer and Japanese beetles. If you'd like to control all these pests, check our list of deer-resistant plants and best and worst plants for Japanese beetles to know which plants might do best. Choose plants such as forsythia, lilac bush, marigolds, zinnias, daffodils, lavender, and snapdragons for rabbits. This might help to reduce your rabbit population. This is not a guaranteed solution, as hungry rabbits will eat almost anything, but filling your garden with these plants might make your garden less appetizing than another one. Here are more plants that rabbits dislike:

Woody Plants
● Azalea (Rhododendron sp.)
● Boxwood (Buxus sp.)
● Bush cinquefoil (Potentilla fruticosa)
● Butterfly bush (Buddleia davidii)
● Cotoneaster (Cotoneaster sp.)
● Japanese maple (Acer palmatum)
● Mountain laurel (Kalmia latifolia)
● Rhododendron (Rhododendron sp.)
● Tatarian dogwood (Cornus alba)
● Tulip tree (Liriodendron tulipifera)

Perennials
● Adam's needle (Yucca filamentosa)
● Creeping phlox (Phlox stolonifera)
● Foam flower (Tiarella cordifolia)
● Lamb's ear (Stachys byzantina)
● Meadow rue (Thalictrum rochebrunianum)
● Peony (Paeonia hybrids)
● Perennial salvia 'East Friesland' (Salvia x superba)
● Primrose (Primula x polyantha)
● Russian sage (Perovskia atriplicifolia)
● Sedum 'Autumn Joy' (Sedum)
● Speedwell (Veronica sp.)
● Spring cinquefoil (Potentilla verna)
● Stokes' aster (Stokesia laevis)

Annuals
● Four o'clock flower (Mirabilis jalapa)
● Geranium, zonal and bedding (Pelargonium x hortorum)
● Mexican ageratum (Ageratum houstonianum)
● Pot marigold (Calendula officinalis)
● Spiderflower (Cleome hasslerana)
● Vinca (Catharanthus roseus)
● Wax begonia (Begonia x semperflorens-cultorum)

GARDENING	Plant Pests & Diseases	Pests	Rabbits			
				Bulbs ● Daffodil (Narcissus sp.) ● Hyacinth (Hyacinth orientalis) ● Persian onion (Allium giganteum) **Vegetables** ● Asparagus ● Leeks ● Onions ● Potatoes ● Rhubarb ● Summer squash ● Tomatoes	**Herbs** ● Basil ● Marjoram ● Mint ● Oregano ● Parsley ● Savory ● Tarragon		

GARDENING Plant Pests & Diseases Pests Skunks

Skunks

Skunks are nocturnal animals that are naturally mild-mannered and non-aggressive; they prefer small animals and insects for dinner instead of your garden. They occasionally visit gardens and if they do, it may be because corn or other plants are close to the ground.

The skunk claims homesteading rights from coast to coast. Distributed across the country are 4 species of skunks, including the striped skunk (Mephitis mephitis) and the spotted skunk (Spilogale putorius). The common striped skunk lives mostly in sparse forests and fields.

Skunks can be very nice to have around because they dig up and feed on the larvae of cutworms, Japanese beetles, hornworms, and other crop-destroying insect life. However, skunks are not only partial to insects; they will eat leaves, buds, grasses, grains, garbage, any fruit or berries within reach, and even small game. They also may disturb your plants while digging for these grubs. This is what can make them a bit of a nuisance to gardeners.

Damage	If your lawn or flower bed has lots of holes in it, you may have a skunk problem. Skunks dig up the turf looking for grubs. They move around at night and dig in grassy areas, making distinct 3- to 4-inch deep holes. Skunk activity increases in the spring and then lessens naturally, so any problems may stop all on their own. Skunks sometimes feed on corn, but they tend to only eat the lower ears that they can reach. If a corn stalk has been toppled over, the culprit is more likely a raccoon. Planting taller varieties of corn can minimize this damage.
Prevention	● Spray a mixture of castor oil and dish-washing detergent diluted in water. Skunks find the smell offensive. Spray the area at night when the skunk is away foraging. ● Probably the best skunk repellent is a light. Skunks are nocturnal and their eyes are very light sensitive. A bright light or a motion sensor flood light will scare skunks away. ● Most animals, including skunks, dislike the smell of citrus fruits. Place orange or lemon peels around the yard as a natural skunk repellent. ● Predator urine (dogs, coyotes) can be used to repel a skunk. These are commercially sold in garden centers. ● Many readers have found success placing ammonia-soaked rags around the yard, however, these need to be replaced often. ● If the skunks are in a smaller garden patch, put bars of strong–smelling soap or a room deodorizer near your garden. Ironically, skunks hate strong scents.

● If nothing works, there are humane ways for professionals to trap raccoons and skunks and transport them elsewhere. Often, skunk removal by trapping is the only answer, and there just isn't a lot you can do if it is a skunk. However, be aware that many species of wildlife do not survive when placed in a new territory, and it may not even be legal to trap and relocate wild animals in your area.
● As skunks love to find lots of grubs in your garden, one of the best preventative methods is to treat your lawn so that you get rid of their favorite snacks. Spray your lawn with milky spore disease or beneficial nematodes. This will also help to control Japanese beetle larvae, so it's a win-win! Contact your local Cooperative Extension Service for suggestions.
● Fencing may also be a good idea for small areas, such as a garden patch.
● If you don't want skunks living under your deck or shed, seal these areas with chicken wire. Leave at least one foot of additional wire on the ground extending from the structure to prevent skunks from digging under to enter.

GARDENING Plant Pests & Diseases Pests Crows

Crows

Crows are often unwanted neighbors, but they're also fascinating birds. Here are some common questions and answers about these raucous pests. Crows and ravens are in the same genus (Corvus), and they have many similarities, but they are in fact different birds. Ravens are bigger and have shaggy throat feathers, while crows are smaller. Ravens also have wedge-shaped tails, while crows do not. Ravens soar more often than crows and sometimes do somersaults in the air. One of the main differences between ravens and crows is the sounds that they make. The call of a crow is a harsh, strong caw. The sound of a raven is a deeper, more throaty croak. Crows will eat almost anything, but they tend to feed on the ground. They eat any insects like earthworms, but they will also eat other small animals, seeds, and fruit. Crows are known for fishing through garbage, eating carrion, and robbing chicks from their nests. Crows will live in any open place where they can perch in a tree and have a good supply of food. During the winter, crows live in communal roosts with hundreds or thousands of neighbors.

Damage	If your seedlings, such as corn, are being pulled up, chances are you have crows. Also, be aware of any chicks that go missing from bird nests in your yard or of any visitors to your garbage cans.
Prevention	● Fruit crops can be protected with flexible bird netting. You can find some at a local garden center or hardware store. Four-inch mesh is recommended as it will keep the big crows out, but still allow smaller birds to slip through. ● Place netting securely at the base of a shrub or the trunk of a tree. This keep crows out from the bottom of your trees. Nets can also be used for growing crops. ● Use visual scare tactics. Shiny pie tins or CDs hung from trees, Mylar scare tape, Mylar balloons, scarecrows, and flags can all be used to startle crows. An old-fashioned scarecrow may also work. ● Protect seedlings with covers. Corn can be protected by placing a cup or bag over each ear after the silk has turned brown. ● Fishing line or cord can be placed in grid like patterns high above the garden to prevent crows from swooping in from above. ● Crows are smart and will eventually learn that even Mylar balloons are no threat. Try changing the position of these items often enough to confuse the crows and keep them away. ● Old folklore says that to make a scarecrow more effective, you should make its arms from hickory wood. If you build a scarecrow, be sure to move it around and change certain elements.

● Crows will kill the young of other birds. Prevent this in the first steps of nest box building: make sure there is more than six inches between the entry hole and the bottom of the box. Removing the perch or ledge under the hole will also prevent crows from having a stand where they can wait for young to peep their heads out.
● Try using feeders that are too small for crows but big enough for small birds.

GARDENING Plant Pests & Diseases Pests

Groundhogs

GARDENING Plant Pests & Diseases Pests Groundhogs

If every day is Groundhog Day in your garden, you'll probably agree with those who call that gluttonous rodent their least favorite backyard creature. Even skunks get more respect. Speaking of Groundhog Day, find out the origins of that funny holiday and some folklore surrounding groundhogs and weather. The problem is that groundhogs—also known as woodchucks or whistle-pigs—are binge eaters who can wipe out your vegetable garden in a matter of minutes. They climb, they burrow, they swim, and they eat—an adult consumes about a pound to a pound-and-a-half of vegetation daily. Between spring and fall, they double their body weight.

Soon after they emerge from a winter's hibernation, they mate, giving birth in mid-spring—at a time when the picking are at their slimmest. Neat rows of seedlings must look like manna from heaven to hungry groundhogs, who sometimes perch on garden fence posts as if they are looking over the salad bar. When hibernating, groundhogs—who are never speedy—really slow down, drawing a breath only about once every five minutes. Hibernation is curious behavior: Barely breathing, these mammals cool off to just a few degrees above the ambient temperature, sometimes as low as 39º to 40ºF. Their metabolic rate drops, and they sleep profoundly in their winter dens, neither eating nor drinking for four-and-a-half to five-and-a-half months, drawing all their nourishment from the body fat they accumulated during the summer.

Identification	Members of the squirrel family, groundhogs are squarish, stocky animals that typically weigh between 4 and 14 pounds. The have short, strong legs; coarse, grizzled, gray-brown fur; small ears; a short, bushy tail; and curved claws. Groundhogs look a bit like runaway fur coats as they waddle back to their burrows. This critter can grow to be about 3 feet long. They have large, competent, chisel-like teeth that make them efficient, but not quite endearing. Wondering where groundhogs live? See any deep tunnels in your yard, under your deck, or near your foundation? You may have a groundhog; they dig burrows to live in and the entrances are usually 10 to 12 inches wide with the excavated soil spread around the entrances. There are usually 2 or 3 entrances.
Damage	What do groundhogs eat? Everything from flowers to vegetables. Favorite foods include alfalfa, clover, peas, beans, lettuce, broccoli, plantain, and soybeans. Groundhogs will often devour your seedlings before they even have time to grow. Rabbits and deer eat some of the same plants, so make sure to check for burrows before concluding that you have groundhogs. If you don't have vegetables around, groundhogs will settle for twigs, bark, bugs, and blossoms. Groundhogs eat mostly during the early morning and afternoon, so try to see when your garden is receiving the most damage. These creatures will also gnaw and claw at fruit trees, so check your trees for any such marks.
Prevention	● Sprinkle blood meal, ground black pepper, dried blood, or talcum powder around the perimeter of your garden. You can try using hair clippings as well. ● Puree and strain hot peppers and garlic, mix them with water and enough liquid soap to make it stick, and spray it liberally around the garden. ● Put some harmless but strong-smelling substance just inside the burrow (such as urine-saturated clumps of kitty litter). Loosely seal the entrance, so the smell stays inside the burrow. ● Would you eat lettuce tossed with bobcat urine? Neither would a woodchuck! Fox, coyote, wolf, and bobcat urines are among the forbidding predator scents now sold as groundhog repellents. ● Eliminate woodpiles and other places where groundhogs nest. ● Keep undergrowth and grass cover low to deter groundhogs.

● Groundhogs are always looking for vacant burrows. Close down their tunnel systems. Bury a three-foot-square panel of welded wire, centered over the entrance hole before an abandoned burrow is rediscovered.
● Traps and relocation may be the only solution. Place traps in front of burrow entrances or in the garden. Bait them with broccoli, apple slices, fresh lettuce, carrots, or sweet corn, and work the bottom of the trap into the earth. Check the trap often after setting it to minimize stress and injury to trapped creatures.

The best woodchuck deterrent is a fence. Excluding woodchucks from the garden will also keep out deer, rabbits, raccoons, and stray pets. Since groundhogs climb and also burrow, you'll need to build a secure enclosure using six-foot-wide woven-wire fencing. Above ground, the fence should be about four feet high, with the top 12 inches unattached to fence posts (i.e., floppy and facing away from the garden, so that when a groundhog tries to go over the top, its weight will flip it back). The two feet of fencing buried underground should form an L-shape, with 12 inches going straight down and the bottom 12 inches bent at a right angle away from the garden.

An apron of weighed-down black plastic around the garden discourages some diggers, as does an electric fence strung four to six inches off the ground about four to six inches outside the woven-wire fence. Pay special attention to areas facing fields where woodchucks live or places where they have been digging; sometimes extra fortification in just these spots is called for. Be sure the gate is protected, too. Fencing is not inexpensive, but it's an investment in serious gardening.

Raccoons

Raccoons (Procyon lotor) have masks over their eyes because they could rob even a bank vault. These resourceful animals are second in persistence and imagination to no other animal (unless it's a squirrel at a bird feeder).

Raccoons are great climbers, swimmers, jumpers, and runners. Their five-toed paws make them very dexterous, and their agility can allow them to outsmart every human concoction used to deter them. If they aren't breaking into your garden, they might try to climb into your chimney to use it as a den.

Raccoons do not hibernate during the winter, but they will live in dens for periods of severe weather, causing them to lose a lot of their body fat in northern areas. They often live in hollow trees during the warm part of the year. Populations of raccoons often include many youngsters, and families will stay together for about a year.

Identification	Raccoons are small mammals 2 to 3 feet in length and weighing about 10 to 30 pounds. Raccoons have distinct black "masks" on their faces, which often characterizes them as bandits. They have fluffy, ringed tails and their bodies are varying shades of gray, with hints of light brown. The forepaws of raccoons resemble tiny human hands with five toes, which makes raccoons very dexterous. Raccoons are nocturnal creatures, meaning that they feed at night. This might make it hard for you to identify them, as you might only see the damage they cause. Looking for raccoon tracks near the damage might also help you to identify them. Learn more about identifying animal tracks.
Damage	If your lawn has a lot of holes in it, or your mulch pile has a lot of holes, you probably have a nightly visitor. Raccoons will dig up lawns and mulch piles looking for insects to eat. They will also empty bird feeders, so keep an eye on your feeders to see if you have a raccoon problem. Additionally, raccoons are known to raid chicken coops, stealing eggs and even killing chickens. Of course, if you have corn, there's nothing more infuriating than finding stalks toppled and ears ripped open and half eaten. (Even more frustrating is the idea, offered by animal researchers, that raccoons are wasteful because they don't really like sweet corn all that much; in fact, they seem to prefer sunflower seeds, dog food, and sardines.)

Prevention

The persistence and proliferation of raccoons has inspired many solutions; one of them is bound to work for you. Here are tips from all our readers and staff! See what works for you.
● If your raccoon problem is persistent, you can set live raccoon traps in your garden and release the animal at least three miles away (check local and state laws first). Raccoons will eat virtually anything; try fish-flavored dry cat food, chicken necks, ears of corn, or whole peanuts for bait.
● To keep raccoons at a distance, try scattering blood meal around corn plants. Also try sprinkling wood ashes around your plants.
● Grind up garlic, mix it with an equal portion of chili powder, and spread it around the garden. Frequent applications are needed.
● One reader says, "Hang shoes and clothes that smell of human perspiration around your garden or corn patch." Similarly, "You can try to repel raccoons by putting dog hair or human hair around the garden."

● Tune a radio to a rock station and set it in the middle of your garden and/or corn patch. Leave it on all night. The noise will scare away the raccoons.
● Put lights in the garden. A bright lantern will sometimes keep Sun-shy raccoons away.
● Plant enough corn for man and beast alike.
● Add some pinwheels and streamers to your garden to scare the creatures.
● Folk wisdom suggests that you spread newspapers around the perimeter of the garden.
● Build a good fence around your garden. Beware though, raccoons are agile and intelligent; make sure your fence will keep them out. You may need to install an electric fence. This is a good measure. A two-wire fence, with one wire four to six inches above the ground and the other at 12 inches, should be effective.
● If your home is near your garden, remove any possible food sources from the area, including pet food and bird seed. Buy garbage cans with locking lids and keep garbage inside if possible. Keep pet doors sealed shut between dusk and dawn. Cap your chimneys. Seal any holes or gaps in attics and roofs.

● Grow tall varieties of corn such as 'Silver Queen', 'Kandy Korn', and 'Lancelot'. Taller plants bear their ears higher, causing raccoons trouble getting leverage to topple stalks and ravage them. They prefer shorter plants.
● You can also plant squash around your corn or other plants to deter raccoons; they don't like walking on the prickly squash vines.

Thrips

Thrips are tiny insects about as fat as a sewing needle that dine on many plants worldwide. Also known as thysanoptera or thunderflies, thrips are sucking insects that can cause some damage to plants. However, their damage can be much worse when they transmit viruses to plants.

Thrips Life Cycle: The life cycle depends on the species of thrips as well as the location, host plant, and other factors. Adult thrips overwinter in plant debris, bark, or other materials. They become active in early spring and lay eggs in plant tissue. These eggs hatch after 3–5 days, and the nymphs then feed for 1–3 weeks before resting to molt in 1–2 weeks. Thrips can have up to 15 generations per year outdoors. Adult thrips live short lives of about one month.

Identification

Adult thrips are slender and tiny, at 1 / 50- to 1 / 25-inches long. Their colors can be anywhere from yellow to brown or black, and if you try to get close to them, they will probably leap or fly away. They have narrow, fringed wings. The nymphs look like even smaller adults, though they tend to be light green or yellow rather than darker colors. Their wings are also not fully developed, and they sometimes have red eyes.

Thrips appear to be tiny dark slivers on your plants. It is hard to see their bodies well without a magnifying glass, but up close, they look a bit like lobsters. Shake them onto a white background in order to see them well.

Damage

Thrips damage includes streaks, silvery speckling, and small white patches. This happens because the thrips suck plant cells from many garden plants, flowers, fruits, and shade trees. If you have a major infestation of thrips, your plants might be stunted with damaged flowers and fruit. The damage that you notice might instead come from the virus that the thrips spread (usually tomato spotted wilt virus).

Prevention

● To keep thrips populations under control, try using yellow or blue sticky traps.
● Shaking branches to remove the thrips and catching them on a cloth underneath is one easy way to quickly remove them.
● For onion thrips: Take a dark piece of paper into the garden and knock the onion tops against it; if thrips are present, you will spot their tan-colored bodies on the paper. A couple of treatments with insecticidal soap kills them. Follow the package directions. Spray the plants twice, three days apart, and the thrips should disappear.
● For fruit trees: Spray dormant oil on the trees.
● As a last resort, dust the undersides of leaves with diatomaceous earth.
● For flower thrips on gladiolus: Mix 1 tablespoon Lysol household cleaner with 1 gallon water. Soak gladiolus corms in the liquid and plant while still wet to prevent thrips.
● You can plant various flowers to attract beneficial insects that are natural predators to thrips. Some good predators include pirate bugs, lacewings, and lady bugs. Learn more about attracting those predators.
● For onion and western flower thrips, try releasing minute pirate bugs or the predatory mite Amblyseius cucumeris.

● Reflective mulches can help to hide your plants from thrips.
● If there is a very big thrips problem in your area, some plants have resistant varieties.
● Try not to overfertilize plants, as this can lead to more thrips damage.

Cabbage Worms

Cabbage worms are the same pest as "imported cabbageworms." The adult butterflies are sometimes called cabbage whites or small whites. The Latin name is Pieris rapae, or Artogeia rapae.

This is a common pest for cabbage, kale, cauliflower, broccoli, and other members of the cabbage vegetable family. Do not be overly concerned if you see a hole in a leaf; plants can withstand much leaf loss without consequence. It is during seedling establishment or early head formation that plants will incur true damage to their growth and yield.

Identification

Cabbage worms are velvety green larvae. They have a few faint yellow stripes. They are not to be confused with cabbage loopers, which are yellow-green caterpillars. Unlike cabbageworms, cabbage loopers raise and lower their bodies as they move because they have no middle legs. Cabbage worms become cabbage white butterflies, which are mostly white with a few black markings. Cabbage white butterflies might seem like a pretty addition to the garden, but they are probably laying eggs on the undersides of leaves.

Where you find cabbage worms and cabbage loopers, you also might find the eggs and larvae of the diamondback moth and the zebra caterpillar. The camouflage of these creatures is excellent, so you will often see the frass, or fecal matter, that they leave behind before you see them.

Damage

Cabbage worms can happily eat away at the bases of cabbage, cauliflower, or the heads of broccoli without being noticed. They feed on foliage, and eventually they can leave plants only with stems and large veins. If left to their own devices, cabbage worms can devour your crops. Their fecal matter can also stain and contaminate the produce.

GARDENING Plant Pests & Diseases Pests Cabbage Worms

Prevention	● Manually remove (handpick) the eggs if possible. ● Yellow sticky traps will catch the adult butterflies, but may also catch beneficial insects. ● Spraying with Bt (Bacillus thuringiensis var. kurstaki) every 1 to 2 weeks will also help control cabbage family pests. Sevin also is effective. And, the few pests that remain on the vegetables can be washed out after harvest using water and a small amount of detergent or other surfactant. ● It is said that if you dampen cabbage leaves and sprinkle them with cornmeal, the caterpillars will eat the meal, swell, and die. ● Check with your local Cooperative Extension for your area's regulations on chemical control. ● Years ago, people sprinkled rye flour over cabbage plants in the early morning. The flour dehydrated the cabbage worms. ● Cover your plants with row covers to deter the adult butterflies from laying eggs on the cabbages.

● Trichogramma wasps (very tiny; they do not sting humans) parasitize the eggs of the imported cabbage worm; these beneficial insects are available by mailorder, although you'll need to time their release appropriately—the mailorder company would be able to help you. Read more about beneficial insects.
● Companion planting is a useful deterrent for many pests. Cabbage worms are repelled by thyme, so it would be a good idea to plant thyme near your susceptible plants. Cabbage worms are attracted to mustard plants, so planting mustard near more valuable plants can be a good trap for cabbage worms. Once they take over the mustard, you can destroy the plant.
● Try planting red leafed varieties of cabbage. The cabbage worms won't be able to camouflage, so they are less likely to choose these plants.

Cucumber Beetles

If you find that the stems of your seedlings are being eaten off, leaves are yellowing and wilting, and holes are appearing, you may have a striped or spotted cucumber beetle problem. Striped cucumber beetles are specialists on cucurbits (such as cucumbers, squash, pumpkin, watermelons) while spotted cucumber beetles feed on other plants in addition to cucurbits.

Often, the beetles leave their hibernating sites early in the season (mid-April to early June), and feed on seedlings right as they are emerging, usually killing them. Then their larvae feed on the roots of the host plants. As they grow into adults (mid-July to September), the beetles will once again feed on the leaves, vines, and fruit of plants that survive, leaving deep marks in the rind.

Cucumber beetles hold another threat too: They can spread bacterial diseases and viruses from plant to plant, such as bacterial wilt or mosaic virus.

Identification	Adult striped cucumber beetles are about ¼ inch long and have a yellow-and-black–striped abdomen and a dark-colored head and antennae. Spotted cucumber beetles are the same length but have 12 black spots on a yellow abdomen. The larvae are worm-like, white, dark-headed, and have three pairs of legs on the thorax.
Damage	While cucumber beetle larvae feed on cucurbit roots, adult feeding is more damaging to the crop. Adults feed on leaves and can stunt plant growth. Look for holes and yellowing and wilting leaves. Feeding on flowers can reduce fruit production, and direct feeding on fruits causes unattractive scars and pock marks on the fruit, too. Often, the cucumber beetles alone will not kill the plants or cause major damage, but the spread of disease will. Feeding by adult cucumber beetles can spread bacterial wilt disease among cucurbit plants, even when population density of the insect is low. Adult cucumber beetles overwinter in weeds, garden debris, and woody areas. The diseases they carry can also overwinter internally.
Prevention	● Inspect newly planted cucurbit plants for the presence of this beetle; be watchful when plants are seedlings. ● Use yellow sticky traps to catch cucumber beetles and other pests. ● Knock beetles to the ground and catch them with a piece of cardboard placed under the plant. Or, use a handheld vacuum to suck up the beetles. They are very hard to hand pick, but it is easier to hand pick them with yellow gloves coated in petroleum jelly. ● Cover seedlings with row covers, though you must remove during blossoming time several hours each day to allow for pollination. ● Few insecticides can be used on cucurbit plants because they are very sensitive. They would need to be used when plants are just beginning to emerge through the soil. Please contact your local cooperative extension for a list of approved insecticides for your area. ● Nasturtiums and wood ashes are effective against cucumber beetles.

● If you till your garden in the late fall, you will expose cucumber beetles hiding there to harsh winter conditions and reduce their populations next year. Remove all debris after fall harvest to reduce overwintering habitat.
● Rotate crops so cucurbit crops are not planted directly into soils containing overwintering populations.
● Transplanting young plants rather than direct seeding can protect vulnerable seedlings from damage.
● Planting trap crops (cucurbit varieties highly attractive to cucumber beetles) at the perimeter of the harvested crop can keep cucumber beetles from migrating into the harvested crop.
● Where cucumber beetles are a problem, let the beetles come out of hiding and plant late. They have a knack for finding vulnerable seedlings. When yours are up and growing, the cucumber beetles will be gone, fooled into thinking you don't have any cucumbers in your garden.
● Natural predators include beneficial insects like braconid wasps, some nematodes, and soldier beetles.
● Companion planting your vegetables with flowers can help to keep pests away from the plants you don't want the beetles to attack.
● Once bacterial disease has entered the plant, there's very little that you can do. If it's bacterial wilt, you'll see the leaves dry up and the plant will quickly wilt and die. Take prevention for next year, as described above.

Flea Beetles

Flea beetles are small, shiny-coated beetles with large rear legs, which allow them to jump like fleas when threatened (the source of their name!).

There are many species of flea beetles. Some species attack a wide range of plants, while others target only certain plant families. In the garden, a number of vegetable crops are susceptible to these pests, particularly those in the Brassica family, like broccoli, cabbage, kale, radishes, and turnips, as well as Nightshades such as tomatoes, peppers, and eggplants.

Identification	Given that there are so many species of flea beetles, they vary in appearance quite a bit. Colors range from black to tan, with other, brighter colors mixed in, and the beetles may have a solid, striped, or spotted pattern depending on the species. To identify flea beetles, it's easier to look for signs of their damage (described below) than for the beetles themselves. At only 1/16 of an inch in length, flea beetles are very tiny and will quickly spring away—like fleas—if they see you approach! Adult flea beetles overwinter in brush and wooded areas. Adults pose the biggest threat early in the planting season as they are emerging, typically when outdoor temperatures reach 50°F (10°C). At this time, seedlings are being planted, too, and they are most susceptible to beetle damage. Eggs are laid at the base of plant stems in early summer after the spring feeding period, and larvae feed at the roots.

GARDENING Plant Pests & Diseases Pests Flea Beetles

Damage	Adult beetles feed on foliage, producing "shotholes" in the leaves. Look out for these holes especially on young seedlings, where damage is most rapid and will cause the most harm. The holes they make will be round and can quickly damage leafy greens. New leaves are usually damaged first, and they will have a lacy appearance. Flea beetles usually don't cause fatal damage to established plants because the leaves are already large enough to survive with a few holes. The real danger is that the beetles can spread bacterial diseases, such as wilt and blight, from plant to plant. Therefore, they are still important to consider a pest.
Prevention	● Try this homemade spray to control flea beetles: 2 cups rubbing alcohol, 5 cups water, and 1 tablespoon liquid soap. Test out the mixture on a leaf of the plant, let it sit overnight, then spray the rest of the plant if you don't notice any adverse effects. Spray the mixture on the foliage of garden plants that are susceptible to these pests. ● Dusting your plants with plain talcum powder repels flea beetles on tomatoes, potatoes, peppers, and other plants. ● Use white sticky traps to capture flea beetles as they jump. ● Insecticides may be used early in the season, but are generally unnecessary in the control of flea beetles on adult plants. Be extra diligent if your soil has history of bacterial diseases. Please contact your local nursery or cooperative extension for further advice. ● In the spring, emerging flea beetles will be waiting to feast on your garden. Cut off their food supply by delaying transplanting or planting by a couple weeks if possible. ● In the fall, till the garden to unearth any hiding flea beetles. This will also make soil easier to work the next spring.

● Row covers may be successful at keeping these pests out, as long as they are completely sealed. They should be used immediately after transplanting, so the pests do not have time to find the plant.
● Flea beetles are repelled by catnip and basil. They are attracted by nasturtium and radishes. You can plant these as traps for the flea beetles so that they do not attack other more valuable plants.

Cutworms

"Cutworm" is the name used for the larvae of a number of species of adult moths. Eggs that hatch in the fall can produce larvae capable of overwintering in the soil or a woodpile. They do the most damage early in the gardening season, when they emerge from hibernation. Cutworms are caterpillars, but they are often mistaken for the grubs of beetles such as Japanese beetles (which are damaging in their own right).

Identification	Cutworms are common on a wide variety of vegetables and any fresh seedlings. To identify them, try patrolling your garden in dusk and evening hours, when cutworms will begin to feed. They are also partial to cloudy days. Different species range in color from grey to pink, green and black and can be as long as two inches. They can be solid, spotted, or striped. They tend be curled up when they are not on the move. Cutworms are stealthy, and tend to feed only at night, while hiding in daylight hours. Black cutworms, also known as Agrotis ipsilon, are some of the most common cutworms. They have small dark spots on their bodies and mature into the dark sword-grass moth. Variegated cutworms, another common species, are mottled brown and have a faint white stripe down their backs. Adult cutworms are moths of dark wing colors. They are usually brown or gray, and they are about 1 ½ inches long with a 1 ½-inch wing length. You should keep an eye out for them, because the females will lay eggs in dry soil after they mate.
Damage	Cutworms chew through plant stems at the base. They primarily feed on roots and foliage of young plants, and will even cut off the plant from underneath the soil. In most cases, entire plants will be destroyed; they do a lot of damage in no time at all. Even if only the bottom of the plant is destroyed, the top will often shrivel and die. In the summer, cutworms sometimes crawl to the tops of plants and do damage there. Be careful not to mistake this damage for slug damage.
Prevention	● Make plant collars. Put a 4-inch piece of cardboard around each plant stem to help stop cutworms from reaching tender stems, especially right at transplanting. This time-consuming task works, though it is only efficient for a smaller garden. ● Save toilet paper tubes, cut them in half, fill with potting soil, and stand up in a tray. Use for planting seeds. When young plants are ready, plant them, tube and all. ● Hand pick. Go out at night with a flashlight and gloves. Pick off the cutworms and drop into soapy water; repeating this every few nights. ● Sprinkle used coffee grounds or egg shells around your plants. ● Circle stems with diatomaceous earth, a natural powder made from ground up fossils which kills insects when they walk over it. ● Apply an insecticide late in the afternoon for best control. Some readers use Bacillus thuringiensis, a natural way to kill cutworms. However, note that this bacterium may harm butterflies, an important pollinator. ● A mulch of oak leaves is useful against cutworms.

● Tansy planted near cabbages keeps them free of cutworms.
● A hog turned into a garden in early spring will root up cutworms.
● In the spring, emerging cutworms will be waiting to feast on your garden. Cut off their food supply by delaying transplanting or planting by a couple weeks if possible.
● Keep up with cultivation. The moths prefer to lay eggs in high grass and weeds. At the end of the season, plow or till the garden and mow surrounding areas to expose cutworms and destroy their winter habitat.
● Fireflies are a fun insect to have around the garden, plus they are a natural predator to cutworms. Check out these tips to attract fireflies to your garden.
● Birds are another natural predator to cutworms. Learn how to make your garden bird-friendly.

Aphids

Aphids seem to find their way into every garden. They are small, soft-bodied insects that feed by sucking the nutrient-rich liquids out of plants. In large numbers, they can weaken plants significantly, harming flowers and fruit. Aphids multiply quickly, so it's important to get them under control before reproduction starts. Many generations can occur in one season. The good news is that they tend to move rather slowly and aphid control is relatively easy.

Identification	Aphids are tiny (adults are under ¼-inch), and often nearly invisible to the naked eye. Various species can appear white, black, brown, gray, yellow, light green, or even pink! Some may have a waxy or woolly coating. They have pear-shaped bodies with long antennae; the nymphs look similar to adults. Most species have two short tubes (called cornicles) projecting from their hind end. Adults are usually wingless, but most species can develop a winged form when populations become crowded, so that when food quality suffers, the insects can travel to other plants, reproduce, and start a new colony. Aphids usually feed in large groups, although you might occasionally see them singly or in small numbers. While aphids in general feed on a wide variety of plants, different species of aphids can be specific to certain plants. For example, some species include bean aphids, cabbage aphids, potato aphids, green peach aphids, melon aphids, and woolly apple aphids.

Damage

Nymphs and adults feed on plant juices, attacking leaves, stems, buds, flowers, fruit, and/or roots, depending on the species. Most aphids especially like succulent new growth. Some, such as the green peach aphid, feed on a variety of plants, while others, such as the rosy apple aphid, focus on one or just a few plant hosts.

- Look for misshapen, curling, stunted, or yellowing leaves. Be sure to check the undersides of leaves; aphids love to hide there.
- If the leaves or stems are covered with a sticky substance, that is a sign that aphids may have been sipping sap. This "honeydew," a sugary liquid produced by the insects as waste, can attract other insects, such as ants, which gather the substance for food. When aphids feed on trees, their honeydew can drop onto cars, outdoor furniture, driveways, and so on.
- The honeydew can sometimes encourage a fungal growth called sooty mold, causing branches and leaves to appear black.
- Flowers or fruit can become distorted or deformed due to feeding aphids.
- Some aphid species cause galls to form on roots or leaves.
- Aphids may transmit viruses between plants, and also attract other insects that prey on them, such as ladybugs.

Prevention

- Try spraying cold water on the leaves; sometimes all aphids need is a cool blast to dislodge them. Typically they are unable to find their way back to the same plant.
- If you have a large aphid invasion, dust plants with flour. It constipates the pests.
- Neem oil, insecticidal soaps, and horticultural oils are effective against aphids. Be sure to follow the application instructions provided on the packaging.
- You can often get rid of aphids by wiping or spraying the leaves of the plant with a mild solution of water and a few drops of dish soap. Soapy water should be reapplied every 2-3 days for 2 weeks.
- One variation of this soap-water mix includes cayenne pepper: Stir together 1 quart water, 1 tsp liquid dish soap, and a pinch of cayenne pepper. Do not dilute before spraying on plants.
- Diatomaceous earth (DE) is a non-toxic, organic material that will kill aphids. Do not apply DE when plants are in bloom; it is harmful to pollinators, too.
- For fruit or shade trees, spray dormant horticultural oil to kill overwintering aphid eggs.

- Beneficial insects, such as ladybugs, lacewings, and parasitic wasps, will feed on aphids. Supplemental populations of these insects can be ordered online and should help keep the aphid populations controlled from the start.
- Aphids are repelled by catnip.
- Aphids are especially attracted to mustard and nasturtium. Plant these near more valuable plants as traps for the aphids. (Check your trap plants regularly to keep aphid populations from jumping to your valued plants.)
- Nasturtiums spoil the taste of fruit tree sap for aphids and will help keep aphids off of broccoli.
- Garlic and chives repel aphids when planted near lettuce, peas, and rose bushes.

Earwigs

Earwigs can be found in almost any growing zone, although they are more likely to inhabit warm, humid climates. You might have trouble spotting one—not only are they quick movers, they are also nocturnal, and tend to hide out during the day when you are tending the garden. They like decaying wood and plant material, and dark, damp spaces. Oftentimes, they can be found in basements and woodpiles.

Earwigs are the sole members of the insect order Dermaptera, ancient bugs that began crawling around Earth about 208 million years ago. Today, nearly 2,000 species are scattered everywhere but in Earth's polar regions. The name "earwig" comes from the Old English ear-wicga, which means "ear wiggler"—so named because the insect was once thought to seek out human ears to reside in. In France, they're called "ear piercers," and in Germany, "ear worms."

Earwigs enjoy a lively social scene. They congregate during the day because they tend to find the same hiding places. Their nests can number in the thousands, and they aren't territorial, so they often live together.

Pincher bugs are omnivores, meaning they'll eat pretty much anything that's made available to them. In the garden, they primarily feed on dead or decaying plant and animal matter. However, they will also readily prey on aphids, insect eggs, maggots, grubs, and army worms. When their population gets out of control, they may turn to feasting on living plant matter, especially the seedlings or young foliage of vegetables and flowers. This creates a conundrum for gardeners… Should earwigs be allowed to remain in your garden to eat up aphids and other pests? Or should they be removed before they turn their attention on your plants? Generally, earwigs do not cause enough damage to be worth fighting. However, if you do see large numbers of them around your plants, you can consider taking action.

The pincers at the end of an earwigs abdomen look rather formidable. They are capable of pinching (and sometimes biting) humans, but the pinch is not particularly powerful. Earwigs usually use their pincers to ward off enemies like toads and birds, or—in some species—to catch prey. The pincers, or "cerci," are also important for romance. They are indicators of gender, like tusks on an elephant. A male earwig's pincers are long and curved, while a female's are shorter and straighter.

Identification

- Earwigs get to be about ¾-inch long. They're reddish-brown insects with appendages on their tail-ends that look like forceps. Few other insects have a set of scary-looking pincers like the earwig has. This is why some folks call them "pincher bugs" or "pinching bugs." Attached at the insect's abdomen, these appendages are called cerci.
- Earwigs run very quickly and can also fly, though they rarely do so. They actually have two sets of wings, and their pincers aid in unfolding the wings.
- What do earwigs eat? Nocturnal by nature, an earwig's main meal is decaying plant material and wood, but it will attack living plants, including vegetables, fruit trees, and ornamentals, if given the opportunity. Earwigs are especially fond of flowers, lettuce, celery, and fruits.
- Female earwigs lay 40 to 50 shiny eggs in underground tunnels. The eggs are protected from predators and hatch in about a week, making it very difficult to control earwig populations before they hatch.
- Nymphs simply appear to be miniature versions of adult earwigs. They shed several skins, and ten weeks later, they reach adulthood.
- Earwigs often hide underneath pots during the day and then eat the flowers in the pots at night.

Damage

- Leaves will appear jagged and full of holes. Plants will become ragged overnight, and some leaves will only be partially eaten. There will also probably be a scattering of earwig excrement, which will be small, black pellets.
- Damage will often occur after rainy weather, which forces earwigs to seek dry shelter and climb up into plants and leaves.
- You might find the earwigs under pots that contain damaged plants.
- Earwig damage looks similar to that of slugs and snails. To tell the difference, look for the tell-tale sign of slugs and snails: a trail of slime residue on foliage.

Prevention

Generally, earwigs are not as much of a threat to your garden as other pests, like Japanese beetles and aphids, though they can be as big of an annoyance! They can also produce a foul odor when disturbed, so keep that mind. Try these remedies:

- Lay one-foot sections of bamboo or garden hose in the beds between your plants. Check these "traps" each morning, and dump the earwigs into a bucket of soapy water.
- Spread petroleum jelly around the stems of your plants. Earwigs won't crawl over it.
- If they are infesting your woodpile, try sprinkling borax around it, but keep pets and children away from this area after doing so.
- Oil pit traps are a great remedy for earwigs. Combine equal parts soy sauce and olive or vegetable oil, put it in a small plastic container, and secure the lid. Punch holes in the top of the container, near the lid. Make the holes large enough for the earwigs to get in. Bury the container in the soil just up to the holes. The soy sauce will attract the earwigs, and the oil will prevent them from escaping. Change the mixture as needed.

- Alcohol controls these pests by acting as a surfactant, or wetting agent, that can penetrate an insect's waxy coat of armor and kill on contact with the body. Isopropanol (rubbing alcohol) works fine and is easy to find, but be sure it doesn't have additives. Ethanol (grain alcohol) seems to work best. Alcohol usually comes in 70 percent strength in stores (or 95 percent strength purchased commercially). To make an insecticidal spray, mix equal parts 70 percent alcohol and water (or, if using 95 percent alcohol, mix 1 part alcohol to 1 ½ parts water).
- WARNING: Before using an insecticidal spray on your plants, test it on a single leaf. Wait 24 hours and observe to see if the plant has an adverse reaction. If it does, dilute your alcohol solution more and test again.
- Earwigs are also susceptible to diatomaceous earth (DE), so consider placing a ring of DE around the bases of plant if the soil is dry enough. In wet weather, DE is not effective.
- Expect more earwigs during rainy years, and prepare accordingly.
- Avoid growing susceptible plants near walls covered in ivy or hedges, as many earwigs might live in these areas.
- Birds and toads are both natural predators of earwigs. Check out our tips for creating a bird-friendly garden.

- Occasionally, earwigs will move from mulch and other moist material outside into your house. They aren't harmful, but can be an annoyance nonetheless. To prevent this, check for bugs on everything you bring inside, especially laundry, lawn furniture, flowers, vegetables, houseplants, and firewood. Also, move mulch away from your house's foundation and establish a zone of bare soil that will dry out. If earwigs do happen to get into your home, vacuum them up.

Squash Bugs

Squash bugs can be the bane of a gardener's existence! They are very difficult to manage and can cause a lot of havoc. Squash bugs are most commonly found on squash plants (hence the name) such as zucchini, winter squash, and pumpkins, but they may also affect other crops in the cucurbit family (like cucumbers, cantaloupe, and watermelon). Other pests that are commonly found on squash include squash vine borers.

Squash bugs are often mistaken for stink bugs, as they are similar in appearance and both have a foul odor when squashed. However, stink bugs are wider and rounder than squash bugs.

Identification	The squash bug is fairly large (over ½-inch long) with a brownish or gray body and flat back. The edges and undersides of the abdomen have orange stripes. They are able to fly, but they often simply walk around on plants. Young squash bugs, or squash bug nymphs, are gray and have black legs. They move quickly and often in groups on the undersides of leaves. Squash bugs overwinter in your dead leaves, vines, under boards, and even in buildings. They fly to garden plants to mate as soon as vines start forming, and they lay egg masses on the undersides of the leaves. You'll find adults beneath damaged leaves and near the plant crown.
Damage	These bugs inject a toxin into the plant and suck the sap right out of it with their sharp, sucking mouthparts. This causes yellow spots that eventually turn brown. The leaves will wilt because the damage prevents the flow of nutrients to the leaves, and then they will dry up and turn black, crisp, and brittle. The leaves also sometimes have ragged holes. Smaller plants will die, and squash bug feeding can decimate young fruit. The wilting can resemble bacterial wilt, which is a disease spread by cucumber beetles (yet another squash pest), so be sure to find the bugs or eggs and identify them correctly.
Prevention	● Early detection is critical! You want to catch squash bugs before they grow into adults or they are very difficult to get rid of completely. ● Pick egg masses off the plants in the morning and later in the day. One reader fills a vase with water and liquid dish soap and flicks the squash bugs into the water. Once the bugs are dead, it's fine to dump the water anywhere. You can also simply scrape the eggs off the leaves with a butter knife and let them fall onto the ground, where beetles will eat them. Eggs hatch in about ten days, so be sure to check for them on at least a weekly basis. ● Place a board or shingle in the garden at night. During the night, both adults and nymphs will congregate underneath the board. Squash between two hard surfaces in the morning and dispose. ● Insecticides (such as carbaryl/Sevin) are most effective if applied when eggs are hatching. See your local garden center or cooperative extension service for controls that are locally approved. ● Keep checking your plants, at least daily. If there are no more than a few vines infected, keep collecting and destroying the bugs and crushing the egg clusters that you find on the undersides of leaves.

- Prevention is key: In the fall, be sure to burn or compost old squash vines to rid your garden of any possible shelters for breeding and over-wintering.
- Avoid deep, cool mulches like straw or hay that provide an environment that these bugs seem to love.
- Practice crop rotation.
- Consider keeping vines covered until blossoming begins. Remove the cover for pollination needs. There is only one generation of squash bugs per year, and you can avoid them by covering your plants for the first month of spring. You can also delay planting your squash until the early months of summer.
- Companion planting can be useful in repelling squash bugs. Try planting nasturtium and tansy around your plants that are commonly affected by squash bugs.
- Select varieties of squash that are resistant to the squash bug if you have a big problem. 'Butternut', 'Royal Acorn', and 'Sweet Cheese' varieties are all more resistant to squash bugs.

Whiteflies

Whiteflies are soft-bodied, winged insects closely related to aphids and mealybugs. Despite their name, whiteflies are not a type of fly, though they do have wings and are capable of flying. Whiteflies can be as small as 1/12 of an inch, are somewhat triangular in shape, and are often found in clusters on the undersides of leaves. They are active during the day and will scatter when disturbed, so they can be easier to spot than some nocturnal insect pests. There are hundreds of species of whiteflies, but most affect only a small number of host plants. However, there are a few whitefly species that affect a wider range of plants, which make them the most problematic in horticulture. These whitefly species include the greenhouse whitefly, bandedwinged whitefly, giant whitefly, and silverleaf whitefly, among others. Silverleaf whiteflies, which are slightly smaller and more yellow than other whiteflies, are especially common in the southern United States.

In USDA Zone 7 and colder, whiteflies are not able to survive winter outdoors, so their presence tends to be limited to indoor plants or greenhouse environments. However, if outdoors plants are bought from an infested greenhouse, whiteflies may become a seasonal outdoor garden pest. (Always inspect plants before bringing them home!) In warmer regions, whiteflies are capable of overwintering and reproducing outdoors throughout the year, so they can be a problem for both indoor and outdoor plants. You'll often start to see whiteflies in mid- to late-summer when it gets warm and humid.

Whiteflies can be found on a wide variety of plants, from ornamental flowers to warm-weather vegetables, including tomatoes, eggplant, peppers, and okra. Some species may attack sweet potatoes, plants from the cabbage family, and citrus trees. Indoors, they will feed on most common houseplants, especially those with soft, smooth leaves.

Identification	Like aphids, whiteflies use their piercing mouthparts to suck up plant juices and, in turn, produce a sticky substance known as honeydew. Honeydew left on its own can cause fungal diseases such as sooty mold to form on leaves. With heavy whitefly feeding, plants will quickly become extremely weak and may be unable to carry out photosynthesis. Leaves will wilt, turn pale or yellow, growth will be stunted, and eventually leaves may shrivel and drop off the plant. Honeydew is a sign that the whiteflies have been feeding for several days. You might also see ants, which are attracted to the sweet honeydew. Whiteflies tend to prefer to feed on new growth, so check around any newly unfurled leaves first. Check the undersides of leaves—especially around the veins—for white insects, even if they aren't immediately visible, and feel leaf surfaces for sticky honeydew. If the whiteflies are feeding, they'll suddenly all fly off the leaves in a swarm, so it's very obvious. You may also find eggs laid on the undersides of leaves.
This is the beginning of a new generation! When the eggs hatch, the larvae will look like teeny white ovals without legs; they don't move but they immediately start sucking the plant juice. This is why gardeners often miss whiteflies until it's too late. Adult females can produce up to 400 eggs, which hatch in about one week to a month after laying. They are usually laid in a circular pattern. Eggs are pale yellow when newly laid and brown when about to hatch.	
Damage	
Prevention	To control whiteflies, there are various solutions and traps that you can use. The biggest tip is: start early! In the mornings and evenings, as you wander the garden or tend to your houseplants, check the back of the leaves for eggs or notice when little bugs "fly away" as you approach your plants. ● Always start with blasting whiteflies (as with aphids and many other insect pests) with your watering hose or a spray bottle. This will cause them to scatter and will dislodge nymphs and eggs to some extent. ● Consider spraying your plants' leaves with an insecticidal soap, following the directions on the packaging. Be sure to spray the undersides of leaves, too. Follow up 2 or 3 times, as necessary. ● According to the National Gardening Association, the following simple homemade mixture should be helpful to control and deter whiteflies: Use a mix of dish soap and water. A good squirt of soap to a gallon of water should work. As mentioned above, only spray in cooler temperatures; late in the day is best. The NGA mixture is a pretty benign combination, and whiteflies are nearly impossible to get rid of, so it's best to try more preventative tactics first, as mentioned below.
● Tip: Spray plants in the evening when temperatures are cooler, as mid-day heat may cause an adverse reaction in your plant. Plus, spraying in the evening allows you to avoid accidentally spraying any pollinators or beneficial insects. ● If all else fails and your whitefly population is persistent, you can use a handheld vacuum every few days to remove them from your plants. This gets rid of both nymphs and adults. Just be sure NOT to empty your vacuum into a trash can inside your home afterward! ● Your first line of defense should be inspecting all plants for pests before you bring them home, as well as keeping any new additions away from the rest of your plants for a period of time. This will allow you to identify and curtail any pest or disease issues that appear. ● Keeping natural predators around will prevent whiteflies from ever exploding in population. For this reason, avoid using insecticides. Ladybugs, spiders, green lacewing larvae, and dragonflies are a few of many beneficial insects that can control a whitefly population. Hummingbirds are another natural predator. Try creating a habitat that will attract dragonflies and damselflies (which also helpfully eat mosquitoes) or beautiful hummingbirds. ● When it comes to whiteflies, avoid chemical insecticides; they're usually resistant and all you end up doing is killing the beneficial insects—their natural predators—and the insects that pollinate the garden for a better harvest! ● Mulch early in the season with aluminum reflective mulch, especially around tomatoes and peppers. The reflective mulch makes it challenging for whiteflies to find their preferred host plants. ● Set out yellow index cards coated with petroleum jelly to monitor whiteflies, especially when it comes to tomatoes, peppers, sweet potatoes, or cabbage crops. A half-and-half mixture of petroleum jelly and dish soap, spread over small boards painted bright yellow, is sticky enough to catch little whiteflies, too. To whiteflies, the color yellow looks like a mass of new foliage. The bugs are attracted to the cards, get stuck in the jelly, and die.	

Diseases

Rust Plant Disease

What is rust plant disease? This fungal disease affects a wide range of woody and herbaceous plants. Even though it rarely kills plants, it reduces a plant's health, vigour, and flower production.

Causes	Rust disease is caused by a fungal parasite that needs living plants to survive. Rust diseases occur most often in mild, moist conditions. Rust is spread by spores that are transferred from infected plants to healthy plants. These spores can be transferred either by the wind or by water, which is why rust disease often spreads after watering. Wet surfaces are also needed to cause infections.
Identification	Rust diseases come in different varieties and can affect a wide range of plants. People often struggle with rust on their roses. It is easy to remember the defining characteristics of this fungus, as they match its name. Rust plant disease will look similar to the rust that appears on that old bicycle in the shed. ● Look for yellow or white spots forming on the upper leaves of a plant. ● Look for reddish to orange blister-like swellings called pustules on the undersides of leaves. ● Orange or yellow spots or streaks appear on the undersides of the leaves. ● Within these spots that form are spores. ● Usually leaf distortion and defoliation occur.
Control / Prevention	● Remove all infected parts and destroy them. For bramble fruits, remove and destroy all the infected plants and replant the area with resistant varieties. ● Clean away all debris in between plants to prevent rust from spreading. ● Avoid splashing water onto the leaves, as this can help spread rust. ● Dust your plants with sulphur early in the season to prevent infection or to keep mild infections from spreading. ● Space your plants properly to encourage good air circulation. ● Avoid wetting the leaves when watering plants. ● There are many effective rust fungicides you can try. Ask your local nursery for which products you should use.

Powdery Mildew

GARDENING | Plant Pests & Diseases | Diseases | Powdery Mildew

Wondering about that white fungus on your plants? The fungal disease powdery mildew affects a wide variety of plants and takes away a plant's nutrients. This causes the plant to bloom less and become weaker. There are many different species of the fungal disease powdery mildew, and each species attacks a range of different plants. Unlike many other fungal diseases, powdery mildew thrives in warm, dry climates, though it does require fairly high relative humidity (i.e., humidity around the plant) to spread. In cooler, rainy areas, it does not spread as well.

That being said, it is capable of infecting your plants under a wide variety of conditions. When the fungus begins to take over one of your plants, the mildew that forms is made up of many spores. These spores carry the infection to other plants through the wind. Powdery mildew can slow down the growth of your plant. In some cases, if the infection is severe enough, powdery mildew can kill your plants.

Identification	● Plants infected with powdery mildew look as if they have been dusted with flour. ● Powdery mildew usually starts off as circular, powdery white spots, which can appear on leaves, stems, and sometimes fruit. ● Powdery mildew usually covers the upper part of the leaves, but may grow on the undersides as well. ● Young foliage is most susceptible to damage. Leaves turn yellow and dry out. ● The fungus might cause some leaves to twist, break, or become disfigured. ● The white spots of powdery mildew will spread to cover most of the leaves or affected areas. ● The leaves, buds, and growing tips will become disfigured as well. These symptoms usually appear late in the growing season.
Control / Prevention	● Remove all the infected plant parts and destroy them. Remember, do not compost any infected plant, as the disease can still be spread by the wind and persist in the composted materials. ● Spray infected plants with fungicides. Effective organic fungicides for treating powdery mildew include sulphur, lime-sulphur, neem oil, and potassium bicarbonate. ● Choose plants that are resistant or tolerant to powdery mildew. Many mildew-resistant varieties of cucurbits (melons, cucumbers, squash, etc.) have been developed and can be bought from major seed suppliers. ● Avoid watering plants from overhead in order to reduce relative humidity. ● Selectively prune overcrowded areas to increase air circulation; this also helps to reduce humidity around your plants. ● Spray your plants with the fungicides mentioned above according to the directions included with the products. ● If you don't want to use fungicides, try spraying your plants with a bicarbonate solution: Mix 1 teaspoon baking soda in 1 quart of water. Spray plants thoroughly, as the solution will only kill fungus that it comes into contact with.

Tomato Diseases and Disorders

Resisting Pests

Diatomaceous Earth

Diatomaceous earth (DE) is the fossilized skeletons of microscopic single-celled aquatic organisms called diatoms. Their skeletons are made of a natural substance called silica—which makes up 26% of the Earth's crust by weight. Deep deposits of diatomaceous earth are mined in the western United States in places where lakes once covered the area millions of years ago. Snugs and snails do not like to crawl over DE because the silica skeletons are very sharp—like tiny pieces of broken glass. (Slugs and snails don't like eggshells either!) If their soft bodies do get cut, they eventually dehydrate and die.

This process works on other soft bodied insects, too, including caterpillars and aphids, as well as on those with hard shells, such as beetles, fleas, cockroaches, and even bed bugs. The tiny particles of DE get into the insects' joints, causing irritation and dehydration. The downside to DE is that it does not discriminate between pests and beneficial insects. Ladybugs, green lacewings, butterflies, bees, and other "good guys" will also be affected by DE.

● When shopping for DE, look for the "food grade" quality. The DE used in pool filters is not effective against garden pests.
● Sprinkle bands of DE around the plants you are trying to protect. It's important that the ring of DE does not have any gaps for pests to sneak through.
● If pests are eating the leaves of your plants, you can dust the leaves with DE, which should discourage further damage. However, you should avoid applying DE near the plants' flowers, where pollinators might inadvertently come into contact with it.
● When using DE, it's recommended to wear eye protection and a dust mask, as the small particles can be irritating.
● DE works best in dry conditions. It clumps together when wet, so reapply after it rains.

Even though the industry states that this product does not cause lung damage, I would still refrain from breathing it in. Remember, it might feel soft to the touch, like talcum powder, but it still is an abrasive and can cause irritation to your eyes, nose, lungs, and throat. Wear a dust mask and eye protection when handling it just to be on the safe side. Surprisingly, DE is not toxic if eaten! In fact, we probably have been eating it for years unknowingly, since it is often mixed with grain in storage to kill insects. It can also be found in toothpastes and skin care products. Some people take it a step farther and use it for treating internal parasites! DE does not harm the soil since it is made from silica, the same as sand and many rocks.

It does not break down when exposed to sun. Rain can wash it into local water sources but it is non-toxic to fish and other aquatic life. It is not harmful to birds or other wildlife. It has been added to livestock feed for years. If pests are enough of a problem that you would be tempted to resort to a chemical pesticide, give DE a try first. It is considered organic by the Organic Materials Review Institute (OMRI) and the National Organic Program considers it a non-synthetic and permits it use in crop production.

Aeroponics

Aeroponics

Aeroponics is the process of growing plants in an air or mist environment without the use of soil or an aggregate medium (known as geoponics).

Aquaponics

Aquaponics refers to any system that combines conventional aquaculture (raising aquatic animals such as snails, fish, crayfish or prawns in tanks) with hydroponics (cultivating plants in water) in a symbiotic environment.

GARDENING Permaculture

Hydroponics

Hydroponics is a subset of hydroculture, the method of growing plants without soil, using mineral nutrient solutions in a water solvent.

Aquaculture

Aquaculture is the farming of aquatic organisms, including fish, molluscs, crustaceans and aquatic plants.

Plants

Identification tips for plants to determine its uses and edibility

"If a plant is sad, do other plants photosympathise with it..."
Unknown

Introduction

This section will guide you on how to identify wild plants with a high accuracy, however you will need the separate TPE Plant Identification section, a plant database or book to search in. The additional plant section is not included due to the size and containing over 5,000 rows. The section at the end will detail ways you can obtain a plant database.

Purpose	The aim of PLANTS is to provide a list of identification factors which can be used to help identify shrubs, plants and trees. It then discusses how to properly forage food and includes an edibility test for unknown plants.
Lost?	● For information on edible plants and growing your own food, see the GARDENING section. ● For a list of plants that grow in certain climates, see the SURVIVAL section. ● For information on the use of medicinal plants, see the NATURAL REMEDIES section. ● For a list of recipes for commonly foraged plants, see the RECIPES section. ● For information on the legality of drug plants by region, see the GEOGRAPHY section.

2 Stem Identification

Stem Type

Thorns, prickles, or spines	
Pendulous	
Twisted or Curved	

Leaf Branching

Alternate Branching	
Opposite Branching	

3 Leaf Identification

Leaf Features

Leaf Type

Simple Leaf (One Part)	
Compound Leaf (Multiple Parts)	

Leaf Apex (Leaf Tip)

Leaf Length

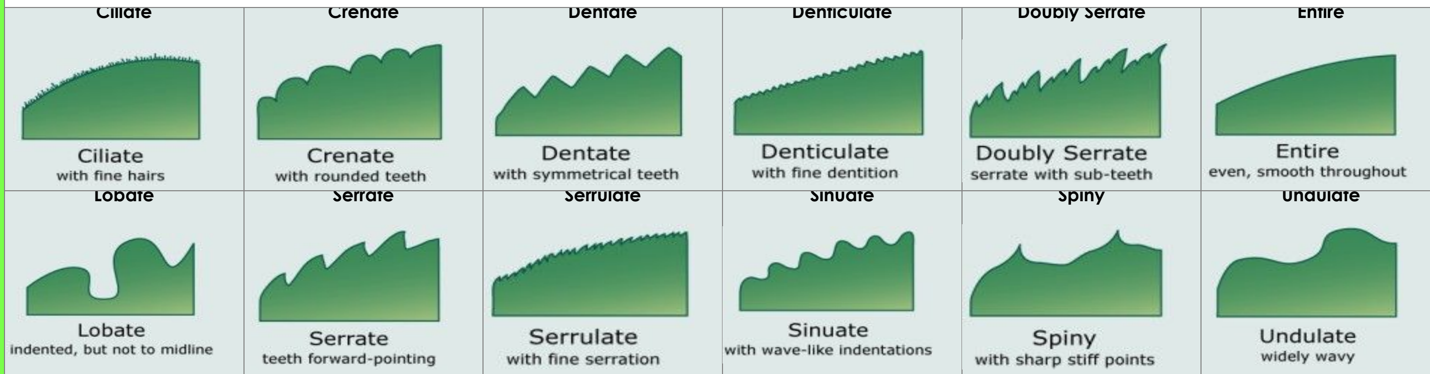
<3cm	
3-8cm	
8-15cm	
15-25cm	
25cm+	

Leaflet Count

Two Leaflets	
Three Leaflets	
Four Leaflets	

Leaf Margin

The leaf margin is the edges of a leaf.

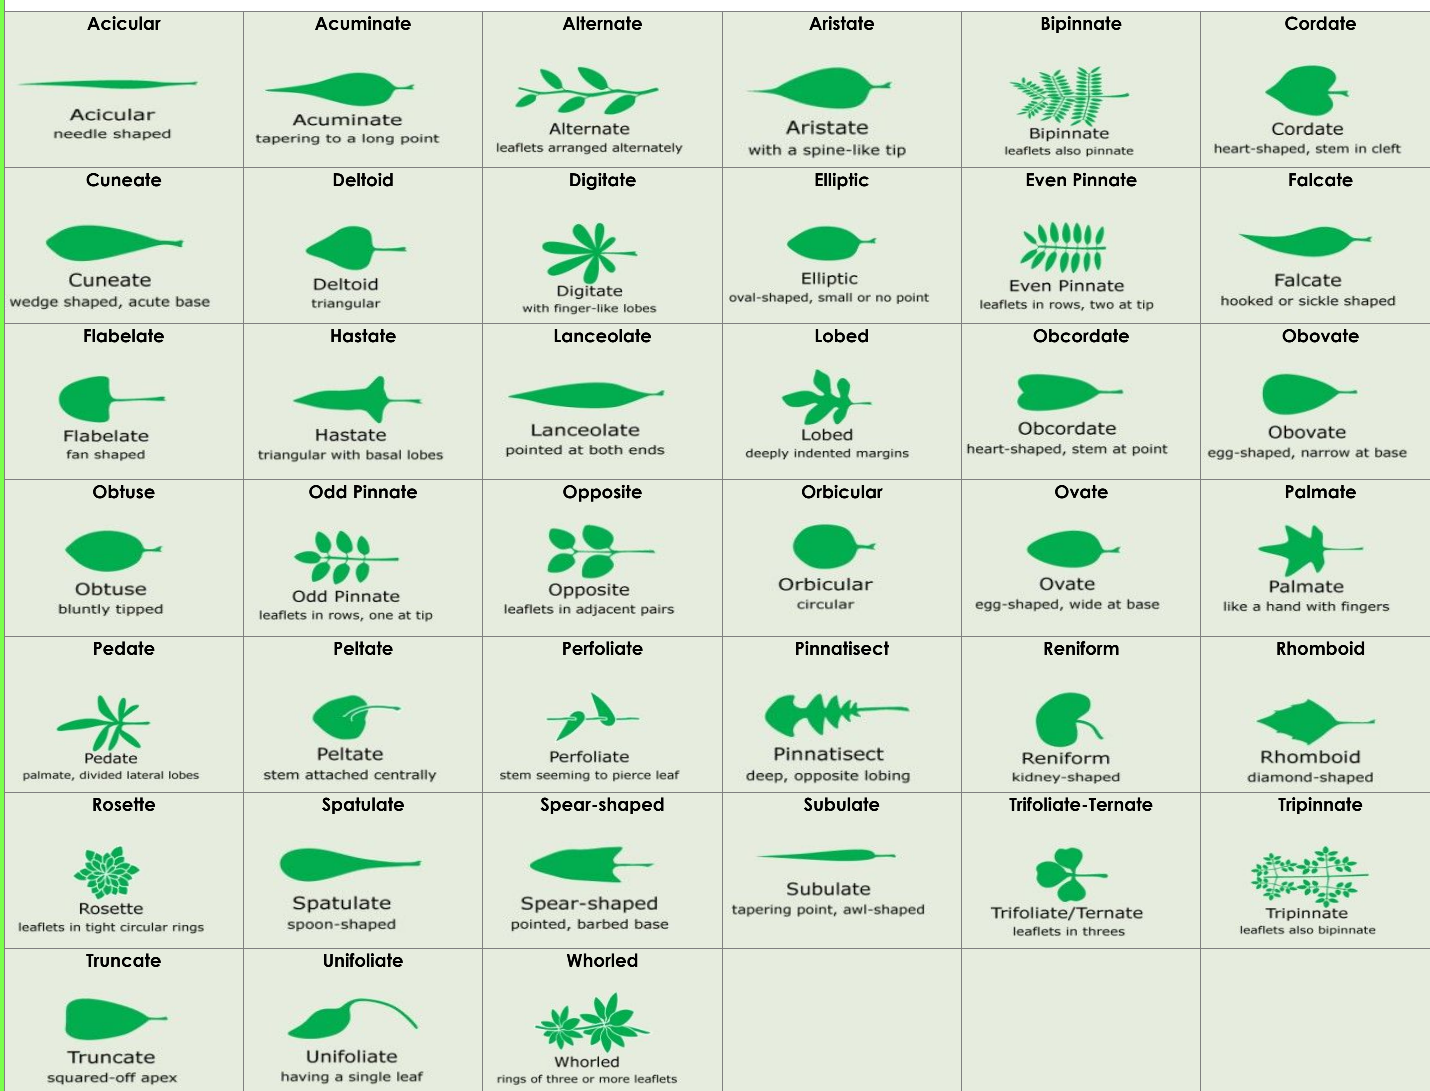


Leaf Base (Start of the Leaf)

Leaf Orientation

Leaf Shape

The leaf shape is the overall shape and look of a leaf.



Leaf Venation

Leaf venation is the pattern of the veins on the leaves.

Arcuate	Cross-Venulate	Dicotomous	Longitudinal	Palmate	Parallel
 Arcuate secondary veins bending toward apex	 Cross-Venulate small veins connecting secondary veins	 Dichotomous veins branching symmetrically in pairs	 Longitudinal veigns aligned mostly along long axis of leaf	 Palmate several primary veins diverging from a point	 Parallel veins arranged axially, not intersecting
Pinnate	**Reticulate**	**Rotate**			
 Pinnate secondary veins paired oppositely	 Reticulate smaller veins forming a network	 Rotate in peltate leaves, veins radiating			

Leaf Stipules

Stipules in general are appendages emerging in most cases at the base of the petiole (leaf stalk). They can appear in a range of different forms; as a pair of rolled up sheaves (encasing the developing leaf and being discarded as the leaf unfurls), as tendrils (without being discarded), as small leaves and also as spines. They can be easily noticeable to minute in size. The presence or absence of stipules, their different appearances and scaring of young branches (after detaching) can greatly assist in identification of tree species.

4 Flower Identification

Size

Not Showy	Tiny or of little ornamental value
Showy	Obvious, colourful or abundant, etc.

Position of Flower

Only on Top	
Raceme - Spike	
Umbel-cyme-panicle	
Individually on Several Stems	
Whorled Group	

Predominant Colour

White/Gray	Red	Violet	Green	Yellow	Blue
Orange	Pink	Purple	Brown		

Petal Count

No Petals

4 Petals	
5 Petals	
6 Petals	
7+ Petals	
Numerous	The petals are so numerous that they are hard to count.

Shape of Corolla

Radiate	
Slightly Mirror-Symmetrical	
Mirror-Symmetrical	
Bell-Shaped	
Capitular Flower	
Other	

Breadth of Corolla

<1cm	
1-3cm	
>3cm	

5 Fruit Identification

Shape

Oblong	A pod or rod-like fruit shape, e.g. pea pod, banana, redbud, magnolia.
Spherical or ovoid	e.g. rose hips, black walnut, pecan
Winged	e.g. ash, maple, elm, etc.
Catkin or cone-like	e.g. birch, alder
Acorn	e.g. oak
Other	Lobed, hemispherical, cone, etc.

Colour

White/Gray	Red	Violet	Violet/Lilac	Yellow	Orange
Green	Brown	Black	Pink	Blue	

Smell

6 Tree Identification

Tree Type

Evergreen	Doesn't lose its leaves during the course of the winter.
Deciduous	Lose their leaves at the end of the growing season and grows them back again typically in the spring.

Bark Identification

Bark Types

Scaly	
Furrowed	

Papery	
Smooth	

Bark Scent

7 Foraging

How to find and forage wild food, what to avoid and the health benefits of them.

Foraging Weeds

Dandelion

Benefits

Phosphorus	• Chickweed				
Zinc	• Dandelion • Amaranth				
Iodine	• Stinging Nettle				
Folate	• Amaranth				
Copper	• Amaranth				
Thiamine	• Amaranth				
Niacin	• Amaranth				

8 Edibility Test

How to test unidentified food to ensure it's safe to eat.

1	Find a plant that is plentiful. You don't want to go through the rigorous process of testing a plant if there's not a lot of it to eat.
2	Abstain from eating or drinking anything but purified water for 8 hours before the test. (If you have to use this method, this step will probably be unavoidable.)
3	Separate the plant into parts. Some plants have edible parts and poisonous parts. In order to test if a plant is edible, you must separate it into the leaf, stem, and root and test each part separately for edibility. After you have separated the plant into parts, inspect each part you are preparing for parasites. If you encounter worms or small insects inside the plant, discontinue the test with that sample and consider seeking a different sample of the same plant. Evidence of worms, parasites or insects indicates that the plant is rotten, especially if the organism has vacated the plant. Many parts of plants are only edible during certain seasons (for example, acorns collected after the fall are usually rotten). If you find grubs inside the plant, the plant is rotting, but the grubs are edible and contain high amounts of protein (although they taste sour and are gritty).
4	Find out if the plant is contact-poisonous. A contact-poisonous plant is one that causes a reaction merely by touching your skin. Rub the selected plant part on the inside of your elbow or wrist. Crush it so that the sap touches your skin, and hold it there for 15 minutes. If the plant causes a reaction in the next 8 hours, do not continue testing that part of that plant. Do this with each part of the plant until you find a part that isn't contact-poisonous.
5	Cook a small portion of the plant part. Some plants are poisonous only when raw, so it's a good idea to cook the plant part you are testing if possible. If you can't cook the plant or if you don't anticipate that you will be able to cook it in the future, just test it raw.
6	This portion of the test is where things get dangerous, so proceed very slowly and carefully. Take the following steps to test the plant in your mouth: Hold a small portion of the prepared plant part against your lip for 3 minutes. Do not put the plant in your mouth. If you notice any burning, tingling, or other reaction, discontinue testing.
7	Place another small portion of the plant part on your tongue. Hold the plant on your tongue without chewing for 15 minutes. Discontinue testing if you notice any reaction.
8	Chew the plant and hold it in your mouth for 15 minutes. Chew the plant well, and do not swallow. Discontinue testing if you notice any reaction.
9	Swallow the small portion of the plant.
10	Wait 8 hours. Do not eat or drink anything during this period except purified water. If you feel sick, immediately induce vomiting and drink plenty of water. If activated charcoal is available, take that with the water. Discontinue testing if you experience any adverse reaction.
11	Eat 1/4 cup of the same kind of plant part prepared the same way. It is critical that you use exactly the same part of exactly the same kind of plant, and that you prepare it in exactly the same way as you did the initial sample.
12	Wait an additional 8 hours. Abstain from any other food except purified water. Induce vomiting immediately as above if you should feel ill. If no reaction has occurred, you may assume only that particular part of the plant is safe to eat, and only as prepared during the test.

PLANTS E

13	Begin a new test if the plant part you have chosen fails any of the tests. If the first plant part you choose appears contact-poisonous, you may immediately test a new plant on your other arm or behind your knee. If the plant causes a reaction before you have swallowed it, wait until the symptoms have disappeared before testing a new plant. If you have an adverse reaction after you've swallowed the plant, wait until symptoms have disappeared and start a new test. Although there may be edible parts of the plant you initially chose, it is preferable to move on to a different plant for subsequent tests.

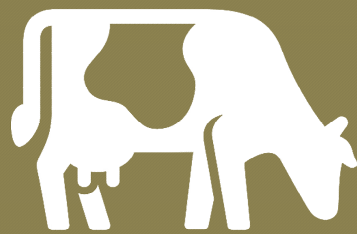
9 Plant Databases

PLANTS Plant Databases

Below you can find a list of plant databases available for purchase and download. Unfortunately I couldn't include an entire plant database of 7,000+ plants on TPE although I definitely tried. Therefore this section will recommend ways you can obtain your own database so you can use the information listed above to identify the plants.

Databases

Plants For A Future	If you are interested in the PFAF database of plants see the link below. You could also download the entire website using a mirror program like HTTRACK.	https://pfaf.org/user/shop.aspx
Plantfile	They have a database of 2,900 commonly cultivated plants. Not perfect for identifying weeds but still helpful.	http://www.plantfile.com/plantfile-standard-version



Animal Husbandry

Raising and sustaining animals for food or companionship

"Until one has loved an animal a part of one's soul remains unawakened."
Anatole France

Introduction

Animal husbandry is the raising of animals for something in return, whether it's meat, wool or company.

Purpose	The aim of ANIMAL HUSBANDRY is to help the reader raise any kind of animal to full maturity, and to help harvest the resources it provides, whether it's wool, milk or leather.
Lost?	• If you've been bitten or stung by an animal, go to the INJURY > Animal & Plant section. • For information on dangerous and poisonous animals, see the ANIMALS section. • If you want to prepare an animal for consumption, see the FIELD DRESSING section. • For information on setting up a homestead with animals, see the HOMESTEADING section. • For utilizing animals for transport, see the TRANSPORT section. • For defence against animals and insects such as mosquitos, see the DEFENCE section. • For animal-based disasters such as locust swams, see the NATURAL DISASTERS section.

Introduction
There's a lot to like about raising chickens in your backyard. The eggs are a real temptation - tastier and fresher than any store bought eggs and better for baking, too. The shells, along with the chicken poop, can be tossed right into the compost pile. Much of the day, the birds entertain themselves, picking at grass, worms, beetles, and all of the good things that go into making those yummy farm eggs. Plus, with their keen eye for insect pests, chickens make for great gardening companions!

Benefits

Eggs	These eggs are fresh, taste great, and are full of nutrition because you control what goes into egg production with the food you give your chickens. You can also try your hand at selling fresh eggs to make some extra money, which is a great idea for kids. Expect one egg per day from each hen you have. Some breeds do not lay eggs daily, but will lay 3 to 4 eggs weekly.
Meat	If raising your chickens for meat, home-grown chickens taste better and are healthier than factory farmed poultry. You'll enjoy more flavour, less fat and calories.
Fertilizer	Chicken manure contains a good deal of nitrogen, phosphorus and potassium – the primary ingredients in lawn and garden fertilizers. Chicken manure can be composted and added to the soil of your garden, flowers, trees, shrubs, and lawns. The all-natural homemade fertilizer will save you money and help produce great results. Speak to the experts at your local Grange Co-op to learn more about composting.
Company	Chickens have their own individual personalities and are affectionate toward humans. Each is its own bird, as they say, with some being sweet, shy, grouchy, or playful. You will find yourself having a lot of fun with your unique flock of backyard chickens.
Pest Control	Without the use of chemicals and insecticides, you can control over-population of crickets, grasshoppers, snails, slugs and other pests in your garden as chickens eat them up.
Little Maintenance	A low-maintenance animal, chickens basically need to be fed, watered, and given a coop to nest in. You may find this less work in comparison to other livestock.
Health Care	Just like other pets or farm animals, chickens can get sick or injured, which may require professional pet care. The most common chicken illnesses include poultry bumblefoot, a prolapsed vent, mites, and respiratory problems.

Drawbacks

Noisy	Chickens can be noisy with the familiar barnyard sounds. But they can also provide quieter sounds of cooing and clucking that many find relaxing and even enjoyable. Also, some chickens are definitely noisier than others so research before you buy.
Poop	Chickens will poop a lot. However chicken poop is a wonderful fertilizer, but it will require some work to clean up and utilize.

Holes	They will dig a lot in the yard. Chickens scratch when they dig for bugs and can really tear up their space.
Salmonella	Chickens have the potential of carrying Salmonella germs in their droppings and on their feathers, feet, and beaks. It's important to wash your hands after handling chickens or touching places where they live to avoid the risk of illness.
Legality	If you're raising chickens in town, check your local ordinances and zoning code regulations to make sure you can keep chickens legally. For example, in Medford, Oregon, residents can raise chickens and roosters within city limits but "the environment they are kept in must be kept odour and debris free; and the chickens cannot cause a noise disturbance to neighbouring properties."
Chicken Rivalry	Unfortunately, you will have to deal with some chickens bullying each other. They will peck at each other and even draw blood, which can make them peck more until one dies.
Predators	If your yard is accessible to predators such as foxes, raccoons, skunks, possums, coyotes, or other animals who pose a threat to the safety of your chickens, you may consider making it a mandatory part of your routine by bringing them in each night for their safety.
Requires Shelter	Chickens require a shelter known as a chicken coop. Chickens don't need a lot of space, but they need room to stretch their legs.
Social Animals	Chickens are social animals and need other chickens for companionship. One chicken by itself can die of loneliness so we always encourage a small flock for the happiest, healthiest backyard chickens.

Breeds

Breeds for Eggs

These breeds are used for the best eggs.

Australorp	The Australian Orpington. An excellent egg layer that currently holds the world record for egg output in one year – 364! The Australorp is a dual purpose hen too. They dress out at a respectable 5-6lb and the meat is said to be good.
Delaware	These birds were all set to become the broiler bird of the US, and then the Cornish cross was introduced. The Delaware fell into near obscurity but has been making a comeback with the 'backyard crowd' of chicken keepers. The Delaware is a respectable layer of 4 brown eggs per week. The hen is also a good dual purpose bird dressing out at 5lb.
New Hampshire	This is a good dual purpose hen. The New Hampshire will lay around 200 eggs per year and as a dual purpose hen will dress out to an average of 5-6lb.
Buckeye	A dual purpose hen that thrives in the cold! The Buckeye has the distinction of being the only breed to have been created by a woman. Buckeyes will give you around 200 eggs each year. They can be butchered as young as 16 weeks and can dress out to a respectable 7-9lb bird.
Plymouth Rock	One of our favourites, the Plymouth Rock is a great all-rounder. She will give you about 280 eggs per year. As a dual purpose bird, they will dress out to 5lb or more.
Sussex	The Sussex has been well thought of in its' homeland of the UK for centuries now. A good dependable layer in the region of 250-300 eggs per year. The speckled Sussex was the table fare of England until the newer, faster maturing breeds came along.
Brown Leghorn	The Brown Leghorn is a useful dual purpose bird. It will lay an average of 280 eggs per year. They can be butchered at 16 weeks and weigh a good 5-6lb. They are also good foragers, so the feed ratio is good. Although Leghorns are not usually known for their meat qualities, the meat is said to be decent on the brown variety. If you're interested in reading more about egg laying breeds, make sure to read 10 Breeds of Chicken That Will Lay Lots of Eggs for You.

Meat Breeds

These breeds are used for the best meat.

Cornish Cross	They are the quintessential meat chicken. They grow fast, too fast for their bodies to keep up; hence they must be butchered to save them from suffering. They are ready to cull at 4-6 weeks and by this age will weigh around 8lb. The downside to this bird is their feed consumption which is high, making them not so great in the feed ratio.
Bresse	The original Bresse line of chickens is still alive and well, living in France. The French Bresse hen is a breed apart. They are cared for and fed a special diet, all of which is monitored by the French Agriculture Department. All this attention makes for a costly chicken dinner. There are now American Bresse chickens. They are essentially much the same bird but raised differently. The meat is said to be superb tasting. They are culled at 16-20 weeks and will dress out at 5-7 lb. They are slower growers so feed conversion is average.
Jersey Giants	Jerseys are one of the largest chickens you will ever see; the Jersey Giant is huge! Although the size of the current bird is smaller than its ancestors, this chicken will dress out at 10-13lb. They are slow growers and can start to be culled around 16 weeks.

Friendliness Breeds

These breeds are just really friendly and make great pets.

Brahmas	They are large cuddly hens. They can be shy, but are usually friendly and enjoy human company.
Cochin	The fluffy hen that loves to be cuddled and can easily become a lap chicken. This bird would be suitable as a therapy bird.
Faverolles	These hens will make you smile. They are talkative, curious, friendly and a bit scatter brained!
Orpingtons	A very calm and friendly bird. Never in a hurry to go anywhere, curious and will be your friend for life if you give her treats.
Polish	This bird will light up your day with their antics and crazy hairdo. They are a very friendly bird, making great house pets and therapy birds.
Sultan	The hen is a very poor layer and was really created centuries ago as a bird of leisure and pleasure. They make good house hens and would likely make a good therapy bird choice.

Appearance Breeds

These breeds are chosen for appearance and showmanship.

Polish	The Polish hen is unmistakable with the pom-pom on the head. The pom-pom can get in the way of their vision at times, so may need light trimming.

Silkie	The chicken that looks like a cuddly toy! Silkies have feathers that do not latch together, so they look like they are wearing fur not feathers. They are friendly and cuddly too.
Phoenix	A German breed created from the Japanese Onagadori. It has a long tail that can reach up to several feet in length.
Onagadori	The original long tailed chicken. Tails have been recorded with lengths up to 27ft! This is possible because the male Onagadori has a non-molting gene and can take up to 3 years to completely shed some of its feathers.
Houdan	The Houdan reminds you a bit of the Polish chicken with its' elaborate head feathers. It is described as a sweet bird, a fair to moderate layer and doesn't like the cold.
Turken	The Transylvanian Naked Neck chicken (aka Turken) has an unusual appearance. The neck area is completely devoid of feathers, giving it a turkey like appearance. It is a very hardy bird usually kept for meat; egg laying is moderate. Due to the genetic issue with the feathers it really doesn't do well in extreme heat or cold.

Requirements

Land	How much land and what type of land chickens should have.
Shelter	The type of shelter and protection the chicken needs.
Environment	To wrap it up, what your hens need are laying hen pellets, fresh water, greens, fresh air and exercise. Indulge them by giving them an interesting environment, compost to shred, and your delighted attention. Once in a while, toss them something really special. Your treat will be having healthy, active, laying, hens.
Separation	Separation from other animals or chickens.

Raising

How to raise a chicken from an egg.

Insemination
To lay a clutch of fertilized eggs, a hen must have first mated with a rooster. The hen will then form an egg- a process which takes all of approximately 25 hours. This process will begin with the formation of the egg yolk, it is produced by the hens ovary during the ovulation process- the yolk is referred to as the oocyte at this stage. As it travels down the oviduct, it will be fertilized internally by the sperm of the rooster. As it continues to travel down the oviduct it becomes covered with a white membrane called 'vitelline membrane', as well as some layers of the egg white or 'albumen'. Still travelling further down the oviduct, a casing for the egg white and yolk will begin to form. Eventually, the shell will be completely developed, and thus the egg is completely formed. The hen will then lay this new life form in a comfortable and quiet spot. A hen will generally lay a clutch of approximately 12 eggs, with each egg being laid a day apart.

Egg Stage
The hen will then lay this new life form in a comfortable and quiet spot. A hen will generally lay a clutch of approximately 12 eggs, with each egg being laid a day apart. If hatching naturally, the mother hen will sit on the eggs to maintain the optimum temperature so they can develop until it is almost hatching time. Sometimes hens won't take to sitting on their eggs, and so you may need to purchase an incubator and do this step yourself. (See the row below)

Incubation

1

Set Up an Incubator
Depending on how many eggs they accommodate and how automated they are, Incubators run from around $50 for the homesteader favourite 'Hova-Bator' into the thousands of dollars for commercial scale incubators. With top-of-the-line incubators, you put in an egg, close the door and out pops the chick three weeks later. You can also go the DIY route, which saves money, but is almost as much work as sitting on the eggs yourself. No matter how fancy or jerry-rigged, all incubators must accomplish a few basic things:

Temperature	The eggs need to be kept at 99.5 degrees at all times; just one degree higher or lower for a few hours can terminate the embryo.
Humidity	40 to 50 percent humidity must be maintained for the first 18 days; 65 to 75 percent humidity is needed for the final days before hatching.
Ventilation	Egg shells are porous, allowing oxygen to enter and carbon dioxide to exit; incubators need to have holes or vents that allow fresh air to circulate so the fetuses can breathe.

Homemade versions usually involve some sort of insulated box – a cheap Styrofoam cooler will do. An adjustable heating pad or a light bulb on a dimmer switch will suffice for the heat source and a pan of water with a sponge in it will make the air humid. Low-end commercial incubators don't amount to much more than this, but the more you pay, the more automated the temperature and humidity controls will be. A high-quality thermometer and hygrometer (a device to measure humidity) are the most important tools of incubation; cheap models are usually not accurate enough. If you're not working with an incubator that has these instruments built in, opt for a combo thermometer/hygrometer with an external display.

These have a sensor that goes inside the incubator with an LED screen on the outside that shows the temperature and humidity readings without having to open the incubator and ruin your carefully calibrated environment. One time-saving feature is a device to rotate the eggs automatically. Much of the fussing that a hen does over her eggs comes from an evolutionary instinct to constantly move them about. The finely tuned ecosystem inside a chicken egg is kept in balance by constantly changing the position of the egg.

High-end incubators have a built-in egg turning device, but there are also standalone egg turners that can be placed inside a homemade incubator to do the job. Or, you can rotate manually according to the instructions below. The incubator should be placed in a location with the least possible fluctuation in temperature and humidity throughout the day – a basement is ideal, a sunny window is not.

2

Find Fertile Eggs
If you already have a flock of chickens that includes a rooster, the majority of the eggs they lay will be fertile. Collect them as soon as possible after laying and transfer to the incubator. If you don't already have chickens, find a friend or a nearby farmer who does and ask if you can buy some fertile eggs. Websites like Craigslist and BackyardChickens.com are a good way to link with people that may have eggs to spare. Some feed stores sell fertile eggs in the spring and there are many suppliers that sell eggs online.

The closer to home, the better the egg source. The jostling about and fluctuations in temperature and humidity that occur during transport are hard on the developing fetus. Hatching rates on eggs straight from the coop are often in the 75 to 90 percent range; with mail-order eggs, there is no guarantee that any will hatch. When picking eggs to incubate, use those that are clean, well-formed and full-size. Above all, do not clean the eggs – there is a naturally occurring coating that is vital to the success of the embryo. Wash your hands before handling and be as gentle as possible, as the embryos are extremely susceptible to damage from sudden movements.

ANIMAL HUSBANDRY Medium Animals Chickens Raising

Ideally, the eggs are transferred directly to the incubator, but it's possible to store them in egg cartons if needed. Kept at temperatures between 50 and 60 degrees and 75 percent humidity, the development of the eggs can be delayed for up to ten days without sacrificing the viability of the embryos. However, they must be stored with the fat side of the egg pointed up to keep the embryo alive.

3	**Incubate** It takes 21 days on average for an egg to hatch once incubation begins. Before placing the eggs inside, turn on the heat source and measure the temperature and humidity over a 24-hour period, making adjustments as necessary to create the optimal environment. If the humidity is too high or low, use a sponge with more or less surface area to adjust it. Raise and lower the temperature of the heat source in tiny increments until the thermometer reads 99.5. Once the incubator is functioning properly, it's just a matter of maintaining the environment until the chicks hatch. Place the eggs on their side in the incubator, close the door and check the levels religiously to make sure nothing goes askew. Water may have to be added to the pan occasionally to keep the humidity up. At day 18, add more water to boost the humidity level.

If you're going to turn the eggs yourself, there is a standard method to mimic the efforts of a hen:

- Draw an 'X' on one side of the egg and an 'O' on the other to keep track of which eggs have been turned.
- At least three times a day, gently turn the eggs over; more frequent turning is even better, but the number of turns per day should be odd (3,5,7 etc.) so that the eggs are never resting on the same side for two consecutive nights. Experts also recommend alternating the direction of turning each time – the goal is to vary the position of the embryo as much as possible.
- Continue turning until day 18, but then leave the eggs alone for the last few days.

4	**Hatching** In the final days before hatching. the eggs may be observed shifting about on their own as the fetus becomes active. The chick will eventually peck a small hole in the large end of the egg and take its first breath. It is normal at this point for the chick to rest for six to 12 hours while its lungs adjust before continuing to hatch. Resist the urge to help with the hatching process – it's easy to cause injury. Once the chick is free from the egg, let it dry off in the warmth of the incubator before moving it a brooder, where it will spend the first weeks of its life.

Chick Stage

The chick inside the egg will generally grow for 21 days, using the egg yolk as a means of nutrition as it grows. Along with sitting on the eggs, the hen will also use her beak to turn them to aid their development. On about day 19 of the incubation period, the chicks will begin the pipping process. This involves the baby chick using their 'egg tooth' to peck a hole in the eggshell around the air sac to access oxygen, before pipping an area large enough for it to be free of its shell. This process can take up to 24 hours and should not be rushed. The chicken will emerge with wet 'down' feathers, however they dry quickly, and will be extra fluffy and adorable in no time.

Most chickens are able to stand and walk about straight after birth, however some may be a bit wobbly at first. After birth, a baby chicken will need to be placed in a brooder- an indoor space that is heated up by the heat of an infrared lamp. The chickens will remain in the brooder for the first few weeks of their life- they will be fed in the brooder and sleep in the brooder, so it's important it is cleaned regularly, so the chickens can remain at the height of their health. A chick will start developing it's first true feathers at around 5 days old, and at approximately 12 days the chick will begin to show defining breed bone development, as will it's wing feathers.

By day 18, the chicken should have significant feathering, and by day 30, it will have developed the characteristics that identify it with its breed. Unfortunately many young roosters are discarded as soon as they can be sexed- especially if they were being bred for egg production. Some may be kept and raised for meat, or to produce the next generation of chickens, but for most this is not the case. A chicken will continue to grow and develop- learning common chicken behaviours such as roosting and foraging under the guidance of their mothers. Within six months the bird will have developed all of it's adult features, and is now considered a mature chicken.

Pullets (Young Chicken)

Younger hens are known as pullets and may be ready to lay as young as 18 weeks, however this will vary between breeds. All birds tend to come into lay earlier during periods of increasing sunlight, or later if they reach maturity in early winter. A healthy and productive female hen will lay eggs until they are about 72 weeks old, however this will also depend on the period of their first moult.

Adults

Birds have an annual moult in which they lose their old feathers, a grow lovely new ones in their place. This generally occurs in late summer or early Autumn, and the result is a tatty and quite alarming looking bird. During moult, chickens will generally cease egg production, although they may lay one here and there, as all their energy and nutrients are going into producing a delightful new covering of feathers. While many birds will start laying again in no time at all, older birds may be expended from their egg laying days, and their egg production will dwindle significantly. As hens get older, they will start showing signs of their age. A wrinkled and dull face, heavy eyes, increasing rear size, and lack of energy are all possible indications that a chicken is approaching old age. Despite this, they will still remain the delightful creatures they once were through to their very last days.

Labour

Daily Maintenance	**Feeding:** Ensuring the chickens have enough food and water. **Egg Check:** Check for laid eggs and collecting them if needed. **Check-Up:** Monitoring the chickens to ensure they are behaving and are safe from predators. **Coop Opening/Closing:** Opening and closing the coop if you've let them out during the day.
Weekly Maintenance	
Monthly Maintenance	**Bedding Change** ● Change the bedding and remove the droppings to use in the garden.
Yearly Maintenance	**Coop Cleaning** ● A thorough clean and disinfection of the coop.

Diet

Water

The one most essential thing to provide your flock is fresh water. Even though it does seem as if chickens prefer muddy pools always have clean water for them. Put the water font up off the ground so that it stays clean. Scrub the water font weekly. In the winter, if you are located in an area with freezing temperatures, either use an electric heating stand under the waterer (these are designed for chicken waterers) or be prepared to swap frozen waterers for fresh several times a day. A chicken without water will die within a day. In the summer I put an extra waterer out in the pen near the shady area where the hens like to hang out. Chickens overheat easily and water will go a long way to keeping them healthy and alive.

Food

When your chickens start to lay eggs they will needs to be fed 'layers pellets' or 'layers mash'. This is usually 15-17% protein and will help them to regularly lay eggs.

How Much Food

Your chickens should have a constant supply of food throughout the day. Chickens will eat when they need it and should go to bed with a full crop as they need lots of food to produce eggs. A fully grown chicken will typically eat about 120 grams of layers pellets a day. You should check the feeders every day to ensure they are topped up. It can be a good idea to have two feeders, one inside of their coop run and one outside of their run (if they are free ranging). This will stop any dominant chickens stopping less dominant chickens from getting their share of food.

Grit	Chickens need to eat small stones in order to help digest their food. Chickens don't have teeth so swallow whatever they choose to eat whole. Any grit they eat is used to grind up food in their Gizzard. When keeping chickens it is important to give them a supply of grit as they may not be able to naturally find enough grit. Grit with oyster shells is even better as the oyster shells provide calcium which your chickens need to lay eggs with strong shells. You can choose to add a handful of grit to their food, or just provide grit from a separate feeder such as the Grit Station Feeder.
Corn	Chickens absolutely love corn, and will come running at the sound of you getting their corn. Corn is a great way to tame your chickens. However mixed corn is high in fat so should only be given as a treat, as an overweight chicken won't lay as many tasty eggs. A handful of corn per hen scattered on the ground is plenty.
Kitchen Scraps & Greens	Chickens will eat most things that you give them (within reason). They will enjoy pasta, green veggies, cereals, raisins, banana….the list goes on. Its nice to give them a treat, but do make sure you aren't giving them too many treats as they will fill up on those and not eat their layers pellets.

Food (Chicks)

For the first two days of life the chick makes use of the yolk that is still inside of it. After that, the chick needs food and water. Chicks should be given free-choice finely ground feed that is 18% protein. They shouldn't eat laying hen pellets because it is too high in calcium and too low in protein. The easiest way to feed chicks is to purchase chick starter. Do not purchase chick finisher or special "grow" feeds, as those are for meat birds that are slaughtered before maturity. Chicks remain on the chick feed for the first 14 to 18 weeks, which is about when they are mature enough to lay. Some people use medicated feed to protect the chicks against a protozoan disease called coccidia. I don't believe in using medicated feeds unless the chicks show symptoms of illness. Most chicks are kept in brooders, which are essentially heated boxes bedded with pine shavings. These are safe places for the chicks to grow but not ideal. I think it is essential to give the chicks a clod of dirt with some greens attached the first week.

The clump of earth is beneficial to the chicks in many ways. It exposes them to small amounts of local microbes so that they develop natural immunity. It gives them something to do, as even chicks get bored! It gets a bit of grit into their gizzards. Most importantly, it teaches the chicks to peck the ground and not each other. Providing that clod of dirt will greatly reduce aggression and pecking issues later. Do make sure, though, that there isn't fine grass clinging to it. The greens should be sturdy so that the chicks peck little bits off. Dandelions are perfect for this. You don't want them getting impacted crop from fine blades of grass. It is tempting to give the chicks other treats as well, everything from sunflower seeds to strawberries. But, remember that if the chicks were outside with a mamma, that they'd be moving and eating tiny bits of things and not standing still and gorging. You can give them treats, but in very small amounts, and make sure that they fill up on chick feed first. As soon as it is warm enough the chicks can go outside and peck and eat whatever they want. Just make sure that the bulk of their diet is a balanced chick feed that they get free choice.

Disease

Diseases that can affect chickens and other poultry.

External Parasites (Ticks / Fleas / Lice)	Poultry can carry a large variety of parasites on their bodies. These range in size from large, blood sucking ticks up to 1cm in size, down to the microscopic scaly face (and leg) mite that is less than 0.5mm in size. Other external parasites that are commonly encountered are the stickfast flea (small, black fleas on the comb that do not move), and lice (small, white insects that move rapidly through the feathers). External parasites generally cause mild clinical signs such as feather damage, anaemia and irritation, but they may also carry severe, life threatening diseases such as tick fever. Backyard poultry should be examined regularly, and treated for external parasites every two to three months. Products to treat these diseases can be recommended by your veterinarian.
Internal Parasites (Roundworms)	Backyard poultry also carry a wide range of internal parasites. These range from large roundworms (Ascarids) that are visible with the naked eye; to small, single celled organisms only visible under a microscope (Coccidia, Trichomonas, and Giardia). Internal parasites attack the lining of the intestine, and absorb nutrients from the gut that the bird should be using for maintenance of its own body and production of eggs. Worms (and other internal parasites) are spread from bird to bird by the ingestion of eggs from the faeces of infected birds. Regular removal and cleaning of faeces from the bird's enclosure will result in less worm eggs in the environment, and less chance of worms spreading from bird to bird. Signs of internal parasitism may include weight loss, pale combs or diarrhoea. Your local veterinarian will be able to look at faeces under the microscope, and advise you which type of worms and protozoan parasites are present by the type and number of eggs they observe in the faecal sample. Some types of worms, such as Capillaria, are more difficult to treat than others.

Your veterinarian will be able to advise you of a suitable treatment that is specific for the parasites they observe. It is important that withholding periods for treatments are observed. This requires that eggs and meat from birds treated with certain drugs be discarded for a period of time after the drug has been used. This prevents humans ingesting the drugs the chickens were treated with via the eggs or meat. Make sure you check the exact withholding period with your veterinarian, or on the label of the product.

Marek's Disease	Marek's disease is a viral infection that only affects poultry. The virus is spread from bird to bird in feather dander and dust. It lives in the environment for long periods, and can spread between properties on people's clothes and on shared equipment. Birds are usually infected at a young age, but may not show signs of disease until some months later. The virus that causes Marek's disease attacks the white blood cells of the bird, and results in cancer. These cancers most commonly affect the nerves and cause paralysis. Usually, the legs are affected, but the tumours may also affect the nerves in the wings and neck. Birds may also develop tumours in the body. As they grow, these tumours may cause a number of signs including weight loss, diarrhoea, ill thrift, and difficulty breathing. A vaccine should be given to birds at one day of age. It is recommended that all birds be vaccinated, even though the vaccine is not as effective as it used to be. This is due to the virus that causes the disease mutating slightly over time. Most large hatcheries vaccinate their chicks, so birds purchased from them should be protected, and vaccine is available at a reasonable cost for birds hatched privately.
Leucosis	Avian leucosis is also a viral disease affecting chickens which causes tumours or cancers. These tumours occur in older birds than those affected by Marek's disease, usually more than 6 months old. It causes listlessness and loss of weight and the bird eventually dies. The viruses affect the white cells and tumours usually appear in the liver and spleen but also in other sites. Sometimes the tumour appears as white lumps, at other times the liver and spleen appear larger than normal. The viruses are transmitted through the egg and commercial producers attempt to eliminate it from their strains of birds. There is very little that a poultry owner can do except keep the bird comfortable and destroy it when life becomes unpleasant for it.

Respiratory Disease	There are many causes of respiratory disease in poultry. Respiratory signs such as coughing, sneezing and discharge from the eyes and nostrils can be caused by parasites (such as the gapeworm, Syngamus trachea), dust, high ammonia levels, or a variety of bacteria or viruses. In all cases, a veterinarian with experience in poultry disease must diagnose the exact cause, particularly if mortalities occur. Some of the respiratory viruses such as Infectious laryngotracheitis virus (ILT), Newcastle disease and Avian influenza are notifiable or exotic diseases, and must be reported to a Government Veterinarian or Animal Health Officer if they are suspected. Treatment will depend on the cause of the respiratory signs. For some viral causes such as ILT, vaccination is recommended.
Fowl Pox	Another viral infection of birds is fowl pox. This disease is spread by biting insects and sometimes by fighting. The virus enters the body through a scratch or scrape, and raised scabs form on the scratch and surrounding areas particularly noticeable on the combs and wattles. Scabs can also form in the mouth and throat. Most cases improve without treatment, although some birds become ill from secondary infection. Birds that recover are immune for life. Symptoms are characterized by distinctive bumps that look like warts and are visible on the wattle and comb. In addition, young birds experienced stunted growth and egg production decreases. Prevention is again the best idea, and vaccination is available, although this may need to be done every few years to give complete protection.
Nutritional Deficiencies	Many small flocks of birds are fed only table scraps. This diet is not sufficient to meet the nutritional demands of growing birds or layers. Common deficiencies include calcium (resulting in poor bone growth and rickets), energy (poor growth, weight loss, poor egg production), and vitamin A (poor skin and feathering). Formulated diets are available for all stages of a hen's life, (starter, grower and layer) and these should be fed in conjunction with table scraps, fruit and vegetables to form a balanced diet.
Reproductive Problems	Commercial birds are bred to lay for only one or two laying seasons. If they are then sold to backyard producers for extended laying, they are prone to reproductive problems. This includes egg binding (where the egg is unable to be passed out of the bird), metritis (inflammation of the oviduct and shell gland), and yolk peritonitis (free yolk in the abdominal cavity, leading to infection). Affected birds stop laying eggs, are depressed, stop eating and eventually die. They often develop a swollen abdomen, and may have respiratory difficulties. Surgery by a veterinarian is possible to resolve these conditions, however, the surgery results in the bird being unable to lay eggs. Hence, it is reserved only for pet birds.
Fowl Cholera	Fowl Cholera is a chronic disease caused by Pasteurella Multocida that can affect the joints, wattles, infraohits, sinuses and other tissues. Common symptoms include loss of appetite, diarrhoea with a greenish tinge, ruffled feathers, swollen purple wattle, swollen comb, swollen joints, lameness, oral, nasal and ocular discharge and sudden death. Most commonly found in older chickens, Fowl Cholera affects more cocks than it does hens.
Coccidiosis	Coccidiosis is a parasitic disease caused by Coccidian protozoa that lives in and damages a specific region of the gut in chickens. The trouble starts when chickens consume a sporulated oocyst which is broken down by chemicals in the gut, releasing an infective sporocyst. This begins the life cycle that causes the destruction of intestinal epithelial cells. Together with damage to the gut walls, it causes loss of appetite, diarrhoea, ruffled feathers, weight loss and inability to absorb nutrients.
Newcastle Disease	Newcastle disease is an acute respiratory disease that can spread rapidly. Symptoms of the disease depends on whether the infecting virus has a predilection for respiratory, digestive, or nervous systems. While it can affect both wild and domesticated fowl, domestic poultry is much more susceptible to contract severe symptoms.
Salmonellosis	Salmonellosis is a bacterial disease that can cause septicemia and enteritis in young chickens. With a low mortality rate, infections are contracted orally and can be spread by rodents. Symptoms of salmonellosis include diarrhoea, closed eyes, loss of appetite, thirst, ruffled feathers and dejection.

Life Span

The lifespan of a backyard chicken can be anything from 3-10+ years but 7-9 on average. In rare circumstances they can live up to 15 years long.

Cost

Baby chicks cost $1-$5 each, depending on a variety of factors including the sex (females are more expensive than males) and how rare the breed. Started pullets (young hens that have just started laying eggs) should cost $15-$25 each.

Start-up Costs
Chicken Coop: From $100 up but can be constructed yourself.
Food: About $25 a month. This can be substituted with kitchen scraps.
Bedding: Around $30 a month.
De-wormers: $20 a year.

Tips

You shouldn't have just one chicken as they are social creatures and will not do well alone. A minimum of two is best. Roosters are VERY noisy, and contrary to popular belief, they don't just crow in the morning. They crow all day long. Hens are much quieter - you basically won't hear them until they've just laid an egg, or if they're threatened. Standard chickens weigh 4-7 pounds depending on the breed and the sex (roosters weigh more than hens). "Bantam" chickens - which are the same as standard chickens, only smaller -- weigh 1-2 pounds. Chickens will come back to the same place to sleep every night -- so you can let your chickens roam your yard during the day and when it gets dark they will return to their coop to catch up on their beauty rest. (A "roost" is a pole they perch on, which they much prefer to sleeping on the ground.)

Chickens can sort of fly. Smaller (lighter) breeds, and "bantams" -- which are the same as "standard" breeds but about 1/4 the size -- can fly 25-50 feet and will roost in trees if allowed to. Heavier breeds have much more limited flight. The chickens in your backyard will lay eggs unlike any you've tried before. A good rule of thumb: the more orange the egg yolk, the more healthy and better-tasting the egg is.

Plus, research shows that if you allow your chickens to roam your yard freely (which we highly recommend you do) your eggs will be higher in Omega-3 fatty acids and lower in cholesterol, among other health benefits. The colour of the egg has no effect on how healthy it is. However, how chickens are kept DOES have an effect on how healthy the eggs are! See the next question for more on this topic.

HOMESTEADING

Homesteading

Creating a sustainable lifestyle in a self-sufficient off-grid home

"The ordinary acts we practice every day at home are of more importance to the soul than their simplicity might suggest."
Thomas Moore

Introduction

Information on developing a sustainable lifestyle from a homestead and how to build it up. Generally a homestead contains everything you need to live self sufficiently from food to water, shelter and tools. Some homesteads may be advanced and contain looms, blacksmiths, electronics bay, advanced power tools etc.

Purpose	The aim of HOMESTEADING is to provide a framework for a self-sufficient, off-grid lifestyle with an emphasis on security. Specifically it contains information on the best way to set-up and organise your home far from the amenities of a modern lifestyle.
Lost?	• For information on building your own shelter and viewing shelter protection levels, see the SHELTER section. • For a list of household items you can craft, see the CRAFTING section. • If you're looking for information on raising animals on your homestead, see the ANIMAL HUSBANDRY section. • For more information on security on your homestead, see the SAFETY & SECURITY and DEFENCE sections. • For additional information on budgets and money, see the ECONOMY section. • For off-grid electricity systems, see the ELECTRICITY section.

Contents

1 Location

Location

Ensure some form of water is on the property whether a spring or flowing river. Know your land boundaries and put up a fence if possible. Build a basement for storage of foods and for shelter during attacks. A cooler location would be better to build as it's easier to heat a home. Know how far it is to resources like the hospital, police station, water treatment plant and other high priority locations in SHTF.

Risks

Ensure the house isn't in a flood-prone area. Know the population density and how far to the nearest major city. Research how often cyclones, hurricanes, earthquakes and fires occur in the region. Know what the ground consists of and whether it's safe to build on. Is the site in a violent or crime laden area, or is there a prison or mental facility nearby.

Terrain

Know every inch of your bug out location and exactly what you own. Know the ground composition and local flora and fauna. Know the history of the land and if any major events transpired on it.

Weather

Know the seasons and what weather is considered normal in the region. Research the chance of every disaster affecting the location.

Rights

Ensure you have the rights to use any water on your land either to drink or for energy generation. Ensure you have the correct build rights and are allowed livestock on your land. Ensure you can install a septic system for sewage. Make sure the land isn't protected or has endangered native animals living on it.

Positioning

Positioning where you are in the landscape is important to develop a successful defensive plan. When buying land look for defensible positions and how your enemies may use it against you. Land on a hill with your house on a slightly higher part of the hill is ideal for observing every direction.

Ensure the bedrooms are on the west side of the house. A square shape house with a central gardening section would be the strongest design for defence and allows harvesting food in safety. Positioning a house in the centre of your land will allow you to plan more with regards to security and give more time to detect intruders.

Resources

Determine what resources are nearby and which ones you can harvest.

Resources List
- River Water
- Water Table
- Trees
- Sunlight
- Wind
- Rapid Water

2 Common Rooms

Common rooms are areas of homes which almost everyone has.

Common Rooms
- Bedroom
- Lounge
- Kitchen
- Dining Room
- Bathroom

Bedroom

Ensure the bedrooms are on the west side of the house. Have an ensuite for luxury.

Lounge

Heating: Has a smaller fireplace than the basement for heating during events.

Kitchen

Water: Should have its own water tank connection with a filter between it for washing dishes.
Pantry: Use a walk-in pantry for storage of non-perishable foods which don't need to be kept cool.
Fridge / Freezer: Run a small fridge off the battery bank to store perishable items.
Appliances: Have a large area for machinery required to create food such as a mill/grindstone for making bread.
Water Filter: Have a free standing gravity ceramic water filter from the water tank.

Dining Room

Bathroom

Toilet: Connect to a water tank for flushing and to the garden for waste disposal.
Shower / Bath: Connects directly to the water tank and a gas heating system.

3 Uncommon Rooms

Uncommon rooms are areas of homes which some people may have in their home or that aren't frequented often.

Uncommon Rooms
- Basement
- Garage
- Attic
- Lookout
- Roof

Basement

Food Storage	One of the rooms dedicated for food storage to keep it at a level temperature. Keep it as far from the fireplace as possible.
Water Storage	Backup internal water storage to protect against the elements, animals and thieves.
Fireplace	Includes a fireplace to generate heat and distribute it throughout the house, comes with a vent to let the hazardous smoke outside.
Security Monitoring	Contains the computer attached to the security cameras for monitoring the property. A desk containing a monitor displaying the status and screens of the security cameras at all times. Ideally the desk should be manned most of the time, but all times in periods of strife or at night when you suspect thieves.
Generator	Produces power in emergencies when the other methods fail, includes vents joined with the fireplace to release toxins.
Structure	Reinforced walls to protect occupants with a blast floor leading down to the basement. Protects against disasters such as earthquakes and cyclones with it's structural integrity. Contains pillars for extra strength.
Battery Bank	Contains the battery bank array to store the collected power. Includes regulators and controllers to prevent overcharge.
Toilet	Contains a second toilet for complete self-sufficiency within the basement.
Wood Storage	Have a stockpile of wood to get through the winter.
Water Treatment	Treats water for particles, bacteria and viruses before being pumped back up.
Water Pump	Have a pump on hand for water leaks in the house. Connect it to the river for pumping water from the river when supplies get low.
Guns / Explosives	Store guns on a rack or in a gun cabinet and as much ammo as needed.

Panic Room

A panic room is an extremely secure room, often underground which should be able to withstand natural disasters, strong gunfire and basic bombs and missiles. Ideally it should be attached to the basement and slightly deeper underground with two points of access, one for entry and one for exit. The panic room is not designed for extended stays, but rather the ride out the primary disaster with a maximum of about 3 days for a family.

Foundations	The walls should be thick concrete with lots of reinforced steel beams on every wall as well as pillars for even more roof strength. Most surfaces should be rock, stone or concrete to prevent fire spread.	
Resistance	The following items are resistances that the panic room should comply with to be fully effective.	**Resistances** • Highest Category Winds • Hand Shot Missiles • Grenades • Earthquakes • Volcanos • Floods • Fireproof • Bulletproof

Entry Door	The entry should come from an already secure location such as the basement and would help if the room is already completely or partially underground. Ideally the entry door from the house should be disguised or hidden behind a bookcase, a rug or other inconspicuous object.
Exit Door	The exit should lead back to the surface via a manhole which can only be accessed from the inside. The manhole should be completely watertight but remain easy to open from the inside. The exit location should be hidden from plain sight and on raised ground to avoid water entering when opened. Labelling the exit location as a "Sewer Access Point" should be enough to deter people from attempting to enter it, but even if attempted, there would be no way of opening it from the outside.
Resources	The following items is a list of resources that should be included in the panic room. There should be enough for 3 days without having to leave. **Stocked Resources** • Water • Food • Hygiene Products • Entertainment
Air	There should be two air intake vents that weaves through the house to the roof to allows fresh air to be brought into the room. Two because one may become blocked or sabotaged by the enemy or naturally become clogged. Automatic and manual ways to pump the air in should also be included along with various filters to remove particulate and radiation if required. A backup canister of oxygen with slow release valve if the outside air is contaminated.
Electricity	A small battery bank should be included to charge small devices and power an internal light for up to 3 days.

Garage

Room	Allow room for two cars and extra space for tools, storage and workbenches.
Workbenches	Have some workbenches for home improvement projects and store the larger fixed power tools here.
Storage	Have room for tool storage on the walls and shelves for bigger power tools.
Sound	Soundproof the room to allow the ability to use power tools and the silent entry/departure of cars.
Garage Door	Have a fast yet silent door opening/closing system for fast getaways if you have a bug-out vehicle already stocked. Use individual doors for each side.
Refuelling Pump	A pumping station for biodiesel, electricity and other home made fuels.

Attic

Insulation	Keep the house cool in summer and warm in winter.
Storage	Use for backup storage of various goods.
Access	Allow easy access to the solar panels on the roof for cleaning and repairs.

Lookout Tower

View	Ensure you can view every side of the land and your view isn't obstructed.
Staircase	Have a staircase for access to the attic and lookout tower. use the space for storage of household cleaning items.
Access	Allow easy access to the solar panels on the roof for cleaning and repairs.
Weapons	If required, have vertical sliding windows to allow guns to be fired from it. Add sound dampening walls to prevent noise.
Windows	These should be bullet proof to protect the lookout from gunfire or snipers.
Communications	Have a HAM radio in this room for communication and for observation of the local environment.
Satellite Dish	Add a dish to the roof for maximum signal transmission.

Roof

Solar Panels	Used for electricity generation.
Satellite Dish	Used for communications and receiving internet and radio waves.
Guttering	Used for directing water to the water tanks, include wire mesh to prevent leaves entering.
Snow Mechanisms	Stops the snow building up on the roof and causing a collapse.
Wind Turbine	Used for electricity generation.
Skylight	Used for natural light.
Solar Heating	Have a solar heating system to prevent the use of gas as often.

Communications Dish	For receiving Tv, radio and internet signals as well as allowing transmission over short distances.

4 Exterior

External locations which consists of any areas on or outside the house that may have their own structure.

House Exterior	
Garden	
Solar Farm	
Windmill / Turbine	
Dam / Lake	
Workshop	Useful if you produce any of your own items such as furniture.

House Exterior

Water Tank	Split the water tanks up to lessen the loss if one becomes contaminated.
Cameras	Face cameras in all four directions to cover all the land. Ensure there's no blind spots intruders could hide in.
Floodlights	Have flood lights facing out in all directions with the ability to switch different ones on if the need arises.
Hot Water Tank	Have an electronic hot water tank to heat water if the solar one fails.
Window Protection	Have electronic metal rolling blinds to prevent intruders and to protect the glass during storms. Ensure there's no light leaking out for emergency situations.
Gas Tanks	Tuck gas tanks away in an inset into the house with a wall in front to protect from gunfire.
Walls	Reinforce walls with bullet resistant materials for safety.
Frame	Have a steel frame to greatly strengthen the house in extreme weather or gunfire.

Garden / Greenhouse

Sewage Treatment	Use the waste from the house to produce manure which will grow crops better.
Garden	Grow food in the relative safety near the house or inside the house if possible.
Fence / Boundary	Have a fence to mark your land and use as a first line of defence.
Farm	Have visibility of the animals from the house and keep under surveillance.
Trees	Make sure trees are sturdy and won't fall on the house in a disaster. Make sure they don't reduce the line of sight.
Well	Have a well and a electricity free pumping system to retrieve the water if water is nearby.
Windmill	Use a windmill to procure water from a well or to generate electricity.
Solar Farm	Have an external solar farm where the panels turn to face the sun if your electricity requirements are high.
River	Use a hydroelectric generator to produce electricity and return it to the basement for use or storage.
Shipping Container	Have a shipping container to store various other gardening items such as ride on mowers and other tools.
Garden Defence	Your garden will be a highly sought after looting location especially if food is scarce. Building 3m (10ft) concrete walls around the garden will deter thieves. Additionally if you put barbed wire on the top it will make it much more difficult to get over the fence in one piece. Combining this with a detection method such as adding bells to the barbed wire you will be able to hear anyone attempting to climb over. The thick concrete walls will also provide a very secure perimeter against bullets and prevent enemies (snipers) seeing into your home. Ensure it isn't too easy to get under the wall either as people may attempt this instead of going over.
Garden Defence

Dam / Lake

Well

5 Distant External

Distant external items are any items outside your primary living residence which may take more than a minute to get to. It includes items still on your own private land or on an allies land and generally applies to large properties. If you look at your house like a medieval castle with everything inside those walls being your home, all the villages nearby are your property but not your primary residence. The purpose of distant fixtures is the ability to see attacks coming long before they are visible from the main residence. Your allies in the area can also provide vital information.

Distant External Areas
- Lookout Towers
- Security Cameras
- Mines / Traps
- Kill Zones
- Allies

Lookout Towers

Towers built in the corners of your land allowing you to view the area within and the land outside. They can be tall towers to provide a greater area of view or a pillbox style which is bullet resistant and stealthier.

Security Cameras

Multiple disguised cameras pointed around the exterior of your land will provide you with additional notice of anything going on. They can be hidden in trees with small solar panels up high beyond the leaf level to hide the fact they are there. They should transmit wirelessly back to the control centre in the house and be monitored frequently.

Mines / Traps

Having some traps on your land would be an ideal setup to deter any intruders.

Deadfall	
Pitfall	
Mines	
Manual Explosives	

Kill Zone

The kill zone is a designated area which manipulates adversaries accordingly that they are easier to kill. A kill zone can be a funnel which forces people to go through that area, where you have explosives or a line of sight from a powerful gun. It's worth thinking about how the enemy could approach your land and fix up the weak points.

Allies

Allies are vital in a SHTF scenario, as long as you can trust them. The aim is to establish a mutual neighbourhood watch pact where you inform each other about the approach of hostiles.

Be sure not to reveal too much about your setup, and don't reveal that you're a prepper if they aren't.

6 Utilities

Utilities are the internal systems to your house that are virtually essential to modern living.
Utilities include: Heating, Cooling, Water, Gas, Electricity and Sewage.

Heating

Have a fireplace in the basement with heating pipes transmitting the warmth to the bedroom and Lounge Room upstairs. Have a backup gas heater to prevent going out for wood in winter.

Heating Systems
- Water Heating
- Air Heating
- Fireplace
- Gas Heating

Cooling

Cooling Systems
- Air Conditioning
- Air Heating
- Windows
- Fans

Water

Have at least 1,200L per person in your water tanks. This amount should be enough for one person for an entire year. Use the roof for water catchment and store it in the water tanks. Triple your water requirements for redundancy and have them located at different points around the house. Store one of the tanks in a basement for protection against the elements and from contamination from radiation or pests. Put a water tank up higher than the house to eliminate the need for electricity to pump it.

Gas

Electricity

Solar Panels	Calculate how much sunlight you will receive based on the daylight hours and any obstacles between the sun.
Hydroelectric	Make sure you can create a small dam to harvest the water or utilize a waterfall.
Steam Power	Combine the fireplace with a generator to heat the home and generate electricity. Add thermoelectric panels on the external wall to produce even more.
Fuel Generator	Have a backup fuel generator in the basement in case the other electricity methods fail and you need it fast.
Wind Power	Have a couple of wind turbines on the roof for additional power - especially useful in windy areas or during storms.

Know how much electricity everything in the house uses and how much you need to generate different times of the year to run them.

Sewage

Removes any sewage from your house and brings in flushing water.

7 Security

Have security cameras positioned around the land to cover every blind spot from the lookout tower.

Security	Put a high fence around your land to deter intruders. Try to remove objects that can be used for advancing intruders to hide behind, unless there's a plan behind having it.
Deterrence	The first level of security is deterring potential criminals. This can be achieved by menacing signs such as "Trespassers will be shot". If your house looks like a fortress with barbed wire and high fences it will also deter most common people. However the more secure your house looks - the more people will think there's goodies inside.
Physical Blockages	Internal walls, wooden stakes and barbed wire will slow down people enough to give you time to detect them.
Warning Shots	If you have a vantage point in your home to shoot from, you can wait and give some warning shots to those attempting to enter.
Explosives	Mines and other manually controlled explosives are the last line of defence to protect yourself. A sign mentioning a minefield alone will prevent most people entering an area. Manual explosives such as those used in "I Am Legend" can be used to obliterate an oncoming wave of people and severely scare any others.
Security	

8 Storage

General Storage

A section detailing storage solutions for household items.

Wooden Box	For packing of heavy goods, fragile items and has resistance to handlings.
Plastic Storage Box	Often comes in large sizes and has wheels for ease of transport.
Wooden Pallet	Allows transportation via forklift and keeps materials off the ground and in airflow.
Shelving	Storage of multiple items such as food cans, water and medical equipment. Comes in wood or metal varieties.
Shipping Container	Provides extreme protection. Check for dents, rust and holes. Can be layered with wood on the bottom. Weight from 2T-4T.
Plastic Barrel	For water or food storage if it's food grade and BPA free.
Metal Grid Reinforced Water Container	Heavy duty water container for large water requirements, transport requirements or protection from the elements.

Storing Gear

Water Storage

Small Containers (Easily Portable) (1-25L)

Plastic Container **1-25L** Any fixed size portable water container.	**Collapsible Container** **1-20L** Any flexible container that grows with the volume of water.	**Metal Container** **1-25L** o			

Small Container Tips
Ensure the plastic is capable of holding water without leeching chemicals. See the water section for a list of plastics safe for storing water. Stacking containers will make it easy to store water and maximise the use of the storage space. Barrels with large circular lids can be easily cleaned on the inside. For ease of use, ensure the container has a tap on it.

Medium Containers (Portable with Transport) (50-1000L)

IBC Tote (Caged Water Tank) (Rectangular) 1000L	**Metal Drum** (Cylindrical) 200L	**Plastic Drum** (Cylindrical) Air Tight Lid Store off cement floors			

Plastic Rainwater Tanks (Fixed Containers) (340-5,000L)

Round Poly Water Tank (Cylindrical) 340-34,000L	**Slimline Poly Water Tank** (Double Figure 8 Vertical) 450-5,000L	**Underground Water Tank** (Double Figure 8 Flat) 3,000-5,000L	**Underdeck Water Tank** (Rounded Rectangle) 1,000-5,000L		

Metal Rainwater Tanks (Fixed Containers) (1,000-378,000L)

Round Steel Tank (Round) 1,000-27,000L Corrugated Design	**Slimline Steel Water Tank** (Thin Rounded Rectangle) 1,000-8,000L Corrugated Design	**Modline Steel Water Tank** (Thick Rounded Rectangle) 1,000-7,000L Corrugated Design	**Square Steel Water Tank** (Thick Rounded Rectangle) 1,000-7,000L Corrugated Design	**Large Steel Panel Tank** (Thick Rounded Rectangle) 24,000-378,000L Corrugated Design Needs Assembly	

Other Rainwater Tanks (1-1000L)

Cement Tank (Above or underground) (Round or Square) 1-378,000L	**Water BOB** 378L Used for filling a bathtub with water in emergencies.				

Storing Water Long Term (Using Household Water)
To store household water long term first get a suitable container. Some plastics are unsuitable for water storage as the chemicals leak out. See the Water section for more information. Never use a container which has previously had food or foreign liquids inside it such as juice or milk. Make sure the container is washed out thoroughly and that there's no particles, bugs, leaves or droppings inside it. Fill the container with water, the less oxygen there is - the less chance that bacteria can spread. Put on the lid and shake the bubbles to the top and then fill the gap. Drop in some chlorine tablets equivalent to the volume of water to be stored.

Typically 1L = 1 Tablet (Or use as directed) Put the cap on tightly and ensure no water escapes when you tip it upside-down. Store the water in a cool, dry location until used. It's better to rotate the water out every 6 months to keep it's freshest, but it's not necessary. When you need to use the water always check for any growth inside the container, if there's any bacteria you should add more purification tablets and filter the water prior to drinking to be safe. You may need to re-oxygenate water that has been sitting for a while as it would have become 'flat'. To do this just tip some out into a bottle and give it a shake for a few seconds, then shake the rest of the container as there's now air inside it.

Food Storage

Fuel Storage

Here you'll find the recommended storage methods for all types of fuels.

Wood Storage

Woods should be stored in a dry, sheltered area to protect it from rain and allow it to dry out more. Wood should be dried for half a year for optimum performance as a firewood. The location need not be internal

Gas Fuel Storage

For petrol fuels, most stove manufactures will recommend that you use metal containers for storage. Although metal is ideal for safety reasons, many plastics can be used to store petroleum based liquids. In fact, some companies even sell camp fuels packaged in plastic containers. If you decide to pack petroleum fuels in a plastic bottle, you should test store it in a bottle prior to packing it in your pack. This should be of course done is a safe place where leakage or fire will not be a concern. You may also need to use a good gasket on your cap to prevent leakage.

Alcohol Fuel Storage

Alcohol can simply be stored in an empty light weight disposable water/juice bottle. And unlike the image shown below, you should remove the water or drink label and mark your bottle so that it says "DANGER FUEL DO NOT DRINK" on it. I like to also add several skull and crossbones on it for the non English readers that may be rummaging through my pack. Then when you use your fuel bottle, try not to spill any fuel on your writing if it isn't protected. It is illegal to use a food container for storage of fuel or other poisons in Australia. Remove any labels that would suggest that the contents are drinkable and mark all bottles with "FUEL". Many fuel stabilizer and lead substitute bottles may be ideal, as they are light weight, can be easy to find and has a measuring chamber on top that allows you to measure generally in 1/4oz increments. They also come in many sizes, (4oz, 8oz, 16oz, 32oz, etc). Metal fuel canisters used for other fuels are heavy and entirely unnecessary for alcohol storage.

Utensils	**Syringe** Syringes and disposable pipettes found at a drug store (a short length of flexible tubing is also nice to have) may aid in precision fuel measurement and help in avoiding over priming a stove.	**Funnel** A funnel aids in getting most the of the fuel you pour out of your original fuel can into your trail fuel bottle.			

Shipping Containers

Sizes

10ft Container (3m)	• Length: 3m • Width: 2.4m	• Corten Steel • 2.8cm Thick • 2.8cm Ply Flooring	Excellent for burying to store weapons, food or water.
20ft Container (6.1m)	• Length: 6m • Width: 2.4m • Weight: 2,267kg • Ground Support: 12ton • Roof Support: 200kg	• Corten Steel • 2.8cm Thick • 2.8cm Ply Flooring	Excellent for burying to store weapons, food, water or as a shelter.
40ft Container (12m)	• Length: 12m • Width: 2.4m • Weight: 3,900kg • Ground Support: 33ton • Roof Support: 200kg	• Corten Steel • 2.8cm Thick • 2.8cm Ply Flooring	Excellent for burying to store weapons, food, water or as a shelter.

Styles

Flat Rack Container	Perfect storage for vehicles.
High Cube Container	Extra 305mm high. Less claustrophobic with the extra headroom and storage space.
Insulated Container	Protection from temperature swings for sensitive goods or small living quarters.
Open Top Container	Useful for transporting tall cargo with a smaller footprint. Great as a container for storing dirt easily accessible by dump trucks.
Refrigerated Container	Refrigerated containers for storage of food, medicine and water. Requires access to air if buried underground. **Refrigeration:** Single phase chillers 0-10°C (32-50°F), Three phase freezers -20-20°C (-4°F-68°F)
Side Opening Container	Useful to store larger objects that won't fit in the main entry. Useful storage for two quads to drive them straight out.

Location

Shipping Storage Above Ground
Shipping containers above ground are essentially giant ovens which will heat up significantly over summer greatly increasing the chance to spoil food over this period. Therefore it's recommended that non food, water, combustible or medical related items should be stored in this location. It will be ideal for a workshop with benches, power tools and other equipment which is semi-used. The doors can be opened to allow airflow when the container is in use such as if it's set up as a workshop. The ability to stack containers above ground will let you store additional equipment at no footprint cost due to the strengthened corners of the container. Although a way to the second container needs to be considered.

Shipping Storage Below Ground
Below ground shipping containers can be used for storage of food, water, explosives and medical equipment as they will last much longer. They are ideal for storing waxed cheeses, wines, spirits, beer and other forms of drinks which will age well in the cooler environment. Another benefit of underground storage is the camouflage factor where an entrance can be easily disguised in the form of a backyard shed. The shipping container may need extra reinforcement on the walls due to the pressure of the dirt from the sides and top which over time could crush the container.

Cache

A cache or survival cache is a hidden collection of items typically underground which is usually dug up at a later date when required. Containers are typically plastic or metal, waterproof and airtight that are resistant to the elements and rustproof. They are typically buried underground at a minimum of 15cm deep and up to 1m. The shallower - the easier they are to be found by others but they can be retrieved faster. Document the location well using a GPS if possible and the alignment of three visible landmarks. Beware of shifting grounds or erosion which could reveal the container over time.

HOMESTEADING Storage Cache Building a Cache

Building a Cache

Creating a PVC Pipe Cache
Use PVC Pipe to create small caches as a weatherproof means to store any supplies you will require later. PVC fits together snugly and can be sealed with a primer and glue rendering it waterproof and won't degrade underground over time.

1	Select the width of the pipe you require to store equipment in, ensuring it will fit everything you need. Pressure pipe is slightly thicker and will provide better resistance to the elements if required.
2	Ensure the pipe size you selected has stoppers and screw ends to allow easy recovery of the contents.
3	Cut the pipe to the required sizes and sand down the ends until they are flat and free of burrs.
4	Glue the ends on using a primer first and then let it sit for 24 hours.

Positioning

The Three Minute Rule
Try to position the cache so you can get to it quickly and it won't take too long to align the landmarks if the scenery has changed. It should take a maximum of 3 minutes total to retrieve a cache during a bug out situation starting from the car and stopping when you return to the car. This gives you about one minute to walk to the location from the nearest road, one minute to dig it up, retrieve the cache and to cover the hole again and another minute to return to your transport. You can modify this any way such as having 30 seconds travel time each way and 2m to dig it up and cover it again.

This rule generally only applies to transport bugging out to allow a swift bug-out and prevent vehicle theft but can also apply to on-foot bugging out to speed up the process. During a disaster less emphasis can be placed on covering up the location afterwards as you're not likely to ever be returning to that point again which can save some valuable time.

Position the cache in a rarely travelled location away from possible future land development sites. A national park is ideal as they are very unlikely to be turned into developments. Be aware of water courses as they may erode the soil above the cache over time - revealing it. Therefore put it near the low point of a hill, or on flat terrain. If the location is a dried riverbed, take note that when you attempt to retrieve the cache, that the water level could be higher than anticipated. Always try to place the cache in a location next to an unmovable landmark such as a large tree or a rock which can be easily identified for future recovery. Scout the surroundings prior to planting a cache to check for people who might see you or for threats such as wild animals. Once planted, make sure the ground looks just like the surrounding area with no obvious marks. Try not to leave any scent or smell of food at the location as animals could dig it up.

Positioning Locations

Your Land	The most secure choice is burying it on your own land at your BOL where it's extremely unlikely to be found.
Friends Land	The second best location, although there is a risk in telling them, because when a disaster happens they could remember and go dig it up themselves.
National Park	A secure location which is very unlikely to be found in the thick scrub and undergrowth and the necessity to keep the area untouched.
Beside Roads	Probably the most convenient location in a bug-out situation due to not having to travel far from the car to retrieve it. However it may be found in more suburban areas due to hole digging for poles and posts and other construction.
Near Streams	In and on the banks of streams could be other secluded locations, however beware of erosion. Between the roots of trees would be secure if packed tightly and attached to the roots by a rope if the roots dip into the water. Be careful of the water level.
Parks	Generally parks don't change much over the years which could make them useful to hide caches in the bushes.

Documenting

Don't trust your memory if you plant a cache. Not only could you forget the location but it could dramatically change by the time you want to recover the contents, with new bushes, trees and undergrowth. Write down the coordinates of the location to get within a few metres of the cache easily. However don't rely on GPS's working when SHTF. Use a trifecta of solid landmarks to accurately pinpoint the location of the cache and jot down which side of the landmark it's on. (N, E, SW etc.) I recommend also pinpointing the location of the cache on an offline mapping program such as a Garmin GPS or the Alpine Quest app.

Example Cache Notes **Location Name** Richard Lawson Park Fuel Cache **GPS Location** 27° 20' 45.2" S 152° 53' 21.4" E **Visible Landmarks** Large Oak Tree - NW Lake - NNE Road - SSE	**Positioning** On the east side of the lone pine tree in the field, one step away. **Planted** - 2 May 2018 **Depth** - 30cm **Container Type** - PVC **Soil Hardness** - Soft **Waterproof** - Yes	**Contents** 2L Petrol, 40 Matches, Various Medications, 2L Water, 3 MREs, 1 Water Filter. **Expirable Items** Medications (2021) MREs (2040) Petrol (Feb 2020)	You could encrypt the coordinates if required by adding a simple number modifier to the location in case somebody comes across your notes. An example is adding 1 to each coordinate grouping. **From:** 27° 20' 45.2" S **To:** 28° 21' 46.2" S

Retrieval

When retrieving a cache either to refresh the contents or during bugging out - be sure you aren't being followed or observed when digging up the location. Practice occasionally on a variety of test locations where possible to get used to finding them again. Returning to the same place yearly and modifying a cache would be ideal as the area would likely have changed slightly. Going geocaching will sharpen your navigation skills and may give you some great ideas of hiding your own caches. Otherwise get friends to hide a cache, marking it and getting you to find it.

Cache Supplies

Caches Locations	Keeping a note of additional caches in the area is possible but be sure to encrypt the coordinates in case one is found.
Fuel	One of the most common items to stash in caches en route especially long ones as liquid is heavy and volatile to transport. Although it must be refreshed every year or so if the fuel has a stabiliser added.

Water / Water Filters	Another heavy item, however water does not go off if stored properly. This is more useful if the surrounding water is contaminated or you're hiking through the area.
Food	Long life foods such as canned food, freeze dried food and MREs are ideal as a restock along the way. Food can last from 5 years to indefinitely and will store well as it's cooler underground.
Tools	Tools will be essential for backups in case your primaries fail. This type of cache would only need to be visited if your tools are broken. Ensure the cache is weather proof to prevent rust.
Shelter	Backup shelter for element protection such as snow or heavy rain - especially if on foot.
Medical	It's always important to have additional medical gear in case your supplies dwindle or you need more specialised gear for emergencies like splints.
Misc	Items such as paracord, region maps, compass, whistle, notepad, money, barter-items, clothing, traps, firearms, ammo, gas masks, duct tape, playing cards, hygiene items, tubing, snare wire, condoms, garbage bags and batteries.

Theft Protection

Safes	
Vaults	
Lock Types	

Mobile Protection

These are the different types of mobile locks and protection you can enable on most phones.

Swipe	No security, just swipe left or right to unlock.
Pattern	Low security level, uses a directional pattern to unlock.
PIN	High level of security, uses 4-8 digits as a pin.
Password	Very high level of security, 8 characters or more.
Biometrics Finger	High level of security, uses your finger's pattern to unlock the phone.
Biometrics Face	Medium level of security, uses your face to unlock the phone. May also work with a photo.
Biometrics Iris	High level of security, uses your iris pattern to unlock the phone. However there's a small chance it could be fooled by a photo - if someone happens to have a photo of your eye.

Information Storage

Different ways you can store digital information so that it's secure and weather resistant.

Types of Storage	• USB Flash Drive • Phone Internal Storage • Hard Drive • Portable SSD Drive				
Element Storage	**Water Protection** ○	**Fire Protection** ○	**EMP Protection** ○		
Encryption					

Limited Storage

You may live in very small quarters or have a very limited area for storing supplies such as an apartment in a city. This section will help you make the most of limited, tight or strangely shaped storage options.

For more information about living in and making the most of small quarters see the Minimalism section below.

9 Conservation

How to conserve any type of resources you have such as water, electricity, gas and heat.

Conserving Water

Different ways you can conserve water.

Conserving Electricity

To start conserving electricity your house should be based on a 12v circuit especially if you're off grid or aiming to go off grid. Avoid using inverters as you lose between 5-30% of the energy during conversion. Turn off appliances when they aren't needed.

Conserving Gas

Different ways you can conserve gas.

Conserving Heat

Ways you can conserve heat.

Conserving Oxygen

How you can conserve oxygen if you have a limited amount.

10 Reusing

We throw away a lot of items in the trash that we could reuse around the house throughout our lives. Reusing not only saves the environment but saves the cost of recycling the materials in the first place. The MATERIALS section has useful tips on alternative survival uses for items around the house.

Finding Alternative Uses

11 Recycling

This section is dedicated to recycling at home either in the recycling bin or doing it yourself.

Recyclables

Newspaper	
Paper / Cardboard	
Plastics	Depending on the type of plastic it may be able to be recycled. See the MATERIALS section for recyclable materials.
Glass	
Metal	
Food Scraps	
Electronic Waste	
Hazardous Waste	

Recycling Water

How you can recycle used water, whether it's bore, grey water or black water.

Non-Recyclables

Items which aren't recyclable.

- Cellophane
- Ceramics
- Clothes
- Drinking Glasses
- Food Waste
- Garden Waste
- Heat-Proof Dishes
- Nappies
- Photographs
- Needles
- Plastic Bags
- Polystyrene Foam
- Soft Plastics
- Tissues
- Toilet Paper
- Wax Coated Paper

Recycling at Home

This section details how you can recycle items at home which you can then reuse. For tips on reusing materials in different ways, scroll down to the "Reusing" section.

Recycling Paper

Recycling Plastic

Recycling Metal

12 Alternatives

The aim of this section is to find any alternatives for technology which draws its power from the grid. It can be also useful if you're looking for compact entertainment or other items to fit into your BOB. These recommendations are best used when you want to live an easy and simple life off the grid relying off solar.

General

Electricity (Small Power)	• **Power Bank:** Perfect to charge phones and other electronic devices. • **Batteries:** The ideal solution to keep your torches on, just swap and go.
Electricity (Big Power)	• **Petrol/Diesel Generator:** Good to power the heavy-draw devices around the house such as fridges and air-conditioners. • **Electric Power Station:** A viable solution for silent portable power equal to generators. They can also be recharged with solar.
Electricity (Renewable)	See the ELECTRICITY section.

Kitchen

Toaster	• **Gas Stove:** A gas stove with a hot plate can toast bread. • **Open Fire:** Using a fire and something to hold the bread you can toast it nicely.
Kettle	• **Gas Stove:** A gas stove can boil water quickly.
Coffee Machine	• **Instant Coffee:** Simply put it into a cup and add water. This is freeze-dried and lasts many years. • **Camping Percolator:** A manual percolator which is pumped by hand and uses either pods or ground coffee.
Blender / Mixer	• **Hand Mixing:** Mixing the ingredients by hand to combine them.
Non Electric Fridge	• **Yakhchāl:** An early form of fridge used for storing items that require a cool environment. • **Icebox:** o • **Evaporative Cooler:** o • **Zeer Pot:** o • **Radiant Fridge:** o • **Root Cellar:** o • **Gas Fridge (Absorption Fridge):** o • **Kerosene Fridge (Absorption Fridge):** o
Portable Electric Fridge	• **Vaccine Fridge (Compression):** o
Freezer	• **Outdoors:** If you live in a location where it snows, you could store food outside in a special freezer box.
Microwave	• **Gas Stove:** A gas stove can reheat food - albeit slower.
Grill	• **Gas Heater:** Using a gas heater very close to the food you can grill it slowly.
Oven	• **Solar Oven:** These are quite large and bulky and take all day to cook, as well a requiring a bright sunny day to cook food. • **Hot Coals:** A fire or the hot coals remaining from a fire can be used to cook food if you want to go to the effort.
Garbage Disposal Unit	• **Compost Bin:** A great way to recycle scraps and it can be used in the garden.
Dishwasher	• **Handwashing:** The only alternative generally. • **Disposable Plates:** You could go for this option however it generates a lot of waste.

Lounge

Lights	• **Natural Light:** Use natural light to light up your home. • **String Lights:** Use string lights to provide enough light to allow navigation and reading at night.
Tv	• **Laptop:** Laptops can do almost everything a Tv can do but doubles as a computer to save space. • **Tablet:** Again, basically a mini Tv, but can provide some computing and gaming functions. • **Mobile Phone:** The smallest package with the most power and very compact and easily transported.

Speakers	• **Headphones / Earphones:** The most compact listening method for one person. Can be used anywhere and fits into a pocket or backpack. • **Phone Speakers:** Wired or wireless speakers to let others listen as well.
Computer	• **Laptop:** Can be used for business work as well as gaming and fits into a much smaller space than a pc. • **Tablet:** Tablets have their uses for watching movies, listening to music and playing some casual games. • **Mobile Phone:** Similar to tablets but even more compact allowing games, music and Tv to be watched as well as some work completed.
Game Console	• **Handheld Console:** Similar to a console but doesn't require wall power. Some older consoles can even be modded into handheld types. • **Card Games:** A classic way to keep entertained although not as entertaining as consoles to modern kids. • **Board Games:** Not as compact as card games but still viable for keeping you entertained. • **Reading:** Get a good book or a series of good books and spend the time in another universe.
Air Conditioner	• **Open Window:** Having an open window can let natural airflow through the house. • **Evaporative Cooler:** Can be used to cool the air by natural evaporation. May be used with ice if that's possible to generate. • **Fan:** A ceiling or pedestal fan can take the edge off when it's an extremely hot day out. • **Reducing Clothing:** Taking off some layers can relieve you of a bit of heat.
Fan	• **Open Windows:** Having an open window can let natural airflow through the house. • **Reducing Clothing:** Taking off some layers can relieve you of a bit of heat.
Heater	• **Fireplace:** The natural heating method for centuries but ensure it's safely operated inside. • **Gas Heater:** Uses gas canisters to heat the space although watch out for carbon monoxide build up.
Sewing Machine	• **Hand Sewing:** If you have the skills you can hand sew whatever you are making instead.

Bathroom

Hair Dryer	• **Sun:** Getting out into the sun can dry your hair naturally and give you some vitamin B as well. • **Air Dry:** Your hair will dry naturally over time but lie down and spread it out so it dries faster. • **Gas Heater:** A gas heater can be used to dry hair if it's dark or cold outside.
Hair Trimmer	• **Razor:** A battery operated trimmer uses little power and can easily be recharged via solar power. • **Scissors:** A simple pair or scissors can be used to trim any type of hair, but it's best if you have another person to help with some training.
Hair Straightener	• **None:** Not many viable options for off grid hair straightening.
Ceiling Heat Lamp	• **Gas Heater:** A gas heater could warm you up and help dry you after a shower.

Laundry

Washing Machine	• **Hand Washing:** For a non powered washing machine alternative you can use a hand washing method or use a bucket/barrel. • **Camping Washer:** You can purchase small barrels which you put your clothes into and spin around repeatedly to clean them.
Dryer	• **Mangle / Wringer:** Wind the wringer to press all the water from the clothes to dry it faster. • **Clothesline:** Pegging out the clothes in the sun will dry them within a few hours.
Iron	• **Fire Iron:** An iron which has a metal base and is placed into a fire to heat up. • **Pegging Out:** Hanging clothes in the warm sun can remove some wrinkles. • **Steaming:** Steaming clothes removes wrinkles quickly if you have the ability to do so.
Vacuum Cleaner	• **Broom:** Sweep up and collect the dirt manually. • **Manual Vacuum Cleaner:** o

Garage

Automatic Door	• **Manual Door:** A door which you lift and lower yourself.
Power Tools	• **Wireless Tools:** Battery operated tools with a solar recharger. • **Hand Tools:** Tools from the olden days where effort and force is required.
Lawn Mower	• **Manual Lawn Mower:** A lawn mower that you push around which cuts the grass with the blades. • **Machete:** Sure, you can cut the grass with a machete or other bladed items such as scissors. • **Animals:** Animals such as sheep, cows and horses can stop your grass growing too long.

External

Water Heater	• **Solar Heating:** Rooftop solar heating can generate hot water from the sun. • **Gas Heating:** Gas heating generates instant heat for on demand applications such as showers.
Water Pump	• **Solar Pump:** A pump which uses the sun to work. • **Hand Pump:** A pump that requires someone to manually pump it when required.
Security System	• **Dogs:** Dogs can hear and smell people from much further away than humans and work as a great deterrent. • **Fences:** If they can't climb it they aren't likely to keep trying to get onto your land.

13 Minimalism

Minimalism isn't just about having few possessions, but about the relaxed and carefree lifestyle that comes with thinking, being and working efficiently and away from distractions. It also covers getting away from the bustle of the cities and suburbs in search of an off-grid or country lifestyle where the pleasures and company are easier.

Physical Minimalism

Physical minimalism or simple living is the art of only using and doing what is essential to stay alive. There are a number of minimalism styles from possession minimalism to digital minimalism. People try to limit their possessions down to a suitcase, backpack or limit it by an item count such as 100.

The art of reducing physical possessions down to only the essentials you need for continued survival.

Prepping and Physical Minimalism	Prepping and minimalism seem like two opposite ends of the spectrum but you can in fact be a minimalist prepper with some skill. The trick is to count your prepper backpack as one item and have a minimal number of everything else you own so that you're ready for disaster and lightweight. It also makes leaving home permanently easier when you have so few possessions and you might even be able to bring them all.
Removing Items	A simple way to get rid of everything you don't need is to put everything into boxes and only take out what you need at the time. After a month or so, just sell or give away the remaining items as if you haven't used them by now, you're not likely to. This is much harder than it sounds as you become more attached to items just before you go to get rid of them.

Possessions

Tips to downsizing your possessions to live clutter-free.

Start with the Big	Remove the larger possessions first, you will be invigorated by how much new space you have and want to continue.
Eliminate Unnecessary	Our houses are often filled with junk we buy, use once and then forget about. Try to remove anything you haven't used in months.
Simplify Your Wardrobe	Reduce that over cluttered wardrobe in your bedroom with multiple pairs of pants and that shirt that only goes with one pair of pants.
Simplify Pc Files	Digital clutter can be as stressful as real clutter. Keep your files orderly and off the desktop, it will appear much cleaner.
Limit Purchases	Ask yourself "Do I really need this to live?"
Clean Desk Policy	Always aim to keep your desk clear of clutter. Put it into the drawer when finished.
Live Frugally	Have simple inexpensive meals that still taste appealing.
Smaller Car	If you can't remove the car altogether, try to drive a smaller, more economical car.
Recycle	Recycle old bottles, cartons and boxes, even if you don't use the resultant product, it's better for the environment.

Possession Quiz

Start at the first question and work towards down if you are directed to the next question. Otherwise take the recommended action.

Can it and should it be digitalised?	Documents, photos, cods, DVDs, books and some games can be converted to a digital format which eliminates the space they require.	**Yes: Digitalize it** **No: Next Question**
Can you substitute, downsize or reduce the duplicates you have?	Items such as cutlery, dishes, containers and stationary.	**Yes: Keep it** **No: Next Question**
Do you use it Regularly?	Items such as TVs, toothbrush, phone, watch, kettle.	**Yes: Keep it** **No: Next Question**
Does it have Sentimental Value?	Items such as photos, gifts or memorabilia?	**Yes: Keep it** **No: Next Question**
Are you 100% likely to use it within a month or year?	Items you are guaranteed to use within a month like food, tools, vacuum, car cleaners but may not use week to week.	**Yes: Keep it** **No: Next Question**
Is it a tool or used in conjunction with another object?	These items are generally useful and required for daily life such as cutlery, power tools, screwdrivers and cables.	**Yes: Keep it** **No: Next Question**
Is it worth money?	If the item is worth money and you've passed the other questions, you should sell it.	**Yes: Sell the item** **No: Discard or donate it**

Digital Minimalism

Digital or online minimalism is your overall exposure to digital media formats. It involves reducing spam or catalogue emails, having few files and no desktop clutter and only the essential apps and programs. It does not include the amount of time spent on digital devices, this falls under time minimalism.

Digital Exposure

Ads & Spam

Desktop Clutter

Files

Time Minimalism

How you spend your time and prioritization of the most important things. It's good to start with a blank schedule and begin to fill in what you have to do. Write down all the tasks and group them by how essential they are to do.		**Task Groupings** ● Essential ● Preparation ● Social ● Leisure
Essential Tasks	First start with the essential tasks that you must complete for staying alive.	**Essential Tasks** ● Sleep (7-9 Hours) ● Work (Varies) ● Eating (1 Hour)
Preparation Tasks	This grouping of task is used in preparation for the essential tasks such as travel to and from work.	**Preparation Tasks** ● Bed Time Routine ● Work Travel ● Cooking
Social Time	Time spent with family or friends including parties, movies and drinks.	
Leisure Time	Any remaining time is considered leisure time and during this window you can do whatever you want or use it to finish an earlier uncompleted task.	
Wasted Time	Time which is spent when you're actually supposed to be doing something else such as Facebook, twitter, instagram. These aren't considered wasted time if it's part of leisure time or you use it for your business as a means to interact with customers.	**Wasted Time** ● Facebook ● Twitter ● Instagram

Budget Minimalism

This type of minimalism is the spending of money wisely and setting up a budget. A study has shown that the average person is subjected to over 500 adverts per day, every one at them either aimed at us buying a product or altering our thoughts on a subject. With this much exposure to ads it makes it significantly harder to hold on to your cash, especially when most of these ads are targeted specifically to you.		
Bugdeting	Budgeting is the first, and most powerful step to saving money. Not only are all funds allocated based on needs but you will have a surprising amount of leeway if a surprise expense comes up. Try not to exceed your budget when buying food, appliances and entertainment as this will hurt you in the future. You'll be amazed by the amount of money you can save by budgeting properly and avoiding excess purchases - which often end up in landfill anyway.	**Bugdet** ●
Subscription Services	There are endless ways companies part us from our money these days and they are more and more turning into subscription based services. These services are paid for automatically behind the scenes which is intended to help us forget the cost over time and make us dependant on them. Unnecessary subscription services such as YouTube, Spotify, Cloud Storage, Adobe Software, Netflix etc can easily drain our income as soon as it's in our bank. Consider which services are essential to your requirements, what you would do without them and then cut off the rest of the services you don't need while transitioning to alternative methods to accomplish it without the service.	**Subscription Services** ● Mobile Internet ● Home Internet ● Music Streaming ● Video Streaming ● Website Hosting ● Cloud Storage ● Productivity Suites
Extras	When shopping we're often presented with aisles of great deals marked down from crazy prices and we're often coerced into making these purchases because we perceive the mto be great deals. This comes in the form of cheap chocolates, drinks and lollies at the checkouts which we don't need but feel we deserve. Saying no to anything outside your budget is a skill to learn, particularly if you're prone to making additional purchases.	**Example Extras** ● Chocolates ● Sweets ● Sugary Drinks
Lower Quality & Less Features	We don't always need the best of everything when making purchases as the marketing seems to suggest. Sometimes the cheaper version can get the job done just as well and you don't waste your hard earnt cash on additional features you'll never use. Keep in mind that it's better to have a good quality device (such as a phone) over multiple cheap devices because this saves space and will often last longer with daily use.	**Examples** ● Smaller packs of food ● Basic Appliances

Minimalism Tips

Evaluation

Evaluate Time	Work out what you spend your time on every day and eliminate the unnecessary.
Evaluate Commitments	Repeating commitments suck a lot of time, evaluate and ditch the ones you find you don't need.
Simplify Jobs	Simplify the routine jobs you do or split them up into multiple smaller tasks.

HOMESTEADING	Minimalism	Minimalism Tips	Evaluation		
HOMESTEADING	Minimalism	Minimalism Tips	Evaluation	Say No	Free up your spare time by saying no to outings, trips and events.
HOMESTEADING	Minimalism	Minimalism Tips	Evaluation	Limit Communication	Today's life is full of continuous contact even when you're far away, try to reduce this contact to weekly.
HOMESTEADING	Minimalism	Minimalism Tips	Evaluation	Limit Media	Slow your mind and prevent the inflow of the useless by switching off from all media forms where possible.
HOMESTEADING	Minimalism	Minimalism Tips	Evaluation	Develop a Budget	A budget can help assist you get your spending under control and save easier as well as reduce clutter.
HOMESTEADING	Minimalism	Minimalism Tips	Evaluation	Debt	The biggest stress of all is debt, try to pay it off as quickly as possible to gain financial freedom. Or don't get in debt at all.

Daily Tasks

HOMESTEADING	Minimalism	Minimalism Tips	Daily Tasks		
HOMESTEADING	Minimalism	Minimalism Tips	Daily Tasks	Eat Slowly	In our busy lives we often forget to enjoy the simple pleasures, slow your eating and enjoy the experience.
HOMESTEADING	Minimalism	Minimalism Tips	Daily Tasks	Drive/Walk Slowly	Not only is it safer, but travelling slower can let you experience the world around us we don't often get the time to.
HOMESTEADING	Minimalism	Minimalism Tips	Daily Tasks	Notice the Small Things	There's so much complexity in the world today but we miss it rushing by. Literally stop to smell the roses.
HOMESTEADING	Minimalism	Minimalism Tips	Daily Tasks	Eat Healthily	Healthy eating can simplify your lifestyle and help that weight to stay off.
HOMESTEADING	Minimalism	Minimalism Tips	Daily Tasks	A Place for Everything	You should store every item you own in it's own place, know where it goes and store it there when not in use.
HOMESTEADING	Minimalism	Minimalism Tips	Daily Tasks	Live without a Car	Nothing feels as freeing then ditching your car in favour of living without a money guzzling pollutant.
HOMESTEADING	Minimalism	Minimalism Tips	Daily Tasks	Single Tasks	Set a single task for the day and then relax once it's done. Don't overcomplicate your schedule.
HOMESTEADING	Minimalism	Minimalism Tips	Daily Tasks	Doing Nothing	Everyone needs some time alone, especially time alone to just do nothing and relax, feel how calm you are without stresses.

Simplify

HOMESTEADING	Minimalism	Minimalism Tips	Simplify		
HOMESTEADING	Minimalism	Minimalism Tips	Simplify	Quality not Quantity	Own fewer better quality possessions and you will save space and value them more.
HOMESTEADING	Minimalism	Minimalism Tips	Simplify	Small Pleasures	Enjoy the small pleasures in your daily life and celebrate the minor achievements you complete.
HOMESTEADING	Minimalism	Minimalism Tips	Simplify	Pack Light	You probably don't use 2/3rds of what you pack on a daily basis, leave it at home and favour only the essentials you need.
HOMESTEADING	Minimalism	Minimalism Tips	Simplify	Smaller Home	There's nothing like freedom by downsizing your home and possessions in favour of simple living and having no debt.
HOMESTEADING	Minimalism	Minimalism Tips	Simplify	Live Closer to Work	This will make ditching your car so much easier and give you one more inch of freedom.
HOMESTEADING	Minimalism	Minimalism Tips	Simplify	Re-Use and Repair	Most items today are discarded and deserted rather than repaired. Try to pick up the old tradition of repairing clothes and re-using old objects.

Time

HOMESTEADING	Minimalism	Minimalism Tips	Time		
HOMESTEADING	Minimalism	Minimalism Tips	Time	Free Up Time	See what activities you don't need to do and set that time aside. When you have free time, don't fill it straight away.
HOMESTEADING	Minimalism	Minimalism Tips	Time	Do what you Love	In your free time, do what you love over anything.
HOMESTEADING	Minimalism	Minimalism Tips	Time	Spend Time with Your Love	The time your spend with people you love is always the best spent time and memories are kept forever.
HOMESTEADING	Minimalism	Minimalism Tips	Time	Alone Time	We need our alone time to self reflect and ponder our life decisions and the big questions in life.
HOMESTEADING	Minimalism	Minimalism Tips	Time	Live in the Present	Don't worry too much about the future or remember the problems of the past.
HOMESTEADING	Minimalism	Minimalism Tips	Time	Planning	Planning activities and what you aim to achieve will increase your productivity and efficiency.
HOMESTEADING	Minimalism	Minimalism Tips	Time	Establish Routines	Routines will keep your life simple and have regularity so you won't have any surprises.

Population

Details on prepper circles, gangs and surviving with others

"In order to stabilize world population, we must eliminate 350,000 people per day."
Jacques-Yves Cousteau

Introduction

Information regarding population, country strength, types of people, gangs etc.

Purpose	The aim of POPULATION is to look into each nation, social class and individual that comprises the population of the world, including information on how they currently interact and how they could interact in a disaster.
Lost?	● For information on hiding from others, see the STEALTH & TACTICS section. ● For a description of the countries of the world, their population and their laws, see the GEOGRAPHY section. ● For communication between people of other languages, see the LANGUAGE section. ● For leading your party during a disaster, see the LEADERSHIP section. ● For tips and rehearsals on bugging-out when others are nearby, see the PREPAREDNESS section. ● For information on communicating with others, see the COMMUNICATION section. ● For information on how people will react in times of turmoil, see the DISASTER TRIGGERS section. ● For information on the religions of the world and what people believe, see RELIGION. ● For preparedness skills you can learn, see the SKILLS section.

1 Population Facts

Population Facts

Current Population[n] 7,866,588,747 (Dec 2020)	During the 20th century alone, the population in the world has grown from 1.65 billion to 6 billion. Population in the world is currently growing at a rate of around 1.09% per year. (2018[n]) 106 billion people have been born since the dawn of the human species until now. 6% are currently alive.	• 131.4 million births per year. • 250 births each minute. • 55.3 million people die each year. • 105 people die each minute. • Average life expectancy is 67 years.

Country Population

A list of the most populated countries on earth, sorted by population as at 2018.[n]

Country Population Density (P/km^2) Land Area (Km^2)	**China** 1,415,045,928 151 9,388,211	**India** 1,354,051,854 455 2,973,190	**U.S.A.** 326,766,748 36 9,147,420	**Indonesia** 266,794,980 147 1,811,570	**Brazil** 210,867,954 25 8,358,140	**Pakistan** 200,813,818 260 770,880	**Nigeria** 195,875,237 215 910,770	**Bangladesh** 166,368,149 1,278 130,170	**Russia** 143,964,709 9 16,376,870	**Mexico** 130,759,074 67 1,943,950	**Japan** 127,185,332 349 364,555

2 Psychology

Hierarchy of Needs

Maslow's hierarchy of needs is a theory in psychology proposed by Abraham Maslow in his 1943 paper "A Theory of Human Motivation" in Psychological Review. Maslow subsequently extended the idea to include his observations of humans' innate curiosity. His theories parallel many other theories of human developmental psychology, some of which focus on describing the stages of growth in humans. The goal of Maslow's Theory is to attain the fifth level or stage: self-actualization needs.

Maslow's hierarchy of needs is often portrayed in the shape of a pyramid with the largest, most fundamental needs at the bottom and the need for self-actualization and self-transcendence at the top. The most fundamental and basic four layers of the pyramid contain what Maslow called "deficiency needs" or "d-needs": esteem, friendship and love, security, and physical needs. If these "deficiency needs" are not met – with the exception of the most fundamental (physiological) need – there may not be a physical indication, but the individual will feel anxious and tense.

Maslow's theory suggests that the most basic level of needs must be met before the individual will strongly desire (or focus motivation upon) the secondary or higher level needs. Maslow also coined the term "metamotivation" to describe the motivation of people who go beyond the scope of the basic needs and strive for constant betterment.

The human brain is a complex system and has parallel processes running at the same time, thus many different motivations from various levels of Maslow's hierarchy can occur at the same time. Maslow spoke clearly about these levels and their satisfaction in terms such as "relative", "general", and "primarily". Instead of stating that the individual focuses on a certain need at any given time, Maslow stated that a certain need "dominates" the human organism.

Physiological Needs • Breathing • Water • Food • Sleep	Physiological needs are the physical requirements for human survival. If these requirements are not met, the human body cannot function properly and will ultimately fail. Physiological needs are thought to be the most important; they should be met first. This is the first and basic need on the hierarchy of needs. Without them, the other needs cannot follow up.
Safety Needs • Personal Security • Emotional Security • Financial Security • Health • Safety	Once a person's physiological needs are relatively satisfied, their safety needs take precedence and dominate behaviour. In the absence of physical safety – due to war, natural disaster, family violence, childhood abuse, etc. – people may (re-) experience post-traumatic stress disorder or transgenerational trauma.

POPULATION Psychology Heirachy of Needs

Love / Belonging ● Friends ● Intimacy ● Family	After physiological and safety needs are fulfilled, the third level of human needs is interpersonal and involves feelings of belongingness. This need is especially strong in childhood and it can override the need for safety as witnessed in children who cling to abusive parents.
Esteem ● Prestige ● Accomplishment	Esteem needs are ego needs or status needs develop a concern with getting recognition, status, importance, and respect from others. All humans have a need to feel respected; this includes the need to have self-esteem and self-respect. Esteem presents the typical human desire to be accepted and valued by others. People often engage in a profession or hobby to gain recognition. These activities give the person a sense of contribution or value.
Self-Actualization ● Achieving Full Potential ● Creative Activities	"What a man can be, he must be." This quotation forms the basis of the perceived need for self-actualization. This level of need refers to what a person's full potential is and the realization of that potential. Maslow describes this level as the desire to accomplish everything that one can, to become the most that one can be. Individuals may perceive or focus on this need very specifically. For example, one individual may have the strong desire to become an ideal parent.
Self-Transcendence ● Spirituality ● Greater Good	Later, Maslow explored a further dimension of needs, while criticizing his own vision on self-actualization. By this later theory, the self only finds its actualization in giving itself to some higher outside goal, in altruism and spirituality. He equated this with the desire to reach the infinite.

POPULATION Psychology

Bunker Survival

POPULATION Psychology Bunker Survival

Large scale bunkers have shared facilities, and some people may not get along well. Humans are meant to be free, not confined in a box without sunlight and air. Agreed upon schedules, rules and regulations essential, however this could break down over time. Requires strong leadership and governance for multiple people. People may attempt to escape, become diseased, become oppositional or become mentally ill. Conditions will deteriorate over time as people become irritable, anxious and desperate for fresh air. Each person requires their own space away from people if required. Shifts may need to be taken to watch for threats and intruders. Each inhabitant needs to watch out for the mental health of other's inside the bunker.

Attitude of inhabitants needs to be kept optimistic to keep their drive for survival. Mental health needs to be kept in check such as ADHD, Schizophrenia and OCD. People struggling with substance addiction will be struggling with withdrawal and will seek an outlet for their vices. Medicine dependence can cause negative psychological effects. Simulated night/day sleep cycle. Lack of sunlight causes disorders. Entertainment essential, lack of stimulation causes irritability. Depression, suicide and self harm can manifest over time living underground. Lack of intel from the outside. Group goals, what are we working towards.

Lack of Sunlight

POPULATION Psychology Lack of Sunlight

These are some of the effects from a lack of sunlight.

Depression	Cooler temperatures can bring on gloomy moods. Whether you call it the winter blues, cabin fever, or seasonal affective disorder (SAD), doctors often chalk up cold-weather mood dips to lack of sunshine. In fact, a study published in the American Journal of Geriatric Psychiatry found that people with lower levels of vitamin D are 10 times more likely to be depressed than those who have a healthy dose of the so-called “sunshine vitamin.” “Basically, it comes down to levels of the hormone serotonin in your brain,” explains Wesley Delbridge, RN, spokesperson for the Academy for Nutrition and Dietetics. “With exposure to bright light, like sunlight, serotonin will increase.”
Weight Gain	Along with prompting skin to manufacture vitamin D, sunshine supplies the important nutrient nitric oxide, which keeps your metabolism running smoothly and discourages binge eating. A study published in the journal Diabetes found that exposure to UV rays can slow weight gain and ward off diabetes.
Risk of Heart Disease	There’s still the risk of skin cancer to worry about. But if you’re limiting your sun exposure—some researchers say we spend 90 percent of our lives indoors!—you could be more likely to develop breast and prostate cancer, as well as cardiovascular disease. Last year, the Harvard School of Public Health found that men with vitamin D deficiencies caused by lack of sunlight were twice as likely to develop a heart condition. Some doctors recommend spending about 15 minutes a day in the sun without sunscreen to give your body a chance to create its daily dose of vitamin D.
Bones Ache	What might be mistaken as arthritis or fibromyalgia (chronic muscle pain and fatigue) in adults could actually be a vitamin D deficiency due to a lack of sunlight, according to Delbridge. Adults who don’t get enough sunshine, especially in the winter when it’s too cold to spend time outside, often feel aches and pains in their muscles and bones, or they might feel a bit stiffer in the morning. Nutrients like calcium and collagen work together to build bones, but without a proper dose of vitamin D, the process is interrupted, and “your bones can actually ache and throb,” says Delbridge.
Sick More Often	Avoiding daylight could be making you sicker. A healthy dose of vitamin D gives your immune system a boost, which decreases your chance of developing infections and the flu. To knock out a pesky cold, try to spend about 10 to 15 minutes outside, recommends Michael Holick, MD, professor of medicine, physiology, and biophysics at Boston University Medical Centre and author of The UV Advantage, on everydayhealth.com. Try these other ways to get vitamin D—even if it’s not summer.
Not Sleeping Well	A lack of sunlight could wreak havoc on your body long after the sun goes down. Research shows that spending an extended amount of time in artificial lighting or staring at electronic screens causes serious sleep problems. In fact, if you skimp on the sun’s rays by staying indoors, you can throw off your circadian rhythm (your body’s internal clock), which could mean you’re not sleeping deeply enough, and may easily trigger insomnia.
Excessive Sweating	Excessive sweating on your forehead, especially if you’re not exercising or overheated, is one of the classic signs that you’re not getting enough vitamin D. If your forehead has a little extra shine (even if your body temperature and activity level is normal), it might be time to ask your doctor about getting your blood checked for a vitamin D deficiency. Even moderately low levels of vitamin D may be linked to a surprising number of health conditions, including diabetes, osteoarthritis, and cancer.

POPULATION ology

Others

Isolation

We are social creatures and we need interaction to survive. Need people to share our lives with in good times or hardship.

Fear

Fear

Energy of the nervous system to flee or engage the situation.
- Fear, stress and anxiety is needed for optimal performance.
- Control your emotions, body and thoughts and you can control the fear.
- Fear can cause compromising moves to be made running headstrong towards or away from the source of fear.
- Become tense and have other visual signs of fear/stress.

Hysterical Strength
A display of extreme strength by humans, beyond what is believed to be normal, usually occurring when people are in life-and-death situations.

Fear Outcomes
- Fight
- Fight
- Freeze
- Faint

Cannibalism

Survival Psychology

Let go of the familiar and embrace the change as everything will be different when SHTF. Preppers attempt to carry over their previous lives into the new world. Adapt to the changing circumstances. See the alternative possibilities in all situations, other uses for all objects. Addiction is the inability to adapt to changing circumstances.

3 Personalities

Personalities Overview

ISTJ - The Inspector	At first glance, ISTJs are intimidating. They appear serious, formal, and proper. They also love traditions and old-school values that uphold patience, hard work, honour, and social and cultural responsibility. They are reserved, calm, quiet, and upright. These traits result from the combination of I, S, T, and J, a personality type that is often misunderstood.
ISFJ - The Nurturer	ISFJs are philanthropists and they are always ready to give back and return generosity with even more generosity. The people and things they believe in will be upheld and supported with enthusiasm and unselfishness. ISFJs are warm and kind-hearted. They value harmony and cooperation, and are likely to be very sensitive to other people's feelings. People value the ISFJ for their consideration and awareness, and their ability to bring out the best in others.
INFJ - The Counsellor	INFJs are visionaries and idealists who ooze creative imagination and brilliant ideas. They have a different, and usually more profound, way of looking at the world. They have a substance and depth in the way they think, never taking anything at surface level or accepting things the way they are. Others may sometimes perceive them as weird or amusing because of their different outlook on life.
INTJ - The Mastermind	INTJs, as introverts, are quiet, reserved, and comfortable being alone. They are usually self-sufficient and would rather work alone than in a group. Socializing drains an introvert's energy, causing them to need to recharge. INTJs are interested in ideas and theories. When observing the world they are always questioning why things happen the way they do. They excel at developing plans and strategies, and don't like uncertainty.
ISTP - The Craftsman	ISTPs are mysterious people who are usually very rational and logical, but also quite spontaneous and enthusiastic. Their personality traits are less easily recognizable than those of other types, and even people who know them well can't always anticipate their reactions. Deep down, ISTPs are spontaneous, unpredictable individuals, but they hide those traits from the outside world, often very successfully.
ISFP - The Composer	ISFPs are introverts that do not seem like introverts. It is because even if they have difficulties connecting to other people at first, they become warm, approachable, and friendly eventually. They are fun to be with and very spontaneous, which makes them the perfect friend to tag along in whatever activity, regardless if planned or unplanned. ISFPs want to live their life to the fullest and embrace the present, so they make sure they are always out to explore new things and discover new experiences. It is in experience that they find wisdom, so they do see more value in meeting new people than other introverts.
INFP - The Idealist	INFPs, like most introverts, are quiet and reserved. They prefer not to talk about themselves, especially in the first encounter with a new person. They like spending time alone in quiet places where they can make sense of what is happening around them. They love analysing signs and symbols, and consider them to be metaphors that have deeper meanings related to life. They are lost in their imagination and daydreams, always drowned in the depth of their thoughts, fantasies, and ideas.
INTP - The Thinker	INTPs are well known for their brilliant theories and unrelenting logic, which makes sense since they are arguably the most logical minded of all the personality types. They love patterns, have a keen eye for picking up on discrepancies, and a good ability to read people, making it a bad idea to lie to an INTP. People of this personality type aren't interested in practical, day-to-day activities and maintenance, but when they find an environment where their creative genius and potential can be expressed, there is no limit to the time and energy INTPs will expend in developing an insightful and unbiased solution.
ESTP - The Doer	ESTPs have an Extraverted, Sensing, Thinking, and Perceptive personality. ESTPs are governed by the need for social interaction, feelings and emotions, logical processes and reasoning, along with a need for freedom. Theory and abstracts don't keep ESTP's interested for long. ESTPs leap before they look, fixing their mistakes as they go, rather than sitting idle or preparing contingency plans.
ESFP - The Performer	ESFPs have an Extraverted, Observant, Feeling and Perceiving personality, and are commonly seen as Entertainers. Born to be in front of others and to capture the stage, ESFPs love the spotlight. ESFPs are thoughtful explorers who love learning and sharing what they learn with others. ESFPs are "people people" with strong interpersonal skills. They are lively and fun, and enjoy being the centre of attention. They are warm, generous, and friendly, sympathetic and concerned for other people's well-being.
ENFP - The Champion	ENFPs have an Extraverted, Intuitive, Feeling and Perceiving personality. This personality type is highly individualistic and Champions strive toward creating their own methods, looks, actions, habits, and ideas — they do not like cookie cutter people and hate when they are forced to live inside a box. They like to be around other people and have a strong intuitive nature when it comes to themselves and others. They operate from their feelings most of the time, and they are highly perceptive and thoughtful.

ENTP - The Visionary	Those with the ENTP personality are some of the rarest in the world, which is completely understandable. Although they are extroverts, they don't enjoy small talk and may not thrive in many social situations, especially those that involve people who are too different from the ENTP. ENTPs are intelligent and knowledgeable need to be constantly mentally stimulated. They have the ability to discuss theories and facts in extensive detail. They are logical, rational, and objective in their approach to information and arguments.
ESTJ - The Supervisor	ESTJs are organized, honest, dedicated, dignified, traditional, and are great believers of doing what they believe is right and socially acceptable. Though the paths towards "good" and "right" are difficult, they are glad to take their place as the leaders of the pack. They are the epitome of good citizenry. People look to ESTJs for guidance and counsel, and ESTJs are always happy that they are approached for help.
ESFJ - The Provider	ESFJs are the stereotypical extroverts. They are social butterflies, and their need to interact with others and make people happy usually ends up making them popular. The ESFJ usually tends to be the cheerleader or sports hero in high school and college. Later on in life, they continue to revel in the spotlight, and are primarily focused on organizing social events for their families, friends and communities. ESFJ is a common personality type and one that is liked by many people.
ENFJ - The Giver	ENFJs are people-focused individuals. They are extroverted, idealistic, charismatic, outspoken, highly principled and ethical, and usually know how to connect with others no matter their background or personality. Mainly relying on intuition and feelings, they tend to live in their imagination rather than in the real world. Instead of focusing on living in the "now" and what is currently happening, ENFJs tend to concentrate on the abstract and what could possibly happen in the future.
ENTJ - The Commander	An ENTJ's primary mode of living focuses on external aspects and all things are dealt with rationally and logically. Their secondary mode of operation is internal, where intuition and reasoning take effect. ENTJs are natural born leaders among the 16 personality types and like being in charge. They live in a world of possibilities and they often see challenges and obstacles as great opportunities to push themselves. They seem to have a natural gift for leadership, making decisions, and considering options and ideas quickly yet carefully. They are "take charge" people who do not like to sit still.

Detailed Personalities

ISTJ - The Inspector

The ISTJ personality type is thought to be the most abundant, making up around 13% of the population. Their defining characteristics of integrity, practical logic and tireless dedication to duty make ISTJs a vital core to many families, as well as organizations that uphold traditions, rules and standards, such as law offices, regulatory bodies and military. People with the ISTJ personality type enjoy taking responsibility for their actions, and take pride in the work they do – when working towards a goal, ISTJs hold back none of their time and energy completing each relevant task with accuracy and patience.

ISTJs don't make many assumptions, preferring instead to analyse their surroundings, check their facts and arrive at practical courses of action. ISTJ personalities are no-nonsense, and when they've made a decision, they will relay the facts necessary to achieve their goal, expecting others to grasp the situation immediately and take action. ISTJs have little tolerance for indecisiveness, but lose patience even more quickly if their chosen course is challenged with impractical theories, especially if they ignore key details – if challenges becomes time-consuming debates, ISTJs can become noticeably angry as deadlines tick nearer.

When ISTJs say they are going to get something done, they do it, meeting their obligations no matter the personal cost, and they are baffled by people who don't hold their own word in the same respect. Combining laziness and dishonesty is the quickest way to get on ISTJs' bad side. Consequently, people with the ISTJ personality type often prefer to work alone, or at least have their authority clearly established by hierarchy, where they can set and achieve their goals without debate or worry over other's reliability. ISTJs have sharp, fact-based minds, and prefer autonomy and self-sufficiency to reliance on someone or something. Dependency on others is often seen by ISTJs as a weakness, and their passion for duty, dependability and impeccable personal integrity forbid falling into such a trap.

This sense of personal integrity is core to ISTJs, and goes beyond their own minds – ISTJ personalities adhere to established rules and guidelines regardless of cost, reporting their own mistakes and telling the truth even when the consequences for doing so could be disastrous. To ISTJs, honesty is far more important than emotional considerations, and their blunt approach leaves others with the false impression that ISTJs are cold, or even robotic.

People with this type may struggle to express emotion or affection outwardly, but the suggestion that they don't feel, or worse have no personality at all, is deeply hurtful. ISTJs' dedication is an excellent quality, allowing them to accomplish much, but it is also a core weakness that less scrupulous individuals take advantage of. ISTJs seek stability and security, considering it their duty to maintain a smooth operation, and they may find that their co-workers and significant others shift their responsibilities onto them, knowing that they will always take up the slack.

ISTJs tend to keep their opinions to themselves and let the facts do the talking, but it can be a long time before observable evidence tells the whole story. ISTJs need to remember to take care of themselves – their stubborn dedication to stability and efficiency can compromise those goals in the long term as others lean ever-harder on them, creating an emotional strain that can go unexpressed for years, only finally coming out after it's too late to fix. If they can find co-workers and spouses who genuinely appreciate and complement their qualities, who enjoy the brightness, clarity and dependability that they offer, ISTJs will find that their stabilizing role is a tremendously satisfying one, knowing that they are part of a system that works.

ISFJ - The Nurturer

The ISFJ personality type is quite unique, as many of their qualities defy the definition of their individual traits. Though possessing the Feeling (F) trait, ISFJs have excellent analytical abilities; though Introverted (I), they have well-developed people skills and robust social relationships; and though they are a Judging (J) type, ISFJs are often receptive to change and new ideas. As with so many things, people with the ISFJ personality type are more than the sum of their parts, and it is the way they use these strengths that defines who they are. ISFJs are true altruists, meeting kindness with kindness-in-excess and engaging the work and people they believe in with enthusiasm and generosity. There's hardly a better type to make up such a large proportion of the population, nearly 13%. Combining the best of tradition and the desire to do good, ISFJs are found in lines of work with a sense of history behind them, such as medicine, academics and charitable social work. ISFJ personalities (especially Turbulent ones) are often meticulous to the point of perfectionism, and though they procrastinate, they can always be relied on to get the job done on time. ISFJs take their responsibilities personally, consistently going above and beyond, doing everything they can to exceed expectations and delight others, at work and at home.

The challenge for ISFJs is ensuring that what they do is noticed. They have a tendency to underplay their accomplishments, and while their kindness is often respected, more cynical and selfish people are likely to take advantage of ISFJs' dedication and humbleness by pushing work onto them and then taking the credit. ISFJs need to know when to say no and stand up for themselves if they are to maintain their confidence and enthusiasm. Naturally social, an odd quality for Introverts, ISFJs utilize excellent memories not to retain data and trivia, but to remember people, and details about their lives. When it comes to gift-giving, ISFJs have no equal, using their imagination and natural sensitivity to express their generosity in ways that touch the hearts of their recipients. While this is certainly true of their co-workers, whom people with the ISFJ personality type often consider their personal friends, it is in family that their expressions of affection fully bloom. ISFJ personalities are a wonderful group, rarely sitting idle while a worthy cause remains unfinished. ISFJs' ability to connect with others on an intimate level is unrivalled among Introverts, and the joy they experience in using those connections to maintain a supportive, happy family is a gift for everyone involved. They may never be truly comfortable in the spotlight, and may feel guilty taking due credit for team efforts, but if they can ensure that their efforts are recognized, ISFJs are likely to feel a level of satisfaction in what they do that many other personality types can only dream of.

INFJ - The Counsellor

INFJ - The Counsellor

The INFJ personality type is very rare, making up less than one percent of the population, but they nonetheless leave their mark on the world. As Diplomats, they have an inborn sense of idealism and morality, but what sets them apart is the accompanying Judging (J) trait – INFJs are not idle dreamers, but people capable of taking concrete steps to realize their goals and make a lasting positive impact. INFJs tend to see helping others as their purpose in life, but while people with this personality type can be found engaging rescue efforts and doing charity work, their real passion is to get to the heart of the issue so that people need not be rescued at all. INFJs indeed share a unique combination of traits: though soft-spoken, they have very strong opinions and will fight tirelessly for an idea they believe in. They are decisive and strong-willed, but will rarely use that energy for personal gain – INFJs will act with creativity, imagination, conviction and sensitivity not to create advantage, but to create balance. Egalitarianism and karma are very attractive ideas to INFJs, and they tend to believe that nothing would help the world so much as using love and compassion to soften the hearts of tyrants.

INFJs find it easy to make connections with others, and have a talent for warm, sensitive language, speaking in human terms, rather than with pure logic and fact. It makes sense that their friends and colleagues will come to think of them as quiet Extraverted types, but they would all do well to remember that INFJs need time alone to decompress and recharge, and to not become too alarmed when they suddenly withdraw. INFJs take great care of other's feelings, and they expect the favour to be returned – sometimes that means giving them the space they need for a few days. Really though, it is most important for INFJs to remember to take care of themselves. The passion of their convictions is perfectly capable of carrying them past their breaking point and if their zeal gets out of hand, they can find themselves exhausted, unhealthy and stressed. This becomes especially apparent when INFJs find themselves up against conflict and criticism – their sensitivity forces them to do everything they can to evade these seemingly personal attacks, but when the circumstances are unavoidable, they can fight back in highly irrational, unhelpful ways. To INFJs, the world is a place full of inequity – but it doesn't have to be. No other personality type is better suited to create a movement to right a wrong, no matter how big or small. INFJs just need to remember that while they're busy taking care of the world, they need to take care of themselves, too.

INTJ - The Mastermind

It's lonely at the top, and being one of the rarest and most strategically capable personality types, INTJs know this all too well. INTJs form just two percent of the population, and women of this personality type are especially rare, forming just 0.8% of the population – it is often a challenge for them to find like-minded individuals who are able to keep up with their relentless intellectualism and chess-like manoeuvring. People with the INTJ personality type are imaginative yet decisive, ambitious yet private, amazingly curious, but they do not squander their energy. With a natural thirst for knowledge that shows itself early in life, INTJs are often given the title of "bookworm" as children. While this may be intended as an insult by their peers, they more than likely identify with it and are even proud of it, greatly enjoying their broad and deep body of knowledge. INTJs enjoy sharing what they know as well, confident in their mastery of their chosen subjects, but owing to their Intuitive (N) and Judging (J) traits, they prefer to design and execute a brilliant plan within their field rather than share opinions on "uninteresting" distractions like gossip. A paradox to most observers, INTJs are able to live by glaring contradictions that nonetheless make perfect sense – at least from a purely rational perspective. For example, INTJs are simultaneously the most starry-eyed idealists and the bitterest of cynics, a seemingly impossible conflict. But this is because INTJ types tend to believe that with effort, intelligence and consideration, nothing is impossible, while at the same time they believe that people are too lazy, short-sighted or self-serving to actually achieve those fantastic results.

Yet that cynical view of reality is unlikely to stop an interested INTJ from achieving a result they believe to be relevant. INTJs radiate self-confidence and an aura of mystery, and their insightful observations, original ideas and formidable logic enable them to push change through with sheer willpower and force of personality. At times it will seem that INTJs are bent on deconstructing and rebuilding every idea and system they come into contact with, employing a sense of perfectionism and even morality to this work. Anyone who doesn't have the talent to keep up with INTJs' processes, or worse yet, doesn't see the point of them, is likely to immediately and permanently lose their respect. Rules, limitations and traditions are anathema to the INTJ personality type – everything should be open to questioning and revaluation, and if they see a way, INTJs will often act unilaterally to enact their technically superior, sometimes insensitive, and almost always unorthodox methods and ideas. This isn't to be misunderstood as impulsiveness – INTJs will strive to remain rational no matter how attractive the end goal may be, and every idea, whether generated internally or soaked in from the outside world, must pass the ruthless and ever-present "Is this going to work?" filter.

This mechanism is applied at all times, to all things and all people, and this is often where INTJ personality types run into trouble. INTJs are brilliant and confident in bodies of knowledge they have taken the time to understand, but unfortunately the social contract is unlikely to be one of those subjects. White lies and small talk are hard enough as it is for a type that craves truth and depth, but INTJs may go so far as to see many social conventions as downright stupid. Ironically, it is often best for them to remain where they are comfortable – out of the spotlight – where the natural confidence prevalent in INTJs as they work with the familiar can serve as its own beacon, attracting people, romantically or otherwise, of similar temperament and interests. INTJs are defined by their tendency to move through life as though it were a giant chess board, pieces constantly shifting with consideration and intelligence, always assessing new tactics, strategies and contingency plans, constantly outmanoeuvring their peers in order to maintain control of a situation while maximizing their freedom to move about. This isn't meant to suggest that INTJs act without conscience, but to many Feeling (F) types, INTJs' distaste for acting on emotion can make it seem that way, and it explains why many fictional villains (and misunderstood heroes) are modelled on this personality type.

ISTP - The Craftsman

ISTPs love to explore with their hands and their eyes, touching and examining the world around them with cool rationalism and spirited curiosity. People with this personality type are natural Makers, moving from project to project, building the useful and the superfluous for the fun of it, and learning from their environment as they go. Often mechanics and engineers, ISTPs find no greater joy than in getting their hands dirty pulling things apart and putting them back together, just a little bit better than they were before. ISTPs explore ideas through creating, troubleshooting, trial and error and first-hand experience. They enjoy having other people take an interest in their projects and sometimes don't even mind them getting into their space.

Of course, that's on the condition that those people don't interfere with ISTPs' principles and freedom, and they'll need to be open to ISTPs returning the interest in kind. ISTPs enjoy lending a hand and sharing their experience, especially with the people they care about, and it's a shame they're so uncommon, making up only about five percent of the population. ISTP women are especially rare, and the typical gender roles that society tends to expect can be a poor fit – they'll often be seen as tomboys from a young age. While their mechanical tendencies can make them appear simple at a glance, ISTPs are actually quite enigmatic.

Friendly but very private, calm but suddenly spontaneous, extremely curious but unable to stay focused on formal studies, ISTP personalities can be a challenge to predict, even by their friends and loved ones. ISTPs can seem very loyal and steady for a while, but they tend to build up a store of impulsive energy that explodes without warning, taking their interests in bold new directions. Rather than some sort of vision quest though, ISTPs are merely exploring the viability of a new interest when they make these seismic shifts.

ISTPs' decisions stem from a sense of practical realism, and at their heart is a strong sense of direct fairness, a "do unto others" attitude, which really helps to explain many of ISTPs' puzzling traits. Instead of being overly cautious though, avoiding stepping on toes in order to avoid having their toes stepped on, ISTPs are likely to go too far, accepting likewise retaliation, good or bad, as fair play. The biggest issue ISTPs are likely to face is that they often act too soon, taking for granted their permissive nature and assuming that others are the same.

They'll be the first to tell an insensitive joke, get overly involved in someone else's project, roughhouse and play around, or suddenly change their plans because something more interesting came up. ISTPs will come to learn that many other personality types have much more firmly drawn lines on rules and acceptable behaviour than they do – they don't want to hear an insensitive joke, and certainly wouldn't tell one back, and they wouldn't want to engage in horseplay, even with a willing party. If a situation is already emotionally charged, violating these boundaries can backfire tremendously.

ISTPs have a particular difficulty in predicting emotions, but this is just a natural extension of their fairness, given how difficult it is to gauge ISTPs' emotions and motivations. However, their tendency to explore their relationships through their actions rather than through empathy can lead to some very frustrating situations. People with the ISTP personality type struggle with boundaries and guidelines, preferring the freedom to move about and colour outside the lines if they need to. Finding an environment where they can work with good friends who understand their style and unpredictability, combining their creativity, sense of humour and hands-on approach to build practical solutions and things, will give ISTPs many happy years of building useful boxes – and admiring them from the outside.

ISFP - The Composer

ISFP personality types are true artists, but not necessarily in the typical sense where they're out painting happy little trees. Often enough though, they are perfectly capable of this. Rather, it's that they use aesthetics, design and even their choices and actions to push the limits of social convention. ISFPs enjoy upsetting traditional expectations with experiments in beauty and behaviour – chances are, they've expressed more than once the phrase "Don't box me in!" ISFPs live in a colourful, sensual world, inspired by connections with people and ideas. ISFP personalities take joy in reinterpreting these connections, reinventing and experimenting with both themselves and new perspectives.

No other type explores and experiments in this way more. This creates a sense of spontaneity, making ISFPs seem unpredictable, even to their close friends and loved ones. Despite all this, ISFPs are definitely Introverts (I), surprising their friends further when they step out of the spotlight to be by themselves to recharge. Just because they are alone though, doesn't mean people with the ISFP personality type sit idle – they take this time for introspection, assessing their principles. Rather than dwelling on the past or the future, ISFPs think about who they are.

They return from their cloister, transformed. ISFPs live to find ways to push their passions. Riskier behaviours like gambling and extreme sports are more common with this personality type than with others. Fortunately their attunement to the moment and their environment allows them to do better than most. ISFPs also enjoy connecting with others, and have a certain irresistible charm. ISFPs always know just the compliment to soften a heart that's getting ready to call their risks irresponsible or reckless.

'However, if a criticism does get through, it can end poorly. Some ISFPs can handle kindly phrased commentary, valuing it as another perspective to help push their passions in new directions. But if the comments are more biting and less mature, ISFP personalities can lose their tempers in spectacular fashion. ISFPs are sensitive to others' feelings and value harmony. When faced with criticism, it can be a challenge for people with this type to step away from the moment long enough to not get caught up in the heat of the moment.

But living in the moment goes both ways, and once the heightened emotions of an argument cool, ISFPs can usually call the past the past and move on as though it never occurred. The biggest challenge facing ISFPs is planning for the future. Finding constructive ideals to base their goals on and working out goals that create positive principles is no small task. Unlike Sentinel types, ISFPs don't plan their futures in terms of assets and retirement. Rather, they plan actions and behaviours as contributions to a sense of identity, building a portfolio of experiences, not stocks.

If these goals and principles are noble, ISFPs can act with amazing charity and selflessness – but it can also happen that people with the ISFP personality type establish a more self-centred identity, acting with selfishness, manipulation and egoism. It's important for ISFPs to remember to actively become the person they want to be. Developing and maintaining a new habit may not come naturally, but taking the time each day to understand their motivations allows ISFPs to use their strengths to pursue whatever they've come to love.

INFP - The Idealist

INFP personalities are true idealists, always looking for the hint of good in even the worst of people and events, searching for ways to make things better. While they may be perceived as calm, reserved, or even shy, INFPs have an inner flame and passion that can truly shine. Comprising just 4% of the population, the risk of feeling misunderstood is unfortunately high for the INFP personality type – but when they find like-minded people to spend their time with, the harmony they feel will be a fountain of joy and inspiration.

Being a part of the Diplomat personality group, INFPs are guided by their principles, rather than by logic (Analysts), excitement (Explorers), or practicality (Sentinels). When deciding how to move forward, they will look to honour, beauty, morality and virtue – INFPs are led by the purity of their intent, not rewards and punishments. People who share the INFP personality type are proud of this quality, and rightly so, but not everyone understands the drive behind these feelings, and it can lead to isolation. At their best, these qualities enable INFPs to communicate deeply with others, easily speaking in metaphors and parables, and understanding and creating symbols to share their ideas.

The strength of this intuitive communication style lends itself well to creative works, and it comes as no surprise that many famous INFPs are poets, writers and actors. Understanding themselves and their place in the world is important to INFPs, and they explore these ideas by projecting themselves into their work. INFPs have a talent for self-expression, revealing their beauty and their secrets through metaphors and fictional characters.

INFPs' ability with language doesn't stop with their native tongue, either – as with most people who share the Diplomat personality types, they are considered gifted when it comes to learning a second (or third!) language. Their gift for communication also lends itself well to INFPs' desire for harmony, a recurring theme with Diplomats, and helps them to move forward as they find their calling.

Unlike their Extraverted cousins though, INFPs will focus their attention on just a few people, a single worthy cause – spread too thinly, they'll run out of energy, and even become dejected and overwhelmed by all the bad in the world that they can't fix. This is a sad sight for INFPs' friends, who will come to depend on their rosy outlook. If they are not careful, INFPs can lose themselves in their quest for good and neglect the day-to-day upkeep that life demands. INFPs often drift into deep thought, enjoying contemplating the hypothetical and the philosophical more than any other personality type.

Left unchecked, INFPs may start to lose touch, withdrawing into "hermit mode", and it can take a great deal of energy from their friends or partner to bring them back to the real world. Luckily, like the flowers in spring, INFP's affection, creativity, altruism and idealism will always come back, rewarding them and those they love perhaps not with logic and utility, but with a world view that inspires compassion, kindness and beauty wherever they go.

INTP - The Thinker

The INTP personality type is fairly rare, making up only three percent of the population, which is definitely a good thing for them, as there's nothing they'd be more unhappy about than being "common". INTPs pride themselves on their inventiveness and creativity, their unique perspective and vigorous intellect. Usually known as the philosopher, the architect, or the dreamy professor, INTPs have been responsible for many scientific discoveries throughout history. INTPs are known for their brilliant theories and unrelenting logic – in fact, they are considered the most logically precise of all the personality types. They love patterns, and spotting discrepancies between statements could almost be described as a hobby, making it a bad idea to lie to an INTP. This makes it ironic that INTPs' word should always be taken with a grain of salt – it's not that they are dishonest, but people with the INTP personality type tend to share thoughts that are not fully developed, using others as a sounding board for ideas and theories in a debate against themselves rather than as actual conversation partners. This may make them appear unreliable, but in reality no one is more enthusiastic and capable of spotting a problem, drilling through the endless factors and details that encompass the issue and developing a unique and viable solution than INTPs – just don't expect punctual progress reports. People who share the INTP personality type aren't interested in practical, day-to-day activities and maintenance, but when they find an environment where their creative genius and potential can be expressed, there is no limit to the time and energy INTPs will expend in developing an insightful and unbiased solution.

They may appear to drift about in an unending daydream, but INTPs' thought process is unceasing, and their minds buzz with ideas from the moment they wake up. This constant thinking can have the effect of making them look pensive and detached, as they are often conducting full-fledged debates in their own heads, but really INTPs are quite relaxed and friendly when they are with people they know, or who share their interests. However, this can be replaced by overwhelming shyness when INTP personalities are among unfamiliar faces, and friendly banter can quickly become combative if they believe their logical conclusions or theories are being criticized. When INTPs are particularly excited, the conversation can border on incoherence as they try to explain the daisy-chain of logical conclusions that led to the formation of their latest idea. Oftentimes, INTPs will opt to simply move on from a topic before it's ever understood what they were trying to say, rather than try to lay things out in plain terms. The reverse can also be true when people explain their thought processes to INTPs in terms of subjectivity and feeling. Imagine an immensely complicated clockwork, taking in every fact and idea possible, processing them with a heavy dose of creative reasoning and returning the most logically sound results available – this is how the INTP mind works, and this type has little tolerance for an emotional monkey-wrench jamming their machines.

Further, with Thinking (T) as one of their governing traits, INTPs are unlikely to understand emotional complaints at all, and their friends won't find a bedrock of emotional support in them. People with the INTP personality type would much rather make a series of logical suggestions for how to resolve the underlying issue, a perspective that is not always welcomed by their Feeling (F) companions. This will likely extend to most social conventions and goals as well, like planning dinners and getting married, as INTPs are far more concerned with originality and efficient results. The one thing that really holds INTPs back is their restless and pervasive fear of failure. INTP personalities are so prone to reassessing their own thoughts and theories, worrying that they've missed some critical piece of the puzzle, that they can stagnate, lost in an intangible world where their thoughts are never truly applied. Overcoming this self-doubt stands as the greatest challenge INTPs are likely to face, but the intellectual gifts – big and small – bestowed on the world when they do makes it worth the fight.

ESTP - The Doer

ESTP personality types always have an impact on their immediate surroundings – the best way to spot them at a party is to look for the whirling eddy of people flitting about them as they move from group to group. Laughing and entertaining with a blunt and earthy humour, ESTP personalities love to be the centre of attention. If an audience member is asked to come on stage, ESTPs volunteer – or volunteer a shy friend. Theory, abstract concepts and plodding discussions about global issues and their implications don't keep ESTPs interested for long. ESTPs keep their conversation energetic, with a good dose of intelligence, but they like to talk about what is – or better yet, to just go out and do it. ESTPs leap before they look, fixing their mistakes as they go, rather than sitting idle, preparing contingencies and escape clauses. ESTPs are the likeliest personality type to make a lifestyle of risky behaviour. They live in the moment and dive into the action – they are the eye of the storm. People with the ESTP personality type enjoy drama, passion, and pleasure, not for emotional thrills, but because it's so stimulating to their logical minds. They are forced to make critical decisions based on factual, immediate reality in a process of rapid-fire rational stimulus response. This makes school and other highly organized environments a challenge for ESTPs. It certainly isn't because they aren't smart, and they can do well, but the regimented, lecturing approach of formal education is just so far from the hands-on learning that ESTPs enjoy.

It takes a great deal of maturity to see this process as a necessary means to an end, something that creates more exciting opportunities. Also challenging is that to ESTPs, it makes more sense to use their own moral compass than someone else's. Rules were made to be broken. This is a sentiment few high school instructors or corporate supervisors are likely to share, and can earn ESTP personalities a certain reputation. But if they minimize the trouble-making, harness their energy, and focus through the boring stuff, ESTPs are a force to be reckoned with. With perhaps the most perceptive, unfiltered view of any type, ESTPs have a unique skill in noticing small changes. Whether a shift in facial expression, a new clothing style, or a broken habit, people with this personality type pick up on hidden thoughts and motives where most types would be lucky to pick up anything specific at all. ESTPs use these observations immediately, calling out the change and asking questions, often with little regard for sensitivity. ESTPs should remember that not everyone wants their secrets and decisions broadcast. Sometimes ESTPs' instantaneous observation and action is just what's required, as in some corporate environments, and especially in emergencies.

If ESTPs aren't careful though, they may get too caught in the moment, take things too far, and run roughshod over more sensitive people, or forget to take care of their own health and safety. Making up only four percent of the population, there are just enough ESTPs out there to keep things spicy and competitive, and not so many as to cause a systemic risk. ESTPs are full of passion and energy, complemented by a rational, if sometimes distracted, mind. Inspiring, convincing and colourful, they are natural group leaders, pulling everyone along the path less travelled, bringing life and excitement everywhere they go. Putting these qualities to a constructive and rewarding end is ESTPs' true challenge.

ESFP - The Performer

If anyone is to be found spontaneously breaking into song and dance, it is the ESFP personality type. ESFPs get caught up in the excitement of the moment, and want everyone else to feel that way, too. No other personality type is as generous with their time and energy as ESFPs when it comes to encouraging others, and no other personality type does it with such irresistible style. Born entertainers, ESFPs love the spotlight, but all the world's a stage. Many famous people with the ESFP personality type are indeed actors, but they love putting on a show for their friends too, chatting with a unique and earthy wit, soaking up attention and making every outing feel a bit like a party. Utterly social, ESFPs enjoy the simplest things, and there's no greater joy for them than just having fun with a good group of friends. It's not just talk either – ESFPs have the strongest aesthetic sense of any personality type. From grooming and outfits to a well-appointed home, ESFP personalities have an eye for fashion. Knowing what's attractive the moment they see it, ESFPs aren't afraid to change their surroundings to reflect their personal style. ESFPs are naturally curious, exploring new designs and styles with ease. Though it may not always seem like it, ESFPs know that it's not all about them – they are observant, and very sensitive to others' emotions. People with this personality type are often the first to help someone talk out a challenging problem, happily providing emotional support and practical advice. However, if the problem is about them, ESFPs are more likely to avoid a conflict altogether than to address it head-on. ESFPs usually love a little drama and passion, but not so much when they are the focus of the criticisms it can bring.

The biggest challenge ESFPs face is that they are often so focused on immediate pleasures that they neglect the duties and responsibilities that make those luxuries possible. Complex analysis, repetitive tasks, and matching statistics to real consequences are not easy activities for ESFPs. They'd rather rely on luck or opportunity, or simply ask for help from their extensive circle of friends. It is important for ESFPs to challenge themselves to keep track of long-term things like their retirement plans or sugar intake – there won't always be someone else around who can help to keep an eye on these things. ESFPs recognize value and quality, which on its own is a fine trait. In combination with their tendency to be poor planners though, this can cause them to live beyond their means, and credit cards are especially dangerous. More focused on leaping at opportunities than in planning out long-term goals, ESFPs may find that their inattentiveness has made some activities unaffordable. There's nothing that makes ESFPs feel quite as unhappy as realizing that they are boxed in by circumstance, unable to join their friends. ESFPs are welcome wherever there's a need for laughter, playfulness, and a volunteer to try something new and fun – and there's no greater joy for ESFP personalities than to bring everyone else along for the ride. ESFPs can chat for hours, sometimes about anything but the topic they meant to talk about, and share their loved ones' emotions through good times and bad. If they can just remember to keep their ducks in a row, they'll always be ready to dive into all the new and exciting things the world has to offer, friends in tow.

ENFP - The Champion

The ENFP personality is a true free spirit. They are often the life of the party, but unlike Explorers, they are less interested in the sheer excitement and pleasure of the moment than they are in enjoying the social and emotional connections they make with others. Charming, independent, energetic and compassionate, the 7% of the population that they comprise can certainly be felt in any crowd. More than just sociable people-pleasers though, ENFPs, like all their Diplomat cousins, are shaped by their Intuitive (N) quality, allowing them to read between the lines with curiosity and energy. They tend to see life as a big, complex puzzle where everything is connected – but unlike Analysts, who tend to see that puzzle as a series of systemic machinations, ENFPs see it through a prism of emotion, compassion and mysticism, and are always looking for a deeper meaning. ENFPs are fiercely independent, and much more than stability and security, they crave creativity and freedom. Many other types are likely to find these qualities irresistible, and if they've found a cause that sparks their imagination, ENFPs will bring an energy that oftentimes thrusts them into the spotlight, held up by their peers as a leader and a guru – but this isn't always where independence-loving ENFPs want to be. Worse still if they find themselves beset by the administrative tasks and routine maintenance that can accompany a leadership position. ENFPs' self-esteem is dependent on their ability to come up with original solutions, and they need to know that they have the freedom to be innovative – they can quickly lose patience or become dejected if they get trapped in a boring role.

Luckily, ENFPs know how to relax, and they are perfectly capable of switching from a passionate, driven idealist in the workplace to that imaginative and enthusiastic free spirit on the dance floor, often with a suddenness that can surprise even their closest friends. Being in the mix also gives them a chance to connect emotionally with others, giving them cherished insight into what motivates their friends and colleagues. They believe that everyone should take the time to recognize and express their feelings, and their empathy and sociability make that a natural conversation topic. The ENFP personality type needs to be careful, however – if they rely too much on their intuition, assume or anticipate too much about a friend's motivations, they can misread the signals and frustrate plans that a more straightforward approach would have made simple. This kind of social stress is the bugbear that keeps harmony-focused Diplomats awake at night. ENFPs are very emotional and sensitive, and when they step on someone's toes, they both feel it. ENFPs will spend a lot of time exploring social relationships, feelings and ideas before they find something that really rings true. But when they finally do find their place in the world, their imagination, empathy and courage are likely to produce incredible results.

ENTP - The Visionary

The ENTP personality type is the ultimate devil's advocate, thriving on the process of shredding arguments and beliefs and letting the ribbons drift in the wind for all to see. Unlike their more determined Judging (J) counterparts, ENTPs don't do this because they are trying to achieve some deeper purpose or strategic goal, but for the simple reason that it's fun. No one loves the process of mental sparring more than ENTPs, as it gives them a chance to exercise their effortlessly quick wit, broad accumulated knowledge base, and capacity for connecting disparate ideas to prove their points. An odd juxtaposition arises with ENTPs, as they are uncompromisingly honest, but will argue tirelessly for something they don't actually believe in, stepping into another's shoes to argue a truth from another perspective. Playing the devil's advocate helps people with the ENTP personality type to not only develop a better sense of others' reasoning, but a better understanding of opposing ideas – since ENTPs are the ones arguing them. This tactic shouldn't be confused with the sort of mutual understanding Diplomats seek – ENTPs, like all Analyst personality types, are on a constant quest for knowledge, and what better way to gain it than to attack and defend an idea, from every angle, from every side? Taking a certain pleasure in being the underdog, ENTPs enjoy the mental exercise found in questioning the prevailing mode of thought, making them irreplaceable in reworking existing systems or shaking things up and pushing them in clever new directions. However, they'll be miserable managing the day-to-day mechanics of actually implementing their suggestions.

ENTP personalities love to brainstorm and think big, but they will avoid getting caught doing the "grunt work" at all costs. ENTPs only make up about three percent of the population, which is just right, as it lets them create original ideas, then step back to let more numerous and fastidious personalities handle the logistics of implementation and maintenance. ENTPs' capacity for debate can be a vexing one – while often appreciated when it's called for, it can fall painfully flat when they step on others' toes by say, openly questioning their boss in a meeting, or picking apart everything their significant other says. This is further complicated by ENTPs' unyielding honesty, as this type doesn't mince words and cares little about being seen as sensitive or compassionate. Likeminded types get along well enough with people with the ENTP personality type, but more sensitive types, and society in general, are often conflict-averse, preferring feelings, comfort, and even white lies over unpleasant truths and hard rationality. This frustrates ENTPs, and they find that their quarrelsome fun burns many bridges, oftentimes inadvertently, as they plough through others' thresholds for having their beliefs questioned and their feelings brushed aside. Treating others as they'd be treated, ENTPs have little tolerance for being coddled, and dislike when people beat around the bush, especially when asking a favour.

ENTP personalities find themselves respected for their vision, confidence, knowledge, and keen sense of humour, but often struggle to utilize these qualities as the basis for deeper friendships and romantic relationships. ENTPs have a longer road than most in harnessing their natural abilities – their intellectual independence and free-form vision are tremendously valuable when they're in charge, or at least have the ear of someone who is, but getting there can take a level of follow-through that ENTPs struggle with. Once they've secured such a position, ENTPs need to remember that for their ideas to come to fruition, they will always depend on others to assemble the pieces – if they've spent more time "winning" arguments than they have building consensus, many ENTPs will find they simply don't have the support necessary to be successful. Playing devil's advocate so well, people with this personality type may find that the most complex and rewarding intellectual challenge is to understand a more sentimental perspective, and to argue consideration and compromise alongside logic and progress.

ESTJ - The Supervisor

ESTJs are representatives of tradition and order, utilizing their understanding of what is right, wrong and socially acceptable to bring families and communities together. Embracing the values of honesty, dedication and dignity, people with the ESTJ personality type are valued for their clear advice and guidance, and they happily lead the way on difficult paths. Taking pride in bringing people together, ESTJs often take on roles as community organizers, working hard to bring everyone together in celebration of cherished local events, or in defence of the traditional values that hold families and communities together. Demand for such leadership is high in democratic societies, and forming no less than 11% of the population, it's no wonder that many of America's presidents have been ESTJs. Strong believers in the rule of law and authority that must be earned, ESTJ personalities lead by example, demonstrating dedication and purposeful honesty, and an utter rejection of laziness and cheating, especially in work. If anyone declares hard, manual work to be an excellent way to build character, it is ESTJs. ESTJs are aware of their surroundings and live in a world of clear, verifiable facts – the surety of their knowledge means that even against heavy resistance, they stick to their principles and push an unclouded vision of what is and is not acceptable. Their opinions aren't just empty talk either, as ESTJs are more than willing to dive into the most challenging projects, improving action plans and sorting details along the way, making even the most complicated tasks seem easy and approachable.

However, ESTJs don't work alone, and they expect their reliability and work ethic to be reciprocated – people with this personality type meet their promises, and if partners or subordinates jeopardize them through incompetence or laziness, or worse still, dishonesty, they do not hesitate to show their wrath. This can earn them a reputation for inflexibility, a trait shared by all Sentinels, but it's not because ESTJs are arbitrarily stubborn, but because they truly believe that these values are what make society work. ESTJs are classic images of the model citizen: they help their neighbours, uphold the law, and try to make sure that everyone participates in the communities and organizations they hold so dear. The main challenge for ESTJs is to recognize that not everyone follows the same path or contributes in the same way. A true leader recognizes the strength of the individual, as well as that of the group, and helps bring those individuals' ideas to the table. That way, ESTJs really do have all the facts, and are able to lead the charge in directions that work for everyone.

ESFJ - The Provider

People who share the ESFJ personality type are, for lack of a better word, popular – which makes sense, given that it is also a very common personality type, making up twelve percent of the population. In high school, ESFJs are the cheerleaders and the quarterbacks, setting the tone, taking the spotlight and leading their teams forward to victory and fame. Later in life, ESFJs continue to enjoy supporting their friends and loved ones, organizing social gatherings and doing their best to make sure everyone is happy.

At their hearts, ESFJ personalities are social creatures, and thrive on staying up to date with what their friends are doing. Discussing scientific theories or debating European politics isn't likely to capture ESFJs' interest for too long. ESFJs are more concerned with fashion and their appearance, their social status and the standings of other people. Practical matters and gossip are their bread and butter, but ESFJs do their best to use their powers for good. ESFJs are altruists, and they take seriously their responsibility to help and to do the right thing.

Unlike their Diplomat relatives however, people with the ESFJ personality type will base their moral compass on established traditions and laws, upholding authority and rules, rather than drawing their morality from philosophy or mysticism. It's important for ESFJs to remember though, that people come from many backgrounds and perspectives, and what may seem right to them isn't always an absolute truth.

ESFJs love to be of service, enjoying any role that allows them to participate in a meaningful way, so long as they know that they are valued and appreciated. This is especially apparent at home, and ESFJs make loyal and devoted partners and parents. ESFJ personalities respect hierarchy, and do their best to position themselves with some authority, at home and at work, which allows them to keep things clear, stable and organized for everyone. Supportive and outgoing, ESFJs can always be spotted at a party – they're the ones finding time to chat and laugh with everyone!

But their devotion goes further than just breezing through because they have to. ESFJs truly enjoy hearing about their friends' relationships and activities, remembering little details and always standing ready to talk things out with warmth and sensitivity. If things aren't going right, or there's tension in the room, ESFJs pick up on it and to try to restore harmony and stability to the group. Being pretty conflict-averse, ESFJs spend a lot of their energy establishing social order, and prefer plans and organized events to open-ended activities or spontaneous get-togethers. People with this personality type put a lot of effort into the activities they've arranged, and it's easy for ESFJs' feelings to be hurt if their ideas are rejected, or if people just aren't interested.

Again, it's important for ESFJs to remember that everyone is coming from a different place, and that disinterest isn't a comment about them or the activity they've organized – it's just not their thing. Coming to terms with their sensitivity is ESFJs' biggest challenge – people are going to disagree and they're going to criticize, and while it hurts, it's just a part of life. The best thing for ESFJs to do is to do what they do best: be a role model, take care of what they have the power to take care of, and enjoy that so many people do appreciate the efforts they make.

ENFJ - The Giver

ENFJs are natural-born leaders, full of passion and charisma. Forming around two percent of the population, they are oftentimes our politicians, our coaches and our teachers, reaching out and inspiring others to achieve and to do good in the world. With a natural confidence that begets influence, ENFJs take a great deal of pride and joy in guiding others to work together to improve themselves and their community. People are drawn to strong personalities, and ENFJs radiate authenticity, concern and altruism, unafraid to stand up and speak when they feel something needs to be said. They find it natural and easy to communicate with others, especially in person, and their Intuitive (N) trait helps people with the ENFJ personality type to reach every mind, be it through facts and logic or raw emotion.

ENFJs easily see people's motivations and seemingly disconnected events, and are able to bring these ideas together and communicate them as a common goal with an eloquence that is nothing short of mesmerizing. The interest ENFJs have in others is genuine, almost to a fault – when they believe in someone, they can become too involved in the other person's problems, place too much trust in them. Luckily, this trust tends to be a self-fulfilling prophecy, as ENFJs' altruism and authenticity inspire those they care about to become better themselves. But if they aren't careful, they can overextend their optimism, sometimes pushing others further than they're ready or willing to go.

ENFJs are vulnerable to another snare as well: they have a tremendous capacity for reflecting on and analysing their own feelings, but if they get too caught up in another person's plight, they can develop a sort of emotional hypochondria, seeing other people's problems in themselves, trying to fix something in themselves that isn't wrong. If they get to a point where they are held back by limitations someone else is experiencing, it can hinder ENFJs' ability to see past the dilemma and be of any help at all. When this happens, it's important for ENFJs to pull back and use that self-reflection to distinguish between what they really feel, and what is a separate issue that needs to be looked at from another perspective.

ENFJs are genuine, caring people who talk the talk and walk the walk, and nothing makes them happier than leading the charge, uniting and motivating their team with infectious enthusiasm. People with the ENFJ personality type are passionate altruists, sometimes even to a fault, and they are unlikely to be afraid to take the slings and arrows while standing up for the people and ideas they believe in. It is no wonder that many famous ENFJs are US Presidents – this personality type wants to lead the way to a brighter future, whether it's by leading a nation to prosperity, or leading their little league softball team to a hard-fought victory.

ENTJ - The Commander

ENTJs are natural-born leaders. People with this personality type embody the gifts of charisma and confidence, and project authority in a way that draws crowds together behind a common goal. But unlike their Feeling (F) counterpart, ENTJs are characterized by an often ruthless level of rationality, using their drive, determination and sharp minds to achieve whatever end they've set for themselves. Perhaps it is best that they make up only three percent of the population, lest they overwhelm the more timid and sensitive personality types that make up much of the rest of the world – but we have ENTJs to thank for many of the businesses and institutions we take for granted every day. If there's anything ENTJs love, it's a good challenge, big or small, and they firmly believe that given enough time and resources, they can achieve any goal.

This quality makes people with the ENTJ personality type brilliant entrepreneurs, and their ability to think strategically and hold a long-term focus while executing each step of their plans with determination and precision makes them powerful business leaders. This determination is often a self-fulfilling prophecy, as ENTJs push their goals through with sheer willpower where others might give up and move on, and their Extraverted (E) nature means they are likely to push everyone else right along with them, achieving spectacular results in the process.

At the negotiating table, be it in a corporate environment or buying a car, ENTJs are dominant, relentless, and unforgiving. This isn't because they are cold-hearted or vicious per se – it's more that ENTJ personalities genuinely enjoy the challenge, the battle of wits, the repartee that comes from this environment, and if the other side can't keep up, that's no reason for ENTJs to fold on their own core tenet of ultimate victory. The underlying thought running through the ENTJ mind might be something like "I don't care if you call me an insensitive b*****d, as long as I remain an efficient b*****d".

If there's anyone ENTJs respect, it's someone who is able to stand up to them intellectually, who is able to act with a precision and quality equal to their own. ENTJ personalities have a particular skill in recognizing the talents of others, and this helps in both their team-building efforts (since no one, no matter how brilliant, can do everything alone), and to keep ENTJs from displaying too much arrogance and condescension. However, they also have a particular skill in calling out others' failures with a chilling degree of insensitivity, and this is where ENTJs really start to run into trouble.

Emotional expression isn't the strong suit of any Analyst type, but because of their Extraverted (E) nature, ENTJs' distance from their emotions is especially public, and felt directly by a much broader swath of people. Especially in a professional environment, ENTJs will simply crush the sensitivities of those they view as inefficient, incompetent or lazy. To people with the ENTJ personality type, emotional displays are displays of weakness, and it's easy to make enemies with this approach – ENTJs will do well to remember that they absolutely depend on having a functioning team, not just to achieve their goals, but for their validation and feedback as well, something ENTJs are, curiously, very sensitive to.

ENTJs are true powerhouses, and they cultivate an image of being larger than life – and often enough they are. They need to remember though, that their stature comes not just from their own actions, but from the actions of the team that props them up, and that it's important to recognize the contributions, talents and needs, especially from an emotional perspective, of their support network. Even if they have to adopt a "fake it 'til you make it" mentality, if ENTJs are able to combine an emotionally healthy focus alongside their many strengths, they will be rewarded with deep, satisfying relationships and all the challenging victories they can handle.

Discussing Feelings

Because children have fears, which can be more intense than those of an adult, they are discussed by the instructor during the Child Survival lecture. The following words are addressed to the students, and elaborated. Talking about FEELINGS, and knowing how to deal with them, is very important. Nobody likes being scared or frightened. Help yourself keep calm by singing, whistling or even telling yourself jokes or stories. Do anything it takes to make yourself feel better. Try using your imagination to pretend you are somewhere else that you really enjoy. You usually do not have to worry about wild animals. They do not like to be near people. If they hear or smell you, they will usually run away. A good rule is 'Answer a Noise with a Noise'. If you hear a noise in the woods, make a noise back. If it is an animal it will run away, if it is a searcher then you will be found. The fear of dark can be easily overcome by memorizing your surroundings during daylight so that you can see with your memory when it gets dark. Nothing changes just because it gets dark. Try practicing in your bedroom. There is no punishment for being lost and yet children have been known to hide or run away from searchers in fear of punishment. Children should not have any fear of returning home. Mum and Dad, or whoever is looking after you are going to be very happy to see you again. There will be NO punishment. There are Friendly strangers who will help you when needed. Some of these are police officers, fire fighters, ambulance personnel and Search and Rescue teams. Generally, these Friendly strangers always work in groups.

Child Survival Kit

During the presentation of this Child Survival lecture, the instructor would show the students each item and how it is made. For instance the reflector is tin foil pasted to cardboard (no sharp edges), and, the right and safe way to tear a face hole in the bright orange garbage bag is demonstrated.

Make an Emergency Survival Kit (and practice using it):
- A Zip Lock sandwich bag for the container (also used as a cup for drinking water)
- A snack of high energy trail mix (contained in its own zip lock bag)
- A whistle used for calling for help (three short blasts)
- A signal flag that can be cut from orange plastic garbage bag
- A reflector for sending signals (use soft, flexible material)
- A large, bright colour garbage bag used as poncho (pre-tear slit for face opening - Do not "cut" hole)

The 9 Rules for Survival

Prepare yourself and your Child	Child survival needs adult assistance. You can help children learn what to do if they get lost in the woods, by discussing and practicing the "Rules for Survival". Nobody ever expects to get lost, but it happens. Hopefully, this information will ensure a safe return of your child should this misfortune ever occur.
Stay Together, do not Separate - if with a friend or pet.	The reason for this rule is body heat. Cuddling up to a large dog or friend will help keep you warm. If with a dog, do not let it run loose, it can help you more by staying close and providing heat and companionship.
Stay in one place or area, do not wander	This is the MOST important rule of them all. If you wander - We Can not Find You. One reason is that people looking for you move very slowly while searching for clues. If you are out front running along, we won't be able to catch up. Another reason for not wandering is the possibility of falling and hurting yourself while travelling. Being lost and hurt could be tragic.
Keep Warm	This rule means to keep warm with the clothes you are wearing. NEVER take any clothes off. Cover up all the exposed skin you can. If you are wearing a sweater or jacket, do it up. Watch out for your shoe laces. Branches have a tricky way of undoing them. The most important part of your clothing is a hat or something that covers your head. Over 70% of all your body heat escapes through your head.
Find a Cosy Waiting Place, Not a Hiding Place.	A cosy waiting place means, a warm place out of the wind and rain but not a place where searchers can not see you. Under a large tree is a good place.
Put Out Something Bright	Put out something bright or make something to tell people searching for you where you are. Make a flag using what you have, but do not take off any clothes to do so. Some suggestions are white paper, money, hair ribbons, a strip from an orange garbage bag, etc. Spell the word "HELP" or "SOS" on the ground using rocks and sticks or make a large arrow with them, pointing to where you are. Do anything to attract attention!
Look Bigger For Searchers	If possible, your waiting place should be near an open space. When you hear someone coming or a helicopter overhead, move to the middle of the clearing and call. Do Not Run in the direction of the noise. If it is an aircraft you heard, lie down so the pilot has a bigger target to look at. Then wave with both your arms and legs, like making an angel in the snow. Stand up immediately after the aircraft has passed, as the ground can be very cold.
Do Not Lie on the Bare Ground	The only exception to this rule is the one above. Laying on the cold ground for a very short period of time, attracting attention, is OK. Being in direct contact with the ground for any length of time is dangerous. The cold ground can rob precious body heat from you. Build a mattress using available materials such as branches, moss, leaves, etc. This mattress should be as thick as the mattress you sleep on at home! After the mattress is completed, gather the same amount or more, of the same material and use it for the blankets. This is called a survival bed.
Do Not Eat Anything you are not sure of	Do Not eat any berries, mushrooms or anything else unless you are 100% sure what they are. Being hungry is not too bad of a feeling compared with being violently sick. And remember, there won't be anyone there to look after you. You can go without food for a long time, but you cannot go without water.
Stay Away from Large Rivers and Lakes	You must have drinking water to survive, but be careful where you get it from. Do Not go near any large bodies of water. Instead, drink from a water supply that is smaller than you are, so you can not fall in. Another source of water can be found on leaves in the form of dew.

5 Global Firepower

This is an estimation of a countries military power and other details about the military. The statistics may be out dated numerically however the general order of superpowers will typically remain the same. This section is aimed at giving you an estimate at each countries military power if a war does break out. If certain countries join forces you can combine the military power and do basic checks to estimate who will win the conflict. This will only be correct however if a country doesn't have a game-changing weapon like the nuclear bomb was in 1945. The information of each country has been compressed to fit into 11 rows total. Countries are listed by power index - The strongest to the weakest.

6 Prepper Circle

A prepper circle is a small band of people (typically 1-7) whom you prep and practice with, share tips, resources and bug-out with if the time comes. They are trusted completely. Try to limit your prepper circle to 2-8 people or it may become overwhelming to deal with and control them. The smaller the less rebellion there could be during SHTF.

You (1 Person)	The only person you can absolutely trust and share your darkest secrets with.	Can trust this person
Spouse (1 person)	The second most important person in your life, you can typically put your life in their hands. It's best to share prepping with this person if you're married.	Can trust this person
Immediate Family (1-6 people)	The family that raised you from birth including parents and siblings. You can share prepping with them if you believe they will be of benefit to you.	Can usually trust these people
Closest Friends (1-4 people)	These people could be much more like-minded than family members and support your prepping completely.	Can usually trust these people
Extended Family	Grandparents, Aunts, Uncles and Cousins. It's strongly advised against telling these people you are prepared unless they also prep. A few could be included in your circle if needed.	Can sometimes be trusted
Skilled Individuals (1-5 people)	People who aren't your friends yet but live nearby and have useful skills such as welding, farming, hunting, law enforcement and more.	Rarely to be trusted
Neighbours (2-8 people)	These people are outsiders who you may or may not have met which could be beneficial during SHTF to help protect your street from looters if bugging in.	Not to be trusted
Citizens	Everybody else not covered. These people can't be trusted at all and you must be wary around them, they may try to loot or kill you - never have them in your circle.	Not to be trusted

Other People

Blue Collar Workers	A working class person who performs manual labour. Blue-collar work may involve skilled or unskilled manufacturing, mining, sanitation, custodial work, textile manufacturing, commercial fishing, food processing, oil field work, waste disposal, and recycling, construction, mechanic, maintenance, warehousing, technical installation, and many other types of physical work. Blue-collar work often involves something being physically built or maintained.
White Collar Workers	A white-collar worker is a person who performs professional, managerial, or administrative work. White-collar work may be performed in an office or other administrative setting.
Pink Collar Workers	In the United States and (at least some) other English-speaking countries, a pink-collar worker refers to someone working in the care-oriented career field or in jobs historically considered to be "women's work." This may include jobs in nursing, teaching, secretarial work, waitressing, or child care.
Green Collar Workers	A green-collar worker is a worker who is employed in the environmental sectors of the economy. Environmental green-collar workers (or green jobs) satisfy the demand for green development. Generally, they implement environmentally conscious design, policy, and technology to improve conservation and sustainability.
Grey Collar Workers	Grey-collar refers to the balance of employed people not classified as white- or blue collar. It is used to refer to occupations that incorporate some of the elements of both blue- and white-collar, and generally are in between the two categories in terms of income-earning capability. Grey-collar workers often have licenses, associate degrees or diplomas from a trade or technical school in a particular field. They are unlike blue-collar workers in that blue-collar workers can often be trained on the job within several weeks whereas grey-collar workers already have a specific skill set and require more specialized knowledge than their blue-collar counterparts.

Law Enforcement	
Hobos	
Mobs/Gangs	

7 Gangs

These are the types of gangs that operate around the world and their goals.

Drug Cartel	A drug cartel is any criminal organization with the intention of supplying drug trafficking operations. They range from loosely managed agreements among various drug traffickers to formalized commercial enterprises.
Organized Crime	Organized crime is a category of transnational, national, or local groupings of highly centralized enterprises run by criminals who intend to engage in illegal activity, most commonly for money and profit.
Outlaw Motorcycle Club	An outlaw motorcycle club is a motorcycle subculture that has its roots in the immediate post-World War II era of American society. It is generally cantered on the use of cruiser motorcycles, particularly Harley-Davidsons and choppers, and a set of ideals that celebrate freedom, nonconformity to mainstream culture, and loyalty to the biker group.
Prison Gang	A prison gang is an inmate organization that operates within a prison system. It has a corporate entity and exists into perpetuity. Its membership is restrictive, mutually exclusive, and often requires a lifetime commitment. Prison officials and others in law enforcement use the euphemism "security threat group" (or "STG").
American Mafia	The American Mafia (commonly referred to as the Mafia or the Mob) or Italian-American Mafia, is the highly organized Italian-American criminal society. The organization is often referred to by members as Cosa Nostra and by the government as La Cosa Nostra (LCN).
Mexican Mafia	The Mexican Mafia (Spanish: Mafia Mexicana), also known as La Eme (Spanish for "the M"), is a highly organized Mexican American criminal organization in the United States. Despite its name, the Mexican Mafia did not originate in Mexico, and is entirely a U.S. criminal prison organization. Sureño gangs use the number 13 to show allegiance to the Mexican Mafia, as M is the 13th letter of the alphabet.
Russian Mafia	Russian organized crime or Russian mafia, sometimes referred to as Bratva (Russian: братва: "brotherhood"), is a collective of various organized crime elements originating in the former Soviet Union. The acronym OPG is Organized Criminal Group, used to refer to any of the Russian mafia groups, sometimes modified with a specific name, e.g. Orekhovskaya OPG. Sometimes the acronym is translated and OCG is used.
Sicilian Mafia	The Sicilian Mafia, also known as simply the Mafia and frequently referred to by members as Cosa Nostra, is a Mafia-terrorist-type organized crime syndicate based in Sicily, Italy. It is a loose association of criminal groups that share a common organisational structure and code of conduct. The basic group is known as a "family", "clan", or "cosca". Each family claims sovereignty over a territory, usually a town or village or a neighbourhood (borgata) of a larger city, in which it operates its rackets.

Gangs Per Country

This is a list of gangs operating in each country.

America	• 14K Triad • 38th Street gang • Abergil crime family • Albanian mafia • Almighty Black P. Stone Nation • Almighty Vice Lord Nation • Armenian Power • Bandidos Motorcycle Club • Barker–Karpis gang • Black Disciples • Black Dragons • Bloods • The Breed Motorcycle Club • Chaldean Mafia • Chicago Gaylords	• Crips • Diablos Motorcycle Club • Dominicans Don't Play • Dotbusters • El Forastero Motorcycle Club • Four Corner Hustlers • Free Souls Motorcycle Club • Freight Train Riders of America • Friends Stand United • Galloping Goose Motorcycle Club • Fullerton Boys • Grim Reapers Motorcycle Club (USA) • Gypsy Joker Motorcycle Club • Hammerskins • Hells Angels	• Hidden Valley Kings • Highwaymen Motorcycle Club • Iron Horsemen • La Raza Nation • Latin Eagles • Latin Kings • Los Solidos • Mickey Cobras • Ñetas • Nine Trey Gangsters • Norteños • Outlaws Motorcycle Club • OVS • Pagan's Motorcycle Club • Playboys (gang)	• Sex Money Murda • Silver Dollar Group • Simon City Royals • Sons of Silence • Spanish Gangster Disciples • The Stopwatch Gang • Sureños • TAP Boyz • The Dillinger Gang • Tiny Rascal Gang • Vagos Motorcycle Club • Vatos Locos • Wah Ching
Albania	• Albanian Mafia • Gang of Çole • Gang of Gaxhai • Gang of Pusi i Mezinit			
Argentina	• Ashkenazum • Pincheira Brothers • Puccio Family • Zwi Migdal			
Australia	• Bandidos • Coffin Cheaters • Comanchero • DLASTHR	• Finks • Black Bandits • Gypsy Joker • Hells Angels	• Nomads • Notorious • Rebels	
Belgium	• Albanian Mafia • Bandidos Motorcycle Club • Blue Angels Motorcycle Club	• Brabant Killers • Hells Angels • Outlaws Motorcycle Club	• Scarface gang • Sun Yee On • Turkish mafia	
Brazil	• Amigos dos Amigos • Cangaço • Comando Vermelho	• Hells Angels • Pacifying Police Unit • Primeiro Comando da Capital	• Sun Yee On • Terceiro Comando • Terceiro Comando Puro	

Canada	• 14K Triad • 18th Street gang • 856 gang • Aboriginal-based organized crime (Canada) • Albanian mafia • Almighty Vice Lord Nation • Bandidos Motorcycle Club • Crips	• Dixon Bloods • Flying Dragons (gang) • Grim Reapers Motorcycle • Club (Canada) • Hammerskins • Hells Angels • Indo-Canadian organized crime • Latin Kings (gang)	• Lynx gang • Manitoba Warriors - 1323 • Mara (gang) • Markham Gang • Mickey Cobras • Mongols Motorcycle Club • MS-13 • Outlaws Motorcycle Club

Denmark	• AK81 • Albanian Mafia • Bandidos Motorcycle Club	• Black Cobra (gang) • Hells Angels • Serb mafia in Scandinavia		
France	• Corsican Mafia • The Affair of the Gang of Barbarians • Albanian mafia • Apaches (subculture) • Bandidos Motorcycle Club • Bonnot Gang • Cape Verdean organized crime	• Corsican mafia • Gang de la Brise de Mer • Gang des postiches • Gang des Tractions Avant • Hammerskins • Hells Angels • Hornec gang	• 2015 Marseille shooting • Outlaws Motorcycle Club • Scarface gang • Sun Yee On • Turkish mafia • Unione Corse	
India	• Chaddi Baniyan gang • D-Company • Kala Kaccha gang • Thuggee			
Italy	• Banda della Magliana • Mongols Motorcycle Club • Albanian mafia	• Bandidos Motorcycle Club • Hammerskins • Hells Angels	• Mongols Motorcycle Club • Outlaws Motorcycle Club • Rebels Motorcycle Club	
Kenya	• Mungiki • Sabaot Land Defence Force			
Mexico	• Juárez Cartel • Mongols Motorcycle Club • Sinaloa Cartel	• Tijuana Cartel • Beltrán-Leyva Cartel • Gulf Cartel	• Los Ántrax • Los Negros • Sonora Cartel	
Netherlands	• Ah Kong • Bandidos Motorcycle Club • Black Jackets • Cape Verdean organized crime • Hammerskins	• Hells Angels • Hopi Boys • Lanzas Chilenos • No Limit Soldiers (organized crime group) • Penose	• Rebels Motorcycle Club • Satudarah • Scarface Gang • Sun Yee On	
New Zealand	• 14K Triad • Black Power (New Zealand gang) • Fourth Reich (New Zealand gang) • Gang Patch • Hammerskins • Head Hunters MC	• Hells Angels • Highway 61 Motorcycle Club • Killer Beez (gang) • King Cobras (gang) • Lone Legion Brotherhood • Lost Breed	• Mongrel Mob • New Zealand Nomads • Rebels Motorcycle Club • Road Knights • Tongan Crip Gang • Tribesmen Motorcycle Club	
Nigeria	• Area Boys • Bakassi Boys • One Million Boys			
Norway	• Bandidos Motorcycle Club • Gypsy Joker Motorcycle Club • Hells Angels • Original Gangsters (gang) • Outlaws Motorcycle Club			
Pakistan	• Chotu gang • D-Company			
Russia	• A.U.E. • GTA gang • Kazan Phenomenon • Russian Mafia • Sun Yee On • Thief in law			
South Africa	• Foster gang • Hard Livings • Khumalo gang • The Numbers Gang • Sun Yee On • The Americans			
Spain	• Albanian Mafia • Blue Angels Motorcycle Club • Galician Mafia • Garduña • Hammerskins • Hells Angels • Latin Kings (gang) • Rebels Motorcycle Club			
Sri Lanka	• Aava Gang			

Sweden	• Albanian Mafia • Bandidos Motorcycle Club • Black Cobra (gang) • Brödraskapet • Fu**ed For Life • Hammerskins	• Hells Angels • Naserligan • Original Gangsters (gang) • Outlaws Motorcycle Club Sala gang • Serb Mafia in Scandinavia		
United Kingdom	• Bandidos Motorcycle Club • Blue Angels Motorcycle Club • British Firms (organised crime) • Hells Angels • Outlaws Motorcycle Club			

Gang Details

Bloods

Originally from Los Angeles, the Bloods are one of the largest associations of street gangs in the United States. These extremely violent and aggressive street gangs, referred to as sets, have adopted a common gang philosophy. Members use violence to protect and expand their drug distribution. The sets share a comprehensive philosophy, expressed in an oath, a prayer, a song, a motto, a concept of war, and 31 common rules including an Initiation, where a new member must withstand 31 seconds of beating or sexual relations.

Identifiers
- Colours red, black, brown and pink
- B's up, C's Down
- MOB = Member of Bloods
- Dog paws made up of three dots
- CK Crip Killa
- 031 / 021
- Red, black, brown or pink bandanas and wave caps

Phrases
- Blatt Blatt
- Greetings: "What dat red be like?"
- Referred to each other as dogs
- DAMU = Brother/Blood
- DAMUETTE = Sister Bloodettes Ruby Red
- Blood Love
- What's popping?

Crips

Originally from Los Angeles, the Crips are an organization of aggressive and brutal gang members who are heavily involved in the drug trade. Throughout the 1980's and 1990's the Crips developed intricate networks and a respected reputation with other gangs across America. Crip gangs are well established across the United States.

Identifiers
- Colours blue, gray, orange and purple
- 6 Pointed Star of David
- C's up, B's down
- Blue, gray, orange or purple bandanas or wave caps
- Crip Walks
- B's crossed out

Phrases
- BK Blood Killa
- Loc (Love only crips)
- C-Ya
- Slobs (Derogatory Bloods)
- C's Up Cuzz
- What's Crackalacking?
- Refer each other as cousins

Latin Kings

Originally from Chicago, the Latin Kings are extremely violent and a well organized gang. The gang is active in New York, New Jersey and Pennsylvania. Its main source of income is from the distribution of drugs and robbery.

Identifiers
- Colours black and gold
- 3 or 5 pointed crowns
- Eyebrows cut to form five points
- Pittsburgh sports team apparel
- Yellow and black bandanas, beads or wave caps

Phrases
- Kingism
- Pee Wee King (for those under18)
- ADR Amor de rey (Love of the king)
- 360° whole, complete and unbreakable

Ñeta

Ñeta originated in the prisons of Puerto Rico and is an extremely violent gang. The group was formed to address prisoners' rights issues in the Puerto Rican prison system. In the United States, Ñeta chapters exist inside and outside of prison.

Identifiers
- The colours black, red, white and blue
- The term 150%
- Tattoo with the numbers 1.50
- Depicting shackles and handcuffs
- Beads
- Bandanas

Phrases
- DeCorazon
- Primos
- Insectos

Ms 13

Originating in Los Angeles, MS 13 is one of the most violent street gangs in the United States. Members smuggle and distribute illicit drugs and are extremely violent.

Identifiers
- Heavily tattooed
- Typical Latin gang tattoos
- "Heavy Metal" tattoos
- Blue and black bandanas

Phrases
- "La Mara" stands for Gangs
- "Salva" stands for Salvadorian
- "Trucha" stands for "look out"
- EME ESE stands for MS
- Locotes
- Cliques

POPULATION | SHTF Population

A section which will outline the types of people that could be found during an extended disaster. They are categorised into Good, Neutral and Evil types although some may be some classified in between groups.

People Categories
- Individuals
- Families
- Groups
- Village/Town

Good

Good people typically spend their time helping those around them. They refrain from stealing, killing and may give items away to those in need.

Virtuous Individual	Individuals who go around helping the needy and lending a hand to those who need it.
Virtuous Families	
Religious Groups	Those of religious faith will stick to their convictions and try to help those in need giving selflessly. They base their goodness in the knowledge that it is rewarded in heaven later. Churches will attempt to do what they can to help people in need including purifying water and giving away food.
Democratic Town	A village of like minded people who work together to farm the land and let people take refuge within their walls.

Neutral

Neutral people typically keep to themselves and don't give or take items. They follow the majority of the population and try to keep on living.

General Population	
Desperate People	These people are at a junction where they are at the point they could do anything to get what they need, but they aren't bad people. Even normal people will be so desperate for food and water that they can become criminals.

Evil

Evil people take what they want for themselves from anyone and everyone. They focus inwardly and only care to fill their current desires for themselves or for their group.

Gangs	Gangs and organized crime will be prevalent due to the desperation of common folk seeking food, water and safety.
Solo Criminals	Solo criminals work alone and do what they want to acquire what they need. Being solo they are likely to travel and steal in the cover of night.
Criminals	Criminals are classified as people who are currently acting out a criminal life. Acts may include stealing, murder, rape, destruction and terrorism. Their personality will be quick to anger, itchy trigger fingers and come across as abrasive and hateful.

9 SHTF Individual

10 SHTF Families

11 SHTF Groups

12 SHTF Towns

Here you will find information about the different types of towns in a SHTF world. Democratic towns, dictatorship towns, slave towns etc. It also contains information about setting up your own town and

Democratic Towns

Towns that use democracy and a system of voting to elect a leader.

Dictator Towns

Towns that have one primary leader who is typically the founder and cannot be changed. The word dictator typically has negative connotations as an evil ruler, but they could also be a fair and just ruler.

Slave Towns

Slave towns run on the backs of slaves who are forced to work.

Leadership

How to lead your family, small group or town post-disaster

"Leadership is your ability to hide your panic from others."
Lao Tzu

Introduction

This section focuses on how to lead different types of groups and the considerations that must be made. It dives into how you can establish a functioning town with individual jobs, roles and responsibilities.

Purpose	The aim of LEADERSHIP is to help people become strong, decisive, accountable and honest leaders who can make the tough decisions while leading their family, group or an entire town through times of disaster.
Lost?	● For information on communicating with others efficiently, see the COMMUNICATION section. ● For information on hiding from others if you're solo, see the SECURITY section. ● For a description of the different laws around the world, see the GEOGRAPHY section. ● For communication between people of other languages, see the LANGUAGE section. ● For tips and information on bugging-out when you're leading a group, see the PREPAREDNESS section. ● For preparedness skills you can learn, see the SKILLS section.

Contents

1 Self Leadership

Being comfortable with yourself and being able to set goals and work towards them is the first step in becoming a great leader. The more you can trust your skills, equipment and others, the more you can flourish in a SHTF environment.

2 Family Leadership

Family leadership is a tough form of leadership because they are still likely to see you the same way they have their whole lives. This may be a position of superiority to you, for example if you are the youngest child and they still only see you as that even if you're 40.

3 Group Leadership

4 Town Leadership

Leading an entire town may seem like a daunting task but when broken into smaller tasks it's much more achievable. The section below does just that, breaking everything down into easy to follow steps. A functioning town is much stronger than a collection of the same number of people each trying to survive on their own.

Subheadings

1. Starting Resources	2. Bounds	3. Law	4. Discipline
5. Roles & Responsibilities	6. Leading	7. Trade	

1 Starting Resources

First check if you have the resources to plant a town.

Minimum Population	Around 25+ people should be a sufficient number to start a town. You will need enough people to do all the word that is required to maintain it.
Minimum Buildings	Between 3-5 buildings should be enough to start off your town. They should be located adjacent to each other and have a road down the middle or around the outside.
Minimum Resources	Before starting a town you should have a few basic resources to ensure you can complete the journey to a successful town. 1. Enough able-bodied people to construct barriers and set up defences. 2. Skills, Knowledge and eBooks about farming, raising animals, security, etc. Or this spreadsheet. 3. Enough people to cover all the required fields and establish a 24/7 defence watch. 4. Enough food for the town's population for at least a month. 5. Enough clean water or a water source that is easily obtained to sustain people for a month. This includes washing and bathing water. 6. Guns, ammo and defensive equipment. 7. A form of contact between houses.

Goals

Setting goals for the town is essential in getting everything set up and running correctly and gives you objectives to work towards. Take a note whether they are short, mid or long term goals.

Recurring Goals
You can have goals that reoccur every so often

Importance	**Low Importance** Can be done when nothing else needs doing.	**Medium Importance** Should be completed when possible.	**High Importance** Should be done reasonably quickly.	**Critical Importance** Complete ASAP.	
Timeframe	**Short Term Goal** Should be completable within 1-3 weeks.	**Mid Term Goal** Should be completable within 1-6 months.	**Long Term Goal** Should be completable within a year or more.		
Examples	**Example Goal** Train everyone in first aid. **(High Importance)** **(Mid Term Goal)**	**Example Goal** Set up a tall barricade system around the town. **(Critical Importance)** **(Mid Term Goal)**	**Example Goal** Add security methods around the perimeter such as jingling bells and dogs in every house. **(Critical Importance)** **(Short Term Goal)**	**Example Goal** Have a population of 500. **(Low Importance)** **(Long Term)**	

Winning People
You may have to win a lot of people over to your cause before they want to join willingly. This may involve having to sacrifice resources to do so. Ultimately you want and need people to join your cause to form a stronger town, but once you're established you can be more selective.

2 Bounds

The first thing to work out is the boundary of the town and what land you consider to be yours. Be sure to research and not settle on land which is already owned to avoid conflict.

Boundary Marking	Have a way to mark the established boundaries of your land so others know not to trespass.
Fortification	Fortification of the town to allow control of who enters and leaves would be recommended to vet everyone residing within your town and those passing through. Outer boundaries could also be fortified with a fence or make use of natural barriers such as the coast, fallen trees and cliffs.

3 Law

Laws keep society held together in a package which everyone can understand. If someone isn't following the laws they either need to be disciplined or kicked out from the town. Below are some example laws which you can base your town's laws on.

LEADERSHIP | Town Leadership | Law

Citizenship	Some people may want to join your town over time and become citizens. Generally this is fine except you have to make sure they fit the prerequisites first. In fact when looking at it closely it's more of a trade. You give them safety, security, food and water in exchange for work, knowledge and sometimes resources to help sustain the village. Potential citizens should meet a few minimum number of requirements first and be on a probationary period to see how they fit into the environment. (See the prerequisites in the row below then return here) Once they have passed your minimum checks they should select their occupation based on current openings. Show them their residence and where they can store their possessions. Assign someone to give them a tour and to keep track of them and how they are faring in this new environment. After your assigned probation period is up, you should review their case and either grant full citizenship or kick them out.
Citizenship Prerequisites	**Inspection:** They should be checked for weapons, listening devices and other items that risk the safety of those inside. **Reason:** Listen to their reason for wanting to join. **Observe:** Take note of the condition they are in and how desperate they might be. **Skills:** Take a note of what skills they possess and their job before SHTF. **Interaction:** How they interact with the town and get along with the population is important to decide whether they will be a good fit. **Deception:** Appearances can be deceiving so be careful you're not letting a spy in.
Citizens	Citizens should be granted additional rights over those on probation to instil loyalty. Have a scale of trust for people living in your town, where they can earn more over time and have additional responsibility, currency or power.
Identification	People of your town should have some form of identification so you and guards etc can tell who's not supposed to be here. It will also assist in those returning from scavenging missions to gain entry easier.
Weapons	The following are potential rules for weapons you could set. Are weapons allowed to be visibly carried in the town by all citizens?
Curfew	A mandatory curfew can help protect your town at night. If everyone's safe in their homes the town guards can be more certain anyone they see is an intruder.
Leaving Permanently	Some people may way to leave permanently for different reasons, you shouldn't try to stop them however you should at least know why.

4 Discipline

LEADERSHIP | Town Leadership | Discipline

People in your town are bound to break the rules set up by yourself and the other leaders so you need a form of punishment to help deter this behaviour in the future.

Aims of Discipline
People are punished for a purpose. Often the aims of a punishment overlap, eg the death penalty aims to protect the public from the individual who has committed a specific crime whilst deterring others from committing similar acts. There are six recognised aims of punishment:
● Deterrence - punishment should put people off committing crime
● Protection - punishment should protect society from the criminal and the criminal from themselves
● Reformation - punishment should reform the criminal
● Retribution - punishment should make the criminal pay for what they have done wrong
● Reparation - punishment should compensate the victim(s) of a crime
● Vindication - the punishment makes sure that the law is respected

Crimes

LEADERSHIP | Town Leadership | Discipline | Crimes

This is a list of common crimes which currently occur today. Some of them won't apply in a SHTF situation but are included anyway in case society hasn't collapsed and you want to look them up.

Aggravated Assault	Aggravated assault is an assault which criminal laws punish more severely due to its seriousness. Factors which raise an assault to the aggravated level typically include the use of a weapon, the status of the victim, the intent of the perpetrator, and the degree of injury caused. Assaults that happen in the victim's home can also qualify as an aggravated assault. States classify certain assaults as aggravated under their criminal codes. They may also use more specific names such as assault with a deadly weapon. Often, aggravated assaults qualify as felonies, while simple assaults can be misdemeanors. Many states have multiple degrees of criminal charges for aggravated assault.
Aiding and Abetting / Accessory	A criminal charge of "aiding and abetting" or accessory can usually be brought against anyone who helps in the commission of a crime, though legal distinctions vary by state. A person charged with these accomplice crimes is usually not present when the crime itself is committed, but he or she has knowledge of the crime before or after the fact, and may assist in its commission through advice, actions, or financial support. Andy draws a floor plan of a bank, knowing of Dan's intention to rob it. After Dan commits the robbery, Alice agrees to let him store the stolen money at her house. Both Andy and Alice can be charged with aiding and abetting, or acting as accessories to the robbery.
Arson	Arson is defined as the wilful and malicious burning or charring of property. There are many types of arson crimes, including setting fire to one's property with fraudulent intent--like when someone burns their house to collect insurance money. While the majority of arson crimes involve damage to buildings, arson can also be committed by a person who sets fire to forest land or a boat. Arson statutes typically classify arson as a felony due to the potential to cause injuries or death. In its most basic sense a person commits arson when they knowingly, by means of a fire or explosive: ● Damage any real or personal property of another without their consent; or ● Damage any real or personal property with intent to defraud an insurer.
Assault / Battery	In most states, an assault/battery is committed when one person: 1) tries to or does physically strike another, or 2) acts in a threatening manner to put another in fear of immediate harm. In short, an assault is an attempt or threat to injure another person, while battery is the act of making contact with another person in a harmful or offensive manner. Below is a more in-depth look at both offenses and their elements, which helps explain how these two offenses are so closely tied together.

LEADERSHIP	Town Leadership	Discipline	Crimes	**Attempt**	The definitions for criminal attempt -- in which the defendant ultimately fails to pull off the crime -- vary from state to state. But generally, attempted offenses occur when an individual has an actual intent to commit a crime (in legal terms, specific intent), and takes direct action toward completion of the crime. Once a crime is completed, then those charges would apply and the attempt would not be charged. Not all crimes can be "attempted," legally speaking, only those with specific intent. Specific intent refers to the state of mind in which an individual plans to commit a certain crime, knowing what the outcome may be. For instance, attempted battery is not a criminal charge because the crime of battery doesn't require a premeditated intent to cause harm. But someone who threatens bodily harm may be charged with assault.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Bribery**	Bribery is the offer or acceptance of anything of value in exchange for influence on a government/public official or employee. In general, bribes can take the form of gifts or payments of money in exchange for favourable treatment, such as awards of government contracts. Other forms of bribes may include property, various goods, privileges, services and favours. Bribes are always intended to influence or alter the action of various individuals and go hand in hand with both political and public corruption. No written agreement is necessary to prove this crime, but a prosecutor generally must show corrupt intent. In most situations, both the person offering the bribe and the person accepting can be charged.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Burglary**	Burglary is typically defined as the unlawful entry into almost any structure (not just a home or business) with the intent to commit any crime inside (not just theft/larceny). No physical breaking and entering is required; the offender may simply trespass through an open door. Unlike robbery, which involves use of force or fear to obtain another person's property, there is usually no victim present during a burglary. For example, Dan enters Victor's boathouse through an open window, intending to steal Victor's boat. Finding the boat is gone, Dan returns home. Though he took nothing, Dan has committed burglary.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Child Abandonment**	Child abandonment occurs when a parent, guardian, or person in charge of a child either deserts a child without any regard for the child's physical health, safety or welfare and with the intention of wholly abandoning the child, or in some instances, fails to provide necessary care for a child living under their roof. While abandoning a child typically involves physical abandonment -- such as leaving a child at a stranger's doorstep when no one is home -- it may also include extreme cases of emotional abandonment -- such as when a "work-a-holic" parent offers little or no physical contact or emotional support over long periods of time.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Child Abuse**	Child abuse is broadly defined as any type of cruelty inflicted upon a child, including physical or emotional harm, endangerment, abandonment, neglect or sexual abuse. Severe punishments exist for offenders. Child services agencies also investigate reports of maltreatment and can remove children from unsafe or unhealthy environments. This combination of criminal prohibitions and protective services forms the basis of child abuse laws, which vary somewhat from state to state. One major hurdle to stopping child abuse is the difficulty of uncovering it. That's why states have also enacted mandatory reporting requirements for certain professions. These laws apply primarily to people who have regular contact with children or who are most likely to discover abuse or neglect -- such as teachers, doctors, nurses and social workers.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Child Pornography**	Federal and state laws make it a crime to produce, distribute, or even just possess pornographic materials that portray a minor (someone under the age of 18). Increasingly, child pornography laws are being relied on to punish individuals who use the internet to share or obtain pornographic images and videos involving children. A violation of federal child pornography laws is a serious crime and the penalties are harsh. First-time offenders found guilty of producing child pornography are sentenced to between 15 and 30 years in prison. Individuals caught with child pornography on their personal computers receive prison time. Offenders may be prosecuted under federal or state law (or both).
LEADERSHIP	Town Leadership	Discipline	Crimes	**Computer Crime**	Computer crime describes a very broad category of offenses. Some of them are the same as non-computer offenses, such as larceny or fraud, except that a computer or the Internet is used in the commission of the crime. Others, like hacking, are uniquely related to computers. Read on to find out what kinds of activities are considered computer crimes and how to protect yourself from them. Computer crime laws in many states prohibit a person from performing certain acts without authorization, including: ● Improperly accessing a computer, system, or network; ● Modifying, damaging, using, disclosing, copying, or taking programs or data; ● Introducing a virus or other contaminant into a computer system; ● Using a computer in a scheme to defraud; ● Interfering with someone else's computer access or use; ● Using encryption in aid of a crime; ● Falsifying email source information; and ● Stealing an information service from a provider.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Conspiracy**	A criminal conspiracy exists when two or more people agree to commit almost any unlawful act, then take some action toward its completion. The action taken need not itself be a crime, but it must indicate that those involved in the conspiracy knew of the plan and intended to break the law. A person may be convicted of conspiracy even if the actual crime was never committed. For example, Jason, Alice and Hank plan a bank robbery. They 1) visit the bank first to assess its security, and 2) pool their money and buy a gun. All three can be charged with conspiracy to commit robbery, regardless of whether the robbery itself is ever attempted or completed.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Credit / Debit Card Fraud**	Credit and debit card fraud is a form of identity theft that involves an unauthorized taking of another's credit card information for the purpose of charging purchases to the account or removing funds from it. This theft can occur physically when the actual credit and debit card is taken, or the theft can occur when just the numbers are stolen from an unprotected website or a card reader at a gas station. Debit/credit card fraud can be committed in a variety of ways, such as when a person: 1. Fraudulently obtains, takes, signs, uses, sells, buys, or forges someone else's credit or debit card or card information; 2. Uses his or her own card with the knowledge that it is revoked or expired or that the account lacks enough money to pay for the items charged; or 3. Sells goods or services to someone else with knowledge that the credit or debit card being used was illegally obtained or is being used without authorization.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Criminal Contempt of Court**	Contempt of court generally refers to conduct that defies, disrespects, or insults the authority or dignity of a court. Often, contempt takes the form of actions that are seen as detrimental to the court's ability to administer justice. Judges typically have much discretion in deciding whom to hold in contempt and the type of contempt. Those held in contempt can include parties to a proceeding, attorneys, witnesses, jurors, people in or around a proceeding, and officers or staff of the court itself. There are two types of contempt of court: criminal contempt of court and civil contempt.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Cyberbullying**	The term "cyberbullying" refers to the use of Internet and/or mobile technology to harass, intimidate, or cause harm to another. Although bullying is hardly a new problem, it has moved from the schoolyard to social networking sites such as Facebook, emails, and mobile text messages. Nearly all states have bullying laws in place, many with cyberbullying or electronic harassment provisions. Despite the absence of physical contact or audible insults, cyberbullying can be even more traumatizing than traditional forms of bullying. Through social media and mobile communications, bullying can now potentially be viewed by all of a child's friends, family, and acquaintances. As a result, the embarrassment, shame, and other more severe consequences of bullying can become even more severe.

LEADERSHIP | Town Leadership | Discipline | Crimes

Disorderly Conduct	Almost every state has a disorderly conduct law making it a crime to be drunk in public, "disturb the peace," or loiter in certain areas. Since the statutes are often used as "catch-all" crimes, many types of obnoxious or unruly conduct may fit the definition. Generally speaking, police often use a disorderly conduct charge to keep the peace when a person is behaving in a disruptive manner, but presents no serious public danger. The definition of disorderly conduct can vary from state to state. In New York, for instance, disorderly conduct requires the intent to cause public inconvenience, annoyance or alarm, or to recklessly create such a risk. Examples of such conduct include making unreasonable noise, obstructing traffic, and using obscene or abusive language in public.
Disturbing the Peace	Disturbing the peace, also known as breach of the peace, is a criminal offense that occurs when a person engages in some form of unruly public behaviour, such as fighting or causing excessively loud noise. When a person's words or conduct jeopardizes another person's right to peace and tranquillity, he or she may be charged with disturbing the peace. Laws exist that make it a crime to create a public disruption or commotion. These laws vary from state to state, but they typically prohibit: ● Fighting or challenging someone to fight in a public place; ● Using offensive words in a public place likely to incite violence; ● Shouting in a public place intending to incite violence or unlawful activity; ● Bullying a student on or near school grounds; ● Knocking loudly on hotel doors of sleeping guests with the purpose of annoying them; ● Holding an unlawful public assembly;
Domestic Violence	Domestic violence refers to violent acts committed by a family or household member against another, such as child abuse or the mistreatment of one's spouse. Domestic violence can refer to physical harm inflicted on a member of a household or family, by another member of the same household or family. The catch-all term domestic violence can generally apply to any partners -- married or unmarried, straight or gay, living together or simply dating. Domestic violence (sometimes called "spousal abuse") usually involves repetitive physical and psychological abuse, and a "cycle of violence". Specific crimes charged vary based on 1) severity of the victim's injuries, 2) whether a minor was present, and 3) whether a protective or restraining order was violated.
Drug Manufacturing and Cultivation	Cultivating or manufacturing illegal drugs, such as methamphetamine or marijuana, is illegal under federal and state laws (with limited exceptions for marijuana in certain states). Drug "manufacturing," in a criminal law setting, occurs when an individual is involved in any step of the illicit drug production process. Those who sell certain precursor chemicals, specialized equipment, or simply offer to help produce drugs also may be charged with the crime. The production of drugs typically is charged as a felony, with sentences including prison time, steep fines, and probation. Prison sentences and fines may be doubled for those convicted of manufacturing illegal drugs near schools and playgrounds.
Drug Possession	Federal and state drug possession laws make it a crime to wilfully possess illegal controlled substances such as marijuana, methamphetamine, cocaine, LSD, "club drugs," and heroin. These laws also criminalize the possession of "precursor" chemicals used in drug cultivation and manufacturing, as well as certain accessories related to drug use. However, what constitutes drug possession can vary according to the type of drug, the amount, and the geographic area where the offense took place. Possession of certain illicit drugs can violate both federal and state laws. While drug possession laws vary widely from state to state, the elements of the offense are generally the same, as prosecutors must be able to prove, beyond a reasonable doubt, that the defendant: ● Knew the drug in question was a controlled substance; and ● That he or she knowingly had possession of, or control over, the drug.
Drug Trafficking / Distribution	Drug distribution or trafficking laws penalize the selling, transportation, and illegal import of unlawful controlled substances, such as marijuana, cocaine, heroin, methamphetamines, and other illegal drugs. The punishment for drug trafficking can vary widely depending on several factors including the type and quantity of drugs involved, the type of drugs, geographic area of distribution, and whether children were targeted. Sentences for drug distribution and trafficking can generally range from 3-5 years to life in prison, but can be substantially higher when larger quantities are involved. Drug trafficking/distribution is a felony, and is a more serious crime than drug possession. If you're found in possession of drugs, you could be charged with trafficking if police believe you intended to sell them. If you're found with a large quantity of drugs or cash at the time of your arrest, it is likely you'll be facing drug distribution charges.
DUI / DWI	Most state laws define crimes of drunk driving as driving a motor vehicle on a road or highway while under the influence of alcohol. This can mean that you have driven poorly, even if your blood-alcohol concentration (BAC) is low. Newer statutes also provide for what is called a "per se offense," which a person commits when driving a motor vehicle on a road or highway with a blood-alcohol concentration of .08 percent. This means that even if you have driven perfectly, you can still be charged with driving under the influence. Several state statutes require a person to be driving a vehicle in order to be convicted of a drunk driving offense. Other states use the terms "operating a vehicle" or "being in actual physical control of the vehicle." These terms are not normally synonymous, so it is important to determine how an individual state defines the term in its laws.
Embezzlement	The crime of embezzlement was created to fill a loophole in the theft/larceny statutes of English law. In old English law theft/larceny required a trespass, but there is no trespass with embezzlement. The person who embezzles is in lawful possession of the money or property, they just don't give it back to the owner or use it for unauthorized purposes. The crime of embezzlement is where a person: ● Has lawful possession of the property of another; ● Converts or takes that property for their own use; and ● Has no intention of giving it back.
Extortion	A large, intimidating man walks into a profitable liquor store in the heart of the city, not to buy anything but to offer "protection" to the shopkeeper (for a weekly fee, of course). She declines, but he insists. The man casually lists the names of her four children and states he wouldn't want anything "bad" to happen to them. The shopkeeper relents, agreeing to pay him a set amount each week. Per the above illustration, extortion is the crime of obtaining money or property by threat to a victim's property or loved ones, intimidation, or false claim of a right. The following is an overview of the crime.
Forgery	It was Oscar Wilde that said "Imitation is the sincerest form of flattery . . .", but when an artist attempts to pass on that imitation as the real thing, it's called forgery. We tend to think of forgery in connection with the art world. However, the crime of forgery generally refers to the making of a fake document, the modification of an existing document, or the unauthorized signing of a signature without authorization. Forgery involves a false document, signature, or other imitation of an object of value used with the intent to deceive another. Those who commit forgery are often charged with the crime of fraud. Documents that can be the object of forgery include contracts, identification cards, and legal certificates. Most states require that forgery be done with the intent to commit fraud or larceny.
Fraud	Fraud is a broad term that refers to acts intended to swindle someone. In essence, it's the use of intentional deception for monetary or personal gain. Thousands of people each year fall victim to it. Fraud always includes a false statement, misrepresentation or deceitful conduct. The purpose is to gain something of value, usually money, by misleading or deceiving someone into believing something that the perpetrator knows to be false. Fraud is covered by both criminal and civil laws. The most obvious difference has to do with who files the legal case. Only government prosecutors can bring criminal charges, but a victim of fraud can file a civil lawsuit. Sometimes a person who commits fraud is both criminally prosecuted and sued in a civil action.

Harassment	"Harassment" refers to a broad number of behaviours that are subject to both criminal punishment and civil liability. On the criminal side, states have a wide variety of criminal laws forbidding harassment in many forms, including general harassment crimes as well as specific forms of harassment, such as stalking and cyberstalking. Criminal harassment should not be confused with how "harassment" is often used in contexts such as workplace discrimination lawsuits. Federal and state laws ban discrimination against certain types of people in certain situations, such as at work or in housing decisions. In these non-criminal contexts, the victim can sue the harasser in a private civil lawsuit, alleging that the harassment constitutes discrimination.
Hate Crimes	Hate crime is the violence of intolerance and bigotry, intended to hurt and intimidate someone because of their race, ethnicity, national origin, religion, sexual orientation, or disability. A hate crime (also known as a bias crime) is a criminal offense where the purveyors of hate can use explosives, arson, weapons, vandalism, physical violence, and verbal threats of violence to instil fear in their victims, leaving them vulnerable to more attacks and feeling alienated, helpless, suspicious, and fearful. Others may become frustrated and angry if they believe the local government and other groups in the community will not protect them; this is a reason that hate crimes are often unreported. When perpetrators of hate are not prosecuted as criminals and their acts not publicly condemned, their crimes can weaken even those communities with the healthiest race relations.
Homicide	Not all homicides are crimes. However, all killings of humans are included in the homicide definition. Many homicides, such as murder and manslaughter, violate criminal laws. Others, such as a killing committed in justified self-defence, are not criminal. Illegal killings range from manslaughter to murder, with multiple degrees of each representing the gravity of the crime. **Homicide Types** ● Murder ● Manslaughter ● Legal Homicides
Identity Theft	Identity theft and identity fraud are terms used to refer to all types of crime in which someone wrongfully obtains and uses another person's personal data in some way that involves fraud or deception, typically for economic gain. For example, someone rummages through your garbage and steals an envelope with some old tax records, finding your Social Security number, birth date, and other sensitive information. They use this information to open a credit card in your name. Identity theft laws in most states make it a crime to misuse another person's identifying information -- whether personal or financial. Such data (including Social Security numbers, credit history, and PIN numbers) is often acquired through: 1. The offender's unlawful access to information from government and financial entities or 2. Lost or stolen mail, wallets and purses, identification, and credit or debit cards.
Indecent Exposure	Indecent exposure laws in most states make it a crime to purposefully display one's genitals in public, causing others to be alarmed or offended. While the motive will vary from person to person, indecent exposure is often committed for the sexual gratification of the offender or to entice a sexual response. Exposing one's genitals means just that -- to show your bare genitals. However, flashing one's underwear, no matter how revealing or skimpy, is usually not considered indecent exposure for purposes of most states' laws. While showing a bare female breast could result in a criminal charge, most states carve out an exception for women breastfeeding their babies.
Insurance Fraud	Insurance fraud occurs most often when an insured individual or entity makes a false or exaggerated insurance claim, seeking compensation for injuries or losses that weren't actually suffered. This type of crime also can be committed upon customers through the sale of unlicensed or bogus insurance coverage to unsuspecting clients, or an insurance broker or agent's diversion or theft of insurance premiums paid by clients. Fraud in the context of insurance refers to any duplicitous act performed with the intent to obtain an improper payment from an insurer. This crime is committed by individuals from all walks of life. Law enforcement officials have prosecuted doctors, lawyers, chiropractors, car salesmen, insurance agents, and people in positions of trust. Anyone who seeks to benefit from insurance through making inflated or false claims of loss or injury can be prosecuted.
Kidnapping	Under federal and state law, kidnapping is commonly defined as the taking of a person from one place to another against their will, or the confinement of a person to a controlled space. Some kidnapping laws require that the taking or confinement be for an unlawful purpose, such as extortion or the facilitation of another crime. Additionally, a parent without legal custody rights may be charged with kidnapping for taking their own child in certain circumstances. Most kidnapping cases are prosecuted on the state level. However, federal authorities will typically get involved and file federal charges if the kidnapping crosses state lines. Federal criminal code (18 U.S.C. Section 1201) makes kidnapping a serious felony offense, with prison sentences of 20 or more years, depending on prior convictions and the circumstances of the case. Federal law prosecutes international parental kidnapping under a different code (18 U.S.C. Section 1204), allowing for three-year prison sentences upon conviction.
Manslaughter: Involuntary	Consider the following scenario: Dan comes home to find his wife in bed with Victor. Distraught, Dan heads to a local bar to drown his sorrows. After having five drinks, Dan jumps into his car and drives down the street at twice the posted speed limit. If Dan had killed Victor in a "heat of passion" at the time he discovered the affair, then he could be charged with voluntary manslaughter. However, Dan instead accidentally hit and killed a pedestrian while driving recklessly and intoxicated -- and is now being charged with involuntary manslaughter. Involuntary manslaughter usually refers to an unintentional killing that results from criminal negligence or recklessness, or from committing an offense such as a DUI. It differs from voluntary manslaughter in that the victim's death is unintended. The following is an overview of involuntary manslaughter and how it differs from voluntary manslaughter.
Manslaughter: Voluntary	Voluntary manslaughter is commonly defined as an intentional killing in which the offender had no prior intent to kill, such as a killing that occurs in the "heat of passion." The circumstances leading to the killing must be the kind that would cause a reasonable person to become emotionally or mentally disturbed; otherwise, the killing may be charged as a first-degree or second-degree murder. For example, Dan comes home to find his wife in bed with Victor. In the heat of the moment, Dan picks up a golf club from next to the bed and strikes Victor in the head, killing him instantly. On the spectrum of homicides, this offense lies somewhere in between the killing of another with malice aforethought (aka, murder) and the excusable, justified, or privileged taking of life that does not constitute a crime, such as some instances of self-defence. There is a range of potential sentences and penalties for voluntary manslaughter and it is often left up to the judge to decide the sentence.
Medical Marijuana	The term "medical marijuana" refers to the use, possession, and/or cultivation of marijuana for medical purposes. People who are terminally ill, or suffer from painful or long-term symptoms associated with certain diseases, such as epilepsy, AIDS, glaucoma, and cancer, often request medical marijuana as a form of treatment and/or pain relief. As a general principle, medical marijuana is no different than standard marijuana (or cannabis). A growing number of states have legalized medical cannabis within their borders. Under the federal Controlled Substances Act, however, marijuana is classified as a "Schedule I drug," meaning it: 1. Has the potential for abuse, 2. Has no currently accepted medical use in treatment in the U.S., and 3. Has a lack of accepted safety for use of the drug under medical supervision.
MIP: A Minor in Possession	Many states have laws concerning alcohol and drugs found in the possession of minors, regardless of whether they were using the substances. These are often referred to as "minor in possession" or "MIP" laws. Some states strictly enforce MIP laws and prosecute minors to the fullest extent of the law. In other states, however, a minor in an MIP case may be able to receive probation by entering a court-ordered diversionary program (similar to those offered to DUI offenders), getting medical help, and staying out of trouble.

LEADERSHIP	Town Leadership	Discipline	Crimes	**Money Laundering**	Bob has a cash-only diner downtown that does a so-so amount of business, even though Bob drives a Rolls Royce around town. Turns out, he also operates one of the city's biggest methamphetamine operations. Authorities suspect his real source of income is something much shadier than selling omelettes and pie at the diner, but they can't yet prove it. Turns out, Bob uses the diner to "launder" money from the illicit drug trade in an attempt to hide its true source. Money laundering statutes make it a crime to transfer money derived from almost any criminal activity (including organized crime, white-collar offenses, terrorist activities, and drug transactions) into seemingly legitimate channels, in an attempt to disguise the origin of the funds.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Murder: First-Degree**	In most states, first-degree murder is defined as an unlawful killing that is both wilful and premeditated, meaning that it was committed after planning or "lying in wait" for the victim. For example, Dan comes home to find his wife in bed with Victor. Three days later, Dan waits behind a tree near Victor's front door. When Victor comes out of his house, Dan shoots and kills him. Most states also adhere to a legal concept known as the "felony murder rule," under which a person commits first-degree murder if any death (even an accidental one) results from the commission of certain violent felonies, such as: ● Arson ● Burglary ● Kidnapping ● Rape ● Robbery
LEADERSHIP	Town Leadership	Discipline	Crimes	**Murder: Second-Degree**	Second-degree murder is best viewed as the middle ground between first-degree murder and voluntary manslaughter. While some states don't use the term "second-degree murder," they probably still divide the crime of murder into two different degrees and impose lower sentences for the lesser crime. While the exact definition of murder in the second degree varies by jurisdiction, the crime generally covers killings that: ● Are intentional but lack premeditation. ● Result from acts intended to only cause serious bodily harm. ● Result from acts that demonstrate extreme indifference to human life.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Open Container (of alcohol)**	Can you carry an alcoholic drink in a plastic beer mug while walking down your city's main street? The answer depends on the open container laws in your state and local community. Open containers laws serve a number of goals. Most notably, open container laws seek to: ● Maintain the quality-of-life for community residents and business by preventing people from being drunk in public, preventing rowdy behaviour; ● Prevent car, bus, and other motor vehicle accidents outlawing the use of alcohol by drivers and passengers; and ● Maintain federal highway construction fund subsidies for states (under federal law, states that lack open container laws lose federal transportation subsidies).
LEADERSHIP	Town Leadership	Discipline	Crimes	**Perjury**	Juries and judges often base their verdicts, sentences, or other important decisions on sworn testimony and signed documents. Statements given under oath and certain legal documents are presumed to be truthful, or at least made in good faith. But how do we know for sure that witnesses and other parties involved in a legal matter are telling the truth? We can't always be certain, but those who are caught knowingly misleading a court face serious criminal charges of perjury. To "perjure" yourself is to knowingly make misleading or false statements under oath or to sign a legal document you know to be false or misleading. This crime is taken very seriously because the foundation of the legal system depends on trust and credibility. After all, just one sworn statement has the power to tip the scales of justice and dramatically alter someone's life. Perjury is considered a crime against justice, since lying under oath compromises the authority of courts, grand juries, governing bodies, and public officials.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Probation Violation**	Probation violation is an offense that occurs when you break the terms or conditions of your probation. The punishment for probation violation usually depends on a variety of factors, such as the nature and seriousness of the violation, whether you have any prior violations, and whether there are other circumstances that may lessen (or worsen) the severity of the situation. A probation violation may result in significant penalties, such as heavy fines, extended probation, jail time, or more. Probation violation laws vary among the states and are governed by federal and state law. Generally, a probation violation occurs when you ignore, avoid, refuse, or otherwise break the terms or conditions of your probation at any time during the probation period. Probation typically runs from one to three years, but may also last for several years depending on the original offense.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Prostitution**	Sometimes called "the oldest profession," prostitution is known by many names, from streetwalkers and brothels, to sophisticated call-girl or escort services. However, whatever name it goes by, prostitution is illegal in almost all fifty-states. At its most basic definition, prostitution is the exchange of a sexual act for money. State laws have expanded the definition to make it a crime to offer, agree to, or engage in a sexual act for compensation of any kind.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Public Intoxication**	Public intoxication, often called being "drunk and disorderly," is a legal charge alleging that a person is visibly drunk or under the influence of drugs in public. It's usually a misdemeanor crime under state and local law. These laws exist to prevent people from disturbing others in public and to remove people who appear to be unable to stop themselves from hurting themselves or others. By definition, a public intoxication charge usually has three basic elements, all of which must be met in order to obtain a conviction. Specifically, it must be shown that a defendant: ● Was under the influence of alcohol/drugs/controlled substances; ● Caused a disturbance or harm to another person; and ● Was present in a public place.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Pyramid Schemes**	People are always thinking up new ways to swindle others out of their hard-earned cash. Some of these schemes can take new and creative forms. But the pyramid scheme, which is still prevalent today, hasn't changed much in over 200 years. Although there's arguably a fine line between what we call "multi-level marketing" businesses (such as AmWay) and illegal pyramid schemes, it's an important distinction of which consumers should be aware. These types of scams follow a predictable formula. Usually, one person, known as the "recruiter," will create a fraudulent business which requires others to pay a fee to join. The people he recruits to the business then recruit others to join as well, and pocket the fees (often with fees paid to the recruiter as well). This cycle of recruitment is supposed to continue indefinitely, so that everyone who joins the "business" will continue to receive the recruitment fees of the newest recruits.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Racketeering / RICO**	Racketeering is when organized groups run illegal businesses, known as "rackets," or when an organized crime ring uses legitimate organizations to embezzle funds. Such activities can have devastating consequences for both public and private institutions. Consequently, the federal government and numerous state governments have created systems of laws designed to prosecute these criminals who otherwise may evade police. Most older forms of rackets dealt in industries that were clearly illegal, such as prostitution, sex trafficking, drug trafficking, illegal weapons trafficking, and counterfeiting. These "businesses" organized large groups of people to help keep the racket profitable and covert, allowing them to make illegal products available to the public quickly and in such large amounts that authorities couldn't make all the necessary arrests and prosecutions.

LEADERSHIP	Town Leadership	Discipline	Crimes	**Rape**	The crime of rape generally refers to non-consensual sexual intercourse that is committed by physical force, threat of injury, or other duress. Common law defined rape as unlawful intercourse by a man against a woman who is not his wife by force or threat and against her will. However, most states have refined and broadened the statutory definition of rape so that marriage, gender, and force are not relevant. The victim's lack of consent is the crucial element. A lack of consent can include the victim's inability, due to the effects of drugs or alcohol, to say "no."
LEADERSHIP	Town Leadership	Discipline	Crimes	**Robbery**	Essentially, robbery is theft accomplished by violence or the threat of it. Unlike theft or burglary, the crime of robbery almost always requires the presence of a victim who is threatened with bodily harm. If a weapon such as a gun is used or the victim suffers injury, the robbery may be charged as "armed" or "aggravated." For example, Chris sneaks up on John, demanding John's money while pressing a plastic object into his back, and John gives up his wallet. This would be charged as a robbery. If Chris used an actual gun or John was injured, the crime likely would be elevated to armed or aggravated robbery.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Securities Fraud**	Generally, securities fraud occurs when someone makes a false statement about a company or the value of its stock, and others makes financial decisions based on the false information. In cases of insider trading, insiders (i.e. executives, board members, etc.) buy or sell stocks based on information that isn't available to the public. Although the crime itself isn't complicated, securities fraud can be particularly difficult to grasp if you lack an understanding of securities regulation. The first type of securities fraud occurs when an officer or director of a corporation doesn't accurately report the company's financial information to its shareholders. This can artificially raise the worth of the company's stock and encourage investors to buy shares of an unhealthy company. If the company subsequently goes bankrupt, the people who bought shares based on false information lose their investment completely.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Sexual Assault**	Sexual assaults affect millions of Americans annually. The term encompasses various actions that involve behaviour or contact toward another person without their consent. The actions are defined by state law and can therefore differ by jurisdiction. However, some common examples of sexual assault include: ● Fondling, kissing, or making unwanted bodily contact; ● Forcing another person to perform or receive oral sex; ● Forcing a tongue, mouth, finger, penis, or an object on another person's anus, penis, or vagina; and ● Forced masturbation.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Shoplifting**	"Shoplifting" generally refers to the theft of merchandise from a store or place of business. Shoplifting is a type of larceny, which simply means taking the property of someone else without their permission, and with the intent to permanently deprive the owner of the property taken. Though states may punish shoplifting under their general larceny or theft statutes, many states have enacted statutes to specifically address shoplifting. States may refer to the crime by different names, including "retail theft" and "concealment of merchandise."
LEADERSHIP	Town Leadership	Discipline	Crimes	**Solicitation**	The character Fagin in Charles Dickens' Oliver Twist took young boys under his wing and taught them to be pickpockets. He would then send the boys out into the streets of London to steal for him. Fagin didn't need to personally steal anything, but under modern statutes, Fagin could still be charged with inducing the boys to commit theft under what is known as solicitation. The crime of solicitation is requesting, encouraging or demanding someone to engage in criminal conduct, with the intent to facilitate or contribute to the commission of that crime. Commonly, solicitation often is linked to prostitution with the crime being the request of someone to engage in sex for money.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Stalking**	The crime of stalking can be simply described as the unwanted pursuit of another person. Examples of this type of behaviour includes following a person, appearing at a person's home or place of business, making harassing phone calls, leaving written messages or objects, or vandalizing a person's property. By its nature, stalking is not a one-time event, but rather a pattern of behaviour meant to cause harm or distress. The individual's actions must be considered in connection with other actions to determine if someone is being stalked. It includes repeated harassing or threatening behaviour toward another person, whether that person is a total stranger, slight acquaintance, current or former intimate partner, or anyone else.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Statutory Rape**	Statutory rape refers to sexual relations involving someone below the "age of consent." People who are underage cannot legally consent to having sex, so any form of sexual activity with them violates the law. This is true even in situations where they signal their agreement. While the crime is popularly called statutory rape, many states don't use that term officially but instead classify it as sexual assault, corruption of a minor, or carnal knowledge of a child. Most laws on this subject are state rather than federal ones.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Tax Evasion / Fraud**	As the saying goes, the only sure things in life are death and taxes. If you intentionally fail to pay taxes or underreport your taxable income, you could be charged with tax evasion. While it's certainly a crime in and of itself, it's also commonly charged against those suspected of certain organized crimes where the source of their income is in doubt. For instance, famous Prohibition-era gangster Al Capone was convicted not for murder or racketeering, but for evading taxes. Tax forms are long, the Internal Revenue Code is complicated, and unless you're an accountant or other tax professional, you're bound to make some mistakes that may result in underpaying taxes. Although you should always try to fill out your tax forms correctly, there's no need to worry about being convicted for tax evasion over a simple error.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Telemarketing Fraud**	Many scams take place over the phone, often with the lure of a possible "grand prize" or some other way of keeping you on the line. Scammers often try to extract sensitive information from their victims, such as Social Security numbers, or may try to sell you something with no intention of actually delivering and every intention of taking your money. But if you know how to protect yourself, you can avoid being defrauded. At its core, telemarketing fraud is a pretty simple crime: someone calls the victim, makes a false statement, and the misrepresentation causes the victim to give money or sensitive information to the caller. This definition can cover a large variety of scams. Sometimes, victims are told that they won a prize in a foreign lottery and their personal information is required to receive the prize.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Theft**	The term theft is used widely to refer to crimes involving the taking of a person's property without their permission. But theft has a very broad legal meaning which may encompass more than one category, and multiple degrees, of crimes. This article provides a theft overview, including definitions and specific examples. Theft is often defined as the unauthorized taking of property from another with the intent to permanently deprive them of it. Within this definition lie two key elements: 1. A taking of someone else's property; and 2. The requisite intent to deprive the victim of the property permanently.
LEADERSHIP	Town Leadership	Discipline	Crimes	**Vandalism**	Vandalism laws are designed to prohibit conduct that has the potential to cost states millions of dollars each year in clean-up efforts, and may cause psychological or emotional damage to property owners as well. When a person defaces, alters, or otherwise destroys someone's property, they may be required to clean-up, repair, or replace the damaged property or, more substantially, face criminal penalties in the form of jail time, fines, or both. Vandalism is a broad category crime that's used to describe a variety of behaviours. Generally, it includes any wilful behaviour aimed at destroying, altering, or defacing property belonging to another, which can include: ● Spray painting another's property with the purpose of defacing; ● "Egging" someone's car or house; ● Keying (or scratching) paint off of someone's car; ● Breaking someone's windows; ● Defacing public property with graffiti and other forms of "art"; ● Slashing someone's tires; ● Defacing park benches; ● Altering or knocking down street signs; and ● Kicking and damaging someone's property with your hands or feet.

White Collar Crimes	"White collar crime" can describe a wide variety of crimes, but they all typically involve crime committed through deceit and motivated by financial gain. The most common white collar crimes are various types of fraud, embezzlement, tax evasion and money laundering. Many types of scams and frauds fall into the bucket of white collar crime, including Ponzi schemes and securities fraud such as insider trading. More common crimes, like insurance fraud and tax evasion, also constitute white collar crimes. Securities fraud comes in many flavours, but one common type is "insider trading," in which someone with inside information about a company or investment trades on that information in violation of a duty or obligation. For example, an executive knows confidential information about an upcoming company earnings report decides to sell of a chunk of his stock in the company. That would be considered securities fraud; specifically, insider trading.
Wire Fraud	The crime of fraud can take many forms. Scams that take place over interstate wires, such as telemarketing fraud, phishing, or spam-related schemes, are all called wire fraud. Federal wire fraud is a federal offense and is typically investigated by the Federal Bureau of Investigation, but state laws and charges can also apply. The definition of wire fraud is rather broad and includes any writings, signs, signals, pictures or sounds transmitted by wire, radio or television in interstate or foreign commerce. Federal prosecutors often charge persons with wire fraud in order to bring federal charges against them, typically when the crimes committed would only be subject to state laws.

Punishment Tiers

You should have varying punishments proportionate to the type of crime committed.

5 Roles & Responsibilities

These are the jobs that are available in the town. Vacancies can be filled and people can swap between roles if they desire. The population percentage shows how many of that type of person are in the field. The orange tinted population percentages aren't included in the total percent as they are part time jobs.

Leader

The leader of the town. There should only be one per town.

Population Percentage 1 Person	The leader decides the fate of the town and helps it to grow and expand while keeping peace and order. There may be a chance of assassination depending on rival towns/gangs and if your village hates you or not.	**Roles** •	There's a moderate chance of injury in this job.

Leader Group (Admin)

Assistants to the leader who help on decision making and informing the community.

Population Percentage 5%	These are the gatekeepers who decide who to let in and to keep track of population, and those outside the walls.	**Roles** • Population Tracking • Food Consumption • Food Stocks • Farming Output • Job Availability • Equipment Stores • Ammo Stocks/Usage • Town Escape Plans • Defensive Plans	There isn't a high chance of getting injured in this job.

Farmers

People who grow food to support the rest of the village.

Population Percentage 25%	Farmers are in the sun long hours looking after crops and help sustain the village. More food than necessary should be grown to support any additional people that may come along and to safeguard against crop failure.	**Roles** •	There isn't a high chance of getting injured in this job.

Cooks

The people who turn the produced food into edible food ready for consumption.

Population Percentage 10%		**Roles** •	There isn't a high chance of getting injured in this job.

Cleaners (Part Time)

Cleaners keep the residences and the town in a respectable condition.

Population Percentage 10%		**Roles** •	There isn't a high chance of getting injured in this job.

Doctors (Part Time)

Medical professionals who diagnose and heal the sick. They also look after the medical gear and medicines.

Population Percentage 10%	Doctors should keep the medical equipment locked up when not in use. This excludes the basics such as bandaids. The doctor should be on call 24/7 for any emergency that may occur to members of the town.	**Roles** •	There isn't a high chance of getting injured in this job.

Pastor / Priest

Pastor

A pastor who spends time in communion with God and preaching to the town, giving thanks for meals and teaching the Bible.

Population Percentage 5%	It's one thing to die an earthly death but you don't want to die a second spiritual death, and that's where the pastor comes in.	**Roles** •	There isn't a high chance of getting injured in this job.

Scavengers

The people who leave the town in search of useful equipment, items and food to bring back.

Population Percentage 10%	Setting a priority item for the scavengers to look for can be beneficial if you need certain items quickly. Scavengers should be masters of stealth and be split up into groups of 3 who don't stray far from each other.	**Scavenging Priorities** • Food • Water Filtration • Solar Panels • Weapons / Ammo • Valuables	**Roles** •	They have a high chance of getting injured while outside the town due to wild animals or other people.

Defenders / Law Enforcers

These people patrol the city bringing order to it and watch the boundaries for threats.

Population Percentage 15%	Defenders guard the town 24/7 and have an alert system in place for approaching threats. The defenders train the town how to defend themselves with a gun, sword, bow or knife.	**Roles** •	There's a moderate chance of injury in this job.

Utility Workers

These individuals look after construction, electrical, water, gas and sewage routes, fixing them when they break.

Population Percentage 15%		**Roles** •	There isn't a high chance of getting injured in this job.

Craftsmen

These people are blacksmiths, knitters, toymakers etc who build things from scraps and skill.

Population Percentage 5%		**Roles** •	There isn't a high chance of getting injured in this job.

Tradesmen (Part Time)

Traders who venture out from the town to trade needed items and valuables with others.

Population Percentage 2-3 People		**Roles** •	There's a moderate chance of injury in this job.

Non Workers

There should be little to no people who don't work in the town. Only small children, mothers with babies, the disabled and the elderly shouldn't be working.

Population Percentage 10%		**Roles** •	There isn't a high chance of getting injured in this job.

Universal Knowledge

These are jobs that everyone in the town should have knowledge of or the ability to do.
- Everyone who has mastered their trade will be a teacher of it to continue the generations.
- Everyone should know how to defend themselves with some form of weapon in case the town is under attack.
- The doctor should train everyone in basic first aid.
- Everyone should know about basic security and be on the look out for suspicious acts.

Job Flexibility

As with anything you should adapt the above to your personal situations. If you need more people defending the town then assign people to it instead of another, less essential job. If you are finding that you need more people bringing in food you can set more people to farming or give a food priority to the scavengers.

LEADERSHIP

Town Leadership

Leadin

Once the town is set up you have to lead the people and make wise decisions that will appease most citizens. You will never be able to please everyone so having a democratic village will help solve some problems. You need to be a strong yet merciful leader where necessary but not so much you look like a pushover. Listen to all people, young or old, strong or weak for every idea is worth considering and you may uncover true talent. Have strong unshakable ideals and don't stray from them. Such as a fixed policy on punishment.

7 Trade

Trade

Some form of currency or trade is required if you wish to have a barter economy within your village.

Makeshift Currencies
- Legacy Money
- Bottle Caps
- Valuables

Economy

Storing valuables, precious metals and maintaining a portfolio

"I used to be a banker, but then I lost interest."
Unknown

Introduction

This section discusses money, the economy, your portfolio, storage of cash and the peaks of major economic pillars such as oil.

Purpose	The aim of ECONOMY is to provide an overview of money and how the money system works, as well as information to what happens when this system breaks down. It also has detailed information on identifying genuine precious gems and metals as well as correct storage procedures to help prevent theft. There is also a large section on bartering items if the need arises in a post-disaster world.
Lost?	• For a list of personal money problems such as bankruptcy, see the PERSONAL DISASTERS section. • For man-made disasters such as hyperinflation and recessions, see the MAN-MADE DISASTERS section.

Contents

1 Money

Forms of Money

Assets	Any assets you own that can be used in a SHTF situation to survive which are generally worthless and can't usually be traded. Before the days of banks, people used to trade their crafts at local markets for other items they needed. An example being 1 chicken and a hand knitted jumper for a piglet. In the end the assets you have will help you to survive as you can't eat any form of money, and due to the fact very few people will be without food, it will be the most needed item besides water. Therefore before you begin investing into cash or bullion you should have a stockpile of food and water purification devices.
Tradables	Any physical items you own that could be needed or traded in SHTF. Items like alcohol, condoms, toilet paper, guns, food, water and medical equipment can be traded quite easily if you need another item.
Land	Any pieces of land you may own, with or without a property on it. Land could be a valuable asset in a disaster, especially if you have stored good on site. However it will be tough convincing people you own the land if you discover someone has claimed it for themselves when there's no law.

Housing	Any houses you own irrelevant of who owns the land. Houses provide comfort and protection from people, weather and unrest. Although you will have to abandon it if you bug out you can always return in the hopes it's still standing. A bug out house which is reinforced and assault-proof will prove vital in a situation where your primary property is abandoned.
Metal Bullion	Bullion is any form of precious metal that can be used to trade. This does not include any bullion that's stored in another physical location that you technically own. If you can't touch it then it's not yours when SHTF comes. Commonly stored in smaller values and used as Gold, Silver and Copper in order of value respectively, so have a selection of each type.
Cash	Any coins of paper money used for purchasing items. Cash is generally ignored today in favour of card payments to prevent needing to carry the often heavy coins. Cash may have a value in SHTF situations but primarily depends on if people will deem it worth anything in SHTF. Generally it will be accepted for a short period into a disaster before people run out of it and resort to unsavoury means of getting what they need. For short term, local or national disasters generally people will continue to use cash as a means of payment unless the disaster goes on too long or the disaster is economy based where the currency declines.
Bank Account	Any money in your bank account. Money in the bank will become useless if the internet goes down or the economy breaks down. Therefore it's wise to store some in physical forms for bartering. Many banks close without warning and you could instantly lose all your money stored within without the chance to withdraw it. It may not even be SHTF for this to occur.
Bonds	A bond is a debt obligation from a company that requires money. As soon as things start going downhill companies will lose money and you will lose your investment. You can't just get out of a bond depending on the contract, so choose carefully and watch the state of the world closely.
Stocks	Any company or stocks you've invested in. Good for investment when the grid is up, but as soon as that goes down you've lost all your money. Chances are that businesses will be finding it tougher and tougher as the disaster approaches if it's economy related and therefore you will lose money anyway.
Cryptocurrency	Probably the most volatile and risky form on investment today. Not only does the price fluctuate wildly but it's entirely online and there's no guarantee it will even be used in the future for transactions. Crypto is good for making a little money while the grid is up but for no reason do you want money in it when a disaster is coming, and the whole reason for being prepared is you're not sure when a disaster will occur.

NIIP

The difference between a country's external financial assets and liabilities is its net international investment position (NIIP). If your country is in debt watch out in particular for economical instability, financial problems and job cuts.

2 Valuables Storage

Keeping your valuables safe and sound is essential to protect it against thieving hands. This section covers ways to conceal your treasures to make it much more difficult to find and steal.

Valuable Storage Triangle
There is a constant pull between these three factors. You can have a high level of security but the accessibility and diversity drops. Prioritise the most important for your requirements.

Valuable Storage Triangle
- Security Depth
- Accessibility
- Diversity

Security Depth
This represents how well items are hidden and how many layers they are hidden with. This makes them hard to access and diversity is harder due to the cost of this depth.

Accessibility
The easier to access your valuables are, the more likely they will be found, but it provides a very fast way to retrieve your assets in an emergency.

Diversity
Spreading out your assets may protect them if one is found, but you can't often have very deep security for all of them and it will be a pain to access them all.

Location

On You

You can store a surprising amount of valuables on your person if done correctly. Being always on you there's little risk of being stolen or burnt.

Advantages	• You always know where your valuables are	• No risk of being burnt up	• No worrying about thieves		
Disadvantages	• Could be stolen if you're mugged	• May weigh you down depending on size	• Limited storage space	• Can't store more than a few oz of precious metals	
Wallet	An obvious place to store some valuables, but at least you know where it is at all times. You might be able to get a few gold or silver coins in as well.				

Shoe/Boot	Under the flap of your boot is a great place to store a coin or some paper money. It may become an inconvenience if you try to stash too much especially if you have to run.
Around Neck	You can store precious metals around your neck in the form of gold/silver chains, jewellery or on the end of a pendant. These can be pretty obvious to others that you are carrying it however so it may be a risk.
Phone Case	Store a few hundred dollars inside your phone case for emergencies. You could even fit another bank card if the case is big enough.
Money Pouch	A pouch that is worn around the belly for valuables such as passport, cash and credit cards. Generally this is thin enough to not be seen, but ensure your clothes aren't see-through.
Under Your Skin	At the extreme end you can always store valuables under the skin. This has to be carefully considered as the blood is likely to try to expel the foreign object.
In Your Body	You can even store valuables inside your mouth, nose, butt or vagina if you're attempting to sneak it past someone.

Inside

Interior storage of valuables is a common practice today due to the ease of access. Although it can be just as easily accessed and found by someone looking for it.

Advantages	• Easy to access without much effort	• Don't have to get dirty and go into the rain/snow to retrieve it	• Lots of nooks and crannies to hide valuables in	• Ability to use disguised cans/books etc to hide things in	
Disadvantages	• House fire Risk	• The first place thieves will look	• Limited to a number of common places to hide valuables		
Obvious Hiding Places	Don't use the following storage locations as they are easily found by thieves.				• Inside a Safe • Under a Mattress • Under a Drawer • In a Cupboard • In a Wardrobe
Excellent Hiding Places	These are the best locations to store valuables and are only found by the most explorative person.			• Inside your sneaker/boot • Inside a fake can • In the Fridge • In the wall	• In Hollow Doors • Inside a Mattress • Under any Fake Floor • Inside a Piano
Tips	Make sure the item can't just be picked up and taken away whole such as safes not attached to the ground. It's safer to put items inside larger items that also can't be taken away such as a piano. Be sure to tell your significant other where you hide valuables so they don't throw them away by accident.				

Outside

Hiding your valuables outside is the optimum location if you aren't planning on needing them for many months or years. You can feel relatively safe that your items won't be found if you own the land it's buried on and it's buried deep enough.

Advantages	• Much harder to find valuables hidden outside and especially underground.	• Can bury items in a relatively large amount safely.			
Disadvantages	• Takes time to find dig up	• May be difficult to find the exact location if it becomes overgrown	• Erosion may reveal the cache over time		
Positioning	See the Cache section below for tips on positioning and burying valuables.				
Tips	**Midnight Gardening** Burying a safe at night. Ensure airtight, waterproof, rustproof container. Should be a challenge to find and not obvious if people know.				

Defence in Depth

Store items multiple layers deep such as in a floor safe, under floor boards with a rug over the top. 3 is a great number to aim for when layering security measures. Try to make it less obvious each layer down that there's valuables close by.

Accessibility

Preppers need quick access to their money in the case of an emergency when they have a few minutes to grab their BOB and leave. You absolutely don't want to run around the house pulling money out of every cranny if it will take hours to find it all.

Risk / Reward
o

Diversity

Almost the opposite of accessibility is diversity, the art of spreading out your assets so if one is compromised, the rest will be fine. Diversity makes it hard to retrieve your valuables in the event of an emergency when you have 5 minutes to grab gear, particularly when it's spread among other locations or hard-to-reach-quick locations.

Weight / Space

The more valuables you have the more space it will take up, making it more costly to store and hide particularly precious metals. As the collection of valuables grows the weight could also become an issue if stores in places such as an attic or shelves which could bend or break under the load. Diversity can help to not only protect your valuables by spreading them out to help prevent theft of everything but to distribute the weight around.

Metals
Large amounts of precious metals can become very heavy quickly so it's vital to choose a location strong enough. Silver takes about 128 times more space than gold for the same value, however silver has more uses and is better for low value barter.

Camouflage

The art of hiding valuables in seemingly common invaluable items as a way to reduce the risk of theft.

Decoys

Decoys are the opposite of camouflage - being items which look like they possess valuables but only contain junk or semi-valuable items. Putting semi-valuables inside decoys may make the thief feel like they have the best items even though you have the real cache somewhere else.

Putting a safe in a wardrobe is a sure way to get a thief interested in what's inside it, especially if it has a certain heft to it.

Area Security

Home Security
Cameras for video recording and monitoring.

3 Portfolio

Money Portfolio

A Non-Volatile method of investing money to ensure it survives drops but it's also dependant on the grid being up. You should have an annual or Semi-Annual reallocation of stocks. To be prepared for a grid down SHTF situation most of your money should be safe in non volatile physical cash and metals for trading. It is always better to have items in your possession that provide a function rather than any form of money including bullion and cash. For example you should have a water filter rather than the money needed to buy one.

Grid Up Asset Classes
- Stocks - 20%
- Bonds - 20%
- Cryptocurrency - 0%
- Cash (Physical) - 20%

- Stocks - 4%
- Bonds - 0%
- Cryptocurrency - 1%
- Cash (Physical) - 25%
- Cash (Digital) - 10%
- Metal Bullion - 60%

Protecting Money
Use multiple banks to store digital money like savings in case one of them shuts down without warning and you lose it all. Try to keep 6-12 months of living expenses of cash on hand. This includes everything from food and water to bills.

SHTF Portfolio

When SHTF occurs a lot of people's money will be inaccessible. You should ensure your money is protected from "the system" by being offline and accessible. The following is a list of ways money is commonly stored, the risks they involve and systems they rely on from the highest risk to the smallest risk.

Monetary Type	Description	Risks	Requirements	SHTF Outcome
Cryptocurrency	Any money stored in crypto.	• Online • Intangible • Unstable • Digital Theft	• Internet • Grid Up	You lose it all instantly if SHTF.

Stocks	Any stocks you've invested in.	• Online • Intangible	• Internet • Grid Up	You lose it all instantly if SHTF.
Bonds	Any bonds you may own.	• Online • Intangible	• Grid Up	You lose it all instantly if SHTF.
Cash - Digital	Any money stored in a bank account.	• Online • Intangible • Digital Theft • Bank Closure	• Internet • Grid Up	You lose it all instantly if SHTF.
Precious Metals - Digital	Precious metals you own that are stored in a bank or area not controlled by you in a another location.	• Online • Intangible	• Internet • Grid Up	You lose it all instantly if SHTF.
Cash - Credit Card	Money you don't own therefore no big loss if SHTF.	• Online • Intangible	• Internet • Grid Up	You lose it all instantly if SHTF.
Cash - Physical	Any money you have stored in a physical location.	• Theft • Fire • Undervalued • Unvalued	• Security • Storage Space	Cash may or may not still have value.
Precious Metals - Physical	Precious metals you own physically.	• Theft • Possible Fire Damage • Rust/Tarnish	• Security • Storage Space	Precious metals should always have a value even if you have to wait a few years.
Tradables	Valuable items that you can barter in SHTF excluding precious metals.	• Theft • Expiry • Fire	• Security • Storage Space	Tradable and valuable items will always be useful.
Assets	Any material goods not considered valuable but still useful. E.g. Scissors, linen, metal poles.	• Expiry • Fire	• Storage Space	Items that could be repurposed in a survival situation.

4 Bartering

Everything from clothes, wine, gold, silver and gems has been bartered throughout history as a means of trading something you don't need for another item that you do. The ability to barter goods and services in any disaster will be almost essential due to the lack of survival skills today and the complexity of our current lifestyle. This section will inform you on why to barter, how to barter, how to negotiate and what sorts of items are best to barter.

Subheadings

1. Trade Value	**2. Valuables**	**3. Vices**	**4. Essentials**
5. Others	**6. Negotiating**	**7. Trading**	

1 Trade Value

Trade value is an intrinsic method for calculating the value of products. If you have the value of one item you can extrapolate the value of everything else.

Don't look at the typical dollar value of the trade unit when bartering as prices are subject to multiple conditions in a disaster affected world.	**1oz Copper** = 2 Trade Value **1oz Silver** = 50 Trade Value **1oz Gold** = 4000 Trade Value	**AOCS** American Open Currency Standard

2 Valuables

Precious metals are unsurprisingly, precious to a lot of people as the value isn't inflated like paper money today. Below are a selection of precious metals, their uses and values.

Precious Metals
- Copper
- Silver
- Gold
- Platinum
- Palladium

Precious Metals

Based on intrinsic value, hard to verify quality. Good to trade for in hard times to make a profit afterwards. Buy Silver over Gold pre-SHTF for small transactions during a SHTF scenario. Have fewer Gold coins.

Gold	Used for purchasing expensive items.
Silver	Used for purchasing common items and daily exchanges. Silver can also be used for making colloidal silver and silver can sterilize wounds.
Platinum	Used for purchasing uncommon items and daily exchanges.
Palladium	Used for purchasing uncommon items and daily exchanges.
Copper	Used for cheap purchases and daily use.

Verifying Silver

Verifying any precious metals is vital in ensuring you are getting exactly what you are bartering for. There may be people who try to scam you with fake gems, metals and money. Metals can look and weigh the same as the real thing but may only be plated on the exterior.

Visual Test

Silver has a distinctive look and feel to the coin not too shiny and not too cloudy. Grab an old magnifier, the one's that jeweller's use, and take a good look at the coin. It's always best to have an authentic coin or bar next to the one you are examining. Mismatched surfaces, text spacing, crevices, or edges will stand out if it is a fake. Your tool of choice for this test is a handy magnifying glass or a jeweller's loupe. A loupe if a special magnifying glass without the handle with higher magnification due to its special lens. These are essential to the world of coin collecting & numismatics, making it easier to grade the quality as well as identify counterfeit coins such as fake silver dollars. A dead giveaway is the edges of the coin or reeding. If there are no grooves or reeds, there is a 99.9% chance it is a fake since minted coins non-reeded (errors) are extremely rare. Examine where the coin meets the rim and between the reeds, sometimes silver-plated coins will not fill these in and with a proper magnifying glass they will be detected.

Weight

The best way to take advantage of this is by using a good digital electronic scale. You will want to get a scale that measures at least to 2 decimal points in grams. Silver Eagles have a minted weight of 1 Troy oz. ~ 31.103 grams.

Sound (Ping Test)

The great thing about silver is that it has a certain high-pitched ring to it when struck with another metal, many people refer to this as the ping test and it works fairly well. To do this, simply place one silver coin on your fingertip and take another between your thumb and forefinger and gently tap your coin. It should produce a nice high-pitched bell ring. The neat thing about this test is that silver rings at a certain frequency of about 6145 Hz.

Resistivity

Measuring the resistance of the surface and through the metal then comparing them can determine if it's plated or true metal.

Magnetic

While many fakes can easily pass this test, silver as well as gold bullion for that matter are both non-magnetic. If a bullion coin or bar sticks to a magnet you can easily throw this one out. Fakes that are produced with any iron or steel content in them will give off some magnetic attraction and identify itself as a fake. Metals that have a core of zinc, copper, lead or other non-magnetic metal will not be detected by this test.

Diamagnetism

Continuing on with magnets, another test you can to spot counterfeit silver is using a magnetic slide. Simple and easy to build, this is a fun way to instantly spot fakes without any complicated testing. Even though silver is non-magnetic it has a property known as diamagnetism. This causes silver to repel when in contact with a magnetic field. So real silver moving down a magnetic slide will move slower than fake silver. A fake will move down the slide with no resistance.

Ice Test

Cheap and easy to do, getting some ice from the freezer is a simple way to test both silver coins and bars for authenticity. All you need to do is place the ice on the silver and watch. The ice should begin to melt immediately, this is because silver is the best conductor of heat for all the metals. Below is a chart on thermal conductivity amongst popular metals. You will see that silver tops them all even including copper which is the most popular metal to use. This makes it extremely useful in electronics and as an industrial metal, check out 101 uses of silver, and you will see how useful this metal really is!

Thermal Conductivity
- Silver - 406
- Copper - 385
- Gold - 315
- Aluminium - 205
- Rhodium - 151
- Iron - 79.5
- Palladium - 71.2
- Platinum - 69.1

Bleach Test

Another cheap and simple way to test for real silver vs. fake is to use some household bleach. Silver will tarnish very fast when exposed to any sort of oxidizing chemical like bleach. All you will need is just 1 drop, place it on the silver and if it begins to turn black then you can check it is silver. If your coin has numismatic value of any sort, this test may reduce its premium and you may want to perform another test. (Silver-plated items will also pass this test)

Specific Gravity Test (Highly Accurate)

The specific gravity test of silver is basically a ratio of densities and due to its chemical & composition makeup should equal ~ 10.49, given by the formula:
Specific Gravity of Silver = Weight of Silver / Weight of Silver Submerged

This test will weed out those silver-plated or clad coins if they have a composition of some other base metal. You cannot change the density of metal and pure silver will always give a reading close to 10.49. To calculate this perform the steps below:
- Obtain dry weight of the silver coin or bar with an accurate scale to .01g
- Use a cup of water enough to fully submerge the silver into and measure its weight or reset the scale with it on.
- Tie some string around the coin and setup an apparatus to hold the coin
- Submerge the silver into the water and record the submerged weight minus the weight of the water & cup.
- Divide the dry weight by the submerged weight to obtain the specific gravity of silver

Be warned: Sophisticated counterfeiters also have ways of combining certain metals together to get a similar specific gravity readout. Using this test together with the ring test & visual test should be able to detect these types of fakes.

The Acid Test

Another test with high accuracy, this test uses acid solution usually of nitric acid and muriatic acid. You will have to purchase this from a dealer or on Amazon. Just search for silver acid testing kit or puritest. You will also want to get a testing stone to use with the solution. While this test can immediately verify pure silver, it will damage the coin. So it is best to use this is you bought a lot of coins or bars and want to test 1-2 for purity. If you suspect the outside is silver-plated, you may need to file through an edge to get to the centre metal in order to test. Once the acid is placed, pure silver will stay a certain colour, while fake silver will turn a different colour depending on the metal used to counterfeit. This test is also really useful for testing sterling silver if you're not sure that platter you bought at the goodwill is 925.

XRF Analysers

If you're serious about silver or maybe ultra paranoid, you may consider investing in a portable or handheld XRF Analyser. XRF is short for X-ray fluorescence, and is used not only in detecting precious metals but all sorts of metal alloys, mining samples, environmental assessments etc. These handheld device are just like scanners, point and shoot, and the device will give an accurate readout of the metal composition. If you're interested in getting one of these cool little toys, 2 companies that make them are Niton and Bruker. Be warned these are extremely pricey can run over $10,000 and are usually carried only by gold/silver bullion or jeweller shops.

Ultrasonic Thickness Test

If XRF analysers are out of your price range, but you still want a scientific tool to determine real vs. counterfeit silver, an ultrasonic thickness gauge may be for you. What this test does is measure how long it takes for sound to travel through a metal object, in our case silver. If your bar is pure silver, it will give an accurate reading, if it is a mix of metals, the reading will be off. For different metals, you will get different readouts of thickness. This is also a great way to test for fake gold coins and bars. The speed of sound for silver is 3650 meters/second at room temperature.
You can check the speed of sound of other metals here. Gold is 3240 m/s.

- Set the device to a velocity of 3,650
- Measure the silver bar with a proper caliper
- Place a dab of glycerine on the bar where you will measure the thickness
- Measure the thickness with the sensor
- Readout thickness should match the actual thickness of the bar (in mm)

This works really well for large silver bars or ingots. If the bar is plated in silver/gold it will give an inaccurate thickness tipping you off that the silver is counterfeited with some other metal. From here you could perform a few other tests to confirm your suspicion. If you are a regular buyer of silver bars this maybe the tester for you as you can buy an entry-level gauge for several hundred dollars unlike the expensive XRF analysers. Here is one for less than $200 on Amazon.

Sigma Metalytics Precious Metals Verifier

A step up from an ultrasonic gauge but still less expensive than an XRF analyser is the Sigma Metalytics Precious Metals Verifier. This ingenious product sends electromagnetic waves though the metal & confirms it with stored patterns. This is ideal for any coin shop, bullion dealer, or avid coin collector. Besides silver, also a foolproof way to spot fake gold coins & bars.
- Can verify any metal including gold & silver
- Determines metal from bulk not the coating or plating
- Very fast reading times, only seconds
- No dangerous or wet chemicals
- Can read through packaging, good especially for numismatic coins
- Comes with 3 wands to read 1/10 oz. up to 100 oz. bars

Verifying Gold

Gold Properties
- Resistant to oxidation - it doesn't tarnish or rust.
- Gold is non-magnetic.
- High thermal and electrical conductive – also corrosion resistant. Thus it makes gold indispensable in electronics.
- Gets dissolved only by nitro-hydrochloric acid – a mix of 75% nitric acid and 25% hydrochloric acid which has a yellow-orange colour.
- Malleable – presses into very thin sheets, 10x thinner as a paper sheet. The sheets are then used for infrared reflectivity (by evaporating the sheets onto glass), as fillings for teeth, etc.
- Ductile – can be drawn into thin wires that deposit onto circuits, like transistors, useful as a brazing alloy, industrial solder, orthodontic appliances, jet engine fabrication, etc.
- Sectile – it's a relatively soft metal. To combat its weakness, it must alloy with other metals like silver, nickel, copper or platinum.

Karat Equivalency Table

Gold Content	Karat System	Millesimal Fineness System	Gold / Not Gold		
33.30%	8K	333	Not Gold		
37.50%	9K	375	Not Gold		
41.70%	10K	417	Gold Alloy		
58.30%	14K	583 (585)	Gold Alloy		
62.50%	15K	625	Gold Alloy		
75%	18K	750	Gold Alloy		
83.30%	20K	833	Gold Alloy		
87.50%	21K	875	Gold Alloy		
91.60%	22K	916	Gold Alloy		
95.80%	23K	958	Gold Alloy		
99.90%	24K	999	Pure Gold		

Magnifying Glass Test

The Magnifying Glass Test is the first home test for gold you can take if you want to determine the authenticity of your gold product. This test is straightforward since it requires only your gold bullion or jewellery and a magnifying glass.

Look For
- Discoloration
- Colour
- Shininess
- Purity Hallmark

Discoloration
Gold is chemically inert. This means that gold doesn't react to any environmental factors. So if you spot some discoloration marks on your item, it indicates fake gold or gold-plated. This is especially true if you detect other metal under the discoloured areas.

Colour and Shininess
Genuine gold has a beautiful soft yellow colour and is not very shiny. If your gold piece is too shiny, too yellow or has another colour tone(reddish), then it's not pure gold.

The Purity Hallmark
The purity hallmark can be either in millesimal fineness or Karat system as mentioned above. For example, if you own the purest gold, you should see hallmark "999" or "24K" engravings somewhere on the item. However, keep in mind that this engraving could also be fake. Therefore, you should conduct further tests to authenticate your item. The purity hallmark is a good clue if showing a value less than 10K. It instantly certifies that your item is not genuine gold according to US standards.

Hallmark Test

How to examine gold jewellery at first glance? Start with the Hallmark Test. The terms gold hallmarks or gold markings refer to a set of compulsory marks which are engravings on the gold item. Jewellery producers usually mark their pieces with stamps which are called Gold Jewellery Markings Symbols. On necklaces and bracelets, these jewellery hallmarks can be found on, or near, the clasp. However, on rings they are somewhere on the inside surface. These markings must include the purity of the piece (in Karats or millesimal fineness).

Also, the gold markings on jewellery should include the manufacturer's stamp. This will help you authenticate the producer of your gold item. Some countries have certain hallmark standards. India is an example. Five hallmarks help purchasers identify Indian gold. These include Gold Assay Marks. (BIS Standard Mark, Assayer or Hallmarking Centre's mar), which are third-party assayers). Additionally, you can identify by the Purity Grade expressed in millesimal fineness and year of marking. The year of marking is an alphabet letter approved by BIS and the jeweller's mark.

Gold Plated Stamps
- “HGP” - Heavy (Hard) Gold Plate
- “GF” - Gold Filled
- "GP" - Gold Plated
- "H.G.E." - Hydrostatic gold electroplating
- "G.E.P." - Gold electroplating
- ".925" - Sterling Silver
- "1/20" - 1/20 gold which is just gold-filled

They all mean that the item is gold plated. Also, beware of 800, 925 and 950 marks because these are all silver hallmarks. This means the item is undoubtedly fake. The Hallmark Test isn't 100% accurate because it doesn’t give any reliable evidence that you have real gold coins, bars or jewellery. However, it may help you a little bit by giving you initial clues when the gold is not genuine.

Skin Test

One of the easiest methods of testing gold purity is the Skin Discoloration Test. Real gold won’t leave any stains or spots on your skin. However, if you are wearing fake gold jewellery or handle fake gold bullion - your skin will discolour. Just hold your gold item in your hand for a couple of minutes. If it’s fake gold, the sweat on your skin will create a chemical reaction with the metal. Your skin will discolour to a black or green colour. This is because it will react with the other alloy metals. If it’s genuine gold – it won’t react with your skin. Important: If you test your gold item on a skin area with previously applied liquid foundation or powder, the real gold will leave a black streak on your skin. This may compromise your testing. For this reason, we recommend you ensure that your skin is clean and without makeup. Thus, if your clean skin experiences black or green discoloration – then it’s fake gold. Otherwise, you can perform the next tests to ensure you have pure gold.

Makeup Test

If you'd like to take the skin test one step further, you can also learn how to test gold at home with makeup. Let's explore how to tell if gold is real with makeup. You'll need liquid foundation makeup and powder. First, coat the top of your hand, or your forehead with a thin layer of foundation and powder. Wait until the foundation thoroughly dries. Once the foundation dries, press the gold into your skin. Then, lightly rub the gold against the foundation. If your gold leaves a line or black streak, it is very likely to be authentic gold. If you do not see a line or black streak, the object is likely to be another metal or gold-plated.

Float Test

One of the simplest ways to test gold at home is the Float Test. All you need is a cup (or bowl) of water and your gold item. Place your gold piece into the water. If it’s genuine gold, then it will immediately sink to the bottom of the cup. Pure gold is heavy due to its high density – 19.32 g/ ml. If your gold item floats or hovers above the cup’s bottom – it’s fake or plated gold. Its density is lower: 14K – 12.9 to 14.6 g/ml, 18K – 15.2 to 15.9 g/ml, and 22K – 17.7 to 17.8 g/ml. However, the Float Test is not a 100% accurate test because the fake item can have other heavy metals which sink as well. This is why it must be a preliminary method only. Also, keep in mind that real gold doesn’t rust or discolour if you place in water. Any signs indicating this reaction is a confirmation of a fake gold or gold plated item.

Porcelain Tile Test (Scratch Test)

Another easy to carry out, yet good preliminary gold purity check is the Porcelain Tile Test. This is also known as the Gold Scratch Test. To perform it, you need a piece of unglazed porcelain tile or ceramic plate. You can buy these at any hardware or home maintenance shop. For testing gold jewellery or bullion, you have to rub (or scratch) it across the porcelain tile/ceramic plate. Then you analyse the colour of the produced streak. If the gold is real, then it should show a golden, yellow colour. If you see a black streak instead, then you have pyrite or fake gold. However, keep in mind that by scratching gold, you can cause irreplaceable damage to it. This will alter its value. Thus, you may think of using other harmless testing methods to authenticate pure gold.

Magnet Test

The Gold Magnet Test is one of the most convenient home gold tests. It’s also very quick and easy to use. A magnet is a cheap and portable solution. You can carry this test out anytime you need to check gold authenticity when buying gold bullion or jewellery. To perform this test, you need a high-strength magnet, which you can buy at any local hardware store. Place the magnet near the gold item. Fake gold or gold alloys will be instantly attracted to the magnet. This reveals the true nature of the underlying metal. It is not made of gold or has a meagre percentage of it. Gold is a non-ferrous metal, which means it won't attract the magnet.

So, even if the item is slightly magnetic (but doesn’t stick to the magnet) – it’s gold-plated. This is common for some counterfeit coins that appear like gold. Yet these coins are only gold on the surface. So, if your magnet was attracting your gold piece, you can certainly skip the next tests. You know for sure whether your gold is pure or not. If your gold item doesn’t get attracted at all – it’s likely pure gold. However, remember that the Magnet Test for Gold is not a foolproof test to find out if the item is made of genuine gold.

This is because some counterfeit pieces have other metals which are also not magnetic (like silver). So make sure to perform additional testing to be sure you own a piece of real gold. Also, note that jewellery items may have strength pieces that are not real gold. These include things like clasps and bracelet wire which can be magnetic. So it may look like the jewellery is attracted to the magnet. But it’s the metal inside that specific piece that is doing the attracting, not the gold. Be sure to test the chain and charms to be utterly sure of its purity.

Acid Test

The Gold Acid Test is the most popular and accurate home gold test. This is because it may harm or damage only fake materials. However, make sure to perform the acid test only if your item was identified as non-magnetic during the previous test. This helps to avoid any unnecessary expenses and actions. Additionally, take into consideration to carry out the acid test only on pieces of gold that you won’t mind scratching/damaging. Or, that you won’t sell for aesthetic value.

- Gold Testing Acid Kit – which may include either hydrochloric and nitric acids along with a dropper, or particular samples for each type of gold Karat acids (10K acid, 18K acid, 22K acid, etc.).
- Black Gold Testing Stone – you must thoroughly rub it with a 320 grit sandpaper, wash and rinse it before making each test.
- Acid Test Gold Needles – they have different Karat gold tips to use for comparison with your test pieces.
- Two glass beakers – one with water mixed with baking soda, for washing the stone and other with water to rinse the stone in it.
- Rubber gloves, protective eyewear, a piece of glass and a plain white paper towel – as additional safety measures that you can find in a hardware store.

Once you have all of the above items, make sure to find a well-ventilated area to perform the testing gold with acid. Put on your gloves and eyeglasses. Then, prepare your testing space and proceed to test your gold piece. There are two known ways how to test gold by using the acid kit. However, before beginning them, you should differentiate the peculiarities of your specific acid test kit. The gold testing acid kit, which includes nitric and hydrochloric acids, is good for determining if it’s real or fake gold. You should know that nitric acid (also called aqua fortis) will dissolve any metal that is not gold. Therefore, checking for a reaction with nitric acid will let you see if your gold is fake or is an alloy.

A mix of 3:1 of nitric and hydrochloric acids (also known as the aqua regia) is the only acid mixture that can dissolve gold, even the purest one. You can use this solution only if your gold successfully passed all the nitric acid tests. If you have a gold karat acid test kit, then you should know that each bottle is a different mixture of nitric acid and other components. Therefore, a reaction with a specific Karat bottle shows that your gold piece has a lower fineness. Additionally, a slight response indicates that you’ve matched the Karat. Lastly, an absence of reaction is a sign of higher purity. Now you know the differences between the two gold acid test kits.

Place the gold testing acid directly on your item.
First of all, you should put the piece of glass on your table and cover it with the plain white paper towel to avoid any damage to your working surface. Place your gold item on a towel. Then, use a small sharp graver to make a small notch preferably in a hidden spot. Make sure to penetrate and expose the metal beneath the surface. Then place a drop of nitric acid directly on the notch. Observe the chemical reaction. If you immediately notice a green effervescent, bubbly, and smoky fizz it's fake gold. (contains copper). In some cases, it will burn off plating or discolour the object. At this point, no further testing is required. However, if the notch looks cream-milky, then you have gold-over-sterling-silver.

If the spot turned darker in colour or looks like rusty gold, then you most likely have a low Karat gold. If you have a special gold karat acid test kit, you should repeat the acid test starting with the highest Karat acid. Then watch the results until the acid stays clear like water. No reaction, or a slight one, means that you've matched the right Karat of gold with the correct acid. An important thing to keep in mind is that when testing different Karat acids, you need to wash the acid off the item in the water and baking soda mix beaker. Then, rinse it in the water beaker.

Genuine gold will stand the test by not reacting with the nitric acid. It will leave a clear drop of liquid over the unaffected notch, with no changes in colour. If you want to double test for real gold, you can use the aqua regia mix. However, we do not recommend placing it directly on your item because it will damage your piece. Use a testing stone instead. You should make a small scratch with your gold piece and put a drop of aqua regia. If it's dissolved – you have real gold.

Scratch test gold on the Black Gold Testing Stone
Begin with placing the glass piece on your testing surface. Then take your gold item and scratch it on the Black Gold Testing Stone until it leaves a slight line. Make sure you scratch through any potential plating. Now take the Gold Testing Needles and mark your line with a symbol ("X" or "?") by using any of the needles. Then, for each needle repeat the gold line parallel to yours and write the Karat symbol above the line. Take the first acid to test gold (usually 10K) and apply its content across your gold samples. Or you can make small drops on each sample. After 30 seconds, wash the testing stone in the water/baking soda mixture. Rinse it in water and pat it with the plain white paper towel. If the acid dissolves your testing sample, then you have a lower Karat piece. Yet, if your sample has a slight reaction, you've matched the Karat. If it hasn't changed under the acid's action, then you have a higher Karat gold. In this case, you should repeat the test steps with the following Karat acids until the result matches your sample. If you have a 23K or 24K piece, and the last acid bottle from the kit is the 22K, then you should either proceed to test using gold testing machines. Or, if you have pure nitric and hydrochloric acid, perform the aqua regia acid test for gold on your scratch sample. If it gets dissolved, it's genuine gold.

Vinegar Test

The vinegar is a quick and easy test. You only need a dropper or glass container. You'll also need some white vinegar. To use the dropper follow these steps. First, secure your dropper and fill with white vinegar. Next, hold your gold in your hand or set on a flat surface. Third, place a few drops of vinegar onto your gold. Finally, if the vinegar drops change the gold colour, it is not pure gold. If the colour does not vary, it is pure gold. If you're using a glass bowl or cup, fill it with white vinegar. Let the gold sit in the vinegar for about 15 minutes. Remove the gold piece and rinse it. If the gold is real, it will shine. If the gold is fake, it will change colour. This reaction is to the acetic acid.

Weight / Size Test

This test is ideal if you own bullion coins and want to check the size and weight of your gold. Gold bullion coins are a specific weight and size, made to specification. This will give you a starting point to ensure the authenticity of your gold coin. Since gold is very dense (one of the densest materials in the world)--it is very hard to replicate. Real gold will be less compact. Fake gold materials are different-counterfeiters will need more of the material to replicate the weight of gold. You should know what your gold coin is supposed to weigh, as well as it's diameter and thickness. Now weigh and measure your piece. This will help you to more easily spot real vs fake.

Black Jeweller's Stone Test

For this test, you'll need to purchase a black jeweller's stone. It is critical to ensure you buy the right stone for this test. You can purchase through a local jeweller. Additionally, you can buy one online at a jewellery supply store. Note: Be extremely careful with this test. You risk damaging your gold if done improperly. Position your black jeweller's stone on a flat surface, such as a table. Hold your gold in your hand. Carefully wipe it along the stone. Do this firmly enough to leave a mark, but without damaging your gold piece. If the mark is solid and gold in colour, congrats! Your piece is pure gold. If there is a faint line or no line, your piece is not real gold. Or, it is gold-plated.

Ceramic Plate Test

For the ceramic plate test, you'll need an unglazed ceramic plate. Set your plate on a flat surface such as a countertop or table. Hold your gold steadily in your hand. Carefully scrape item along the plate. Now watch to see if you spot a line, or streak, appear. A black line means it is not gold or it is gold-plated.

Take a Bite Test

Many people have seen movies where a wild west cowboy, or city businessman, will bite into gold to see if it's real. The saying goes that if your teeth leave bite marks on the gold piece, it's real. However, this test isn't recommended for two reasons. The first is that even gold-plated pieces will show bite marks. The second is that biting into gold, or gold-plated pieces, can severely damage your teeth.

Sigma Metalytics Machine

Testing is performed by matching gold's electrical characteristics on each Karat with the results of the gold piece. The gold sample is assessed in less than a second, and it doesn't affect the bar or coin in any way due. This is due to the absence of any physical damage or use of chemicals. The Precious Metal Verifier uses electromagnetic waves that allow you to measure the underlying metal beneath plating or other surface features. It penetrates deeply into the bar or coin. Therefore, it ignores the surface and assesses the main body of your gold piece.

Besides, you don't have to remove your coins or bars from their protective holders because the Verifier can work through these plastic cases. The Sigma Metalytics electronic gold tester comes with different sized sensors for different sized gold samples. The main housing comes with the biggest sensor for large precious metal samples, such as 1 oz. bars and coins. For measuring smaller gold items, you should connect to the main unit, via the cable, one of three external wands:

Advantages
- Fast and Easy
- Universal solution
- Highly Accurate
- Convenient
- Portable and Durable

- Bullion Wand - penetrates the surface of bullion to a depth of .08in (2 mm).
- Small Wand - for small precious metal samples, such as 1 gram bars, CombiBars, and 1/10 oz coins, etc.
- Large Wand - for coins and bars with weights between 1/4 and 1 oz. After placing your gold piece on the right sensor, you must select the gold sample you expect it to be. The Verifier will show the result of your item's resistivity on its display. If the black cursor is displayed between the brackets, your item matches the fineness of your gold sample. If an arrow shows up on the display, it indicates that your item is not consistent with gold. Small changes in alloy will also make a huge difference in the Verifier's results.

XRF Thermo Scientific

ECONOMY Bartering Valuables Verifying Gold

The most accurate gold testing machines use X-ray fluorescence (XRF) spectrometers. These can cost thousands of dollars. The devices send X-rays through the gold piece. It makes its atoms momentarily excited-- moving them into a higher energy state. When returning to their ground state, the atoms release radiation. Then, the XRF precious metal tester detects and reads. It figures out exactly what the piece is made of. The best gold tester is the XRF Thermo Scientific™ analyser. It will give you a fast, accurate, and non-destructive appraisal of your gold item or any precious metal piece. This gold tester comes with the unique AuDIT™ gold-plating detection technology (Au (Gold) Detection & Identification Technology).

It alerts you if your item is plated or not. Also, it provides you with the exact karat weight and percentage of gold and other elements within your item. Thus, you can easily identify advanced counterfeit gold or items with lower karat than expected. The main advantages of using this gold tester are that you will get the precise concentration of gold and other metals. This is without having to manually change any settings or calibration. Besides, since there are no chemicals or physical damage involved, this method is the most accurate and inoffensive test to authenticate your gold items.

Verifying Gemstones

There are nearly an infinite number of combinations of rocks in the earth but if it's attractive to you then you should sell/buy it. Based on intrinsic value, hard to verify quality. Good to trade for in hard times to make a profit afterwards. The more common gems such as diamonds and sapphires are more likely to be fakes.

	Precious Gemstones	Semi-Precious Gemstones	Semi-Precious Gemstones
These are any type of rock that is dug up from the earth and is generally considered valuable.	● Diamond ● Ruby ● Sapphire ● Emerald	● Amethyst ● Garnet ● Lapis Lazuli ● Malachite	● Onyx ● Pearl ● Quartz ● Topaz

Use a gemstone identification chart to help with the identification.

1	Feel the stone's surface. A stone with a rough or sandy texture should not be identified as a gemstone.
2	Check its malleability. A stone that is readily malleable—i.e. easy to shape by hammering, crushing, or bending it—the stone is more likely a metallic ore than an actual gemstone. ● True gemstones have a crystalline structure. This structure can be shaped through cutting, fracturing, and abrasion, but it has fixed planes that cannot be altered by pressure alone. ● Don't hit a stone with a hammer if you don't want to shatter it. Real gemstones don't get bend or reshaped, but they do break.
3	Know which materials are not classified as gemstones. In particular, pearls and fossilized wood can be mistakenly classified as gemstones but do not fit the qualifications in the strictest sense of the term.
4	Watch out for synthetics. Synthetic stones share the same structure, chemical composition, and physical properties of their natural counterparts, but they are created in a lab rather than made naturally. You can usually spot a synthetic by observing several characteristics. ● Synthetic stones often have curved growth patterns inside the stone rather than angular growth patterns. ● Gas bubbles are that are round and come in large strings are often an indication, but be careful, since a gas bubble in an inclusion can occur within natural stones. ● Platinum or gold platelets can stick to synthetic stones. ● Fingerprint-patterned inclusions are common in synthetics, as are nail-shaped inclusions, chevron (v-shaped) growth patterns, wispy veil-like inclusions, and interior columnar structures.
5	Watch out for imitations. An imitation stone is a material that looks like a real gemstone upon first glance in spite of the fact that it is made of a completely different material. These stones can be natural or artificial, but there are a few good techniques used to spot them either way. Pay a special attention while checking Turquoise, Lapis, Sapphire, Ruby and Emerald because there are many treatments available in market which make the stones the same as the natural version. ● The surface of an imitation may look pitted and uneven, like an orange peel. ● Some imitations have swirl marks known as "flow lines." ● Large, round gas bubbles are common within imitations. ● Imitations tend to feel lighter than their natural counterparts.
6	Determine whether or not the gemstone is an assembled stone. Assembled stones are made of two or more materials. These stones may consist entirely of natural gems, but oftentimes, synthetic materials are mixed in. ● Use a penlight to illuminate the stone when checking for signs of assembly. ● Look for differences in lustre or for coloured and colourless cement. ● Also look for the "red ring effect." Turn the stone face down and look for a red ring along the outer part of the stone. If you spot the red ring, you probably have an assembled stone.
7	Look at the colour. The colour of the gemstone is often your first clue. This component can be further divided into three parts: hue, tone, and saturation. ● Do not shine a light into the stone to examine its colour unless you have a dark stone and need to determine whether it is black, dark blue, or another deep colour. ● "Hue" refers to the stone's overall body colour. Be as specific as possible. For instance, if a stone is a yellowish green, identify it as such instead of merely saying "red." The GIA separates stone hue into 31 different colours. ● "Tone" refers to whether a colour is dark, medium, light, or somewhere in between. ● "Saturation" refers to the intensity of colour. Determine whether the hue is warm (yellow, orange, red) or cool (purple, blue, green). With warm colours, check the stone for brown tints. For cool colours, check the stone for gray tints. The more brown or gray you see, the less saturated the stone colour is.
8	Observe the transparency. Transparency describes how light filters through the gemstone. A stone can be transparent, translucent, or opaque. ● Transparent stones are completely see-through (example: diamonds). ● Translucent stones can be seen through, but some colour or haze alters the image (example: amethyst or aquamarine). ● Opaque stones cannot be seen through (example: opal).
9	Check its heft or estimated specific gravity. You can determine heft—how heavy the gemstone is—by simply bouncing it in your hand. This is a quick and easy way to estimate a stone's weight without performing complex specific gravity tests and equations. ● To judge heft, bounce the stone in the palm of your hand and ask yourself if it feels as heavy as you would expect for its size or if it feels heavier or unusually light. ● Specific gravity readings are fairly out-dated as a practice among gemologists, and heft measurements are used as a relatively accurate estimation. ● For example, aquamarine has low heft while blue topaz, which is similar in appearance, has a high or heavy heft. Similarly, diamond has a lower heft than synthetic cubic zirconia.
10	Note the cut. While not a foolproof method of identification, some gemstones are more likely to be cut in certain ways. Oftentimes, ideal cuts are determined by the way light bounces off the crystalline structure of the stone. ● The most common cut styles you will run across include faceted, cabochon, cameo, bead, and tumbled. Within each of these basic cut styles, you will usually see sub-styles, as well.

11	Ask yourself if damage tests are appropriate. There are a few identification tests that you may wish to avoid if you need to preserve the gemstone in its current state. This includes hardness, streak, and cleavage tests. ● Some stones are physically harder than others, and hardness is usually measured by the Mohs' Scale. Use the various substances provided in a hardness kit to scratch the surface of the gemstone. If the stone can be scratched, it is softer than the substance you scratched it with. If the stone cannot be scratched, it is harder than the substance. ● To test streak, drag the stone across a ceramic plate. Compare the streak left behind to the streaks illustrated on a streak chart. ● "Cleavage" refers to the way a crystal breaks. If there are chips along to surface, examine the area inside the chips. If not, you will need to strike the gemstone hard enough to break it. Ask yourself if the area is rounded like rings on a seashell (conchoidal), straight like steps, granular, splintery, or uneven.
12	Check optical phenomena. Optical phenomenon only occurs inside certain stones. Depending on the stone, you might observe colour change, asterism, bands of moving light, or more. ● Check for optical phenomena by passing a pen light across the stone's surface. ● Colour change is one of the most important optical phenomena to look for, and every stone should be checked for colour change. Look for changes in colour between natural light, incandescent light, and fluorescent light.
13	Look at the lustre. Lustre refers to the quality and intensity with which a surface reflects light. When testing for lustre, reflect light off the portion of the gemstone with the best polish. ● To check for lustre, turn the stone, allowing light to reflect off its surface. View the stone with the naked eye and with a 10x loupe. ● Determine if the stone looks dull, waxy, metallic, shiny (adamantine), glass-like (vitreous), greasy, or silky.
14	Observe the gemstone's dispersion. The manner in which a stone separates white light into its spectral colours is called dispersion, and the visible display of dispersion is called fire. Examine the amount and strength of this "fire" to help identify the stone. ● Shine a penlight through the stone and examine the fire inside the stone. Ask yourself if the fire is weak, moderate, strong, or extreme.
15	Determine the refractive index. You can test refractive index (RI) using a refractometer. Using this device, you'll be able to measure the degree at which the course of light is altered within the stone. Each gemstone has its own RI, so discovering a sample's RI can help you figure out what sort of stone it actually is. ● Place a small bead of RI fluid on the metal surface of the refractometer near the back of the crystal hemicylinder (the window on which the stone will sit). ● Place the stone facet face down on the fluid dot and slide it toward the middle of the hemicylinder crystal using your fingers. ● Look through the viewer lens without magnification. Continue looking until you see the outline of a bubble, then look at the bottom of this bubble. Take the reading from there, rounding the decimal to the nearest hundredth. ● Use the magnifying lens to take a more specific reading and round it to the nearest thousandth.
16	Consider testing the birefringence, as well. Birefringence is related to RI. While doing birefringence test, you will turn the gemstone on the refractometer six times throughout the observation period and note the changes. ● Perform a standard RI test. Instead of keeping the stone still, gradually turn it 180 degrees, making each separate turn about 30 degrees. At each 30 degree mark, take a new RI reading. ● Subtract the lowest reading from the highest to find the stone's birefringence. Round it to the nearest thousandth.
17	Check for single or double refraction. Use this test on translucent and transparent stones. You can determine whether the stone is only singly refractive (SR) or doubly refractive (DR) to help identify it. Some stones can also be classified as aggregate (AGG). ● Turn on the light of a polariscope and place the stone face down on the lower glass lens (polarizer). Look through the top lens (analyser), turning the top lens until the area around the stone looks darkest. This is your starting point. ● Turn the analyser 360 degrees and watch how the light around the stone changes. ● If the stone appeared dark and stays dark, it is likely an SR. If the stone starts light and stays light, it is likely AGG. If the lightness or darkness of the stone changes, it is likely DR.

3 Vices

Feeds people's addictions which they will need after a disaster.

Alcohol

Alcohol will be a sought after product as people will want to drown their sorrows. It also has a multitude of other uses too.
Fermentation (Degradation) of the alcohol stops past 20%

Alcohol Uses
- Drinking
- Antiseptic / Sterilization
- Pain Reliever
- Fire Lighting
- Defence / Molotov
- Car Fuel Source
- Stove Fuel Source
- Lighting

Strongest Alcohols
- Stroh Rum $75 - 80%
- King's 190 Proof $129 - 95%
- Spirytus - 95%
- Everclear - 95%

Alcohol Content
- Beer - 3-10%
- Wine 9-18%
- Liquors - 15-45%
- Spirits - 20-55%
- Moonshine / Everclear 70-90%

Spirits (Whisky, Vodka) are the most versatile to trade, ensure it's over 40% ABV. Nips (airplane bottles) would be better to trade in the smaller bottles to transport and trade for less.

Cigarettes

This will still be a black-market item in the apocalypse and people will want to get their fix.

Caffeine / Tea / Coffee

Some people are so addicted to their tea and coffee they will get a throbbing headache if their daily dose isn't met.

Sugar & Lollies

Sugar is another addiction people will want to quench and they could get just as bad reactions if they don't get their fill.

Sugar / Lollies
- Sugars
- Hardboiled Lollies
- Soft / Gummy Lollies
- Chocolates

Drugs

This will still be a black-market item in the apocalypse and people will want to get their fix.

Sex

People are likely to have a lot of sex during disasters and people won't want to raise a child in a world with violence everywhere. Condoms, lubricants and sex toys could become sought after. Some people who have never considered it may even barter sex itself to stay alive.

4 Essentials

These are the essentials everyone needs to survive.

Water

Everyone will need food and water and these essentials will be the main form of trade.

Access to Water	
Milk / Juice	
Soft Drinks	

Food

Everyone will need food and water and these essentials will be the main form of trade.

Fresh Foods	Freshly grown foods are an ideal way to make a profit and to sustain yourself.
Long Life Foods	Long life foods such as certain breads, chips and biscuits will be fairly rare.
Canned Foods	Canned foods will be a common barter item as their infinite life will make them easily available at first.
Lollies / Sweets	These won't be traded often but with their long life they will at least provide some nutrition.

5 Others

Animals

Animals, especially ones that give food will be highly sought after in a SHTF world. You will need to be extremely careful with them however due to the high risk of them being stolen.

Medicine

Medicine will be extremely rare in a long term disaster due to the generally close expiry dates, the need to keep them refrigerated and the amount you need to take to heal a condition.

Non Prescription
- Panadol
- Nurofen
- Imodium
- Hayfever
- Melatonin

Prescription
- Amoxicillin
- Ciprofloxacin
- Cephalexin

Wound Care
- Band-Aids
- Israeli Bandages
- Cleaning Pads

Dental
- Mouth Mirrors
- Toothpaste
- Tooth Filler

Electricity

Electricity can be sold in the form of recharging rechargeable batteries for someone or having a direct line from your solar panels to another location to run a customers device. Although it's a tricky one to sell it can be done with relative ease if say, the customers bring their rechargeable batteries to you and you give them back the next.

Electricity Sources
- Solar
- Generator
- Dynamo/Pedal
- Wind
- Water

Digital Files

Digital files can be traded to those in need of information as long as technology still works. The best part about digital files is that you can barter them out infinitely without needing a physical item while retaining your own copy. Be sure you tell each person you barter with about the value in the digital files and why they shouldn't be given out freely to other people they don't know.

Digital Maps

Maps are a vital source in a world without the internet and many people won't be ready for a world without navigation. Downloaded offline maps can be extremely useful for other people to navigate properly and find their family and other locations they seek.

Map Formats
- .jpg
- .png
- .aqm (Alpine Quest)

Digital Entertainment

People will still want entertainment when the grid goes down and if you have a collection of movies and Tv shows you'll be able to trade them for something you need.

Entertainment
- Movies
- Tv Series
- Games
- Music

Knowledge

Transferring knowledge often takes time to sit down with someone and teach them something unless there's blueprints, plans or books you can give them instead. The easiest way to make a profit would be for selling books on techniques for keeping you alive. Another form that could be marketed is teaching someone how to filter water, ensure food is safe and farming.

Hunter/Gathering	Knowledge on hunting animals and foraging for food.
Water Purification	How to build and maintain a water purification device.
Fire Lighting	How to light fires from items around the house.
Construction	How to build shelters from wood or rebuild a partially destroyed house.
Medical Advice	Many won't have access to doctors and you could charge per client.
Farming	Setting up a farm and how to maintain it.
Home Defence	House reinforcements and defence training.

Skills

Much like today there will be a lot of jobs requiring contractor skillsets which you can make a profit from.	**Skills** ● Doctor ● Plumber ● Bodyguard ● Thousands More	See the "Skills" section for more ideas on skills you can barter.

Payment
Payment of the hired individual should occur at multiple stages throughout the hiring term. An example is if you've hired someone for 12 hours, they should be paid in 2 hour instalments to prevent them ripping you off or vice versa. At minimum the payments should be split into 2, one before they start work and one when they finish.

Other Items

Other barter items.

Guns & Bullets	Never trade these, they could be used against you.
Fuel	Degrades quickly if not stabilised and worthless if the disaster is an EMP.
Condoms	A great item with multiple uses such as sex or water storage.
Toilet Paper	People won't be able to give up their toilet paper easily and this will sell well in the early days of a disaster.
Water Filters & Tablets	Everyone requires water to live and these will be a vital commodity.
Crafted Items	You can create your own items to sell from sun catchers to water filters to homemade meals.

6 Negotiating

This section details how to set up a trade, ensure it's protected and negotiating skills. There may be hubs of trade in a SHTF scenario after the initial panic and the stores are bare and this is what the following section is based around. This guide assumes you have family or friends who can act as bodyguards and protection for your merchandise. It also assumes that you have a few barterable items on you or in a portable trailer if you're selling and a selection of valuables if buying.

Being a SHTF scenario with no form of solid trade in place, prices will always be open for offers and bartering. Haggling has an emotional component. The seller often employs negotiating tactics to elicit an emotional response, hoping you'll feel compelled to pay more than you want to. At the same time your goal is to soften their resolve so they will give you a lower price. The word "bartering" is often used in place of haggling, and while they both require similar skills of negotiation, bartering is an exchange of services or products, whereas haggling is a negotiation for a lower price, most often paid with money. Try to negotiate everything when possible as you could save some "money" which you may need later.

Preparation

Choose the Location	Choose a location far from your prepper stockpile and house to ensure their security. The location should ideally be a public place with lots of bypassers. The location shouldn't be enclosed by trees, houses or other places an ambush could happen. Check that you aren't being followed to or from the location.
The Trader	The trader is the person who has a high charisma and people skills. They are generally unarmed if they have trained bodyguards as a weapon could deter a trade if they are armed. Keeping calm in any situation is vital, you can't let people know you're desperate for an item. The trader keeps a small amount of money on them in a hidden location for change if needed.
Protection	Bring 1 or more trusted people or bodyguards to observe the transaction. Ensure the guards are visibly armed and they have a view of the merchandise and the transaction. The guards should be positioned behind the salesperson near the storage point of the rest of the merchandise with a full view of both. Only have a few items out on display at a time and never bring more then you can carry on your person. Do business with people which have a good reputation. Watch out for thieves if your merchandise is touchable and never let yourself be distracted. If a theft does happen and the bodyguards see it, ensure at least one armed person stays with the rest of the gear while the other chases them down.
Positioning	Polish your gold and silverware to ensure it looks its best when on display. Put the valuables centrally to you and your guards.

Negotiating as the Buyer

ECONOMY Bartering Negotiating

- Don't flash the amount of money you have as it weakens your bargaining position.
- Know the value of the item you're buying and how long it will last. Be sure it's not a counterfeit.
- Know your ceiling and never pass it.
- Don't let your reactions betray you, if you need an item desperately don't show it or the price may go up.
- Never follow a customer back to their house who claims to have an item of value to trade, make them bring it to you.
- Never do a trade at, or near your home.
- Do not go to trade with your best shots all together, it makes you look desperate.
- Do not ever give a reason for someone to attack you because of what you have on you.

Negotiating as the Seller

- Never go below your minimum.
- Look for signs in the customer if they need an item desperately or not. If they do, don't simply mark up the price to make a quick buck particularly if nobody else needs that item.
- Don't fall for "sad" tales such as a family member is terribly ill and needs it.
- Customers are often in worse positions than the seller due, so don't be cold-hearted.

Tips

Watch the customers body language, if something looks wrong stop the trade. Keep your own body language open and cheerful rather than closed and disinterested.

Never give away the location of your home / storage location. Avoid giving hints that you have large stockpiles of resources at home. Never make threats even if the customer is being difficult.

7 Trading

When an agreed price has been reached the trade must then take place.

Selling	Generally the seller gets the money first and then they will give the bartered item. Although at the same time is also recommended if possible. If the customer doesn't get their item after paying for it they have the right to complain and make a fuss that the seller is a bad dealer and tell others to stay away.
Refunds / Replacements	Try to keep customers happy throughout the sale and have a form of guarantee if for some reason something goes wrong. If you sell them a rusted can of beans where a tiny hole is hidden by the label, that's highly dangerous to their health and they deserve a refund or replacement. If the customer accidentally breaks something themselves after payment in view of you then that's generally on them unless you have a kind heart. Some people may try to return an item after replacing it with a cheaper counterfeit so be wary after the item has left your sight. You could also say that all sales are final and no refunds for wrong choice, broken merchandise or incorrect fit apply.

Never Accept

This is a list of items you should never accept in a trade unless you deem the risk safe.

IOU's	"I Owe You's" can never be verified simply by a verbal promise of an item in the future and you are likely to never see them again.
Deflated or Deflating Currency	Forms of modern money aren't worth the paper they're printed on if the entire world has fallen.
Credit Card	Seems obvious, but if for some reason the internet is still functioning, you shouldn't accept this form of payment if you can't withdraw physical money.
Worthless Items	Sure, their collection of ultra rare baseball cards was worth $15,000 before the collapse but if you can't eat them they aren't worth anything now.
Black-Market Items	Any item with a questionable background shouldn't be accepted. This includes drugs and any black market items such as drugs and porn.
Deflating Items	Items which the value can only go down over time such as perishable foods, unless you're planning on eating it yourself.

5 Cash

Cash Stockpile

	Cash Notes Distribution (Percent of total cash)	Australian Coin Weights	American Coin Weights
Store at least $10,000 physical cash on hand for emergencies in a safe location with protection from fire, flood and theft. Only use it after SHTF has occurred as you should have all you need prepared already. If you use a safety deposit box be sure to know when you can access it and if you can withdraw it all if you fear that SHTF will occur. Have a range of notes to give change if necessary and to barter more effectively.	$1 - 10% $5 - 20% $10 - 20% $20 - 20% $50 - 10% $100 - 20% (Same for Australia except use dollar coins instead)	5c - 2.8g 10c - 5.6g 20c - 11.2g 50c - 15.5g $1 - 8.9g $2 - 6.5g	Cent - 2.5g Nickel - 5g Dime - 2.268g Quarter Dollar - 5.67g Half Dollar - 11.340g Dollar - 8.1g

6 Metal

Precious Metal Stockpile

Recommended Metal Ownage Percentage	Recommended Stockpile Distribution	Pure .999 Metal Weight Conversion (Rounded)	Pure .999 Metal Weight Conversion (Rounded)
Copper - 20% Silver - 60% Gold - 20%	1oz - 50% 5oz - 30% 10oz - 15% 1kg (32.1oz) - 4% 100oz - 1%	1g - 0.0321507 toz 5g - 0.160754 toz 10g - 0.321507 toz 1 Tr oz - 31.1035 toz 2 Tr oz - 62.207 toz 5 Tr oz - 155.517 toz	10 Tr oz - 311.035 g 25 Tr oz - 777.587 g 50 Tr oz - 1555.17 g 100 Tr oz - 3110.35 g 1/2 Kg - 16.0754 toz 1 Kg - 32.1507 toz

Actual Silver Weight

1	Determine the coin's weight in grams by consulting a coin collecting book or online guide or by weighing the coin yourself with a precision scale. Ex: 2.50g
2	Determine the coin's fineness, which is given as a percentage of silver in the coin, by consulting a coin collecting book or Internet guide. Ex: 0.900 (90%)
3	Multiply the coin's total weight times the fineness (expressed as a decimal). This product is the amount of pure silver in the coin expressed in metric units (grams). Ex: 2.5g × 0.900 = 2.25g
4	Multiply that number times 0.0321507 oz t (3.21 one-hundredths of a troy ounce), which is the weight of one gram expressed in troy ounces, i.e., 1.00 g = 0.0321507 oz t. This product is the amount of pure silver in the coin expressed in troy units. Ex: 0.0321507 × 2.25 = 0.072339075 oz t (2.249996740996 g)

7 Oil

Peak Oil

8 Gas

Peak Gas

9 Banking

Fractional-Reserve Banking

Fractional-reserve banking is the common practice by commercial banks of accepting deposits, and making loans or investments, while holding reserves at least equal to a fraction of the bank's deposit liabilities. Reserves are held as currency in the bank, or as balances in the bank's accounts at the central bank. Fractional-reserve banking is the current form of banking practiced in most countries worldwide. Fractional-reserve banking allows banks to act as financial intermediaries between borrowers and savers, and to provide longer-term loans to borrowers while providing immediate liquidity to depositors (providing the function of maturity transformation).

However, a bank can experience a bank run if depositors wish to withdraw more funds than the reserves that are held by the bank. To mitigate the risks of bank runs and systemic crises (when problems are extreme and widespread), governments of most countries regulate and oversee commercial banks, provide deposit insurance and act as lender of last resort to commercial banks.

Because banks hold reserves in amounts that are less than the amounts of their deposit liabilities, and because the deposit liabilities are considered money in their own right, fractional-reserve banking permits the money supply to grow beyond the amount of the underlying base money originally created by the central bank. In most countries, the central bank (or other monetary authority) regulates bank credit creation, imposing reserve requirements and capital adequacy ratios.

This can limit the process of money creation that occurs in the commercial banking system, and helps to ensure that banks are solvent and have enough funds to meet demand for withdrawals. However, rather than directly controlling the money supply, central banks usually pursue an interest rate target to adjust the rate of inflation and bank issuance of credit.

Regulatory Framework
In most legal systems, a bank deposit is not a bailment. In other words, the funds deposited are no longer the property of the customer. The funds become the property of the bank, and the customer in turn receives an asset called a deposit account (a checking or savings account). That deposit account is a liability on the balance sheet of the bank.

Each bank is legally authorized to issue credit up to a specified multiple of its reserves, so reserves available to satisfy payment of deposit liabilities are less than the total amount which the bank is obligated to pay in satisfaction of demand deposits. Fractional-reserve banking ordinarily functions smoothly. Relatively few depositors demand payment at any given time, and banks maintain a buffer of reserves to cover depositors' cash withdrawals and other demands for funds.

ECONOMY Banking Fractional-Reserve Banking

However, during a bank run or a generalized financial crisis, demands for withdrawal can exceed the bank's funding buffer, and the bank will be forced to raise additional reserves to avoid defaulting on its obligations. A bank can raise funds from additional borrowings (e.g., by borrowing in the interbank lending market or from the central bank), by selling assets, or by calling in short-term loans. If creditors are afraid that the bank is running out of reserves or is insolvent, they have an incentive to redeem their deposits as soon as possible before other depositors access the remaining reserves. Thus the fear of a bank run can actually precipitate the crisis. Many of the practices of contemporary bank regulation and central banking, including centralized clearing of payments, central bank lending to member banks, regulatory auditing, and government-administered deposit insurance, are designed to prevent the occurrence of such bank runs.

Types of Money
There are two types of money in a fractional-reserve banking system operating with a central bank:
1. Central bank money: money created or adopted by the central bank regardless of its form – precious metals, commodity certificates, banknotes, coins, electronic money loaned to commercial banks, or anything else the central bank chooses as its form of money.
2. Commercial bank money: demand deposits in the commercial banking system; also referred to as "chequebook money", "sight deposits" or simply "credit".

When a deposit of central bank money is made at a commercial bank, the central bank money is removed from circulation and added to the commercial banks' reserves (it is no longer counted as part of M1 money supply). Simultaneously, an equal amount of new commercial bank money is created in the form of bank deposits.

Central Banks
Government controls and bank regulations related to fractional-reserve banking have generally been used to impose restrictive requirements on note issue and deposit taking on the one hand, and to provide relief from bankruptcy and creditor claims, and/or protect creditors with government funds, when banks defaulted on the other hand. Such measures have included:
1. Minimum required reserve ratios (RRRs)
2. Minimum capital ratios
3. Government bond deposit requirements for note issue
4. 100% Marginal Reserve requirements for note issue, such as the Bank Charter Act 1844 (UK)
5. Sanction on bank defaults and protection from creditors for many months or even years, and
6. Central bank support for distressed banks, and government guarantee funds for notes and deposits, both to counteract bank runs and to protect bank creditors.

Reserve Requirements
The currently prevailing view of reserve requirements is that they are intended to prevent banks from:
1. Generating too much money by making too many loans against the narrow money deposit base;
2. Having a shortage of cash when large deposits are withdrawn (although the reserve is thought to be a legal minimum, it is understood that in a crisis or bank run, reserves may be made available on a temporary basis).

In some jurisdictions, (such as the United States and the European Union), the central bank does not require reserves to be held during the day. Reserve requirements are intended to ensure that the banks have sufficient supplies of highly liquid assets, so that the system operates in an orderly fashion and maintains public confidence. In addition to reserve requirements, there are other required financial ratios that affect the amount of loans that a bank can fund. The capital requirement ratio is perhaps the most important of these other required ratios. When there are no mandatory reserve requirements, which are considered by some economists to restrict lending, the capital requirement ratio acts to prevent an infinite amount of bank lending.

Full-Reserve Banking

ECONOMY Banking Full-Reserve

Full-reserve banking (also known as 100% reserve banking) is a proposed alternative to fractional-reserve banking in which banks would be required to keep the full amount of each depositor's funds in cash, ready for immediate withdrawal on demand. Funds deposited by customers in demand deposit accounts (such as checking accounts) would not be loaned out by the bank because it would be legally required to retain the full deposit to satisfy potential demand for payments. Proposals for such systems generally do not place such restrictions on deposits that are not payable on demand, for example time deposits.

Monetary reforms that included full-reserve banking have been proposed in the past, notably in 1935 by a group of economists, including Irving Fisher, as a response to the Great Depression. More recently, there has been renewed interest following the Great Recession. Currently, no country in the world requires full-reserve banking. Banks operating under a full-reserve ratio generally do so by choice or by contract, although the governments in some countries such as Iceland and the US have considered implementing full reserve banking to avoid future financial crises.

Negative Interest Rates

ECONOMY Banking Negative Interest Rates

Negative interest rates refer to a scenario in which cash deposits incur a charge for storage at a bank, rather than receiving interest income. Instead of receiving money on deposits in the form of interest, depositors must pay regularly to keep their money with the bank. This environment is intended to incentivize banks to lend money more freely. While real interest rates can be effectively negative if inflation exceeds the nominal interest rate, the nominal interest rate had been theoretically bounded by zero. Negative interest rates are often the result of a desperate and critical effort to boost economic growth through financial means. Negative interest rates may occur during deflationary periods when people and businesses hold too much money instead of spending. This can result in a sharp decline in demand, and send prices even lower. Often, a loose monetary policy is used to deal with this type of situation. However, with strong signs of deflation still a factor, simply cutting the central bank's interest rate to zero may not be sufficient enough to stimulate growth in credit and lending.

Understanding a Negative Interest Rate Environment
A negative interest rate environment is in effect when the nominal interest rate drops below zero percent for a specific economic zone, meaning banks and other financial firms would have to pay to keep their excess reserves stored at the central bank rather than receive positive interest income. A negative interest rate policy (NIRP) is an unusual monetary policy tool in which nominal target interest rates are set with a negative value, below the theoretical lower bound of zero percent.

Real World Example of a Negative Interest Rate
In recent years, central banks in Europe, Scandinavia, and Japan have implemented a negative interest rate policy (NIRP) on excess bank reserves in the financial system. This unorthodox monetary policy tool is designed to spur economic growth through spending and investment as depositors would be incentivized to spend cash rather than store it at the bank and incur a guaranteed loss. It's still not clear if this policy worked in these countries in the way it was intended, and whether negative rates successfully spread beyond excess cash reserves in the banking system to other parts of the economy.

Offence

Using weapons, crafting your own and hand to hand combat

"Attack the evil that is within yourself, rather than attacking the evil that is in others."
Confucius

Introduction

Sometimes offence is the best defence and there will be times that offence will be needed to defuse a situation. The Offence section is based around an intent to kill or harm another person. It's also wise to understand the forms of weapons and explosives used during wars to be prepared if they are used on your city. Offence should be used as a last measure if the other forms of de-escalation have failed, and should only be used enough to incapacitate your opponent.

There's a fine line between killing for self-interests and killing for self-defence or protecting one's country.
As a great man once said: ►

"True courage is about knowing not when to take a life, but when to spare one."
J.R.R. Tolkien

Every life is precious no matter what people's past, and careless murder of others who are simply trying to survive is not only despicable but you will carry that burden for the rest of your life. This aim of offence is to disarm or disable your opponent so they can no longer injure you.

Conscience
o

Moral Injury
A term coined by Dr. Jonathan Shay, it refers to the outcome of having done something that so contravenes one's sense of right and wrong that it can be devastating to one's sense of self as a decent human being. Killing, which one West Point instructor called "the biggest moral taboo" one can break, certainly applies, and it's clear that the military spends much more time preparing recruits to kill than it does preparing them to deal with the aftermath.

PTSD
Post-traumatic stress disorder (PTSD) is a particular set of reactions that can develop in people who have been through a traumatic event which threatened their life or safety, or that of others around them. This could be a car or other serious accident, physical or sexual assault, war or torture, or disasters such as bushfires or floods. As a result, the person experiences feelings of intense fear, helplessness or horror. Many people experience some of the symptoms of PTSD in the first couple of weeks after a traumatic event, but most recover on their own or with the help of family and friends. For this reason, treatment does not usually start until about two weeks after a traumatic experience. Even though formal treatment may not commence, it is important during those first few days and weeks to get whatever help is needed.

Purpose

The aim of OFFENCE is to help prepare and equip you for a hostile world in which anyone could be armed, dangerous and could kill you in a moments notice. It lists the major categories of modern weapons used today and how to use them safely and effectively. It also covers how to craft some weapons yourself, such as a bow and slingshot. It also covers sections such as improvised weapons, verbal offence, and spiritual offence.

Lost?

- If you're looking for modern guns, see the WEAPONS section.
- For defensive weapons such as tasers and defence against animals and insects, see the DEFENCE category.
- For smithing your own weapons and ammo, see the CRAFTING > Blacksmithing section.
- To help avoid combat with others, have a look at the SECURITY section.
- For information on shooting animals humanely, see the FIELD DRESSING section.
- For large scale warfare and weapons, see the WARFARE section.
- For effects of violence and riots, see the DISASTER TRIGGERS section.
- For information on man-made disasters such as wars and civil-wars, see the MAN-MADE DISASTERS section.
- For the wide scale effects of modern weapons and natural disasters, see the MASS DESTRUCTION section.
- For offence against animals, see the HUNTING or FISHING sections.
- For spiritual offence, and the sword of the spirit see the RELIGION section.

Contents

1 Unarmed

Knowing a form of combat training is vital to defending yourself when needed.

Natural Weapons

A list of naturally strong point on your body from which to inflict damage.

Hand Edge	
Fingers Folded Knuckle	
Second Finger Knuckle	
Heel of Hand	
Foot	
Elbows	
Knees	
Teeth	

Vulnerable Points

A list of vulnerable points on the body which to aim for when you are unarmed.

Eyes	Use your fingers in a V-shape and attack in gouging motion.
Nose	(Extremely vulnerable) Strike with the knife edge of the hand along the bridge, which will cause breakage, sharp pain, temporary blindness, and if the blow is hard enough, death. Also, deliver a blow with the heel of your hand in an upward motion, this will shove the bone up into the brain causing death.
Adam's Apple	This spot is usually pretty well protected, but if you get the chance, strike hard with the knife edge of your hand. This should sever the wind-pipe, and then it's all over in a matter of minutes.
Temple	There is a large artery up here, and if you hit it hard enough, it will cause death. If you manage to knock your enemy down, kick him in the temple, and he'll never get up again.
Back of Neck	A rabbit punch, or blow delivered to the base of the neck can easily break it, but to be safe, it is better to use the butt of a gun or some other heavy blunt object.
Upper Lip	A large network of nerves are located. These nerves are extremely close to the skin. A sharp upward blow will cause extreme pain, and unconsciousness.
Ears	Coming up from behind an enemy and cupping the hands in a clapping motion over the victims ears can kill him immediately. The vibrations caused from the clapping motion will burst his eardrums, and cause internal bleeding in the brain.
Groin	A VERY vulnerable spot. If left open, get it with knee hard, and he'll buckle over very fast.
Kidneys	A large nerve that branches off to the spinal cord comes very close to the skin at the kidneys. A direct blow with the knife edge of your hand can cause death.

2 Hand & Fist Weapons

Hand / Fist	Single-handed weapons not resembling a straight dagger blade, usually wielded without wrist action; often protects the forearm.

Tiger Claws	
Knuckle Dusters	
Cestus	
Deer Horn Knives	
Gauntlet	
Katar	
Pata	
Push Dagger	
Japanese Fan	
Wind and Fire Wheels	
Emeici	

3 Edged & Bladed

Thrusting and slicing weapons for close quarters melee.

Multitool

Swords

Long swords were classified by Gordon as longer than 28 inches/71 cm.

Curved 1-Handed

Straight 1-Handed

Curved 2-Handed

Greatsword 2-Handed

Shortswords

Delineated as 20-28 inches/51–71 cm total length.

Straight Shortsword

Curved Shortsword

Axe-Like Swords

Other Swords

Fighting Knives

Sickles

Generally short, concave blades used for heavy cutting.

Pickaxes

Axes

4 Blunt

Wielded with one or two hands at close quarters with swinging motions.

5 Pole Weapons

Wielded mainly with two hands. Primarily for melee with sweeping, thrusting, and/or hooking motions.

Blunt Staves

Spears (Non Thrown)

Polearms - Axelike

Polearms - Spike

6 Thrown

OFFENCE Thrown OFFENCE Thrown OFFENCE Thrown OFFENCE Ranged Longbows OFFENCE Ranged OFFENCE Ranged Crossbows OFFENCE Ranged Crossbows

All could be used as polearm spears, but were designed and primarily used for throwing.

Spears / Javelins

Throwing Sticks

Throwing Blades

Throwing Axes

Could also be used as axe weapons, but were specifically designed for throwing.

Throwing Balls

Bolas

7 Ranged

The bow and arrow is a ranged weapon system consisting of an elastic launching device (bow) and long-shafted projectiles (arrows).

Longbows

A longbow is a type of bow that is tall – roughly equal to the height of the user – allowing the archer a fairly long draw. A longbow is not significantly recurved.

Decurve Bow

Deflex Bow

Recurve Bows

Choose a bow that compliments your dominant eye as shooting will be more natural. Never release the string without an arrow or it may snap the bow.

Short / Reflex Bows

Crossbows

Crossbows are stock-mounted bows that shoot bolts and primarily used for hunting and target shooting. If you are interested in either field, the first thing you should do is to determine the most suitable type of crossbow for your needs and abilities.

Recurve Crossbow

These have longer draw length compared to ordinary cross bows, which provide reduced hand shock and better acceleration. Using recurved crossbows, however, also produce greater strain on the bow structure itself. Recurve crossbows are often used by advanced archers, shooters, and hunters. They are also noisy to use and thus require the accompanying use of a bowstring silencer.

Compound Crossbow

There are several variants to a compound crossbow, but all of them basically work the same way. The string of a compound crossbow is attached to a number of pulleys, and which one or several of it are connected by cables to the opposite limb. Upon preparing to take a shot, the string will naturally draw back, which makes the pulleys turn and the cables to move accordingly. The limbs will then bend, thus storing energy for the shot. These crossbows are characterized by limbs that are stiffer than usual and require greater pressure from the users because of the design. Their structure, however, allows compound crossbows to become more energy efficient than other types of crossbows.

OFFENCE Ranged Crossbows Rifle

Pistol Crossbow

Pistol crossbows are named so because of their relatively compact size. There are 80lb and 150lb pistol crossbows and other variants.

Rifle Crossbow

These are crossbows primarily designed to provide better aim, just like how rifles perform compared to other guns. Rifle crossbows are one of the most advanced models you can use. A 150lb rifle crossbow, for instance, can come with adjustable sights, foot pull, and heavy-duty fibre construction. It can hit your target as far as 250 feet away. Of course, such power also requires you to possess equivalent strength to launch your shot and cock your bow effectively.

Bullet Crossbow

This type of crossbow is also aptly named because it shoots bullet-looking projectiles made of stone, lead, or clay. Some bullet crossbows come with a string slot and barrel while others have a double string design.

Repeating Crossbow

With this type, you only have to make a single movement and everything, from bow stringing, projectile launching, and shooting, will be completed. This way, you'll be able to shoot at a faster rate than usual.

Arrows / Bolts

8 Slings

Sling

A sling is a projectile weapon typically used to throw a blunt projectile such as a stone, clay, or lead "sling-bullet". It is also known as the shepherd's sling.

Slingshot

A slingshot is normally a small hand-powered projectile weapon. The classic form consists of a Y-shaped frame held in the off hand (non-dominant hand), with two natural-rubber strips attached to the uprights. The other ends of the strips lead back to a pocket that holds the projectile. The dominant hand grasps the pocket and draws it back to the desired extent to provide power for the projectile—up to a full span of the arm with sufficiently long bands.

9 Blowgun

A blowgun (also called a blowpipe or blow tube) is a simple ranged weapon consisting of a long narrow tube for shooting light projectiles such as darts. It operates by having the projectile placed inside the pipe and using the force created by one's forced exhalation ("blow") to pneumatically propel the projectile. The propulsive power is limited by the user's strength of respiratory muscles and the vital capacity of the lungs.

10 Fire

Flamethrower

A flamethrower is a mechanical incendiary device designed to project a long, controllable stream of fire. Most military flamethrowers use flammable liquid thickened into a substance similar to napalm, but commercial flamethrowers tend to use high-pressure propane and gasoline, which is considered safer as they both die out faster and are easier to put out.

Homemade Flamethrower

You can make a homemade flamethrower by using an ignition source with a stream of flammable fluid compressed in a can. Simply light the ignition source so that it's constantly on and spray your fluid through the flame to ignite it. The higher the compression in the can, the further it will shoot. It's highly dangerous to try, so ensure you don't get any flammable fluid on your hands.	**Ignition Sources** ● Lighter ● Camping Stove	**Flammable Fluids** ● WD40 ● Hair Spray

Napalm

11 Flexible Weapons

Whips

A whip is a tool which was traditionally designed to strike animals or people to aid guidance or exert control over animals or other people, through pain compliance or fear of pain, although in some activities, whips can be used without use of pain, such as an additional pressure aid or visual directional cue in equestrianism. Whips are generally of two types, either a firm stick designed for direct contact, or a flexible whip that requires a specialized swing to be effective, but has a longer reach and greater force, but may have less precision. There are also whips which combine both a firm stick (the stock or handle) and a flexible line (the lash or thong), such as hunting whips.

Sectional / Composite

Chains / Ropes

A chain weapon is a weapon made of one or more heavy objects attached to a chain, sometimes with a handle. The flail was one of the more common types of chain weapons associated with medieval Europe, although some flails used hinges instead of chains.

12 Explosives

Harmless Explosives

Molotov's

A Molotov cocktail, also known as a petrol bomb, bottle bomb, poor man's grenade or just Molotov, sometimes shortened as Molly, is a generic name used for a variety of bottle-based improvised incendiary weapons. Due to the relative ease of production, Molotov cocktails have been used by street criminals, protesters, rioters, gangsters, urban guerrillas, terrorists, irregular soldiers, or even regular soldiers short on equivalent military-issue weapons. They are primarily intended to ignite rather than obliterate targets.

Plastic Explosives

Dynamite

Bombs

A bomb is an explosive weapon that uses the exothermic reaction of an explosive material to provide an extremely sudden and violent release of energy. Detonations inflict damage principally through ground- and atmosphere-transmitted mechanical stress, the impact and penetration of pressure-driven projectiles, pressure damage, and explosion-generated effects. Bombs have been in use since the 11th century in Song Dynasty China.

Fuses

Grenades

A grenade is a small explosive weapon typically thrown by hand. Generally, a grenade consists of an explosive charge, a detonating mechanism, and firing pin to trigger the detonating mechanism. Once the soldier throws the grenade, the safety lever releases, the striker throws the safety lever away from the grenade body as it rotates to detonate the primer. The primer explodes and ignites the fuse (sometimes called the delay element). The fuse burns down to the detonator, which explodes the main charge. There are several types of grenades such as fragmentation grenades and stick grenades. Fragmentation grenades are probably the most common in armies. They are weapons that are designed to disperse lethal fragments on detonation.

Land Mines

A land mine is an explosive device concealed under or on the ground and designed to destroy or disable enemy targets, ranging from combatants to vehicles and tanks, as they pass over or near it. Such a device is typically detonated automatically by way of pressure when a target steps on it or drives over it, although other detonation mechanisms are also sometimes used. A land mine may cause damage by direct blast effect, by fragments that are thrown by the blast, or by both.

Naval Mines

A naval mine is a self-contained explosive device placed in water to damage or destroy surface ships or submarines. Unlike depth charges, mines are deposited and left to wait until they are triggered by the approach of, or contact with, any vessel. Naval mines can be used offensively, to hamper enemy shipping movements or lock vessels into a harbour; or defensively, to protect friendly vessels and create "safe" zones.

Car Bombs

A car bomb, lorry bomb, or truck bomb, also known as a vehicle-borne improvised explosive device (VBIED), is an improvised explosive device placed inside a car or other vehicle and detonated. Car bombs can be roughly divided into two main categories; those used primarily to kill the occupants of the vehicle (often as an assassination); and those used as a means to kill, injure or damage people and buildings outside the vehicle. The latter type may be either parked (the vehicle disguising the bomb and allowing the bomber to get away), or the vehicle might be used to deliver the bomb (often as part of a suicide bombing).

Rockets

A rocket is a missile, spacecraft, aircraft or other vehicle that obtains thrust from a rocket engine. Rocket engine exhaust is formed entirely from propellant carried within the rocket before use. Rocket engines work by action and reaction and push rockets forward simply by expelling their exhaust in the opposite direction at high speed, and can therefore work in the vacuum of space.

Missiles

In modern language, a missile, also known as a guided missile, is a guided self-propelled system, as opposed to an unguided self-propelled munition, referred to as a rocket (although these too can also be guided). Missiles have four system components: targeting or missile guidance, flight system, engine, and warhead. All known existing missiles are designed to be propelled during powered flight by chemical reactions inside a rocket engine, jet engine, or other type of engine.

Missile types
- Surface-to-surface
- Air-to-surface missiles (ballistic, cruise, anti-ship, anti-tank, etc.)
- Surface-to-air missiles (and anti-ballistic)
- Air-to-air missiles
- Anti-satellite weapons.

Nuclear

A nuclear weapon is an explosive device that derives its destructive force from nuclear reactions, either fission (fission bomb) or from a combination of fission and fusion reactions (thermonuclear bomb). Both bomb types release large quantities of energy from relatively small amounts of matter. The first test of a fission ("atomic") bomb released an amount of energy approximately equal to 20,000 tons of TNT (84 TJ). The first thermonuclear ("hydrogen") bomb test released energy approximately equal to 10 million tons of TNT (42 PJ). A thermonuclear weapon weighing little more than 2,400 pounds (1,100 kg) can release energy equal to more than 1.2 million tons of TNT (5.0 PJ). A nuclear device no larger than traditional bombs can devastate an entire city by blast, fire, and radiation. Since they are weapons of mass destruction, the proliferation of nuclear weapons is a focus of international relations policy.

See "Mass Destruction" for more information.

13 Improvised Weapons

These are weapons that can easily be picked up from your surroundings and used either offensively or defensively.

Stones	Stoning used to be a popular way for executions in ancient history and stones are still as dangerous today depending on how you throw them.

Frying Pan	A frying pan would make an excellent weapon if there's notihng else nearby.
Lollipop	A lollipop - if held in the palm with the stick between your knuckes makes a powerful weapon if used correctly.
Furniture	Any kind of furniture (that can be picked up) can be used as a weapon. Folding chairs are commonly used in wrestling.
Improvised Explosives	Most compressed gasses can be the source of improvised explosions such as deodorant, LPG and butane gas.

14 Verbal Offence

15 Spiritual Offence

Defence

Self defence from attackers, animals and pests

"The best defence is a good offense."
Jack Dempsey

Introduction

The Defence section (spelt Defense in America) is about defending yourself and de-escalating any form of conflict until you can escape or the threat is neutralised. It also covers all types of armour. Defence is vital in a SHTF situation as people will be desperate to acquire what you have at any cost.

Purpose	The aim of DEFENCE is to give you the skills to be able to defend yourself from any attack whether it's a knife-wielding madman, a horde of thirsty mosquitos or a brutal snowstorm.
Lost?	● For smithing your own armour, see the CRAFTING > Blacksmithing section. ● If you're looking for modern guns, see the WEAPONS section. ● For offensive weapons, look at the OFFENCE section. ● To help avoid combat with others, have a look at the SECURITY section. ● For information on national security and defence, see the SAFETY & SECURITY section. ● For spiritual defence, and the armour of God, see the RELIGION section. ● Some categories have their own safety section such as FIRE and WEAPONS, check to see if it has its own safety section first. ● For household defence see the HOMESTEADING section. ● For shelter defence and what natural disasters they can withstand, see the SHELTER section.

Contents

1 Non Lethal

These are any non-lethal weapons which can help you defend yourself.

Subheadings

1. Pepper Spray	**2. Ammunition**	**3. Explosives**	**4. Directed Energy Weapons**

		5. Other Non Lethal Weapons					

DEFENCE | Non Lethal | Pepper Spray

Pepper Spray

Pepper spray is a lachrymatory agent (a chemical compound that irritates the eyes to cause tears, pain, and temporary blindness) used in policing, riot control, crowd control, and self-defence, including defence against dogs and bears. Its inflammatory effects cause the eyes to close, taking away vision. This temporary blindness allows officers to more easily restrain subjects and permits people in danger to use pepper spray in self-defence for an opportunity to escape. Although considered a less-than-lethal agent, it has been deadly in rare cases, and concerns have been raised about a number of deaths where being pepper sprayed may have been a contributing factor.

Types

Stream	This is a common type that releases a concentrated, ballistic stream of liquid. **Advantages:** Offers greater accuracy, reduced risk of blowback (spraying yourself or bystanders) compared to mist, and a longer effective range (often up to 15-20 feet). **Disadvantages:** Requires more precise aim.
Fogger/Cone/Mist	These sprays release a wide, mist-like pattern. **Advantages:** Covers a broader area, making it easier to hit a target and suitable for multiple attackers or crowd control. Less precise aim is needed. **Disadvantages:** Highly susceptible to wind, which can cause blowback or disperse the spray before it reaches the target. Can make indoor areas temporarily uninhabitable.
Gel	This formulation dispenses a sticky gel rather than a liquid or mist. **Advantages:** Adheres firmly to the attacker, ensuring effective incapacitation and making it harder to remove. Offers greater accuracy and significantly reduces the risk of blowback and cross-contamination, making it safer for indoor use. Can have a longer range than stream sprays. **Disadvantages:** Requires more precise targeting.
Foam	This type dispenses a thick, sticky foam that expands on contact. **Advantages:** Coats the attacker's face, incapacitating them. Suitable for both indoor and outdoor use. **Disadvantages:** Typically has a shorter range (around 6-8 feet).

Creation

DEFENCE | Non Lethal | Ammunition

Ammunition

Non-lethal rounds, or less-lethal projectiles are firearm rounds which are designed to incapacitate, but not kill, a target. The rounds rely on the transfer of kinetic energy and blunt force trauma to accomplish this incapacitation. Rubber bullets, rubber buckshot, soft polymer rounds, wax bullets, plastic bullets, beanbag rounds, sponge grenades, ring airfoil projectiles and rubber bullets with electroshock effect are less lethal than conventional metal bullets, and are also propelled at lower speed by using less propellant.

Rubber Bullets/ Baton Rounds	**Description:** These are among the oldest types of less-lethal projectiles. Despite the name, modern "rubber bullets" often have a metal core with a rubber coating, or are made of a composite material with rubber being a minority component. They can be solid cylindrical or spherical projectiles. **Mechanism:** They deliver a blunt force impact designed to cause pain and incapacitation. **Usage:** Primarily used in riot control and to disperse protests. **Risks:** Historically, rubber bullets have caused significant injuries, including blindness, broken bones, internal organ damage, and even fatalities, especially when fired from close range or at the head/upper body. Their tendency to bounce unpredictably also increases the risk of unintended injuries.
Plastic Bullets	**Description:** Similar to rubber bullets but made from solid plastic (e.g., PVC). They are typically cylindrical. **Mechanism:** Also rely on blunt force impact. **Usage:** Used for similar purposes as rubber bullets, particularly in riot control. **Risks:** Like rubber bullets, plastic bullets can cause severe injuries and fatalities.
Bean Bag Rounds (Flexible Baton Rounds)	**Description:** These are typically fabric bags (like small pillows or socks) filled with fine lead shot or plastic pellets. They are fired from shotguns. **Mechanism:** Upon firing, the bag spreads out in flight to distribute its impact over a larger surface area, aiming to deliver a blow that causes pain and muscle spasm without penetrating the skin. **Usage:** Common in law enforcement for subduing individuals, riot control, and situations where a direct, painful impact is needed. **Risks:** While designed for a wider impact, bean bag rounds can still cause serious injury (e.g., broken bones, internal bleeding) or death if they hit vulnerable areas or are fired from too close a range.
Sponge Rounds/ Foam-Tipped Rounds (Sponge Grenades)	**Description:** These projectiles have a plastic body with a soft, deformable sponge or foam nose. They are typically fired from 40mm grenade launchers. **Mechanism:** The sponge/foam nose is designed to deform on impact, spreading the force over a wider area and reducing the risk of penetration while still delivering a significant blunt trauma. **Usage:** Used by law enforcement for crowd control and tactical situations, often for point-of-aim, point-of-impact application. **Risks:** Can still cause significant injuries, especially if they hit the head or face, or are fired from too close.
Pepper Rounds/Kinetic Impact Projectiles with Irritant Payload	**Description:** These are projectiles (often .68 caliber, similar to paintball rounds) that contain a chemical irritant (like PAVA or synthetic capsaicin) inside a frangible (breakable) shell. **Mechanism:** They combine a kinetic impact with the dispersal of an irritating powder upon striking the target or a hard surface. The powder causes pain, coughing, and irritation to the eyes, nose, and throat. **Usage:** Increasingly popular for civilian self-defense (where legal) and for law enforcement as a less-lethal option. **Risks:** Can cause pain and temporary incapacitation. Direct impact can still be painful and cause bruising. The irritant can exacerbate respiratory conditions.

DEFENCE Non Lethal Ammunition

Nylon Balls/Hard Kinetic Rounds	**Description:** These are solid, hard plastic or nylon balls. Some variations may include powdered metal for added weight. **Mechanism:** They rely purely on kinetic impact to create pain and discomfort. **Usage:** Used in some less-lethal firearms, particularly in regions where other less-lethal options (like pepper rounds) are restricted. **Risks:** Due to their hardness, these can cause significant blunt force trauma, potentially leading to serious injury or even death, especially if impacting sensitive areas or used at close range.

Explosives

DEFENCE Non Lethal Explosives

Stun Grenades (Flashbangs)	**Effect:** Produce a blinding flash of light (often 2.5 to 7 million candela) and an extremely loud bang (over 170 decibels). **Mechanism:** They use a pyrotechnic mix (e.g., magnesium or aluminum with an oxidizer) that detonates without fragmentation. The casing is designed to remain intact. **Purpose:** To temporarily disorient, confuse, and stun individuals through sensory overload, making them unable to respond effectively. **Usage:** Commonly used in close-quarters combat, door breaching, and riot control by police tactical units and special forces. **Risks:** While designed to be non-lethal, close proximity to detonation can cause temporary or permanent hearing loss, burns, or concussive injuries. They can also ignite flammable materials.
Sting Grenades	**Effect:** Combine a loud bang and bright light with the projection of multiple small rubber balls or pellets at a non-lethal velocity. They may also release a chemical irritant. **Mechanism:** These grenades contain a main charge that, upon detonation, expels rubber spheres. Some variations also incorporate a chemical irritant like tear gas or pepper spray. **Purpose:** To inflict blunt trauma pain and psychological deterrent through impact, sound, and sometimes chemical irritation, causing individuals to disperse or comply. **Usage:** Primarily used in crowd management and riot control to push back or disperse aggressive crowds. **Risks:** While generally less harmful than traditional force, direct impact from the rubber pellets can cause bruising or other injuries. Their indiscriminate use in crowds is controversial.
Tear Gas Grenades	**Effect:** Release a chemical irritant that causes severe irritation to the eyes (tearing, pain, temporary blindness), nose, mouth, and lungs (coughing, difficulty breathing). **Mechanism:** These grenades contain lachrymatory agents (like CS, CN, or CR gas) in a solid or liquid aerosolized form. When activated, the chemical is dispersed into the air. **Purpose:** To force compliance, disperse crowds, or flush out individuals from enclosed spaces due to the intense discomfort they cause. **Usage:** Widely used by law enforcement for riot control and by military forces for training and certain operational contexts. **Risks:** While temporary, exposure can lead to severe allergic reactions, chemical burns, or respiratory issues, especially in high concentrations or enclosed spaces. Direct impact from the canister itself can cause serious injury or death.
Smoke Grenades	**Effect:** Produce dense clouds of colored or white smoke. **Mechanism:** These are canister-type grenades containing a pyrotechnic composition that, when ignited by a fuse, produces a large amount of smoke. **Purpose:** Primarily used for signaling (e.g., marking targets, landing zones), obscuring movement (creating smoke screens for concealment or retreat), or for tactical diversions. **Usage:** Employed by military, police, and even in civilian applications like paintball. **Risks:** Generally non-toxic, but can be a fire hazard if used carelessly, especially with dry vegetation. Some specialized military smoke grenades (e.g., white phosphorus) are incendiary and are not considered non-lethal.

Directed Energy Weapons

DEFENCE Non Lethal Directed Energy Weapons

Directed energy weapons are weapons that emit energy in an aimed direction without the means of a projectile. They are non-lethal and can immobilize people as well as machines (e.g. vehicles). Directed energy weapons include electromagnetic weapons, (including laser weapons) and microwave weapons, particle beam weapons, sonic weapons and plasma weapons.

High-Energy Lasers (HELs)

High-Energy Lasers (HELs)

HELs produce a highly concentrated and coherent beam of light, typically in the infrared to visible regions of the electromagnetic spectrum. This beam delivers thermal energy to a target, causing it to heat up, melt, burn, or even vaporize. The effect depends on the laser's power, the material of the target, and the duration of exposure.

Applications:
● Counter-UAS (Unmanned Aerial Systems) / Counter-drone: This is one of the most prominent applications, as lasers can effectively engage and destroy small, fast-moving drones with high precision and low cost per shot.
● Missile defense: Intercepting incoming missiles (ballistic, cruise, hypersonic) by damaging their guidance systems, control surfaces, or warheads.
Area denial/protection: Creating "no-go" zones by making areas hazardous for personnel or equipment.
● Dazzling/Blinding: Temporarily or permanently impairing optical sensors or human vision (though permanent blinding is often prohibited by international conventions).
● Precision strike: Engaging specific components of a target with high accuracy.

Advantages: Speed-of-light engagement, high precision, "deep magazine" (limited only by power), low cost per shot compared to kinetic interceptors.
Challenges: Atmospheric conditions (rain, fog, dust, turbulence) can degrade beam quality and effectiveness, requiring significant power and complex beam-steering and adaptive optics systems. Cooling requirements are also substantial.

Example: The Dazzler

DEFENCE Non Lethal Directed Energy Weapons High-Energy Lasers (HELs)

Dazzlers typically use lasers or intense light sources to overwhelm the retina or the sensor of a camera. The intense light causes temporary flash blindness, making it difficult to see or track targets. The effect is similar to being suddenly exposed to a bright camera flash.

Types of Dazzlers
● Laser Dazzlers: These use lasers, often in the visible or near-infrared spectrum, to create a temporary blinding effect. The power levels are carefully controlled to avoid causing permanent eye damage.
● Light-Based Dazzlers: These use intense lamps or LEDs to generate a bright, disorienting light.

The Light Emitting Diode (LED) Incapacitator is a weapon designed like a flashlight. It emits an extremely bright, rapid, and well-focused series of 'differently-coloured random pulses.' Before the human eyes can focus in on one frequency, another frequency comes on, causing intracranial pressure, which results in headaches, nausea, vomiting, disorientation, irritability, and visual impairment to the target (opponent). The non-lethal weapon is intended as a means of protection by law enforcement officials such as police and border patrols.

DEFENCE Non Lethal Directed Energy Weapons High-Energy Lasers (HELs)

The light emitted is capable of rendering opponents temporarily blind so that they can be subdued more easily. Some test subjects have been completely unaffected by the light, and although the manufacturer makes claims about the product's effectiveness, the CEO of Intelligent Optics, the producer of the device, has commented "I don't think we've had anyone actually be sick." There is debate over how well the devices work and what their effects are.

Applications
● Optical Sensor Disruption: To temporarily blind or degrade the performance of enemy optical sensors (e.g., cameras on drones, binoculars, missile seekers).
● Personnel Incapacitation: To create temporary flash blindness, making it difficult for individuals to aim weapons or coordinate movements.

● Escalation of Force: As a step before resorting to lethal force.
● Maritime Security: To warn or deter approaching vessels.
● Anti-Piracy: To disrupt the vision of pirates.
● Counter-UAS (Unmanned Aerial System): To disrupt the vision of drone operators.

Important Considerations
● Non-Lethal Intent: Dazzlers are designed to be non-lethal, causing temporary visual impairment rather than permanent damage.
● Distinction from Blinding Weapons: International law, specifically the Protocol on Blinding Laser Weapons, prohibits the use of laser weapons specifically designed to cause permanent blindness. Dazzlers operate within the bounds of this protocol by using lower power levels and carefully controlled wavelengths to avoid causing irreversible eye injury. The key distinction is the intent and the effect - dazzlers aim for temporary disruption, while blinding weapons aim for permanent vision loss.
● Power Levels and Safety: Dazzlers are designed with safety in mind, using power levels that cause temporary effects without causing permanent harm when used as intended. However, misuse or excessive exposure can still pose a risk.

DEFENCE Non Lethal Directed Energy Weapons High-Power Microwaves (HPMs) Weapons

High-Power Microwaves (HPMs) Weapons

Also known as High-Power Radio Frequency (HPRF) Weapons, these weapons emit powerful bursts of electromagnetic energy in the microwave or radio frequency spectrum. This energy can couple with and overload electronic systems, causing temporary disruption, degradation, or permanent damage. They can also cause physiological effects on personnel.

Applications:
● Disabling electronics: Neutralizing drones, vehicles, communication systems, and critical infrastructure by disrupting or frying their electronic components.
● Area denial/crowd control (non-lethal): The Active Denial System (ADS) is a well-known example of a millimeter-wave weapon that heats the water molecules in a person's skin, creating an intense burning sensation that forces them to move away without causing lasting injury.
● Anti-missile defense: Disrupting missile guidance systems.

Advantages: Can affect multiple targets simultaneously due to a wider beam, less susceptible to atmospheric conditions than lasers, can penetrate certain materials to affect internal electronics, can be used for both lethal (disrupting electronics) and non-lethal (ADS) effects.
Challenges: Can affect friendly electronics if not carefully directed, attribution can be difficult, shorter range compared to lasers for destructive effects.

Example: The "Heat Ray"

The Active Denial System works by emitting a highly focused beam of millimeter-wave electromagnetic energy (specifically, 95 GHz). When this invisible beam strikes a person, it rapidly heats the outer layer of their skin (to a depth of about 0.4mm, or the thickness of three sheets of paper). This sensation is described as an intense, unbearable burning feeling, similar to touching a very hot oven or frying pan. The pain is immediate and compels the person to instinctively move away from the beam, hence the "active denial" effect. The sensation ceases as soon as the person moves out of the beam or the system is deactivated, and it's designed not to cause lasting injury.

Key Characteristics and Applications
● **Non-Lethal:** The primary design goal is to create a strong deterrent without causing permanent harm or tissue damage. The shallow penetration of the millimeter waves is key to this.
● **Long Range:** ADS can engage targets at distances well beyond the range of small arms (up to several hundred meters, or even a kilometer in some configurations). This provides a significant standoff capability.

● **Speed-of-Light Engagement:** As a directed energy weapon, the effect is virtually instantaneous.
● **Area Denial/Perimeter Security:** Ideal for creating a "keep out" zone around military installations, checkpoints, or secure perimeters.
● **Crowd Control:** Can be used to disperse or deter hostile crowds without resorting to more injurious methods.
● **Personnel Deterrence:** Stopping individuals or groups from approaching a sensitive area or engaging in threatening behavior.
● **Maritime Security:** Demonstrated for repelling boarders from small boats approaching larger vessels.

Main Configurations/Generations
● **Vehicle-Mounted Systems (e.g., on Humvees or trucks)**
The initial and most publicized configurations of ADS were large, vehicle-mounted systems designed for battlefield or base protection. These require significant power sources and a robust platform. Raytheon has been a primary developer and manufacturer of these systems. Examples include the original ADS prototype and later versions like the "Sheriff" system.

● **Containerized Systems**
Some ADS iterations have been designed as armored, containerized units that can be transported by tactical vehicles, offering flexibility for deployment in various scenarios.
● **More Compact and Mobile Systems (Solid-State Technology)**
Ongoing research and development (e.g., by the U.S. Army and others) focuses on reducing the size, weight, and power requirements (SWAP-C) of ADS. This involves leveraging advancements in solid-state technology, such as Gallium Nitride (GaN) Monolithic Microwave Integrated Circuits (MMICs). The goal is to enable integration into smaller, more diverse mobile platforms, potentially even man-portable or airborne versions in the future.

DEFENCE Non Lethal Directed Energy Weapons Particle Beam

Particle Beam Weapons

These weapons accelerate a stream of charged (e.g., electrons, protons) or neutral particles to very high velocities. When these particles impact a target, they transfer immense kinetic energy, causing physical damage or even inducing radiation effects.

Applications (theoretical/research phase):
● Ballistic missile defense: Intercepting missiles in space or the upper atmosphere.
● Anti-satellite warfare: Disabling or destroying satellites.

Advantages: Potentially very high destructive power, can penetrate deeper than lasers into some materials.
Challenges: Highly complex technology, maintaining a focused beam in the atmosphere is difficult (due to thermal blooming for both charged and neutral beams, and electrical blooming for charged beams), requiring massive power sources and large accelerators. Mostly in the research and development phase.

DEFENCE Non Lethal Directed Energy Weapons Pulsed Energy

Pulsed Energy Projectiles (PEPs)

PEP systems fire an invisible infrared laser pulse that, upon striking a target (person or material), creates a rapidly expanding plasma. This plasma generates a pressure wave (acoustic blast), an electromagnetic pulse, and a shockwave.

Applications (non-lethal):
● Pain and temporary paralysis: The combined effect of the sound, shock, and electromagnetic waves can cause significant pain and temporary muscle incapacitation, suitable for crowd control or subduing individuals.
● Material effects: Can also be used to ablate (vaporize) thin layers of material.

Advantages: Non-lethal capabilities, can affect targets without direct physical contact.
Challenges: Limited range, still in developmental stages, potential for unforeseen long-term effects.

DEFENCE Non Lethal Directed Energy Weapons Acoustic Weapons (Sonic Weapons)

Acoustic Weapons (Sonic Weapons)

These systems use highly focused sound waves, often at very high frequencies or infrasound frequencies, to cause discomfort, disorientation, nausea, or even physical pain. The Long Range Acoustic Device (LRAD) is a common example, which can emit highly directional, painfully loud sounds or communicate over long distances.

Applications (non-lethal):
● Crowd control: Dispersing crowds.
● Area denial: Deterring entry into a specific zone. (Active Denial Systems)
● Communication: Broadcasting messages over long distances in noisy environments.

Advantages: Non-lethal, can cover a wider area than some other DEWs for non-lethal effects.
Challenges: Can be affected by environmental factors, potential for hearing damage at close range, ethical concerns regarding their use.

Portable/Handheld LRADs

These are smaller, more compact units designed for immediate deployment and portability.

LRAD 100X: This is a popular and relatively compact model, often described as a "loud hailer on steroids." It significantly outperforms traditional bullhorns and vehicle-based PA systems.
Uses: Cell extractions in correctional facilities, de-escalating confrontations without physical entry, communication in noisy environments, smaller crowd control situations, and tactical communication. It's often used by law enforcement, security personnel, and even for wildlife control (e.g., deterring birds from airport runways).

Mid-Range LRADs

These models offer increased range and volume compared to handheld units, suitable for mounting on vehicles or fixed installations.

LRAD 450XL: A versatile model designed for mounting on tripods, vessels, or vehicles. It provides clear communication over longer distances.
Uses: Mobile operations, maritime security (warning approaching vessels), communication in large open areas, and mid-sized crowd management.

LRAD 500X-RE / 500X-MMT: These are often designed for mobile or permanent tower installations, covering wider areas. The "MMT" version is specifically designed for helicopter mounting for air-to-ground communication.
Uses: Riot control, emergency notifications, long-range communication from vehicles or fixed checkpoints, and air-to-ground communication for public safety or military.

Longer-Range / Fixed-Installation LRADs

These are the most powerful systems, designed for extended communication ranges and large-scale applications.

LRAD 1000Xi: Known as a long-distance communication system, often used for critical infrastructure protection and border security. It's also been used by navies for communication with vessels at sea.
Uses: Border patrol, large vessel communication, perimeter security for critical infrastructure (power plants, military bases), and mass notification during emergencies.
LRAD 950NXT: A highly advanced acoustic hailing device that integrates with radar and motion sensors for automated security alerts, combining communication with surveillance.
Uses: Advanced perimeter security, maritime defense, and integrated surveillance and communication platforms.
LRAD 1950XL: Often cited as the "loudest, longest range single head AHD." It's designed to broadcast voice messages and alert tones effectively over several kilometers.
Uses: Extreme long-range communication, large-scale emergency warnings, and significant standoff distances for security or military operations.

DEFENCE Non Lethal Other Non Lethal

Other Non Lethal Weapons

Any other non-lethal weapons not listed above.

DEFENCE Non Lethal Other Non Lethal Weapons Stun Devices

Stun Devices

Stun devices deliver an electric shock upon direct contact to incapacitate a person. This is distinct from a "Taser," which is a specific brand (Axon) of conducted energy weapon that fires probes connected by wires, allowing for a standoff distance.

Compact/Handheld Stun Guns (Tasers)

These are the most common type of stun gun. They are small, often about the size of a smartphone, remote control, or even disguised as everyday items like lipstick tubes, pens, or flashlights. They typically have two metal prongs or electrodes at one end.
How they work: When activated and pressed against an attacker's body, they deliver a high-voltage, low-amperage electrical shock. This disrupts the attacker's muscle function and nervous system, causing pain, muscle spasms, disorientation, and temporary incapacitation. They do NOT cause "neuromuscular incapacitation" (NMI) like Tasers do, as they lack the spread of probes needed to override the central nervous system.
Purpose: Primarily for self-defense at very close range.
Examples: Many generic brands offer these in various designs.

Stun Batons / Stun Sticks / Stun Flashlights

These are longer devices, resembling a baton or a large flashlight, with electrodes at one end.
How they work: Similar to compact stun guns, they deliver an electric shock upon direct contact. The extended length provides a bit more reach and standoff distance than a compact handheld unit, allowing the user to keep the attacker further away. Many models also include a powerful LED flashlight, which can serve as a deterrent or disorient the attacker. Some may have an electrified shaft to prevent the baton from being grabbed.

Purpose: Self-defense, tactical use (for security personnel or law enforcement), and sometimes for animal control.
Examples: Various brands offer stun batons and flashlight stun guns in different lengths and power outputs.

Disguised Stun Guns

These are stun guns designed to look like ordinary objects to provide an element of surprise or for discreet carry.
Examples: Lipstick stun guns, cell phone stun guns, pen stun guns, ring stun guns, cane stun guns, umbrella stun guns.
How they work: Function identically to compact stun guns, requiring direct contact.
Purpose: Concealed self-defense.

Stun Shields

These are riot shields (often transparent) with embedded electrodes on the front face.
How they work: Designed for crowd control, they can deliver an electric shock upon contact with a crowd member, providing a physical barrier combined with a non-lethal incapacitating effect.
Purpose: Riot control, law enforcement tactical operations.
Status: Less common than other types, often used by specialized units.

Tear Gas

"Tear gas" is a colloquial term for a class of chemical compounds known as riot control agents (RCAs) or lachrymators. Despite the name, they are not true gases but are typically solid or liquid compounds that are dispersed as aerosols (fine particles or droplets) when deployed from grenades, canisters, sprays, or other devices. Their primary effect is to irritate mucous membranes (eyes, nose, throat, lungs) and skin, causing temporary incapacitation.

CS Gas (o-Chlorobenzylidenemalononitrile)

This is by far the most commonly used and recognized form of tear gas globally. It's a white crystalline powder.
Effects: Causes immediate and intense burning sensations in the eyes, excessive tearing (lacrimation), involuntary eye closure (blepharospasm), difficulty breathing, coughing, a burning sensation in the nose and throat, and skin irritation (stinging, redness, sometimes blistering).
Onset/Duration: Effects typically appear within 20-60 seconds of exposure and usually resolve within 10-30 minutes of leaving the contaminated area and getting fresh air.
Deployment: Often deployed as a fine powder mixed with a pyrotechnic charge in grenades or canisters, or dissolved in solvents for aerosol sprays.
History: Developed in 1928, it became widely adopted by the British army in 1958 and the U.S. Army in 1959, replacing older agents due to its perceived higher potency and lower toxicity than CN.

CN Gas (Chloroacetophenone)

An older type of tear gas, also a solid chemical. It's the primary component of the older aerosol agent "Mace" (the original brand name).
Effects: Primarily affects the eyes, causing intense tearing, pain, and irritation. It's considered more toxic and potentially more damaging to the skin and eyes than CS at higher concentrations.
Onset/Duration: Effects are rapid.
History: Developed during World War I. While less common now for widespread crowd control compared to CS, it was widely used before the advent of CS.
Note: Some sources suggest CN is more likely to cause severe injury to the skin compared to CS.

CR Gas (Dibenzoxazepine)

This is considered the most potent of the three main tear gas agents (CS, CN, CR). It's a white crystalline solid.
Effects: Produces very intense irritation of the eyes, skin, and respiratory tract, often described as more severe than CS. It's a powerful TRPA1 agonist, meaning it strongly activates pain receptors.
Onset/Duration: Effects are rapid and may last longer than CS, and it is more difficult to remove from the skin.
Deployment: Less commonly used than CS, but known for its higher potency.
History: Developed in 1962.

OC Gas (Oleoresin Capsicum) / Pepper Spray

While often lumped in with "tear gas" colloquially, OC is chemically different. It's a natural extract from chili peppers, with capsaicin as its active ingredient. It's an oily resin.
Effects: Causes intense burning pain on skin and mucous membranes, profuse tearing, involuntary eye closure, coughing, shortness of breath, and a feeling of suffocation. It works by activating TRPV1 pain receptors.
Deployment: Typically used in handheld aerosol sprays for personal defense or by law enforcement in "pepper ball" rounds or larger canisters. Unlike CS/CN/CR which are synthesized chemicals, OC is derived from natural sources.
History: Developed as an animal repellent in the 1960s and adopted by law enforcement in the 1980s.
Note: While also an irritant, its mechanism and chemical structure are distinct from the synthetic lachrymators like CS, CN, and CR.

Tranquilizer Guns

Tranquilizer guns are specialized devices used to remotely deliver sedatives, tranquilizers, or other medications to animals. They are often called dart guns or chemical immobilization projectors. They are not used on humans in this context, and their use is highly regulated, primarily by veterinarians, wildlife management professionals, and zookeepers.

Tranquilizer Dart Components
Regardless of the projector type, the darts themselves are specialized ballistic syringes. They typically consist of:
- **Needle:** Designed to penetrate the animal's hide. Some have barbs or collars to help retain the dart, ensuring the full dose is administered.
- **Syringe Barrel:** Holds the liquid tranquilizer.
- **Plunger:** Pushed forward to inject the drug.
- **Tailpiece:** Often with fletching (like a dart or arrow) for flight stability.
- **Injection Mechanism:** Upon impact, a mechanism (e.g., compressed air/gas, a spring, or a small chemical reaction/explosive charge within the dart's tailpiece) triggers the plunger to deliver the drug into the animal.

Blowpipes (Blowguns)

These are long, hollow tubes through which a lightweight dart, filled with a sedative, is propelled by the operator's breath.
● **Mechanism:** Manual pneumatic propulsion using lung power.
● **Range:** Short range (typically 1-10 meters).
● **Advantages:** Very quiet, inexpensive, lightweight, and offer a gentle impact. Ideal for small to medium-sized animals, in confined spaces, or when stealth is necessary (e.g., dense vegetation, stables, urban areas where firearms are not suitable).
● **Disadvantages:** Limited range and dart capacity, requires considerable operator skill and practice, not suitable for large or thick-skinned animals that require higher doses or deeper penetration.

CO2-Powered Projectors (Pistols & Rifles)

These devices use compressed CO2 cartridges to propel the dart. They come in both pistol and rifle configurations.
● **Mechanism:** Compressed CO2 gas provides the propulsion. Pressure can often be adjusted to control dart velocity and impact force.
● **Range:** Medium range (pistols typically 3-20 meters; rifles generally 3-80 meters, depending on dart size and pressure settings).
● **Advantages:** More precise control over dart velocity than powder-charged systems, quieter than powder-charged systems, reliable, and versatile for various animal sizes and distances. Good for both short and medium ranges with adjustable pressure.
● **Disadvantages:** Can be affected by very cold temperatures (CO2 pressure drops), limited number of shots per CO2 cartridge (though some have larger tanks).
● **Examples of Brands:** DANiNJECT, Pneu-Dart, TeleDart, Cap-Chur.

Powder-Charged Projectors (Rifles & Shotguns)

These tranquilizer guns use a small blank cartridge (similar to a firearm blank) to generate the gas pressure needed to propel the dart. They are typically in rifle or modified shotgun forms.
● **Mechanism:** A small explosive charge (blank cartridge) generates high-pressure gas to propel the dart. Different strength blank cartridges are used for different ranges.
● **Range:** Longest range (typically 40-100+ meters, some up to 120 meters).
● **Advantages:** Longest effective range, powerful penetration for large or thick-skinned animals, not as affected by ambient temperature as CO2.
● **Disadvantages:** Louder operation (can startle animals), higher risk of impact injury to the animal due to greater force if not precisely controlled, generally less fine-tuned pressure control than CO2 systems, requires careful selection of blank charge.
● **Examples of Brands:** DANiNJECT, Pneu-Dart, TeleDart, Cap-Chur.

Jabsticks (Pole Syringes)

While not a "gun" in the traditional sense, a jabstick is a long pole with a syringe and needle attached to one end. Modern jabsticks often have a mechanism that automatically injects the drug upon full impact.
● **Mechanism:** Manual, direct contact.
● **Range:** Very short range (0-2 meters).
● **Advantages:** Very quiet, no projectile involved, allows for direct and precise drug administration. Ideal for animals in confined spaces, already restrained animals, or when a very gentle approach is needed.
● **Disadvantages:** Requires close proximity to the animal, which can be dangerous with large or aggressive animals in unprotected spaces. Not suitable for open areas or unapproachable animals.

Net Guns

Non-lethal net guns are devices designed to capture or immobilize a target by entangling it in a net, without causing significant injury. They are widely used in various fields, from wildlife management to law enforcement and even counter-drone operations. The primary ways to categorize different types of non-lethal net guns are by their propulsion mechanism and their intended target/design.

Animal Capture Net Guns

Design: Vary widely in size, from small handheld devices for birds or small mammals (e.g., stray dogs, cats) to larger rifle-like systems for bigger animals (e.g., deer, kangaroos). The nets themselves come in different mesh sizes and strengths to suit the target animal.
Purpose: Humane capture, rescue, relocation, and wildlife management.
Nets: Typically made of durable nylon or high-tensile polymers like Dyneema, often with weighted corners to ensure proper deployment and entanglement.

Human/Tactical Net Guns (Law Enforcement/Security)

Design: These are specifically designed to entangle human targets. They often use larger, stronger nets and may have features for rapid reloading.
Purpose: Non-lethal immobilization of suspects, crowd control, or neutralizing threats without using lethal force.
Legality: The use of net guns on humans is highly regulated and controversial, and their deployment by law enforcement is limited to specific circumstances and agencies.

Drone Capture Net Guns

Design: Can be handheld, shoulder-fired, or mounted on another drone. They are specifically designed to entangle drone propellers and rotors.
Purpose: Neutralizing unauthorized or hostile drones in sensitive airspace (e.g., airports, government buildings, military bases).
Nets: Often designed with specific mesh sizes and materials that are effective at fouling drone rotors.

CO2-Powered Net Guns

These are the most common type. They use compressed CO2 cartridges (similar to those used in paintball guns) to generate the burst of air needed to launch the net.
Mechanism: The CO2 cartridge is punctured, releasing gas into a chamber, which then rapidly propels the net and its weights (often small metal or rubber weights at the corners of the net) forward.
Advantages: Relatively quiet, portable, reusable, and offer adjustable power settings for different ranges or targets. They are generally considered reliable and easy to reload.
Applications: Widely used for animal control (stray dogs, cats, raccoons, birds), wildlife research and rescue, and increasingly for drone capture.
Examples: Many commercial "net gun" or "net launcher" products sold for animal control and drone defense operate on CO2.

Powder-Charged (Blank Cartridge) Net Guns

These systems use a small blank firearm cartridge (like a .22 or .308 blank) to generate the gas pressure to launch the net. These often resemble modified rifles or shotguns.
Mechanism: The blank cartridge is fired, and the expanding gases propel the net and its weights.
Advantages: Offer the longest ranges and greatest power, suitable for larger animals or drones at greater distances, and less affected by very cold temperatures compared to CO2.
Disadvantages: Much louder operation (can startle animals), require proper firearm safety protocols (even though they don't fire live ammunition), and the force of impact can be higher, requiring careful calibration.
Applications: Primarily used for larger wildlife capture (deer, elk, kangaroos in some contexts), or for military/law enforcement applications where greater range is needed.
Examples: Some professional wildlife capture companies offer these, sometimes using modified rifle platforms (e.g., Remington Model 700 adapted to fire nets).

Pneumatic/Air-Powered Net Guns (Manual Pump or External Tank)

These systems use compressed air, either from a manual pump (like a bicycle pump) or an external air tank (like SCUBA tanks or paintball HPA tanks).
Mechanism: Air is compressed into a reservoir and then released to propel the net.
Advantages: Can offer consistent power and are rechargeable without needing disposable cartridges (if using a refillable tank). Quieter than powder-charged systems.
Disadvantages: Requires an external air source or manual pumping, which can be less convenient for rapid deployment.
Applications: Less common for commercial net guns than CO2, but might be found in custom or DIY builds, or specialized industrial applications.

Drone-Launched Net Systems

This is a newer and specialized type where a net is launched from another drone, often designed to intercept rogue drones.
Mechanism: The attacking drone carries a compact net launcher (which might be CO2-powered or spring-loaded) and fires the net at the target drone in mid-air. Some designs even involve nets that are dragged by the attacking drone, aiming to entangle the target's rotors.
Advantages: Offers aerial pursuit and interception capabilities, reducing the risk to human operators. Can capture the drone for forensic analysis.
Applications: Counter-drone technology for security, military, and critical infrastructure protection.
Examples: Systems like SkyWall (a ground-based bazooka-like launcher), or drone-on-drone capture systems (e.g., those developed by Tokyo police, or various defense contractors).

Water Cannons

A crowd water cannon is a specialized vehicle, typically a large truck, equipped with a high-pressure pumping system and one or more powerful nozzles designed to project strong jets of water. Its primary purpose is crowd control and dispersal by law enforcement and security forces.

While often described as "non-lethal," water cannons can cause significant injuries, especially at close range, high pressure, or in cold weather. International human rights organizations often raise concerns about their indiscriminate nature and potential for misuse.
How They Work
● Water Source: The vehicle carries a large water tank (ranging from a few thousand liters up to 14,000 liters or more). Some systems can also connect directly to fire hydrants for a continuous supply.
● High-Pressure Pump: A powerful pump creates immense pressure, forcing the water through a specialized nozzle.
● Nozzle/Monitor: The nozzles, often called "monitors," are typically computer-controlled and can be remotely aimed and operated from within the armored cabin. They can rotate 360 degrees and adjust elevation.

● Jet Versatility: Modern water cannons can deliver different types of water jets:
  ● High-pressure streams: Designed to physically push back or knock over individuals. This is the most dangerous mode.
  ● Low-pressure streams / "Rain Shower" mode: Intended to soak individuals, causing discomfort and potentially hypothermia in cold weather, but with less kinetic impact.
  ● Pulsed jets ("slugs" or "bullets"): Delivering short, sharp bursts of water for more targeted impact.

Standard Armored Riot Control Vehicles

These are the most common type, built on heavy-duty truck chassis (often 4x4 or 6x6) with significant armor protection for the cabin, engine, and fuel tank. They are designed to withstand projectiles and attacks from rioters.
Water Capacity: Varying tank sizes, usually from 5,000 to 10,000+ liters.
Nozzles: Typically one or two main water cannons mounted on the roof.

Additional Features:
● Self-protection spray systems: Water or foam nozzles around the vehicle to protect against Molotov cocktails or other incendiary devices.
● Public address (PA) systems: For issuing warnings and commands.
● Surveillance cameras: For monitoring the crowd and aiming.
● Integrated lighting: Searchlights, strobe lights.
● Tear gas/Dye/Malodorant Additives: Many modern water cannons have separate tanks and injection systems to mix chemicals into the water jet.
● Colored Dyes: Used to mark individuals for later identification and arrest. These dyes can be difficult to remove.
● Chemical Irritants (e.g., CS gas, OC spray): Powders or liquids of tear gas agents or pepper spray are mixed with the water to enhance the dispersal effect through irritation and pain. This is highly controversial due to the indiscriminate nature of exposure.
● Malodorants: Foul-smelling chemicals that adhere to people and property, causing extreme discomfort and humiliation.
● Firefighting capability: Many are also equipped to act as basic firefighting vehicles.

Smaller/Lighter Water Cannon Vehicles

Some forces utilize smaller, more maneuverable vehicles (sometimes based on commercial vans or smaller trucks) equipped with water cannons. These may have less armor or smaller water tanks.
Purpose: For use in narrower streets, urban environments, or where a full-sized armored vehicle might be overkill.

Static/Fixed Water Cannons

Less common for crowd control, but in some high-security areas (like prisons or sensitive government buildings), fixed water cannon systems might be installed to deter or disperse intruders.
Mechanism: Connected to a permanent water supply and controlled remotely.

Makeshift/Improvised Water Cannons

In some situations, authorities have adapted standard fire hoses or even agricultural spraying equipment to act as rudimentary water cannons.
Purpose: To disperse crowds when purpose-built equipment isn't available.
Concerns: These are particularly dangerous as they lack the safety features, pressure control, and specialized training associated with purpose-built crowd control vehicles, significantly increasing the risk of severe injury.

Scent Weapons

Scent weapons, or malodorants, are a niche but intriguing category of non-lethal weapons that utilize extremely foul or noxious odors to incapacitate, deter, or identify individuals. The primary goal is to induce intense nausea, discomfort, or psychological distress without causing physical harm.

DEFENCE Non Lethal Other Non Lethal Weapons Scent Weapons

General Characteristics and Challenges of Scent Weapons

- Non-Lethal Intent: Designed to cause extreme discomfort and deter, without causing permanent physical harm.
- Pervasiveness: They are notoriously difficult to contain and can contaminate wide areas, affecting non-targets.
- Persistence: Many malodorants are designed to linger for hours or even days, making decontamination difficult.
- Psychological Impact: While some people might be severely affected, others might build a tolerance or simply endure the smell, limiting its effectiveness. The psychological effect is highly subjective.
- Ethical Concerns: Their use raises significant ethical questions regarding humane treatment, the indiscriminate nature of their effect, and the potential for long-term psychological distress or social stigma from the persistent smell.
- Development Challenges: Developing an effective malodorant that is truly non-toxic, easily dispersible, persistent, and universally repulsive, while also being controllable, is a significant technical hurdle.

"Stink Bombs" / Vomit Inducing Agents (e.g., US Military's "Skunk Bomb")

Description: These are perhaps the most well-known type, designed to produce incredibly repulsive and persistent odors that can induce nausea, vomiting, or overwhelming disgust.
Chemicals Used: Often compounds based on thiols (also known as mercaptans), which are organic sulfur compounds known for their extremely potent and offensive smells (e.g., rotten eggs, skunk spray, decaying flesh).

- "Skunk": Developed by the Israeli Defense Forces (IDF) for crowd control, "Skunk" is one of the most prominent examples. It's a non-toxic liquid composed of food-grade ingredients (but designed to smell like a combination of rotting corpses, raw sewage, and unwashed socks). It's sprayed from water cannons or handheld devices. The smell is incredibly pervasive and difficult to wash off.

- "Whoopee Fluid" / US Military's "Stink Bomb": The U.S. military also explored various malodorants, including "Whoopee Fluid" (based on sulfurous compounds) and a "Malodorant Weapon" designed to mimic the smell of feces and vomit. These efforts aimed to develop non-lethal incapacitants.

Mechanism: Overwhelm the olfactory (smell) sense, triggering strong physiological and psychological reactions like nausea, gagging, difficulty breathing (psychosomatic), panic, and a strong desire to flee the area.

Applications:
- Crowd Dispersal: To make an area so unpleasant that people choose to leave.
- Area Denial: To prevent access to a specific location.
- Psychological Warfare: To demoralize or disrupt an enemy.
- Prisoner Control: To induce compliance.

Limitations: The indiscriminate nature of the smell can affect friendly forces or bystanders, and it's difficult to contain. The psychological effect can vary between individuals.

Tracking/Identification Malodorants (Less about incapacitation, more about detection)

These malodorants are designed to cling to individuals, clothing, and objects for an extended period, allowing for later identification or tracking. The smell might not be overtly nauseating but distinct and persistent.
Chemicals Used: Could be variations of thiols or other highly persistent and identifiable compounds.
Mechanism: The chemical adheres to surfaces and slowly evaporates, releasing a unique, recognizable odor.

Applications
- Marking Rioters: To later identify individuals who participated in illegal activities within a crowd.
- Tracking Suspects: To assist K9 units or human trackers in following a trail.
- Property Protection: To mark stolen goods, making them easier to identify.

Limitations: Ethical concerns about long-term exposure and the persistent nature of the smell on individuals.

Non-Lethal Insect Repellents (Indirect Scent Weapon)

While not directly targeting humans with foul odors, some systems use highly concentrated insect repellents to create an uninhabitable zone due to swarms of insects being driven away. This is more about creating an environmental barrier than directly incapacitating via human smell.
Mechanism: Large-scale dispersal of strong insect repellents.
Applications: Area denial, particularly in environments prone to insect-borne diseases or highly irritating insect populations.
Limitations: Effectiveness depends on the insect population, environmental conditions, and the concentration of the repellent.

Psychochemicals

Psychochemicals, also known as incapacitating agents or "drug weapons," are a class of chemical warfare agents designed to temporarily impair an adversary's mental or physical functions without causing permanent injury or death. Unlike lethal chemical weapons (like nerve agents or blister agents), their goal is to disorient, confuse, or induce hallucinations, making the target unable to fight effectively.

Research into psychochemicals was actively pursued during the Cold War by countries like the US and UK, but they were largely deemed impractical for widespread battlefield use due to unpredictable effects and difficulties in dispersion and dosage. Many of these programs were later terminated or scaled back. However, the concept of using chemicals to alter cognition or behavior for military or control purposes remains a topic of concern in discussions about non-lethal weapons and emerging chemical threats.

Anticholinergics

These compounds block the action of acetylcholine, a neurotransmitter crucial for both the central and peripheral nervous systems.
Effects: They induce a state resembling delirium, characterized by:
Cognitive Dysfunction: Confusion, disorientation, impaired memory, difficulty concentrating.
Hallucinations: Visual and auditory hallucinations, often vivid and disorienting.
Physiological Effects: Dry mouth, dilated pupils (leading to blurred vision), rapid heartbeat, elevated body temperature, and decreased sweating.
Behavioral Effects: Erratic behavior, agitation, ataxia (lack of muscle coordination), lethargy, and sometimes stupor or coma.
Key Example: BZ (3-quinuclidinyl benzilate) is the most well-known anticholinergic psychochemical. The United States extensively researched and even weaponized BZ (e.g., in the M43 BZ cluster bomb), though these stocks were later destroyed. It's an odorless, stable white crystalline powder.

Mechanism: Competitive inhibition of muscarinic acetylcholine receptors.
Limitations: Highly unpredictable effects, varying widely based on dose, individual physiology, and environmental factors. Recovery can take hours to days.

Psychedelics/Hallucinogens

These agents induce profound alterations in perception, mood, and thought.
Effects: Visual and auditory hallucinations, altered sense of reality, euphoria or dysphoria, paranoia, confusion, and impaired judgment.
Key Example: LSD (lysergic acid diethylamide) was extensively investigated by the CIA (e.g., Project MKUltra) and the US Army (Edgewood Arsenal experiments) as a potential psychochemical weapon. Mescaline and psilocybin were also studied.

Mechanism: Primarily by affecting serotonin receptor systems in the brain.
Limitations: Extremely unpredictable effects, even within a controlled environment, making them unreliable for battlefield use. A soldier under the influence might become completely incapacitated, or conversely, agitated and aggressive. Dosage control for a widespread effect is also a major challenge. The "trip" can vary wildly and unpredictably.

Opioids/Analgesics (with incapacitating potential)

While primarily pain relievers, extremely potent opioids can cause profound sedation, respiratory depression, and unconsciousness, leading to incapacitation.
Effects: Extreme drowsiness, sedation, confusion, respiratory depression, nausea, and potentially loss of consciousness.
Key Examples: Fentanyl and its analogues (e.g., carfentanil, remifentanil) have gained notoriety in the context of psychochemicals, particularly after the 2002 Moscow theater siege, where Russian forces used an aerosolized fentanyl derivative to incapacitate Chechen hostage-takers. While effective at incapacitating, the extremely narrow therapeutic window (the difference between an incapacitating dose and a lethal dose) makes them exceptionally dangerous and prone to causing fatalities, as tragically demonstrated in Moscow.

Mechanism: Agonism of opioid receptors in the central nervous system.
Limitations: High risk of death due to respiratory depression. Difficult to disperse evenly and safely. The indiscriminate nature makes them dangerous to non-combatants and even friendly forces.

Dissociatives

Agents that produce a sense of detachment from one's body and surroundings.
Effects: Dissociation, numbness, memory loss (amnesia), confusion, hallucinations, and impaired motor function.
Key Example: PCP (phencyclidine), known as "angel dust," has been studied for its potential to induce psychopathological symptoms. Ketamine (a medical anesthetic and dissociative) also falls into this category.
Mechanism: Primarily by acting as NMDA receptor antagonists.
Limitations: Can lead to unpredictable and sometimes aggressive behavior, high risk of overdose, and difficulties in control.

Sleeping Gas

The term often refers to incapacitating agents or psychochemicals, which are designed to temporarily alter mental or physical functions to the point of incapacitation, including inducing unconsciousness or deep sedation.

These agents are highly dangerous and their use as weapons is generally prohibited under the Chemical Weapons Convention (CWC) due to the high risk of severe harm or death, and their unpredictable effects.

Opioids (e.g., Fentanyl and its Derivatives)

These are synthetic opioids, significantly more potent than morphine, often used medically for pain management and anesthesia. Examples include fentanyl, sufentanil, carfentanil, and remifentanil.
Mechanism: They act on opioid receptors in the brain and central nervous system, leading to profound analgesia (pain relief), sedation, and crucially, dose-dependent respiratory depression (slowing or stopping breathing).

The most infamous real-world incident involving an opioid as an incapacitating agent was the 2002 Moscow theater hostage crisis. Russian special forces used an aerosolized fentanyl derivative (likely carfentanil or remifentanil) to incapacitate Chechen terrorists. While the terrorists were incapacitated, over 120 hostages also died, primarily from respiratory depression, highlighting the extreme dangers of using such agents indiscriminately.

Medical Use: Anesthesia (often intravenous), pain management (transdermal patches, IV, oral), especially for severe acute or chronic pain.

General Anesthetics (Inhalational Anesthetics)

These are volatile liquids or gases administered via inhalation to induce and maintain general anesthesia during surgery.
Mechanism: They depress overall central nervous system activity, leading to unconsciousness, amnesia, and muscle relaxation.
Types:
● Volatile Anesthetics: Liquids at room temperature that are vaporized for inhalation. Examples include Halothane (Fluothane) (older, less common now), Isoflurane, Sevoflurane, and Desflurane.
● Gaseous Anesthetics: Gases at room temperature. The primary example is Nitrous Oxide (N_2O), commonly known as "laughing gas." It's a weaker anesthetic often used in combination with others or for sedation (e.g., dental procedures, childbirth).
Some research into "non-lethal" incapacitating agents has historically considered these. For instance, halothane was mentioned in some discussions about the Moscow theater incident as a potential component, though fentanyl derivatives were confirmed.
Medical Use: Inducing and maintaining surgical anesthesia, sedation for minor procedures (nitrous oxide).

Anticholinergics (e.g., BZ - 3-Quinuclidinyl Benzilate)

These are psychochemicals designed to induce delirium, confusion, and temporary mental incapacitation. While they can lead to stupor or a sleep-like state, their primary effect is profound disorientation.

Mechanism: They block the action of acetylcholine, a neurotransmitter involved in memory, learning, and various bodily functions.
BZ was extensively researched and even weaponized by the U.S. during the Cold War. While not directly a "sleeping gas," severe intoxication can lead to a comatose state.
Medical Use: Some anticholinergics are used medically for conditions like motion sickness, Parkinson's disease, or to dry secretions, but not for inducing general sleep or unconsciousness for non-medical purposes.

Sticky Foam

"Sticky foam," often referred to as "riot foam" or "mobility denial foam," is a type of less-lethal weapon that was developed primarily by the U.S. military and some research institutions for crowd control and to incapacitate individuals. It's not a widely adopted or commonly seen tool in civilian policing, but it has been explored and deployed in specific military contexts.

It consists of highly adhesive and rapidly expanding polymers (a mix of rubbers, resins, oils, fire retardants, and other chemicals) stored in a compressed form with a propellant. When fired from a dispenser, it rapidly expands (often to 30 times its original volume or more) and becomes extremely tacky and tenacious upon contact.

The primary mechanism of action is immobilization and entanglement. When the foam hits a person, it:

1. Adheres immediately: It sticks to skin, hair, and clothing with incredible tenacity.
2. Expands and hardens/becomes viscous: As it expands, it can quickly envelop limbs, making movement difficult or impossible. It doesn't necessarily "harden" into a solid block but becomes a very thick, gooey, and strong viscous material that resists movement.
3. Physically restrains: The stickiness and bulk of the foam can pin a person to the ground, glue their limbs together, or simply make it too cumbersome to move effectively.

Chemical Formulation
Different formulations have been developed over time, aiming for better adhesion, faster expansion, easier cleanup, and improved safety.

Delivery Systems
● Backpack-mounted dispensers: This was the primary mode in early prototypes (e.g., developed by Sandia National Laboratories). A large tank is worn like a backpack, with a hose leading to a "gun" or nozzle. This allows for a continuous stream or multiple shots.
● "Gun"/Launcher Systems: Devices resembling large guns or bazookas designed to fire discrete "shots" of sticky foam.
● Vehicle Arresting Systems: Larger-scale versions developed to immobilize vehicles by deploying large quantities of foam.
● "Sponge Bombs": A more recent concept (reportedly used by the IDF in tunnels) that uses two liquid reagents that mix upon activation, rapidly expanding and solidifying to create a physical barrier. While this shares some chemical principles, its primary goal is sealing, not direct crowd immobilization in the open.

Despite its seemingly "cartoonish" non-lethal concept, sticky foam faces several serious practical and ethical challenges that have limited its widespread adoption:

● Suffocation Risk: This is the most significant concern. If the foam covers a person's nose and mouth, it poses a serious risk of suffocation. This makes it difficult to use indiscriminately in a crowd and raises severe safety and ethical issues.
● Indiscriminate: Like other area-denial weapons, it's hard to control exactly who or what the foam sticks to, potentially affecting friendly forces, bystanders, or even gluing multiple people together.
● Cleanup Difficulty: The foam is extremely adhesive and can take a long time (hours) and specific solvents (like mineral oil or baby oil) to remove from skin, hair, and clothing. This creates logistical problems for apprehension, medical treatment, and decontamination.
● Limited Range and Bulkiness: Early dispensers were often large and bulky, and the effective range was relatively short, making them impractical for controlling large, dispersed crowds.

● Clogging: The dispensing mechanisms could be prone to clogging.
● Public Perception: The visual of someone covered in sticky foam, while perhaps appearing "non-lethal," could still be visually disturbing and lead to significant negative publicity and human rights concerns.

Due to these practical and safety drawbacks, sticky foam has largely remained an experimental or niche technology rather than a frontline tool for crowd control. Other less-lethal options like tear gas, water cannons, and impact munitions are far more common, despite their own controversies.

2 Unarmed

Unarmed combat, often referred to as hand-to-hand combat, self-defense, or martial arts, encompasses a vast array of fighting systems and disciplines that rely solely on the human body as a weapon.

These can be broadly categorized based on their primary focus and techniques.
● Striking Arts: These martial arts emphasize using fists, kicks, elbows, knees, and other parts of the body to deliver blows.
● Grappling Arts: These martial arts focus on grappling techniques, including throws, takedowns, chokes, and joint locks.
● Self-Defence Arts: These systems prioritize practical techniques for self-defense in real-world scenarios.
● Other: Styles of unarmed combat which either combine multiple of the above or use a completely new style.

The ten martial arts below have been chosen as a mix of the above categories and are listed in DEFENCE rather than OFFENCE because their primary focus is to defend oneself from an attacker, rather than to instigate the attack.

Subheadings

Krav Maga

Krav Maga, as a self-defense system rather than a traditional martial art, is structured in a practical and progressive way to train individuals for real-world violent encounters. It doesn't adhere to rigid forms or rituals found in many traditional martial arts, but rather focuses on efficiency, instinct, and adaptability.

Brazilian Jiu-Jitsu

Brazilian Jiu-Jitsu (BJJ) is a martial art, combat sport, and self-defense system that originated in Brazil, but with deep roots in Japanese martial arts. It's renowned for its emphasis on grappling and ground fighting, particularly focusing on the concept that a smaller, weaker person can successfully defend themselves against a larger, stronger assailant by using leverage, proper technique, and taking the fight to the ground.

Muay Thai

Muay Thai, often referred to as "The Art of Eight Limbs," is a dynamic and devastating combat sport and martial art originating from Thailand. It differentiates itself by utilizing a fighter's entire body as a weapon, allowing strikes with fists, elbows, knees, and shins (the "eight limbs"), complemented by powerful clinching techniques for close-range grappling and knee/elbow attacks. This full-contact discipline emphasizes rigorous physical conditioning, mental fortitude, and devastating power, making it highly effective for both competitive fighting and realistic self-defense scenarios.

Boxing (Western Boxing)

Western Boxing, often called "the sweet science," is a combat sport and martial art focused exclusively on punching techniques and highly refined defensive movements. Fighters utilize jabs, crosses, hooks, and uppercuts, combined with intricate footwork, head movement, and body rotation, to deliver powerful blows while simultaneously evading and blocking incoming attacks. It's a discipline that hones precision, speed, endurance, and strategic thinking, making it a highly effective and foundational striking art for self-defense and competitive sport.

Wrestling

Wrestling, as a martial art, is a comprehensive grappling system centered on controlling an opponent through takedowns, throws, and ground control, without the use of strikes. It emphasizes leverage, balance, and strategic positioning to subdue an adversary, aiming to either pin them to the ground or maintain dominance. Rooted in ancient practices, wrestling develops immense strength, endurance, and practical skills for managing close-quarters confrontations, teaching practitioners to effectively neutralize an opponent by dictating the fight's terms and preventing them from standing or gaining an advantageous position.

Judo

Judo, meaning "the gentle way," is a Japanese martial art and Olympic sport founded by Jigoro Kano. It focuses on using an opponent's momentum and balance against them through throws (Nage-Waza), takedowns, and pins (Osaekomi-Waza), as well as joint locks and chokeholds (Shime-Waza and Kansetsu-Waza) on the ground. Judo emphasizes efficient use of energy, respect, and discipline, teaching practitioners to effectively control and submit an opponent without striking, making it a highly effective self-defense system.

Mixed Martial Arts (MMA)

Mixed Martial Arts (MMA) is a full-contact combat sport that integrates techniques from various martial arts and combat disciplines, including striking arts like boxing, Muay Thai, and karate, alongside grappling arts such as Brazilian Jiu-Jitsu, wrestling, and Judo. Competitors engage in stand-up striking, clinching, takedowns, and ground fighting, aiming to defeat their opponent through knockout, submission, or judges' decision. MMA is celebrated for its dynamic blend of skills, demanding comprehensive physical conditioning and strategic versatility from its athletes to compete effectively across all ranges of combat.

Sambo (Russian Sambo)

Sambo, a Russian acronym meaning "self-defense without weapons," is a comprehensive martial art and combat sport developed in the Soviet Union during the early 20th century. It synthesizes elements from Judo, various forms of wrestling, and indigenous martial arts from across the Soviet regions. Sambo is primarily characterized by its dynamic throws, effective ground fighting techniques, and a wide array of leg locks, with two main disciplines: Sport Sambo, which is a jacket wrestling style similar to Judo but with distinct rules regarding gripping and submissions, and Combat Sambo, a more aggressive discipline that incorporates striking (punches, kicks, elbows, knees) alongside grappling, making it a versatile system for both self-defense and military applications.

Wing Chun

Wing Chun is a unique Chinese martial art known for its efficiency, directness, and emphasis on close-quarters combat. Developed with the principle of simultaneous defense and attack, it utilizes economic movements, a strong central line theory, and short-range power generation. Practitioners focus on rapid, continuous striking, trapping, and redirecting an opponent's force, making it highly effective for self-defense in confined spaces and against aggressive, direct attacks.

Kyokushin Karate

Kyokushin Karate is a full-contact Japanese martial art founded by Masutatsu Oyama, emphasizing extreme discipline, rigorous physical conditioning, and powerful, knockdown techniques. Unlike many traditional karate styles, Kyokushin practices full-contact sparring with minimal protective gear, fostering immense resilience, striking power, and a strong fighting spirit. Its training focuses on developing devastating kicks, punches, and knee strikes, along with conditioning the body to both deliver and withstand significant impact, making it a highly effective and physically demanding system for combat and self-defense.

3 Armour

This section describes the types of armour and padding to protect against foreign attacks, both melee or ranged.

DEFENCE Armour Head Armour

Head Armour

Head armour is any piece of defensive apparel designed to protect the wearers head.

Standard Ballistic Helmets (e.g., ACH/MICH)

These helmets are the most common issue for general infantry and special operations forces. Made primarily from advanced aramid fibers (like Kevlar) or Ultra-High-Molecular-Weight Polyethylene (UHMWPE), they offer significant protection against handgun rounds and fragmentation. Their design, often referred to as "mid-cut," balances coverage with compatibility for communication headsets and hearing protection.

Enhanced Ballistic Helmets (e.g., ECH)

Representing an upgrade to the standard ballistic helmets, these typically utilize advanced UHMWPE materials to achieve higher levels of ballistic protection, often against certain rifle threats or higher-velocity fragmentation, while striving to maintain or reduce weight. They generally maintain a similar mid-cut profile for broad applicability.

High-Cut

High-Cut Ballistic Helmets (e.g., FAST Helmets)

Distinguished by a higher cut above the ears, these helmets prioritize compatibility with large communication headsets, active hearing protection, and other mounted accessories like night vision devices (NVDs) and tactical lights. While offering less lateral coverage, their design is favored by special operations units for enhanced situational awareness, reduced weight, and modularity.

Integrated Head Protection Systems (IHPS)

This represents the newest generation of combat head protection, designed as a modular suite. The IHPS aims to provide improved ballistic and blunt force protection, often with lighter weight, and is built for seamless integration with communication systems, hearing protection, night vision goggles, and optional facial and mandibular protection (visors, jaw guards) for comprehensive head and face protection.

Neck Armour

Neck Armour

Neck armour is any piece of defensive apparel designed to protect the wearers neck.

Integrated

Integrated Collar/Throat Protectors (Soft Armor)

These are the most common form of neck protection, designed as detachable or integrated components of modern ballistic body armor vests (like the US Interceptor Body Armor - IBA or UK Osprey systems). They consist of soft ballistic panels (made from Kevlar, Dyneema, or other aramid/UHMWPE fabrics) that extend upwards from the vest to cover the front (throat) and sometimes the sides and back of the neck. They are designed to provide Level IIIA ballistic protection against handgun rounds and fragmentation. While effective, their bulk can sometimes restrict head movement or interfere with weapon shouldering, leading some soldiers to remove them in certain situations.

Mandible Guards (Integrated Helmet Accessories)

These are rigid or semi-rigid pieces of ballistic material that attach to the front of a combat helmet (especially high-cut models like FAST helmets). While primarily protecting the lower jaw and face, they also provide some extended protection to the upper neck and throat area directly below the chin. They are designed to protect against ballistic threats, blunt force, and blast fragments.

Nape Protectors (Integrated Helmet Accessories)

These are ballistic panels that attach to the rear lower rim of the helmet, extending downwards to cover the nape (back) of the neck.
They are specifically designed to provide protection against fragmentation and ballistic threats from the rear.

Ballistic

Ballistic Scarves/Gaiters

Some specialized units or specific manufacturers offer ballistic scarves or neck gaiters made from cut-resistant and/or ballistic fabrics (like Dyneema or aramid blends). These are worn like a regular neck gaiter but provide a layer of protection against slashing, fragments, and potentially some low-velocity ballistic threats. They prioritize flexibility and comfort.

Modular Armor Supplement Systems

Companies like FirstSpear offer "Modular Armor Supplement Systems" (M.A.S.S.) which include standalone throat guards and collars that can be easily added or removed from plate carriers or tactical vests. These provide augmentation to existing armor with varying ballistic protection levels.

Body

Body Armour

DEFENCE Armour Body Armour

Body armour is any piece of defensive apparel designed to protect the wearers chest.

Soft Armour (Soft Ballistic Panels)

Soft Armour

Primarily designed to protect against handgun rounds (up to .44 Magnum), fragmentation (shrapnel from grenades, IEDs), and sometimes stab threats.
Materials: Made from multiple layers of flexible, high-strength synthetic fibers such as Kevlar (aramid), Dyneema, or Spectra (both UHMWPE). These fibers absorb and disperse the energy of a projectile, deforming it and preventing penetration.
Form Factor: Flexible and relatively lightweight, soft armour is often used in concealed vests (worn under clothing), as liners in military vests, or as "backers" behind hard plates to absorb residual energy and blunt force trauma.
Protection Levels: Typically rated from NIJ Level IIA to IIIA, based on the National Institute of Justice (NIJ) standards.

Hard Armour Plates (Ballistic Plates)

DEFENCE Armour Body Armour Hard Armour Plates (Ballistic

Designed to provide superior protection against high-velocity rifle rounds, armor-piercing ammunition, and more severe fragmentation.
Materials:
- Ceramic Plates: Most common in military applications, made from materials like boron carbide, silicon carbide, or alumina. They work by shattering or deforming the projectile upon impact, with a composite fiber backing (often UHMWPE or aramid) catching any fragments and absorbing residual energy. While offering excellent protection and relatively lighter weight, they can be prone to cracking from multiple impacts in the same spot or rough handling.
- Polyethylene (UHMWPE) Plates: Made from compressed, multi-layered sheets of ultra-high-molecular-weight polyethylene. These are exceptionally lightweight and can offer excellent multi-hit capability against certain rifle threats without significant weight penalty. However, they can be thicker than ceramic plates and may have lower heat resistance.
- Steel Plates (with anti-spall coating): Less common in frontline military combat due to their weight and the risk of "spalling" (fragments of the bullet or plate ricocheting off the surface), but some modern steel plates feature advanced anti-spall coatings (e.g., polyurea or rubber compounds) to mitigate this. They are known for their durability and multi-hit capability in the same impact area.

Form Factor: Rigid plates inserted into dedicated pockets in vests or plate carriers.
Protection Levels: Typically rated NIJ Level III or Level IV, with Level IV offering the highest protection against armor-piercing rifle rounds.

Plate Carriers and Vests

DEFENCE Armour Body Armour Plate Carriers

Plate Carriers: These are lightweight, modular vests designed specifically to hold hard armour plates (front, back, and often sides). They feature webbing systems (like MOLLE/PALS) for attaching pouches, magazines, and other tactical gear, allowing soldiers to customize their loadout. Plate carriers prioritize mobility and adaptability.

Tactical Vests (e.g., IOTV - Improved Outer Tactical Vest): These are more comprehensive body armour systems that typically integrate soft armour panels throughout the torso, along with pockets for inserting hard armour plates. They offer broader coverage (including groin, collar, and shoulder protection) than minimalist plate carriers but are generally heavier and bulkier.

Modular and Integrated Systems

DEFENCE Armour Body Armour

Modern trends, such as the US Army's Soldier Protection System (SPS) which includes the Modular Scalable Vest (MSV), focus on highly modular and scalable designs. These systems allow soldiers to add or remove various soft and hard armor components (like deltoid protectors, groin protectors, side plates, and collar inserts) based on the specific threat level and mission requirements, balancing protection with agility.

Shoulder Armour

DEFENCE Armour Shoulder Armour

Shoulder armour is any piece of defensive apparel designed to protect the wearers shoulders.

Integrated Deltoid Protectors (Soft Armour)

Integrated

These are the most common form of modern combat shoulder protection. They are typically detachable or integrated components of comprehensive ballistic vests (like the U.S. Army's Improved Outer Tactical Vest - IOTV, or the Modular Scalable Vest - MSV).
Material: Made from multiple layers of soft ballistic fabrics (such as Kevlar or UHMWPE - e.g., Dyneema, Spectra). These flexible panels are designed to stop handgun rounds and fragmentation.
Attachment: They attach to the main vest via hook-and-loop fasteners (Velcro), straps, or other modular systems, allowing soldiers to add or remove them based on mission requirements and the desired level of protection versus mobility.
Purpose: To provide extended coverage to the upper arm and shoulder area, complementing the torso protection of the main vest.

Hard Plate Shoulder Inserts (Less Common/Specialized)

DEFENCE Armour Shoulder Armour Hard Plate

While most shoulder protection is soft armour, some specialized or heavier body armour systems might incorporate very small, purpose-built hard armour inserts into the deltoid protectors. These are rarer than soft inserts due to the mobility constraints they would impose.
Material: If present, these would typically be made from ceramics or thicker UHMWPE to offer protection against higher-velocity rifle rounds, but their size would be very limited to maintain joint articulation.
Purpose: To offer enhanced ballistic protection to a very specific, critical area of the shoulder, often for specialized roles or high-threat environments where mobility compromise is accepted.

Modular & Scalable Systems

DEFENCE Armour

Modern body armour philosophy emphasizes modularity. Shoulder protection falls under this, allowing commanders or individual soldiers to "scale" their armour based on the threat level, climate, and physical demands of the mission. For instance, a soldier might wear shoulder protection during a dismounted patrol where fragmentation is a high risk, but remove it for mounted operations where agility inside a vehicle is paramount.

Hand Armour

DEFENCE Armour Hand Armour

Hand armour is any piece of defensive apparel designed to protect the wearers hands.

Hard Knuckle Tactical Gloves

These are the most common type of protective glove in military and law enforcement. They feature reinforced knuckles, typically made from molded carbon fiber, hard plastic (like Thermoplastic Rubber - TPR), or Kevlar, to protect against blunt force impacts, abrasion, and minor strikes.
Purpose: To prevent injuries to the knuckles from impacts during close-quarters combat, handling equipment, or operating in confined spaces.
Other Features: Often include durable palm materials (leather, synthetic leather) for enhanced grip, touchscreen compatibility, and sometimes D3O or other shock-absorbing padding in the palm to reduce vibration and impact.

Cut-Resistant Gloves

Designed to protect hands from lacerations and slashes, these gloves are constructed with inner linings or integrated materials made from high-performance fibers such as Kevlar, Dyneema (UHMWPE), or other proprietary cut-resistant blends.
Purpose: To prevent injuries from sharp objects like knives, broken glass, jagged metal, or other debris often encountered in urban combat or hazardous environments.
Levels: Cut resistance is often rated by standards like EN 388 (e.g., Level 5 or higher), indicating the degree of protection against cutting forces.

Impact-Resistant Gloves (General)

While often overlapping with hard knuckle gloves, some tactical gloves offer broader impact protection across the fingers, palm, and back of the hand using various padding materials (e.g., TPR, foam, D3O) and reinforced stitching.
Purpose: To mitigate the effects of blunt force impacts, pinches, and abrasions across the entire hand, crucial for tasks involving heavy equipment, breaching, or operating in rugged terrain.

Flame-Resistant (FR) Gloves

Made from materials that resist ignition and melting when exposed to high heat or flames, such as Nomex, Kevlar, or fire-resistant leather.
Purpose: To protect hands from burns during explosions, vehicle fires, or when handling hot equipment. These are standard issue for aircrews and personnel operating in environments with fire risks.

Specialized/Ballistic Hand Protection (Limited Use)

Full ballistic protection for the hands in a glove form is extremely rare in modern combat due to the severe dexterity limitations it imposes. However, some very specialized units or bomb disposal experts might use gloves with limited ballistic inserts (e.g., small, flexible soft armor panels) for specific high-risk tasks.
Purpose: To offer a minimal level of ballistic or blast fragmentation protection where absolute protection outweighs dexterity. This is not common for general combat roles.

Leg Armour

Leg armour is any piece of defensive apparel designed to protect the wearers legs or groin.

Groin Protectors

These are soft ballistic panels that attach to the front lower edge of the main body armour vest, extending downwards to cover the groin and often part of the inner thighs.
Material: Made from multiple layers of flexible ballistic fabrics like Kevlar or UHMWPE (e.g., Dyneema).
Purpose: To protect the highly vulnerable groin and femoral artery/vein area from ballistic threats, fragmentation, and shrapnel. While crucial, their bulk can sometimes be an issue for mobility.

Thigh Protectors / Upper Leg Armor

These are soft armour panels designed to cover the outer and sometimes inner thigh areas. They are often worn as separate modules that attach to the main body armour system (e.g., plate carrier or vest) or a specialized tactical belt, sometimes wrapping around the thigh.
Material: Constructed from flexible ballistic materials such as aramid fibers or UHMWPE, offering protection against handgun rounds and fragmentation.
Purpose: To protect the large muscle groups and major arteries/veins in the thigh from ballistic threats, fragmentation, and blunt force injuries. Some designs include MOLLE webbing for attaching additional pouches.

Ballistic Lower Leg/Shin Guards

While less common for general infantry due to mobility concerns, specialized units (e.g., those involved in breaching, EOD, or urban operations) may utilize lower leg or shin protection. These are often rigid or semi-rigid pads with ballistic inserts.
Material: Can incorporate soft ballistic panels, hard plastic, or even small ceramic/UHMWPE plates for enhanced protection.
Purpose: To protect the shins and calves from direct impacts, fragmentation, and potentially low-velocity ballistic threats, often in environments where debris or close-range threats are prevalent.

Integrated Knee Pads

While not ballistic armor, modern combat trousers often feature integrated knee pad pockets designed to hold removable protective inserts. These inserts are made of hard plastic and/or dense foam.
Material: Typically plastic (for the hard cap) and high-density foam or gel (for impact absorption).
Purpose: To protect the knees from impacts, abrasions, and blunt force trauma when kneeling, crawling, or moving over rough terrain, enhancing comfort and preventing injury. They are an essential part of modern combat uniform systems.

Foot Armour

Foot armour is any piece of defensive apparel designed to protect the wearers feet.

Standard Combat Boots

These are the most common type, designed for general use across various terrains. They are built for durability, support, and protection.
Protective Features:
- Ankle Support: High-cut designs provide stability and help prevent sprains on uneven terrain.
- Durable Materials: Made from robust leather, nylon, or composite materials that resist abrasion, tearing, and punctures from debris.
- Reinforced Toes and Heels: Often have hardened toe caps (though rarely steel-toed due to thermal conductivity and impact risks in combat) and reinforced heels for impact protection.
- Aggressive Outsoles: Provide superior grip and traction on varied surfaces, preventing slips and falls.
- Puncture Resistance: Soles are often designed to resist punctures from sharp objects on the ground.

Hot Weather / Desert Boots:

Lighter and more breathable versions of combat boots, specifically designed for arid and hot environments.
Protective Features:
- Breathability: Incorporate breathable fabrics (e.g., CORDURA nylon) and drainage vents to allow air circulation and water expulsion, preventing heat accumulation and moisture-related foot issues.
- Sand/Dust Protection: Designed to minimize sand and dust entry while still allowing airflow.
- Reduced Weight: Lighter materials reduce fatigue in hot conditions.

Jungle / Wet Weather Boots

Built to withstand constant moisture, rapidly drain water, and provide grip in slippery, muddy conditions.
Protective Features:
- Drainage Vents: Prominent drainage holes in the instep allow water to quickly escape.
- Quick-Drying Materials: Utilize materials that resist water absorption and dry quickly.
- Enhanced Traction: Outsoles are often designed with deep lugs and specialized patterns for grip in mud and on slick surfaces.
- Puncture Resistance: Soles are typically robust to prevent punctures from sharp vegetation or hidden dangers.

Cold Weather / Mountain Boots

Heavily insulated and waterproof boots designed for extreme cold, snow, and ice.
Protective Features:
- Insulation: Multiple layers of insulation (e.g., Thinsulate, Gore-Tex liners) to retain warmth and prevent frostbite.
- Waterproofing: Fully waterproof membranes to keep feet dry in wet, snowy conditions.
- Stiff Soles: Often feature stiffer soles for use with snowshoes or crampons, and enhanced grip on icy surfaces.
- Blunt Force Protection: Bulkier design offers increased protection against blunt impacts.

Specialized Tactical Footwear

Boots designed for specific roles requiring additional protection.
Protective Features:
- Reinforced Toes/Shanks: May include steel, composite, or even more robust protection in the toe or sole for specific tasks like breaching or EOD (Explosive Ordnance Disposal) work where foot protection from debris or blast fragments is critical.
- Anti-Slip/Oil-Resistant Soles: For environments with fluid spills.
- Electrical Hazard Protection: Some models offer insulation against electrical shock.

Shields

Shields are any piece of defensive apparel held to protect the wearers from any weapon, projectile or shrapnel.

Handheld Ballistic Shields

These are the most common type, carried by an individual operator. They vary significantly in size, from smaller models designed for rapid deployment and maneuverability in confined spaces (e.g., doorways, hallways) to larger versions offering more comprehensive body coverage.
Purpose: Provide mobile protection during dynamic entry operations (e.g., SWAT raids), active shooter scenarios, clearing buildings, or establishing a defensive perimeter. They allow the operator to advance while maintaining a ballistic barrier.
Materials: Typically constructed from advanced lightweight composite materials like Ultra-High-Molecular-Weight Polyethylene (UHMWPE, e.g., Dyneema, Spectra), aramid fibers (e.g., Kevlar) sometimes combined with ceramic plates for higher threat levels.
Features: Often include ballistic viewports (bulletproof glass or transparent composites) for situational awareness, ergonomic handle systems (single or ambidextrous), adjustable forearm straps, and sometimes integrated LED lighting systems for illumination or disorientation.

Tactical Ballistic Shields

These are generally larger and heavier handheld shields specifically designed to withstand rifle rounds (NIJ Level III or higher, up to Level IV for armor-piercing threats). They provide a higher level of protection than those rated only for handgun rounds.
Purpose: Used in situations where rifle threats are anticipated, such as military operations, high-risk engagements, or against heavily armed suspects. They offer enhanced protection but may be more cumbersome due to their weight and thickness.
Materials: Often incorporate ceramic strike faces bonded to a composite backing (UHMWPE or aramid) or thicker, denser UHMWPE.
Features: May include weapon rests or cutouts to facilitate firing a weapon from behind the shield, and often larger viewports.

Rolling Ballistic Shields / Mobile Personnel Shields

These are very large, heavy ballistic shields mounted on wheels or a trolley system. They can be full-body height or even include overhead protection.
Purpose: Designed to provide maximum protection for multiple officers or a team, often used in prolonged standoffs, checkpoints, hostage rescue situations, or when advancing in open areas without natural cover. Their wheeled design reduces fatigue and allows for easier repositioning of a heavy protective barrier.
Materials: Can be made from very thick composites, steel with anti-spall coatings, or a combination, offering high levels of ballistic protection (often Level III or IV).
Features: May include deployable "kick-stands," interlocking features to create a continuous wall, and integrated lighting.

Transparent Ballistic Shields

While most ballistic shields are opaque, some are designed with a transparent ballistic material, usually advanced polycarbonate or acrylic composites.
Purpose: Used in situations where maintaining an uninterrupted line of sight is critical, such as VIP protection, certain crowd control scenarios, or where officers need maximum peripheral vision.
Limitations: While offering good visibility, they typically provide lower levels of ballistic protection compared to opaque shields of similar weight, often limited to handgun or fragmentation threats (Level IIIA or lower), and can be susceptible to scratches.

4 Insect Protection

This section describes how you can protect yourself against insects which may not may not be carrying diseases. In this section, insects are categorised as small, nuisance critters which are no bigger than a fist. The advice is generic for each type of insect and doesn't go into detail on the different varients such as the Tsetse Fly or Horse Fly.

Mosquitoes

Human Detection
First, if she smells carbon dioxide, she accelerates upwind, zigzagging across the path of the gas. Between 5 and 15 meters away, she spots you with her eyes. Then she makes her final approach, using heat, humidity, and the scents on your skin to decide whether (and where) to land. Simply following the trail of CO2 would lead the insect straight into your mouth, where neither of you wants her to be. Looking only for heat would limit the mosquito to targets that are already close by. But by deploying a string of sensory tools, the mosquito can find all her juicy options.

Sensing Area
- **Carbon Dioxide Detection:** 10-50 Metres
- **Mosquito Vision:** 5-10 Meters
- **Thermal / Moisture Detection:** Around 20cm

Active Times
The common house mosquito (Culex pipiens) is most likely to bite during the evening or the first few hours of the night. The Asian tiger mosquito tends to bite during the day, the morning and late afternoon. All types of mosquitoes are least likely to bite during the middle part of the day, when the sun and heat are at their peak. Once a mosquito gains entry into a home or building, they are protected from dehydration and more likely to fly around for many more hours than they normally would. They stay active longer because of the temperature and light controls in your home. They avoid daylight at all costs because sun exposure can dehydrate and kill them. During the day, this species of mosquito seeks out cool, shaded and wet areas until dusk returns. Species of mosquitoes most active at night are likely to bite early in the evening when they first stir from their hiding places. After a night of activity, they will seek out places to rest before dawn. With that activity cycle, most mosquito bites occur early in the evening, but they can also occur throughout the night. That's why it's important to keep mosquitoes out of your home. If one gets inside, it will likely bite repeatedly throughout the night simply because there aren't other targets.

Active Locations
Some areas are more likely to attract large numbers of mosquitoes such as damp areas or areas near farming operations, bogs, salt marshes, standing water or dredge spoil are more likely to have larger mosquito populations than drier areas. The female mosquito lays her eggs in stagnant water, and larvae need only 1cm (1/2 inch) of water to survive. Is it true that you should let mosquitoes finish sucking your blood to prevent itching later? No. The greater the time the mosquito is allowed to feed, the more saliva she'll inject into the skin. Allowing her to feed longer will increase your reaction to the saliva and enhance the risk of infection from mosquito-borne pathogens.

Rain
Mosquitos have a high affinity for warm, standing water. Any stagnant pond or even waterlogged junk you forgot to clean up is ripe for mosquito infestation. On the other hand, where standing water already existed prior, rainfall can disrupt the eggs that have been laid and therefore inhibit later mosquito activity. But once it passes this same rainfall will increase mosquito infestations if the water tends to pool nearby. Young mosquitoes will spend about ten days in the water only, so if a pool forms you may have some time before the problem becomes serious. The bottom line is to prevent pockets of extra, stagnant moisture whenever possible, as soon as possible. In general, heavy rains increase the numbers of mosquitoes in the area.

Weather
It's known that mosquitoes enjoy wet and warm climates. The southern US is favoured mosquito territory, but they exist almost everywhere. Certain weather conditions can bring them out in force, wherever you live. They are most active in temperatures above 26°C (80°F). As temperatures climb higher, mosquito activity can decline. Mosquitoes will bite less when it becomes excessively hot. However, higher temperatures also make any diseases they carry more active and hence more transmissible. So when mosquitoes are around, a cool spell following very hot temperatures could be ripe for mosquito borne diseases, as highly infectious mosquitoes increase their biting activity. Just as important, relatively high night-time lows increase mosquito activity. So if nights are warm for an extended period, beware mosquitoes at all other times as well. When temperatures fall below 10°C (50°F), mosquitoes go dormant. Cold winter temperatures do not, however, actually kill the mosquitoes. As long as the temperature is within a typical range for your region, mosquitoes have documented adaptations that allow them to hibernate during cold and some have reproductive strategies that let their eggs survive to hatch the following season when it warms up.

DEFENCE Insect Protection Mosquitoes

Hiding
● Wear Low Contrast Clothing: The best option is probably to convince someone to wear high-contrast clothing, such as something with black-and-white stripes or spots, while you wear light, muted colours that blend in with the surroundings.
● Avoid Sweating, Salty Food and High Potassium Food: Mosquitoes and other insects are attracted to the smell of lactic acid, so your scent will be even more appealing to them.
● Avoid Sweating and Exertion
● Avoid Floral or Fruity Fragrances: Wearing floral or fruity smelling perfume, body lotions and sunscreen or using scented shampoos and body washes can increase the likelihood of a bug bite. If you smell like flowers or fruit, an insect is likely to confuse you with vegetation and will be attracted to your scent. Even subtle fragrances that come from products like dryer sheets and fabric softeners can attract insects. Washing your clothing in fragrant detergents might also entice bugs.

Flies

Houseflies

Sandflies

Tsetse Flies

Black Flies

Horse Flies and Deer Flies

Stable Flies

Biting Midges / No-see-ums

Biting midges, are tiny, insidious flies belonging to the insect family Ceratopogonidae. They are globally distributed, though often go by local names like "no-see-ums" (in North America) or "sandflies" (in parts of Australia, though distinct from the larger sandflies that transmit leishmaniasis).

These minuscule insects typically range from 1 to 3 millimeters (less than 1/8 inch) in length, making them very difficult to spot. Only the female midges bite, as they require blood meals to produce their eggs. Their bites are disproportionately painful and itchy for their size, often resulting in small, red welts that can persist for days or even weeks. Unlike mosquitoes, biting midges are not significant vectors of human diseases in most regions, though they can transmit diseases to livestock. They are weak fliers and are most active during calm periods around dawn and dusk, or on overcast days, typically thriving in humid environments near water sources like swamps, marshes, riverbanks, and coastal areas.

Personal Protection
Insect Repellents: The most crucial defense. Look for products containing:
● DEET: Highly effective against biting insects, including midges. Use concentrations appropriate for the duration of exposure (higher percentages offer longer protection).
● Picaridin: Another highly effective option, often preferred for its pleasant feel and lack of plastic-damaging properties.
● Oil of Lemon Eucalyptus (OLE) / PMD: A plant-based alternative that is also effective.
● Other Essential Oils: Some individuals find relief with repellents containing rosemary, cedarwood, citronella, or lavender, though their effectiveness and duration can vary. Cream formulations that create a physical barrier can also be effective.
Cover Up: Wear long-sleeved shirts, long pants, socks, and closed-toe shoes, especially during peak midge activity. Loose-fitting, light-colored clothing is often recommended as midges may be drawn to dark colors.
Avoid Peak Activity Times: Limit outdoor exposure around dawn and dusk, when midges are most active.
Fans: Midges are weak fliers, so using ceiling fans or portable fans (indoors or on patios/decks) can create enough air movement to deter them.

Environmental and Home Protection

Fine Mesh Screening: Standard window and door screens often have mesh too large for midges. Install "midge mesh" or "no-see-um mesh" (typically 0.6mm x 0.6mm or finer) on all windows, doors, and vents.
Seal Gaps: Ensure all entry points into homes or tents are properly sealed.
Reduce Breeding Sites: While challenging due to their diverse natural habitats, try to minimize damp areas, standing water, and decaying organic matter around your immediate living space. Keep lawns mowed and vegetation sparse around your home to reduce resting areas for adult midges.
Insecticides/Barrier Sprays: For severe infestations, professional pest control can apply residual insecticides to outdoor surfaces where midges rest (e.g., walls, screens, vegetation). This can provide temporary relief but must be used carefully due to potential impacts on non-target insects. Insecticide vaporizers or coils can offer some localized protection outdoors.
Lighting: Some evidence suggests midges are attracted to bright white lights. Consider using yellow or red "bug lights" outdoors.

DE | Insect Protection | Midg

Treating Bites

Clean the Area: Wash bites with soap and water to prevent secondary infection.
Relieve Itching: Apply cold compresses, over-the-counter anti-itch creams (e.g., hydrocortisone, antihistamines), calamine lotion, or natural remedies like aloe vera.
Avoid Scratching: Scratching can break the skin, leading to infection and prolonged discomfort.

DEFENCE | Insect Protection | Ticks

Ticks

Ticks are small arachnids, related to spiders and mites, that are external parasites. They feed on the blood of animals, including humans, birds, reptiles, and amphibians. Ticks are found worldwide in various habitats, including wooded areas, tall grasses, brush, leaf litter, and even around residential yards. They do not fly or jump; instead, they "quest" by perching on vegetation with their front legs extended, waiting to grab onto a passing host. Once on a host, they crawl to a suitable spot, bite into the skin, and begin to feed, often remaining attached for several days.

The primary concern with tick bites is their ability to transmit a wide variety of pathogens, including bacteria, viruses, and protozoa, which can cause serious illnesses in humans and animals. Some common tick-borne diseases include Lyme disease, Rocky Mountain spotted fever, Anaplasmosis, Babesiosis, and Tick-Borne Encephalitis, among many others. In some regions, ticks can also cause tick paralysis due to toxins in their saliva.

DEFENCE | Insect Protection | Ticks

Before Going Outdoors
Know Tick Habitats: Be aware that ticks live in grassy, brushy, or wooded areas, and even in leaf litter. Stay in the center of trails and avoid walking through tall grass and dense vegetation.

Use Repellents
Apply EPA-registered insect repellents containing DEET, Picaridin, IR3535, Oil of Lemon Eucalyptus (OLE), or 2-Undecanone to exposed skin. Always follow product instructions carefully.
Treat clothing and gear (boots, pants, socks, tents) with products containing 0.5% Permethrin. Permethrin kills ticks on contact and remains effective through several washes. Do NOT apply permethrin directly to skin. You can also buy pre-treated clothing.

Dress Appropriately: Wear long-sleeved shirts, long pants, and tuck your pant legs into your socks or boots to create a barrier. Light-colored clothing can make it easier to spot ticks.

DEFENCE | Insect Protection | Ticks

While Outdoors

Regular Checks: Periodically check yourself, children, and pets for ticks while outdoors, especially after moving through dense vegetation.
Stay on Trails: Stick to cleared paths and avoid venturing into tall grass or dense brush.

DEFENCE | Insect Protection | Ticks

After Coming Indoors

Full Body Check: Conduct a thorough full-body check upon returning indoors. Ticks often hide in warm, moist areas:
● Under the arms, ● In and around the ears, ● Inside the belly button, ● Back of the knees, ● In and around hair, ● Between the legs, ● Around the waist
Shower Promptly: Showering within two hours of coming indoors can help wash off unattached ticks and provides a good opportunity for a tick check.
Check Gear and Pets: Ticks can hitch a ride on clothing, backpacks, and pets. Examine them carefully before bringing them inside.
Clothing Care: Tumble dry clothes on high heat for at least 10 minutes (or longer if damp) to kill any remaining ticks. Washing alone in cold or medium water may not kill ticks.

DEFENCE | Insect Protection | Ticks

Tick Removal

Use Fine-Tipped Tweezers: If you find an attached tick, grasp it as close to the skin's surface as possible with fine-tipped tweezers.
Pull Straight Up: Pull upward with a steady, even pressure. Do not twist or jerk the tick, as this can cause the mouthparts to break off and remain in the skin.
Avoid Folk Remedies: Do not use heat (matches), petroleum jelly, nail polish, or other substances to try to make the tick detach, as these methods can irritate the tick and cause it to regurgitate infectious fluids into the bite wound.
Clean the Area: After removing the tick, clean the bite area and your hands with rubbing alcohol or soap and water.
Monitor: Watch for symptoms like fever, rash, joint pain, or fatigue in the days and weeks following a tick bite. Seek medical attention if you develop any concerning symptoms.

DEFENCE | Insect Protection | Bees

Bees/Wasps/Hornets

DEFENCE | Insect Protection | Ants

Ants

Identify Ant Activity: Before sitting down or setting up camp, visually inspect the area for ant trails, individual ants, and especially ant nests or mounds. Different ants build different types of nests (e.g., dome-shaped mounds for fire ants, smaller holes for others, or nests under rocks/logs).
Avoid Nests: The most aggressive ant attacks occur when their nests are disturbed. If you see a mound or a cluster of ants, give it a wide berth. Teach children to do the same.
Check for Food/Water: Ants are attracted to food and water. Be extra cautious in picnic areas, near food spills, or around pet food bowls.

Protection | Ants

Wear Protective Clothing
● Long Pants and Sleeves: Wear long pants and long-sleeved shirts, especially when walking through grassy or wooded areas.
● Tuck In: Tuck your pant legs into your socks or boots to prevent ants from crawling up your legs.
● Closed-Toe Shoes: Always wear closed-toe shoes outdoors, especially in areas where ants might be present. Avoid sandals or bare feet.
● Gloves: If you're gardening or moving items that might harbor ants (like logs, rocks, or debris), wear sturdy gloves.
● Permethrin-Treated Clothing: Clothing pre-treated with permethrin (an insecticide that repels and kills insects on contact) can offer an additional layer of protection against ants, as well as ticks and mosquitoes. This is different from skin repellents and should not be applied directly to skin.

DEFENCE Insect Protection Ants

Use Repellents
● Insect Repellents on Skin: While not all insect repellents are highly effective against ants, some can offer a deterrent effect. Repellents containing DEET or Picaridin are generally the most reliable for broad-spectrum insect protection. Apply to exposed skin according to product instructions.
● Essential Oil-Based Repellents: Some natural repellents containing essential oils like peppermint oil, tea tree oil, lemon, eucalyptus, or cinnamon are believed to deter ants. These can be sprayed on clothing or applied to skin (test a small area first). Brands like "OzKleen Ants Gone" (available in Australia) specifically market peppermint-based sprays for surfaces and outdoor areas.

Manage Your Outdoor Space (if applicable)
● Clear Debris: Keep your yard clear of leaf litter, fallen logs, and other debris that can provide shelter for ant nests.
● Seal Entry Points: If ants are entering your home from outdoors, seal cracks and crevices in foundations, walls, and around windows and doors.
Reduce Food Sources: Clean up food spills promptly, keep garbage cans tightly sealed, and ensure pet food bowls are not left out for long periods.

If You Encounter Ants
● Move Quickly: If you find yourself on an ant mound or swarmed by biting ants (like fire ants, which often emerge in large numbers), move away quickly.
● Brush Them Off: Aggressively brush ants off your skin before they can bite or sting.

First Aid for Bites/Stings
For most ant bites, wash the area with soap and water. Apply a cold compress to reduce swelling and pain. Over-the-counter anti-itch creams (hydrocortisone, calamine lotion) or oral antihistamines can help with itching and discomfort.
● For Fire Ant Stings: Fire ant stings typically form itchy, painful pustules (blisters). Do NOT break these blisters. Clean the area with soap and water, and apply a cold compress. Seek medical attention if you experience a severe allergic reaction (anaphylaxis: difficulty breathing, swelling of the face/throat, dizziness) or if symptoms worsen.

Scorpions

Fleas

Leeches

Snails & Slugs

Assassin Bugs

Repellents

Repellents only repel insects from the source and only for a short duration of a few hours. They work well when you have to be amongst bugs and insects, particularly at night. Deet is the most effective on insects followed by picaridin, permethrin, deltamethrin and citronella.

Synthetic repellents tend to be more effective and/or longer lasting than "natural" repellents. For protection against mosquito bites, the U.S. Centres for Disease Control (CDC) recommends DEET, picaridin, oil of lemon eucalyptus, ethyl butylacetylaminopropionate and 2-undecanone with the caveat that higher percentages of the active ingredient provide longer protection. Researchers tested 10 commercially available products for their effectiveness at repelling mosquitoes. On the mosquito Aedes aegypti, only one repellent that did not contain DEET had a strong effect for the duration of the 240 minutes test: a lemon eucalyptus oil repellent. All DEET-containing mosquito repellents were active. In one comparative study from 2004, ethyl butylacetylaminopropionate was as effective or better than DEET in protection against Aedes aegypti and Culex quinquefasciatus mosquitoes. Essential oil repellents can be short-lived in their effectiveness, since essential oils can evaporate completely. A test of various insect repellents by an independent consumer organization found that repellents containing DEET or picaridin are more effective than repellents with "natural" active ingredients.

All the synthetics gave almost 100% repellency for the first 2 hours, where the natural repellent products were most effective for the first 30 to 60 minutes, and required reapplication to be effective over several hours. Permethrin is recommended as protection against mosquitoes for clothing, gear, or bed nets. In an earlier report, the CDC found oil of lemon eucalyptus to be more effective than other plant-based treatments, with a similar effectiveness to low concentrations of DEET. However, a 2006 published study found in both cage and field studies that a product containing 40% oil of lemon eucalyptus was just as effective as products containing high concentrations of DEET. Research has also found that neem oil is mosquito repellent for up to 12 hours. Citronella oil's mosquito repellency has also been verified by research, including effectiveness in repelling Aedes aegypti, but requires reapplication after 30 to 60 minutes.

Smoke

Smoke can repel unwanted insects, and this has been a common practice by humans for thousands of years. The effectiveness varies depending on the type of smoke, the insect species, and the concentration of the smoke.

How Smoke Repels Insects
● Irritation and Disorientation: The compounds in smoke (such as phenols, cresols, and other volatile organic compounds) are often irritants to insects' respiratory systems and sensory organs. This irritation makes the environment unpleasant for them, causing them to move away.
● Masking Scents: Smoke can mask the chemical cues (like carbon dioxide, lactic acid, and other bodily odors) that humans and animals emit, which insects like mosquitoes and biting flies use to locate their blood meal sources. By obscuring these attractants, smoke makes it harder for insects to find you.
● Physical Barrier: A dense cloud of smoke can act as a physical barrier, making it difficult for small insects to fly through or see their targets.
● Neurotoxic Effects (in some cases): Some compounds in smoke, particularly from certain plants or burning materials, can have mild neurotoxic effects on insects, further deterring them.

Types of Smoke and Their Effectiveness

● Wood Smoke (e.g., Campfires, Bonfires):
Common Use: This is the most traditional form of insect repellent.
Effectiveness: Generally effective for keeping away mosquitoes, midges/no-see-ums, and some flies in the immediate vicinity of the smoke. The specific wood used can influence effectiveness; woods with aromatic compounds tend to be more potent.
Limitations: The smoke needs to be consistently present, and its effectiveness diminishes rapidly as you move away from the source. It can also be irritating to human eyes and lungs, especially in enclosed spaces.

● Mosquito Coils/Sticks:

Common Use: Specifically designed products that burn slowly to release insecticidal smoke.
Effectiveness: Highly effective. They typically contain pyrethroids (synthetic versions of natural pyrethrins from chrysanthemum flowers) or other insecticides, which are neurotoxic to insects.
Limitations: Designed for outdoor or well-ventilated use due to potential respiratory irritation and exposure to insecticides.

● Incense Sticks/Cones (especially citronella or specific repellent blends):

Common Use: Some incense is formulated with insect-repelling essential oils.
Effectiveness: Can offer some localized, temporary relief, but generally less potent than mosquito coils or strong chemical repellents.
Limitations: Limited range, can be irritating to some people.

● "Smudge Sticks" (e.g., dried herbs like sage, rosemary, or cedar):
Common Use: Historically and culturally used for various purposes, including insect deterrence.
Effectiveness: The smoke from certain aromatic herbs can deter insects due to the volatile compounds released.
Limitations: Requires active burning, limited range.

DEET (Diethyltoluamide)

DEET or Diethyltoluamide is the most common active ingredient in insect repellents. It is a slightly yellow oil intended to be applied to the skin or to clothing and provides protection against many biting insects. A powerful insect repellent which is often sprayed on exposed skin to create a repellent barrier which lasts for up to 8 hours. The higher percentage of deet, the less you will need to use for the same effectiveness. They are generally sold between 25%-100% deet. Deet in combination with permethrin provides an extremely strong barrier against insects. As permethrin only works on clothing it will close the gaps where insects can bite you.

Effective For
● Mosquitoes
● Ticks
● Fleas
● Chiggers
● Leeches
● Other Biting Insects

Effectiveness
DEET serves as a true repellent in that mosquitoes intensely dislike the smell of the chemical. A type of olfactory receptor neuron in special antennal sensilla of mosquitoes that is activated by DEET, as well as other known insect repellents such as eucalyptol, linalool, and thujone, has been identified. Moreover, in a behavioural test, DEET had a strong repellent activity in the absence of body odour attractants such as 1-octen-3-ol, lactic acid, or carbon dioxide. Both female and male mosquitoes showed the same response.

Concentrations
Insect repellents containing DEET are the most effective. The concentration of DEET in products may range from less than 10 percent to over 30 percent. The benefits of DEET reach a peak at a concentration of 30 percent, the maximum concentration currently recommended for infants and children. DEET should not be used on children under 2 months of age. DEET is often sold and used in spray or lotion in concentrations up to 100%. Consumer Reports found a direct correlation between DEET concentration and hours of protection against insect bites. 100% DEET was found to offer up to 12 hours of protection while several lower concentration DEET formulations (20–34%) offered 3–6 hours of protection. Other research has corroborated the effectiveness of DEET. The Centres for Disease Control and Prevention recommends 30–50% DEET to prevent the spread of pathogens carried by insects.

Effects
DEET is an effective solvent, and may dissolve some watch crystals, plastics, rayon, spandex, other synthetic fabrics, and painted or varnished surfaces including nail polish. It also may act as a plasticizer by remaining inside some formerly hard plastics, leaving them softened and more flexible. Though DEET is not expected to bioaccumulate, it has been found to have a slight toxicity for fresh-water fish such as rainbow trout and tilapia, and it also has been shown to be toxic for some species of freshwater zooplankton.

Picaridin (Icaridin, KBR 3023)

DEFENCE Insect Protection Repellents Picaridin

Icaridin, also known as picaridin, is an insect repellent. It has broad efficacy against various insects and ticks and is almost colourless and odourless. Icaridin has been reported to be as effective as DEET without the irritation associated with DEET. According to the WHO, icaridin "demonstrates excellent repellent properties comparable to, and often superior to, those of the standard DEET." Icaridin does not dissolve plastics. Icaridin-based products, first used in Europe in 2001, have been evaluated by Consumer Reports in 2016 as among the most effective insect repellents when used at a 20% concentration. Icaridin was earlier reported to be effective by Consumer Reports (7% solution) and the Australian Army (20% solution). Consumer Reports retests in 2006 gave as result that a 7% solution of icaridin offered little or no protection against Aedes mosquitoes (vector of dengue fever) and a protection time of about 2.5 hours against Culex (vector of West Nile virus), while a 15% solution was good for about one hour against Aedes and 4.8 hours against Culex.

DEFENCE Insect Protection Repellents Citronella Oil

Citronella Oil

Citronella oil is an essential oil obtained from the leaves and stems of different species of Cymbopogon (lemongrass). Citronella oil is popular as a natural insect repellent. Its mosquito repellent qualities have been verified by research, including effectiveness in repelling Aedes aegypti (dengue fever mosquito). To be continually effective, most citronella repellent formulas need to be reapplied to the skin every 30–60 minutes.

Research also indicates that citronella oil is an effective repellent for body lice, head lice, and stable flies. A study conducted by ARPA in 1963 determined that hydroxycitronellal was an effective repellent against both aquatic and terrestrial leeches.

The US Environmental Protection Agency states that citronella oil has little or no toxicity when used as a topical insect repellent, with no reports of adverse effects of concern over a 60-year period. Some products are applied to human skin, so EPA requires proper precautionary labelling to help assure safe use.

If used according to label instructions in the US, citronella is not expected to pose health risks to people, including children and other sensitive populations. The US Food & Drug Administration considers citronella oil as generally recognized as safe (GRAS). Canadian regulatory concerns with citronella as an insect repellent are primarily based on data-gaps in toxicology, not on incidents.

DEFENCE Insect Protection Repellents Tea Tree Oil

Tea Tree Oil

Tea Tree Oil (TTO) (also known as melaleuca oil), can be used as an insect repellent, and research supports its repellent and even insecticidal properties against various pests.

How it works
Tea Tree Oil, derived from the Australian native plant Melaleuca alternifolia, contains a complex mixture of compounds, notably terpinen-4-ol and cineole. These compounds are believed to:
● Mask Human Scents: The strong, distinct smell of tea tree oil can help mask the natural odors (like carbon dioxide and lactic acid) that attract insects.
● Disrupt Sensory Perception: Some compounds in TTO can interfere with insects' neurological pathways, making it difficult for them to locate and process information from their senses.
● Irritation/Toxicity: At higher concentrations, components of tea tree oil can be irritating or even toxic to insects, causing them to avoid treated areas or, in some cases, leading to their demise.

DEFENCE | Insect Protection | Repellents | Tea Tree Oil

Effectiveness and Limitations
● Mosquitoes and Midges: Studies have shown that tea tree oil can be effective in repelling mosquitoes and biting midges. Some research indicates that certain formulations of TTO can provide protection comparable to some synthetic repellents, though often for a shorter duration.
● Other Insects: Anecdotal evidence and some studies suggest it may also help repel flies (including bush flies), ticks, ants, and even some mites.
● Duration: A common limitation of many essential oil-based repellents, including TTO, is their relatively short duration of effectiveness compared to synthetic repellents like DEET or Picaridin. You may need to reapply it more frequently.
● Formulation and Concentration: The effectiveness of tea tree oil as a repellent largely depends on its concentration in the product and how it's formulated (e.g., in a carrier oil, cream, or spray). Higher concentrations (e.g., 5-10%) tend to be more effective, but must be used with caution.
Species Specificity: What repels one insect species might not be as effective against another, even closely related ones.

How to Use Tea Tree Oil as a Repellent
● Dilution is Key: Tea tree oil is potent and should always be diluted before applying to the skin to avoid irritation or allergic reactions. A common dilution ratio is 5-10 drops of tea tree oil per ounce (30ml) of a carrier oil (like coconut oil, jojoba oil, or almond oil) or water (mixed with a small amount of an emulsifier like witch hazel).

● Topical Application: Apply the diluted mixture to exposed skin.
● Diffusers/Oil Burners: For outdoor areas (like a patio), you can use an essential oil diffuser or an oil burner to release the scent into the air, creating a repellent zone.
● DIY Sprays: Create a spray by mixing diluted TTO with water in a spray bottle.
● Blends: Tea tree oil is often more effective when combined with other insect-repelling essential oils like lemon eucalyptus, citronella, lavender, or rosemary.

Tobacco

Nicotine, a fast acting nerve toxin in insects and mammals.

Dimethyl Carbate

Dimethyl carbate is an insect repellent. It can be prepared by the Diels–Alder reaction of dimethyl maleate and cyclopentadiene.

Ethyl Butylacetylaminopropionate

Ethyl butylacetylaminopropionate (trade name IR3535) is an insect repellent. As ethyl butylacetylaminopropionate is solely a repellent, it has no killing action and does not give rise to selection pressure or development of resistance. It is a colourless and almost odourless oil and is intended to be applied to the skin of humans and animals. It has a broad efficacy against various insects like mosquitoes, ticks, lice, and other bugs. Ethyl butylacetylaminopropionate is safe for use on infants, pregnant and breastfeeding women. It is biodegradable and completely degraded in the environment within a very short time.

Metofluthrin

Metofluthrin is a pyrethroid used as an insect repellent. The vapours of metofluthrin are highly effective and capable of repelling up to 97% of mosquitoes in field tests. Metofluthrin is used in a variety of consumer products, called emanators, for indoor and outdoor use. These products produce a vapour that protects an individual or area. Effectiveness is reduced by air movement. Metofluthrin is neurotoxic, and is not meant to be applied directly to human skin. Although metofluthrin has insectidal properties against other insects, it may not be an effective repellent for insects other than mosquitoes.

SS220

SS220 is an insect repellent with a broad range of efficacy. In the field, it has been shown to provide significantly better protection than DEET. It was developed in 2002 at the Chemicals Affecting Insect Behaviour Laboratory of the United States Department of Agriculture and has been found to "exert repellent and deterrent effects upon the behaviour of mosquitoes and sand flies". SS220 has a slightly fruity odour, tends not to provoke allergic skin reactions, lasts longer on the skin than other repellents, does not have an oily consistency, and does not tend to plasticize. Its principal disadvantage is that only one stereoisomer of the molecule is active, meaning it will be much more costly to produce than icaridin. As of 2007 the chemical had not been registered, and the costs involved in registration are prohibitively enormous.

Insecticides

Insecticides are designed to inhibit a vital function of insects so they eventually die after exposure.

Permethrin

Permethrin, sold under the brand name Nix among others, is a medication and insecticide. As a medication, it is used to treat scabies and lice. It is applied to the skin as a cream or lotion. As an insecticide, it can be sprayed on clothing or mosquito nets to kill the insects that touch them. Side effects include rash and irritation at the area of use. Use during pregnancy appears to be safe. It is approved for use on and around people over the age of two months. Permethrin is in the pyrethroid family of medications. It works by disrupting the function of the neurons of lice and scabies mites. Often in combination with piperonyl butoxide to enhance its effectiveness.

Medical Use
Permethrin is available for topical use as a cream or lotion. It is indicated for the treatment and prevention in exposed individuals of head lice and treatment of scabies. For treatment of scabies: Adults and children older than 2 months are instructed to apply the cream to the entire body from head to the soles of the feet. Wash off the cream after 8–14 hours. In general, one treatment is curative. For treatment of head lice: Apply to hair, scalp, and neck after shampooing. Leave in for 10 minutes and rinse. Avoid contact with eyes.

Pest Control
Kills insects within about 5 minutes of contact. Generally too long to kill them before they bite you but good to know they won't bite you again. Permethrin kills ticks and mosquitoes on contact with treated clothing. A method of reducing deer tick populations by treating rodent vectors involves stuffing biodegradable cardboard tubes with permethrin-treated cotton. Mice collect the cotton for lining their nests. Permethrin on the cotton instantly kills any immature ticks feeding on the mice. Permethrin is used in tropical areas to prevent mosquito-borne disease such as dengue fever and malaria. Mosquito nets used to cover beds may be treated with a solution of permethrin. This increases the effectiveness of the bed net by killing parasitic insects before they are able to find gaps or holes in the net. Military personnel training in malaria-endemic areas may be instructed to treat their uniforms with permethrin, as well. Permethrin is the most commonly used insecticide worldwide for the protection of wool from keratinophagous insects such as Tineola bisselliella.

Side Effects
Permethrin application can cause mild skin irritation and burning. Permethrin has little systemic absorption, and is considered safe for topical use in adults and children over the age of 2 months. According to the Connecticut Department of Public Health, permethrin "has low mammalian toxicity, is poorly absorbed through the skin, and is rapidly inactivated by the body. Skin reactions have been uncommon." Excessive exposure to permethrin can cause nausea, headache, muscle weakness, excessive salivation, shortness of breath, and seizures. Worker exposure to the chemical can be monitored by measurement of the urinary metabolites, while severe overdose may be confirmed by measurement of permethrin in serum or blood plasma. Permethrin does not present any notable genotoxicity or immunotoxicity in humans and farm animals, but is classified by the EPA as a likely human carcinogen, based on reproducible studies in which mice fed permethrin developed liver and lung tumours. It is known to be highly toxic to fish and aquatic species.

Other Animals
Permethrin is listed as a "restricted use" substance by the US Environmental Protection Agency (EPA) due to its high toxicity to aquatic organisms, so permethrin and permethrin-contaminated water should be properly disposed. Permethrin is quite stable, having a half life of 51–71 days in an aqueous environment exposed to light. It is also highly persistent in soil. Permethrin has little effect on dogs; however, it is toxic to cats. Pesticide-grade permethrin is toxic to cats. Many cats die after being given flea treatments intended for dogs, or by contact with dogs having recently been treated with permethrin. In cats it may induce hyperexcitability, tremors, seizures, and death. Toxic exposure of permethrin can cause several symptoms, including convulsion, hyperaesthesia, hyperthermia, hypersalivation, and loss of balance and coordination. Exposure to pyrethroid-derived drugs such as permethrin requires treatment by a veterinarian, otherwise the poisoning is often fatal. This intolerance is due to a defect in glucuronosyltransferase, a common detoxification enzyme in other mammals, that also makes the cat intolerant to paracetamol. The use of any external parasiticides based on permethrin is contraindicated for cats.

Deltamethrin

Deltamethrin products are among the most popular and widely used insecticides in the world and have become very popular with pest control operators and individuals in the United States. This material is a member of one of the pesticides called synthetic pyrethroids. This pesticide is highly toxic to aquatic life, particularly fish, and therefore must be used with extreme caution around water. Although generally considered safe to use around humans, it is still neurotoxic to humans. Deltamethrin is able to pass from a woman's skin through her blood and into her breast milk. It is an allergen and causes asthma in some people. There are many uses for deltamethrin, ranging from agricultural uses to home pest control. Deltamethrin has been instrumental in preventing the spread of diseases carried by tick-infested prairie dogs, rodents and other burrowing animals. It is helpful in eliminating and preventing a wide variety of household pests, especially spiders, fleas, ticks, carpenter ants, carpenter bees, cockroaches and bed bugs. Deltamethrin is also one of the primary ingredients in ant chalk.

Malaria Control
Deltamethrin plays a key role in controlling malaria vectors, and is used in the manufacture of long-lasting insecticidal mosquito nets. It is used as one of a battery of pyrethroid insecticides in control of malarial vectors, particularly Anopheles gambiae, and whilst being the most employed pyrethroid insecticide, can be used in conjunction with, or as an alternative to, permethrin, cypermethrin and organophosphate-based insecticides, such as malathion and fenthion. Resistance to deltamethrin (and its counterparts) is now extremely widespread and threatens the success of worldwide vector control programmes.

Resistance
Resistance has been characterised in several insects, including important vectors of malaria like the mosquito Anopheles gambiae as well as non-disease carrying pests like bed bugs. Methods of resistance include thickening of the cuticle of the insect to limit permeation of the insecticide, metabolic resistance and the knockdown resistance (kdr) sodium channel mutations which render the action of insecticides ineffectual, even when co-administered with piperonyl butoxide.

Poisoning
Since deltamethrin is a neurotoxin, it temporarily attacks the nervous system of any animal with which it comes into contact. Skin contact can lead to tingling or reddening of the skin local to the application. If taken in through the eyes or mouth, a common symptom is facial paraesthesia, which can feel like many different abnormal sensations, including burning, partial numbness, "pins and needles", skin crawling, etc. There are no reports indicating that chronic intoxication from pyrethroid insecticides causes motor neuron damage or motor neuron disease. There are no antidotes, and treatment must be symptomatic, as approved by a physician. Over time, deltamethrin is metabolized, with a rapid loss of toxicity, and passed from the body. A poison control centre should be contacted in the event of an accidental poisoning. Cases of toxicity have been observed in cattle following use of agricultural deltamethrin preparation in external application for tick control.

Allethrin

The allethrins are a group of related synthetic compounds used in insecticides. They are synthetic pyrethroids, a synthetic form of a chemical found naturally in the chrysanthemum flower. They are commonly used in ultra-low volume sprays for outdoor mosquito control including many household insecticides such as RAID as well as mosquito coils. The compounds have low toxicity for humans and birds. It is highly toxic to fish and aquatic invertebrates. At normal application rates, allethrin is slightly toxic to bees. Insects subject to exposure become paralysed (nervous system effect) before dying. Allethrins are toxic to cats because they either do not produce, or produce less of certain isoforms of glucuronosyltransferase, which serve in hepatic detoxifying metabolism pathways.

Bifenthrin

Bifenthrin is a pyrethroid insecticide used primarily against the red imported fire ant by influencing its nervous system. It has a high toxicity to aquatic organisms. Although it is listed as a restricted use chemical in the United States, it is allowed to be sold for daily use, provided the product sold has a low concentration of bifenthrin. Bifenthrin is poorly soluble in water and often remains in soil. Its residual half-life in soil is between 7 days and 8 months, depending on the soil type, with a low mobility in most soil types. Bifenthrin has the longest known residual time in soil of insecticides currently on the market. It is a white, waxy solid with a faint sweet smell. It is chemically synthesized in various forms, including powder, granules and pellets. However, it is not naturally occurring.

On a large scale, bifenthrin is often used against red imported fire ants. It is also effective against aphids, worms, other ants, gnats, moths, beetles, earwigs, grasshoppers, mites, midges, spiders, ticks, yellow jackets, maggots, thrips, caterpillars, flies, fleas, and termites. It is mostly used in orchards, nurseries, and homes. In the agricultural sector, it is used in great amounts on certain crops, such as corn. About 70% of all hops and raspberries cultured in the United States are treated with bifenthrin.

Bifenthrin is used by the textile industry to protect woollen products from insect attack. It was introduced as an alternative to permethrin-based agents, due to greater efficacy against keratinophagous insects, better wash-fastness, and lower aquatic toxicity. Bifenthrin is not at all toxic to plants. Though it does not have a large toxicological risk towards mammals or birds, bifenthrin is able to accumulate in food, so it might be dangerous to mammals or birds in some scenarios.

Toxicology

Mosquitoes
Bifenthrin is an effective pesticide to use against malaria and filaria vector mosquitoes. It is still effective when a resistance to other pyrethroids is found. Mosquito nets and indoor walls can be treated with bifenthrin to keep more mosquitoes away. Bifenthrin is an effectively used insecticide, but the risk is high of it working only for a short time. Mosquitoes can develop a resistance to it, as well.

Aquatic Life
Bifenthrin is hardly soluble in water, so nearly all bifenthrin will stay in the sediment, but it is very harmful for the aquatic life. Even in small concentrations, fish and other aquatic animals are affected by bifenthrin. One of the reasons for the high sensitivity of fish is fish have a slow metabolism. Bifenthrin will stay longer in the system of the fish. Another reason for the high sensitivity of fish is the effect of bifenthrin as ATPase-inhibitor. The gills need ATP to control the osmotic balance of oxygen. If the fish is no longer capable of taking up oxygen because ATP can no longer be used, the fish will die. In cold water, bifenthrin is even more dangerous. pH and calcium concentration are also factors that influence the toxicity. Vertebrates are less sensitive to the effects of bifenthrin as ATPase-inhibitor.

Bees
In bees, the lethal concentration (LC50) of bifenthrin is about 17 mg/l. At sublethal concentrations, bifenthrin reduces the fecundity of bees, decreases the rate at which bee larvae develop into adults, and increases their immature periods. Bifenthrin and other synthetic pyrethroids are being used in agriculture in increasing amounts because of the high efficiency of these substances in killing insects, the low toxicity for mammals, and good biodegradability. However, because of its success, they are being used more often (also indoors) and high exposure of bifenthrin to humans can occur.

Human Neurotoxicity
Exposure to bifenthrin can be achieved either by skin contact or ingestion. Skin contact is not toxic, apart from a slight tingling sensation on the specific location of contact. Ingestion is toxic, although only slightly. Commercially available bifenthrin (Ortho Home Defence Max, for example), however, can induce toxic effects in those concentrations, because the added chemicals which improve the sustainability either potentiate bifenthrin or are toxic on their own. Symptoms of excessive exposure are nausea, headaches, hypersensitivity for touch and sound, and irritation of the skin and the eyes.

Bioallethrin

Bioallethrin refers to a mixture of two of the allethrin isomers (1R,trans;1R and 1R,trans;1S) in an approximate ratio of 1:1, where both isomers are active ingredients. A mixture of the two same stereoisomers, but in an approximate ratio of R:S in 1:3, is called esbiothrin. A mixture containing only S-forms of allethrin is referred to as esbioallethrin or S-bioallethrin. Bioallethrin is a synthetic pyrethroid used as a pesticide against household pest insects such as mosquitoes, houseflies and cockroaches. It is claimed to have low mammalian toxicity.

Cyhalothrin (Lambda-Cyhalothrin)

Cyhalothrin is an organic compound that is used as a pesticide. It is a pyrethroid, a class of synthetic insecticides that mimic the structure and insecticidal properties of the naturally occurring insecticide pyrethrin which comes from the flowers of chrysanthemums. Pyrethroids such as cyhalothrin are often preferred as an active ingredient in insecticides because they remain effective for longer periods of time than pyrethrin. It is a colourless solid, although samples can appear beige, with a mild odour. It has a low water solubility and is non-volatile. It is used to control insects in cotton crops. Pyrethroids, including lambda-cyhalothrin, disrupt the functioning of the nervous system in an organism. By disrupting the nervous system of insects, lambda-cyhalothrin may cause paralysis or death. Temperature influences its effectiveness. It is highly toxic to many fish and aquatic invertebrate species.

Cypermethrin

Cypermethrin is a synthetic pyrethroid used as an insecticide in large-scale commercial agricultural applications as well as in consumer products for domestic purposes. It behaves as a fast-acting neurotoxin in insects. It is easily degraded on soil and plants but can be effective for weeks when applied to indoor inert surfaces. Exposure to sunlight, water and oxygen will accelerate its decomposition. Cypermethrin is highly toxic to fish, bees and aquatic insects, according to the National Pesticides Telecommunications Network (NPTN). It is found in many household ant and cockroach killers, including Raid, Ortho, Combat, and ant chalk. Cypermethrin is used in agriculture to control ectoparasites which infest cattle, sheep, and poultry. In veterinary medicine, it is effective at controlling ticks on dogs.

Human Exposure
Cypermethrin is moderately toxic through skin contact or ingestion. It may cause irritation to the skin and eyes. Symptoms of dermal exposure include numbness, tingling, itching, burning sensation, loss of bladder control, incoordination, seizures and possible death. Pyrethroids may adversely affect the central nervous system. Human volunteers given dermal doses of 130 µg/cm2 on the earlobe experienced local tingling and burning sensations. One man died after eating a meal cooked in a 10% cypermethrin concentrate that was mistakenly used for cooking oil. Shortly after the meal, the victim experienced nausea, prolonged vomiting, stomach pains, and diarrhoea which progressed to convulsions, unconsciousness and coma. Other family members exhibited milder symptoms and survived after hospital treatment. Cypermethrin is not a skin or eye irritant, but it may cause allergic skin reactions. Excessive exposure can cause nausea, headache, muscle weakness, salivation, shortness of breath and seizures. In humans, cypermethrin is deactivated by enzymatic hydrolysis to several carboxylic acid metabolites, which are eliminated in the urine. Worker exposure to the chemical can be monitored by measurement of the urinary metabolites, while severe over dosage may be confirmed by quantitation of cypermethrin in blood or plasma.

Animal Exposure
Cypermethrin is very toxic to cats which cannot tolerate the therapeutic doses for dogs. This is associated with glucuronidase deficiency in cats, the enzyme responsible for metabolizing cypermethrin. As a consequence, cypermethrin remains much longer in the cat's organs than in dogs or other mammals and can be fatal in large doses. One study showed that cypermethrin inhibits "gap junctional intercellular communication", which plays an important role in cell growth and is inhibited by carcinogenic agents. Studies have shown that residue from cypermethrin can last for 84 days in the air, on walls, the floor and on furniture.

Environmental Effects
Cypermethrin is a broad-spectrum insecticide, which means it kills beneficial insects as well as the targeted insects. Fish are particularly susceptible to cypermethrin, but when used according directions, application around residential sites poses little risk to aquatic life. Resistance to cypermethrin has developed quickly in insects exposed frequently and can render it ineffective.

Cyfluthrin

Cyfluthrin is a pyrethroid insecticide and common household pesticide. It is a complex organic compound and the commercial product is sold as a mixture of isomers. Like most pyrethroids, it is highly toxic to fish and invertebrates, but it is far less toxic to humans. It is generally supplied as a 10–25% liquid concentrate for commercial use and is diluted prior to spraying onto agricultural crops and outbuildings. Excessive exposure can cause nausea, headache, muscle weakness, salivation, shortness of breath and seizures. Cyfluthrin is used in insecticidal sprays such as Temprid, an odourless insecticide mix (Bayer) which uses a combination of (beta-) cyfluthrin and imidacloprid, a residual control agent.

Etofenprox

DEFENCE | Insect Protection | Insecticides | Etofenprox

Etofenprox is a pyrethroid derivative which is used as an insecticide. Mitsui Chemicals Agro Inc. is the main manufacturer of the Chemical. It is also used as an ingredient in flea medication for cats. Etofenprox is an insecticide which disturbs insect nervous systems following direct contact or ingestion, and which is active against a broad spectrum of pests. It is used in agriculture, horticulture, viticulture, forestry, animal health and public health against many insect pests, for instance Lepidoptera, Hemiptera, Coleoptera, Diptera, Thysanoptera, and Hymenoptera. In agriculture, etofenprox is used on a broad range of crops such as rice, fruits, vegetables, corn, soybeans, and tea.

It is poorly absorbed by roots and little translocation occurs within plants. In the public health sector, etofenprox is used for vector control either by direct application in infested areas or indirectly by impregnating fabrics, such as mosquito nets. Etofenprox is used at low volumes to control adult mosquitoes, non-biting midges, and biting and non-biting flies. Etofenprox is used undiluted for ultra low volume aerosol applications or diluted with a diluent such as mineral oil for direct applications, for the control of pest species in or near residential, industrial, commercial, urban, recreational areas, woodlands, golf courses, and other areas where these pests are a problem.

Etofenprox is harmful if swallowed and causes moderate eye irritation. Contact with eyes, skin or clothing should be avoided. Repeated exposure to etofenprox can cause skin irritation. This pesticide is toxic to aquatic organisms, including fish and aquatic invertebrates. Runoff from treated areas or deposition into bodies of water may be hazardous to fish and other aquatic organisms. Etofenprox is highly toxic to bees exposed to direct treatment on blooming crops or weeds. Time applications to provide the maximum possible interval between treatment and the next period of bee activity. Etofenprox is decomposed in soil by anaerobic and aerobic microorganisms. In sterilized soil, little degradation took place in a 56-day test. Photochemical oxidative degradation is rapid, in air the half life is estimated at 2.07 hours.

Etofenprox is combustible and should not be used or stored near heat or open flame.

Fenvalerate

DEFENCE | Insect Protection | Insecticides | Fenvalerate

Fenvalerate is a synthetic pyrethroid insecticide. It is a mixture of four optical isomers which have different insecticidal activities. The 2-S alpha (or SS) configuration, known as esfenvalerate, is the most insecticidally active isomer. Fenvalerate consists of about 23% of this isomer. Fenvalerate is an insecticide of moderate mammalian toxicity. In laboratory animals, central nervous system toxicity is observed following acute or short-term exposure. Fenvalerate has applications against a wide range of pests including some of the more destructive such as the Helicoverpa Assulta. Residue levels are minimized by low application rates. Fenvalerate is most toxic to bees and fish. It is found in some emulsifiable concentrates, ULV, wettable powders, slow release formulations, insecticidal fogs, and granules. It is most commonly used to control insects in food, feed, and cotton products, and for the control of flies and ticks in barns and stables. Fenvalerate does not affect plants, but is active for an extended period of time. Fenvalerate may irritate the skin and eyes on contact, and is also harmful if swallowed.

Phenothrin

DEFENCE | Insect Protection | Insecticides | Phenothrin

Phenothrin, also called sumithrin and d-phenothrin, is a synthetic pyrethroid that kills adult fleas and ticks. It has also been used to kill head lice in humans. d-Phenothrin is used as a component of aerosol insecticides for domestic use. Phenothrin is often used with methoprene, an insect growth regulator that interrupts the insect's biological life cycle by killing the eggs. Phenothrin is the active agent in the branded product Raid Fly & Wasp Killer. Phenothrin is primarily used to kill fleas and ticks. It is also used to kill head lice in humans, but studies conducted in Paris, France and the United Kingdom have shown widespread resistance to phenothrin. It is extremely toxic to bees. A U.S. Environmental Protection Agency (EPA) study found that 0.07 micrograms was enough to kill honey bees. It is also extremely toxic to aquatic life with a study showing concentrations of 0.03 ppb killing mysid shrimp. It has increased risk of liver cancer in rats and mice in long term exposure. It is capable of killing mosquitoes, although remains poisonous to cats and dogs, with seizures and deaths being reported due to poisoning. Specific data on concentrations or exposure is lacking. Phenothrin has been found to possess antiandrogen properties, and was responsible for a small epidemic of gynecomastia via isolated environmental exposure. In 2005, the U.S. EPA cancelled permission to use phenothrin in several flea and tick products, at the request of the manufacturer, Hartz Mountain Industries. The products were linked to a range of adverse reactions, including hair loss, salivation, tremors, and numerous deaths in cats and kittens. In the short term, the agreement called for new warning labels on the products.

Prallethrin

DEFENCE | Insect Protection | Insecticides

Prallethrin is a pyrethroid insecticide. Prallethrin 1.6% w/w liquid vaporizer is a repellent insecticide which is generally used for the control of mosquitoes in the household. It is marketed as a mosquito repellent by Godrej as "GoodKnight Silver Power" and SC Johnson as "All Out" in India. It is also the primary insecticide in certain products for killing wasps and hornets, including their nests. It is the main ingredient in the consumer product "Hot Shot Ant & Roach Plus Germ Killer" spray. The World Health Organization published in 2004 that "Prallethrin is of low mammalian toxicity, with no evidence of carcinogenicity" and "is very toxic to bees and fish but of low toxicity to birds.

Resmethrin

Resmethrin is a pyrethroid insecticide with many uses, including control of the adult mosquito population. Commercial trade names for products that contain resmethrin are Chrysron, Crossfire, Pynosect, Raid Flying Insect Killer, Scourge, Sun-Bugger #4, SPB-1382, Synthrin, Syntox, Vectrin and Whitmire PT-110.

Tetramethrin

DEFENCE | Insect Protection | Insecticides

Tetramethrin is a potent synthetic insecticide in the pyrethroid family. It is a white crystalline solid with a melting point of 65-80 °C. The commercial product is a mixture of stereoisomers. It is commonly used as an insecticide, and affects the insect's nervous system. It is found in many household insecticide products.

Tralomethrin

DEFENCE | Insect Protection | Insecticides | Tralomethrin

Tralomethrin is a pyrethroid insecticide. Tralomethrin has potent insecticidal properties; it kills by modifying the gating kinetics of the sodium channels in neurons, increasing the length of time the channel remains open after a stimulus, thereby depolarizing the neuron for a longer period of time. This leads to uncontrolled spasming, paralysis, and eventual death. Insects with certain mutations in their sodium channel gene may be resistant to tralomethrin and other similar insecticides. Tralomethrin is also effective against most members of class Arachnida as well as insects, in addition studies by the EPA on the ecotoxicity of tralomethrin shows results as follows:

Aquatic plants
Accumulation

Insects
Mortality, Population

Crustaceans
Intoxication, Population

Molluscs
Intoxication

Fish
Accumulation, Mortality, Population

Zooplankton
Intoxication, Mortality, Population

Tralomethrin is a pyrethroid insecticide. The symptoms of poisoning with pyrethroid compounds are all alike:
- Irritation of skin and eyes.
- Irritability to sound or touch, abnormal facial sensation, sensation of prickling, tingling or creeping on skin, numbness.
- Headache, dizziness, nausea, vomiting, diarrhoea, excessive salivation, fatigue.
- In severe cases: fluid in the lungs and muscle twitching may develop. Seizures may occur and are more common with more toxic cyano-pyrethroids.

Transfluthrin

DEFENCE | Insect Protection | Insecticides

Transfluthrin is a fast-acting pyrethroid insecticide with low persistency. Transfluthrin can be used in the indoor environment against flies, mosquitoes, moths and cockroaches. It is a relatively volatile substance and acts as a contact and inhalation agent. Transfluthrin, if used contrary to product instructions, may cause symptoms of poisoning including nervousness, anxiety, tremor, convulsions, skin allergies, sneezing, running nose and irritation. No specific antidotes are known, but symptomatic treatment with antihistamines may help to control any allergies.

Trapping / Killing

A section detailing different types of ways to trap insects.

Bug Zapper	A device that attracts and kills flying insects that are attracted by light. A light source attracts insects to an electrical grid, where they are electrocuted by touching two wires with a high voltage between them. Bug zappers are usually housed in a protective cage of plastic or grounded metal bars to prevent people or animals from touching the high voltage grid. A light source is fitted inside, often a fluorescent lamp designed to emit both visible and ultraviolet light, which is visible to insects and attracts them. The light is surrounded by a pair of interleaved bare wire grids or spirals. The distance between adjacent wires is typically about 2 mm (0.079 in). A high-voltage power supply powered by mains electricity, which may be a simple transformerless voltage multiplier circuit made with diodes and capacitors, generates a voltage of 2,000 volts or more, high enough to conduct through the body of an insect which bridges the two grids, but not high enough to spark across the air gap. Enough electric current flows through the small body of the insect to heat it to a high temperature. The impedance of the power supply and the arrangement of the grid is such that it cannot drive a dangerous current through the body of a human. Many bug zappers are fitted with trays that collect the electrocuted insects; other models are designed to allow the debris to fall to the ground below. Some use a fan to help to trap the insect.
Light Traps	Insects are attracted to 365nm UV-A light. Light sources may include fluorescent lamps, mercury-vapour lamps, black lights, or light-emitting diodes. Designs differ according to the behaviour of the insects being studied. Light traps are widely used to survey nocturnal moths. Total species richness and abundance of trapped moths may be influenced by several factors such as night temperature, humidity and lamp type.
Carbon Dioxide Traps	Mosquitoes are attracted to carbon dioxide and some traps use this ot their advantage. Mosquito Magnet® Patriot Plus Mosquito Trap: This is one of the traps that emit carbon dioxide, heat & moisture to attract mosquitoes
Adhesive Traps	Sticky traps may be simple flat panels or enclosed structures, often baited, that ensnare insects with an adhesive substance. Baitless ones are nicknamed "blunder" traps, as pests might blunder into them while wandering or exploring. Sticky traps are widely used in agricultural and indoor pest monitoring. Shelter traps, or artificial cover traps, take advantage of an insect's tendencies to seek shelter in loose bark, crevices, or other sheltered places. Baited shelter traps such "Roach Motels" and similar enclosures often have adhesive material inside to trap insects.
Flying Insect Traps	These traps are designed to catch flying or wind-blown insects. Flight interception traps or are net-like or transparent structures that impede flying insects and funnel them into collecting. Barrier traps consist of a simple vertical sheet or wall that channels insects down into collection containers. The Malaise trap, a more complex type, is a mesh tent-like trap that captures insects that tend to fly up rather than down when impeded. Pan traps (also called water pan traps) are simple shallow dishes filled with a soapy water or a preservative and killing agent such as antifreeze. Pan traps are used to monitor aphids and some other small insects. Bucket traps and bottle traps, often supplemented with a funnel, are inexpensive versions that use a bait or attractant to lure insects into a bucket or bottle filled with soapy water or antifreeze. Many types of moth traps are bucket-type traps. Bottle traps are widely used, often used to sample wasp or pest beetle populations.
Terrestrial Arthropod Traps	Pitfall traps are used for ground-foraging and flightless arthropods such as Carabid beetles and spiders. Pitfall traps consist of a bucket or container buried in soil or other substrate so that its lip is flush with the substrate. A grain probe is a type of trap used to monitor pests of stored grain, consisting of a long cylindrical tube with multiple holes along its length that can be inserted at various depths within grain. Soil emergence traps, consisting of an inverted cone or funnel with collecting jar on top, are employed to capture insects with a subterranean pupal stage. Emergence traps have been used to monitor important disease-vectors such as Phlebotomine sandflies.
Aquatic Arthropod Traps	Aquatic interception traps typically involve mesh funnels that or conical structures that guide insects into a jar or bottle for collecting. Aquatic emergence traps are cage-like or tent-like structures used to capture aquatic insects such as chironomids, caddisflies, mosquitoes, and odonates upon their transition from aquatic nymphs to terrestrial adults. Aquatic emergence traps may be free floating on the water's surface, submerged, or attached to a post near shore.

5 Animal Defence

The section is focused on defending yourself against different kinds of animal attacks due to direct attack. They are sorted from most common to least common.

Subheadings

1. Dogs	**2. Wild Dogs**	**3. Cats**	**4. Birds**
5. Horses	**6. Cows / Bulls**	**7. Snakes**	**8. Rats & Mice**
9. Wild Boar & Hogs	**10. Crocodiles**	**11. Alligators**	**12. Deer**
13. Hippopotamuses	**14. Elephants**	**15. Lions**	**16. Sharks**
17. Bears	**18. Coyotes/Foxes**	**19. Jellyfish**	**20. Stingrays**
21. Leopards & Tigers	**22. Rhinoceroses**	**23. Komodo Dragons**

6 Displaced Defence

Tips on how to defend yourself or your group who have no shelter - from various threats such as nature and people.

From Nature

If you're in the open and facing a weather anomaly.

From Man Made Threats

If you're in the open and facing a man-made threat such as an enemy plane or a pandemic infected area.

From People

If you're in the open and in a conflict situation with other people.

7 Home Defence

How to defend your home from various threats such as nature, people and animals.

From Nature

If your shelter is about to face a barrage of natural elements.

- Ensure the building is structurally sound, if not it's recommended you find another building to shelter in.

From Man Made Threats

If your shelter is in a danger zone for a man made threat such as a war or virus. Below are tips you can do to help protect yourself if you can't leave or bug-out.

From Animals

If your temporary shelter such as a tent or log cabin is being attacked by animals or insects. Modern buildings aren't included here due to them being generally impenetrable to most animals.

Insects & Critters

If small creatures such as ticks, leeches, centipedes, ants and mosquitoes are finding their way into your tent or cabin the best way to prevent their entry is to seal up as many of the small holes as possible. Use fine mesh cloth or tent repair kits to fix holes in your tent as soon as you can. You could also utilize a DEET based spray to help discourage their entry.

Small Animals

Small animals include snakes, possums, moles and rabbits, all of which can scurry about your shelter looking for food. Possums in particular can tear holes in your tent or hammock with their large claws when trying to get to food. As always, food should be kept outside any makeshift or portable shelter while you sleep because the last thing you want is some animal making its way into your shelter.

Large Animals

Large animals include bears, rhinoceros, lions, crocodiles, wolves and bulls. These animals will cause a lot of damage to portable shelters such as tents and hammocks if the try to get to any food inside them. It's essential to use a bear bag if you're in bear country - or even for just good practise. A can of bear deterrent may also come in handy for bears among other animals. An air horn can also be of use to deter animals.

From People

If your shelter is about to be attacked by a gang or mob.

Caltrops	(Perimeter Defence)
Tripwires / Claymores	

8 Bullet Defence

The following section shows what kind of materials and thicknesses stop various types of bullets. This is AI generated, so do your own research to confirm the accuracy.

Material	Shotgun Slug (cm/in)	9mm Pistol (cm/in)	.30 Cal Rifle (cm/in)	AK-47 (7.62x39mm) (cm/in)	.50 Cal Sniper (cm/in)

Choosing Shelter

This section will assist you in choosing what objects to hide behind during a gun fight.

The primary way to prevent being shot is to not be seen, therefore objects that break the line of sight are your best bet.

9 Military Defence

Military defence is an existing defence structure that provides a form of tactical advantage and security on the battlefield.

Field Defences
Field defences form an integral part of any soldier's security measures when at the halt or in any defensive post or locality. These include the construction of shell scrapes or sangars and, for longer duration defence, weapon pits containing a fighting bay and sleeping bay, or other forms of hardened defensive structure. It also includes sandbagging, wiring, culverts, Hesco-Bastion bags (mesh baskets containing rubble etc.), and enhancing existing structures, either as part of these structures or for other protective measures. Overhead cover is any light thin covering that is placed over a trench or pit. It should not be confused with overhead protection (OHP), which is a much thicker and heavier covering designed to offer protection from blast. Overhead cover is principally used to provide thermal shielding against the heat and flash effects of nuclear weapons. It also provides a measure of concealment and protection against fallout and the weather. The material used should be opaque and fire-resistant and placed in such a way that soldiers' bodies or clothing do not touch it. The degree of protection provided can be improved by a sprinkling of earth or sand on the cover. Where time permits and the effective use of weapons will not be reduced, overhead cover should be converted to OHP as soon as possible to achieve blast protection as well.

In constructing overhead cover at least one of the following conditions must be met:
a. It must be possible to remove the cover quickly, either completely or sufficiently to enable weapons to be fired.
b. There must be adequate headroom and loopholes beneath the cover so that weapons may be fired without removing the overhead cover.
c. It must be possible to aim and fire through the cover while it is in position.

For gun pits and similar large excavations, the material must also be supported from underneath. Limited thermal shielding for personnel digging can be provided by propping the cover up or by stretching it between two vehicles. It should be noted that if camouflage nets are used to conceal a position, they will at the same time provide a limited measure of overhead cover. In field defences, the normal manner of providing OHP (Overhead Protection) is by placing material excavated from the trench on a roof. Protection will be improved if a layer of stone or broken brick is included in the earth covering. As a general rule the covering should be at least 0.5 m thick. When supported on a flat roof above ground level the earth covering should extend at least 0.5 m beyond the roof wherever possible. To minimise the effect of blast, earth coverings that project above ground level must be gently sloped in all directions and merged into any adjoining parapets. This will also assist in camouflage.

Weapon Pits

DEFENCE Military Defence Weapons Pits

Weapon pits are used to protect soldiers when it is possible to dig into the ground. When the ground is rocky, or in many urban situations, some form of above-ground structure will be required. Since the location of pits, particularly those for crew-served weapons, must fit in to an overall defensive plan, the digging of weapon pits starts only after the commander has visited each section and is satisfied with the pit locations and orientations. Once the location of the weapon pit is confirmed, each soldier begins to construct a shell scrape. This forms the basis for the continuing development of the position. The final structure of the weapon pit includes:

1. Fighting bay, made up of:
- **a.** elbow rests;
- **b.** weapon stakes;
- **c.** revetment/sandbags; and
- **d.** sump; and

2. Sleeping bays, including OHP.

Shell Scrapes
Shell scrapes are a quick means of providing some protection for troops until either moving off or developing the position further. Shell scrapes are dug to a limited depth, and provide only very limited protection from the effects of indirect and direct fire weapons. Shell scrapes are regarded as the first stage of a weapon pit and as such must be tactically sited and correctly aligned. However, when occupying a deliberate defence position, Stage 1 is the digging of a fighting bay, Stage 2 sleeping bays and Stage 3 is OHP on sleeping bays.

Fighting Bay
The fighting bay is developed if the unit is occupying a deliberate defensive position. The dimensions are 2 x 1 x 0.5m. If the unit has occupied a temporary position and has subsequently been told to develop the position, then the fighting bay is to be adjacent to shell scrapes as sited by the commander. The dimensions of the fighting bay must permit efficient operation of personal and crew-served weapons and allow observation of the battlespace while providing reasonable protection against direct and indirect fire. At the front edge of the pit, it is often necessary to provide an elbow rest for firers, which allows them to fire with the maximum amount of support and protection from frontal fire. Revetting or sandbagging is used to reinforce the structure. Weapon stakes are driven into the forward edge of the pit to limit the traverse or elevation of weapons to allow firers to engage targets as dictated by the commander even during periods of obscuration. Revetment is used to support the walls of the pit to prevent their collapse. Corrugated galvanised iron (CGI) can be used as revetment.

Sleeping Bays
Sleeping bays are developed by deepening the shell scrapes and connecting the excavation to the fighting bay. Their floor should be higher than the floor of the fighting bay and they should be covered with at least 0.5 m of OHP. OHP consists of a layer of bearers (logs or star pickets) which support a layer of CGI on which is placed a double layer of filled sandbags. The remaining spoil is then placed on top and the area camouflaged. Once completed, the top of the OHP must not obscure the line of sight from the fighting bay to the engagement area.

Weapons Pit Development

DEFENCE Military Defence Weapons Pit Development

The sequence of development for the most common form of weapon pit. This design may require modification to suit the type of weapon system it is protecting as well as the particular ground and terrain. The sequence followed in fully developing a defensive weapon pit is as follows:

1. Once the pit location is confirmed by the commander, dig two shell scrapes in the locations that will become the sleeping bays.
2. Construct a fighting bay 2 m long, 0.5 m wide and 1.25 m deep to the rear of the shell scrapes.
3. Dig the sleeping bays.
4. Revet the fire trench.
5. Add OHP to the sleeping bays.
6. Local camouflage is applied throughout the construction period and maintained for as long as the pit is occupied.
7. When developing a weapon pit, spoil can be placed in sandbags to develop a temporary sandbag wall constructed in front of the pit to provide immediate protection. Once the pit is completed the sandbag wall is removed and the spoil used for OHP or hidden in dead ground.

Construction Sequence
When constructing roofs at or below ground level the following construction sequence is recommended:
1. revet the trench or pit or slope the walls;
2. on either side of the trench at 0.5 m intervals, dig small trenches the size of the bearers to be used;
3. set the roof bearers into the small trenches;
4. put roofing material across the roof bearers with the corrugations of the CGI or length of other materials at right angles to the bearers;
5. lay two rows of filled sandbags across the whole roof;
6. back-fill earth onto the roof to a depth of 0.5 m; and
7. camouflage.

Construction Notes
- Timber roof bearers are usually the easiest to obtain and they can be quickly cut to the length required. Steel pickets may be used as roof bearers for trenches not more than 0.75 m wide but they must be laid not more than 0.25 m apart.
- When using round timbers that taper, set each bearer the opposite way to its neighbour.
- Roof bearers must be a least 0.5 m longer than the width of the trench or pit and should not be supported on sandbag walls except as a very temporary measure.
- The sheeting must be laid at right angles to the bearers.
- If possible cover the roof with a waterproof material before covering with earth.
- Make sure that the roof is level in both directions before putting earth on it. Stop up any small cracks with sandbags.
- When back-filling the earth on the roof, tread it well down to compact it. Slope it gently wherever possible and blend it into adjoining parapets.

Sangars

DEFENCE Military Defence Sangars

Sangars are improvised defensive walls constructed of locally-gained material such as rocks, rubble and logs. The materials must be hard enough to provide protection from small arms fire and shrapnel. Caution should be taken not to select materials that may become secondary projectiles. Any form of material that can be obtained may be used in the construction of field defences. This may include prefabricated concrete blocks or pipes which may be used for the basic structure of the sangar.

Sandbags

DEFENCE
Military Defence
Sandbags

Sandbags provide a simple and flexible building material for use in the field. The bag can be filled with any material (such as spoil from digging weapon pits or a mixture of sand and cement) but soft sand provides the best opportunity for moulding the shape of the sandbag. Sandbags can be used for revetment but are most often used in above-ground construction to increase the thickness of walls or as free-standing walls to provide blast protection. When using sandbags for field defences, the finished wall should be as shown in Figure 3–5. The following factors should be considered:

1. Sandbags, once laid, should be moulded into a standard shape about 500 x 250 x 125 mm.
2. Free-standing walls must be at least four sandbags wide at the base.
3. Sandbags are laid using headers and stretchers.
4. Tops should be finished with headers.
5. Joins should be staggered.
6. Sandbags should be laid so that the necks and seams are not showing out.
7. Star pickets and wire may be used within the sandbag wall for reinforcement.

Barbed Wire

Barbed wire obstacles are sited to channel and break up enemy assaults. They must be sited so that they are covered by observation and fire from the defensive position. Antipersonnel weapons (Claymores), other obstacles and trip flares can be sited in conjunction with the wire obstacles. Wire obstacles are constructed by wiring parties from the defending troops. Advice is given from the Assault Pioneers or Engineers. The pickets are driven in with the top of the 'Y' facing towards the enemy. The basic types of wire obstacles include:

1. Catwire Type 1 Fence. Double concertina barbed wire is used in an '8' configuration,
2. Catwire Type 2 Fence. Two rows of double concertina barbed wire are used in an '88' configuration.
3. Catwire Type 3 Fence. A single row of concertina wire is used between two rows of double concertina barbed wire in an '808' configuration.
4. Low Wire Entanglement (Bastard Wire). Single strands of barbed wire are woven between trees or pickets at ankle height.

Concertina wire may be used simply by bouncing it out to provide a quick deterrent, such as when setting up a snap vehicle checkpoint or food distribution point, to deny access and to channel. Windlassing is a method of securing wire used in wire obstacles and tightening revetting. It involves using a bar or strong stick to twist the wire.

10 Verbal Defence

Sometimes you have the ability to defuse a fight before it even starts by how you use your words.

Conflict De-escalation

11 Hazard Protection

Subheadings

		1. Respiratory Protection	2. Body Protection	3. Eye Protection	4. Hearing Protection

		9. Skin Protection	10. Height Protection	11. Elemental Protection			

1 Respiratory Protection

Types of Respiratory Protection

Respiratory Protection	**Description** Protection of the airway and access to sufficient oxygen.	**Deficiency Protection** Protects against a deficit of oxygen by supplying some to a face mask.	**Particulate Protection** Reduces the number of particles breathed in.	**Gas/Vapour Contaminants** Protects against gases in the air such as mustard gas.	
Deficiency Protection	**Oxygen Deficiency** An oxygen tank can allow breathing in situations where it wouldn't be normal.				
Particulate Protection	**Surgical Mask** Protect against large droplets, splashes and keeps your own sicknesses inside the mask.	**N-95 Respirator** Protects against dusts, fumes, mists, microorganisms.	**Half-Mask Respirator** Purifies air: protects against variety of particulates, vapours, dust, mists, fumes; depends on filter cartridge used.	**Full-Face Respirator** Same as half-mask, with greater protection factor; eye, mucus membranes and face protection; depends on filter cartridge used.	
Gas/Vapour Contaminants					

Gas Masks

You will only survive about three minutes without air in a chemical attack, so get your gas mask on quickly.

Gas Mask Tips
- Surplus gas masks usually aren't a good deal.
- Gas masks were not created equally. Get an NBC gas mask.
- You'll need spare filters.
- Your gas mask must be secured before the attack or exposure.
- Facial hair will not work with gas masks (and most do not fit children).
- Remove the plastic filter plug and know how to operate your gas mask.
- Your location matters, as attacks will likely happen over large cities.
- You can't live in a gas mask, though you may very well drink from one!

NBC Masks NBC masks cover Nuclear, Biological, and Chemical exposures. These are the top three threats that a soldier would face, which is why military personnel has access to them in targeted zones.	**Nuclear** Nuclear fission or fusion from accident or attack. Protection from particles of radioactive fallout.	**Chemical** Toxic chemicals such as mustard gas, Sarin gas, tear gas (riot control), blister gas, blood gas, or choking gas (nerve agent), etc.	**Biological** Viruses, bacteria, fungi or other micro organisms, such as anthrax (bacterial agent); Ebola; Avian flu and other pandemics; also volcanic ash. Unfortunately, there is no way to give advance notice of a biological attack.

Quality Masks
An NBC gas mask is usually an assurance of a quality gas mask; however, there are many variables. Most people think the highest calibre of gas mask you can buy is an NBC gas mask. Certainly an NBC gas mask protects against Nuclear, Biological and Chemical attacks, and the U.S. Military uses them as do preppers, but if you want to go one step higher, and it is available, get a CBRN gas mask if you can afford one. They are the most expensive and designed for first responders in a terror attack. A CBRN gas mask protects against Chemical, Biological, Radiological and Nuclear threats, though sometimes people confuse the "R" to mean riot protection for civil unrest. The difference between radiological and nuclear in a gas mask is that a radiological mask (CBRN gas mask) provides protection from radioactive material generated from the by-products and waste of industrial or medical therapies, or those occurring naturally in the environment. First responders use them for CBRN incidents. They are often associated with riot control because they have the highest level of protection. Riot control requires the ability to speak through the gas mask. They usually also have a wider field of view as well.

In short, the CBRN gas mask was designed for the military. A CBRN gas mask covers the following increased specifications over an NBC gas mask: ● Increased visor ballistics protection; ● Reduced weight and bulk (greater comfort); ● Improved field of view; ● Lowered breathing resistance; and ● Ability to change out cartridges on a contaminated field. Additionally, a CBRN gas mask may be fire resistant.	**NATO Rating** NATO gas mask filter specifications are those from the North Atlantic Treaty Organization (NATO), and they include a standard for a 40 mm thread. The standard thread ensures you can interchange the replacement cartridges.	**NIOSH Rating** Just because it's NIOSH approved, doesn't mean it's a gas mask! Although some are gas masks, NIOSH approved is simply a rating given by the National Institute for Occupational Safety and Health (NIOSH). Generally, these kinds of masks are "air purifying" and approved for work use. Manufacturers must apply for NIOSH respirator approval and there are categories. The highest category they approve is aCBRN gas mask. It's important to note that a NIOSH respirator will help protect you against airborne contaminants, such as solvents, pesticides, and paint, not necessarily gas. For example, a NIOSH-approved welding respirator is not a gas mask. Another important distinction is that NIOSH doesn't approve surgical masks or medical respirators.

Surplus Masks Owning a surplus gas mask is better than no gas mask at all. Having said this, surplus gas masks usually aren't a good deal for many reasons:	● Surplus usually means it has been sitting on the shelf too long for a reason: the expiration date may be nearing. Expiration dates are the main reason not to buy a surplus gas mask; unless you are on an extreme budget. Many preppers aren't aware that gas masks expire. ● Guarantees for surplus are next to nil. In all fairness, there's no regulation for testing of gas masks in the United States. No agency in the U.S. certifies their respirators for public use, but you have no recourse with an inferior gas mask made overseas. ● Sometimes you can't read the instructions. Sometimes you'll find an Israeli surplus gas mask intended for civilians, or one from China or Russia, but it has instructions in the respective foreign language. Unfortunately, people have died by using gas masks incorrectly. ● You could be breathing asbestos. A Russian GP filter circulating is laden with asbestos, so it may help you live through the Sarin gas exposure, but die of lung cancer years later. ● Surplus gas masks usually aren't a good deal, though you may be able to find some inexpensive Israeli gas masks, your best bet as a prepper is to get an NBC gas mask.

Pandemic NBC Mask
Absolutely an NBC gas mask can protect you in a pandemic crisis. The "B" in NBC stands for biological threats and this includes pandemics. Your family deserves the protection of an NBC mask for nuclear, biological, and chemical threats. NBC gas masks not only serve to protect you from toxic gases and fumes, but they have the benefit in a pandemic situation of sealing over the nose and mouth to create a superior barrier over traditional surgical masks, as well as providing ample coverage for shielding your face from tiny droplets. The only problem being that an NBC gas mask used for combating and preventing Ebola will need to be properly decontaminated and disposed after a one-time-use. It's not very economical, but it's lifesaving!

Respirator vs Gas Mask
A respirator is a general term for a protective device worn over the mouth and nose (or covering the entire face) to prevent inhalation of dust, smoke, or noxious substances. While the CDC refers to gas mask as respirators, and surprisingly doesn't recommend them*, could be as simple as a dust mask or surgical mask. A gas mask on the other hand is a more substantial protective shield and breathing apparatus with the specific purpose of covering a person's face as a defence against poisonous gas.

N95 / N100 Gas Masks
These are not gas masks. The classification of N95 or N100 is for respirators cleared by FDA for use by healthcare workers and are used for minimizing risk of disease transmission both from the patient and from the health professional. Think of them as surgical masks! They are disposable, one time use only and do not protect the entire face. An N-95 or N-100 is not a gas mask. It has been tested to remove 95% of the airborne particles you see N95 on the packaging. It has been tested to remove 100% of threats if you see N100 on the packaging. You'll find N95 and N100 respirators excellent for protection against bird flu, swine flu and the like; however, for a pandemic, like Ebola, you'll want a full-face respirator.

Other Notes The most important thing to know about gas masks is that they can fail from improper use. Problems may also arise from the circumstance of use. If you use a gas mask correctly you can reduce the exposure you might otherwise receive. Consider the problems so you can remedy them:	**Additions** ● Chemical suit (with booties and gloves); ● Canteen and hydration straw; ● Kevlar tactical helmet ● Gas mask pouch (for spare filters in the field) ● Spare filters (check as they expire)		

Wearing Gas Mask

Realistically, you can only wear a gas mask for a few hours for many reasons:

Overheating	A gas mask will become very hot.

Headaches	Severe headaches from pressure were a common complaint during the Gulf war.
Exhaustion	There's a lot of work needed to draw air through a carbon filter in a gas mask.
Eating / Drinking	While there is gear available to drink through your gas mask (be sure you have a hydration plug), eventually you'll need to eat (and you can't do that through a gas mask)!

Gas Mask Problems

Claustrophobia	Kids will become restless and will have the most difficulty in wearing gas masks for extended periods; however, anyone who suffers from claustrophobia is at risk for taking a gas mask off too early.
Training	Improper use of a gas mask could result in injury or death! If you strap a gas mask on too tightly, it can snap your jaw: too loosely and you'll die of the nuclear, biological or chemical exposure. During the gulf war people died simply for not unscrewing the cap from the filter. They suffocated.
Fake Masks	The respirator, right, is a Survivair Opti-Fit Full Face APR Respirator (NIOSH) and provides audio transmission, has anti-fog, a wide viewing area, but it's unclear as to what it's true purpose is. If it doesn't say it's an NBC gas mask, don't buy it.
Fogging	Fogging is a problem, and some gas mask have anti-fog capabilities. It's a particular problem with kids who are you're prone to cry particularly during times of stress! This was true of the gulf war, when kids were crying fogged up their gas masks impeding visibility and effectiveness. Some gas masks have a nose cup to prevent fogging.
Proper Fitting	It's important to ensure you have a good fit with your gas mask. This is especially true if you have children. Typically they are too big. It's also a problem in men who have beards. A man's whiskers can make it difficult to get a secure fit. The respirator, right, works better than a half face respirator for moustaches and goatees NIOSH approved (P100 class); however, it's not an NBC gas mask.
Improper Use	During the Gulf War parents accidentally suffocated their children by forcing them to wear gas mask in which they forgot to properly remove the plastic filter on the carbon filter!
Gas Affects Skin	A gas mask won't protect you against the skin blistering power of mustard gas (though it provides a level of protection from inhalation of mustard gas)! You'll need other protective gear for your skin, including chemical suit, boots, and gloves in addition to your gas mask.
Delayed Use	Chemical detection kits are available to warn you of chemical agents, but such detection kits are difficult to source (without one, you may not know when to put on a gas mask and it may be too late).
Mask Expiry	Gas masks have an expiration date! Many preppers don't realize that gas masks have a shelf life, but they do! Gas masks are not only limited by the, but they are also limited in the absorbent capacity of the filter itself. Sealing caps help protect the filter from air intake prior to use.

Respirator

A respirator is part of an emergency preparedness plan. For nuclear, biological or chemical substances, you should also have a shelter-in-place plan. The goal of a shelter-in-place is to help filter the large amounts of debris which may infiltrate the air and which may be contaminated.

Respirator	**Correct Respirator** Be careful not to buy a costume gas mask. Look for an NBC gas mask that protects against Nuclear, Biological and Chemical attack.	**Fits Properly** Pay close attention to children, people with small faces or facial hair. A respirator will help reduce exposure to certain airborne contaminants; however, misuse may result in sickness or death.	**Know How to Use** Respirators require proper training.	**Availability** By the time you realize you need your gas mask, it might be too late, such is the case with nerve agents, which are the most toxic and fast-acting.	**Already Contaminated** Even the most sophisticated gas mask might be for one use only and should be disposed. Contagion or chemical exposure could render a gas mask useless on the second go around. How many respirators can you stock for Ebola?
Respirator Types	**Respirator** Generic term to mean surgical mask, escape hood or gas mask	**Dust Mask** (N-95, N100) sawing, bagging or processing minerals, coal, iron ore, flour, metal, wood, pollen, and certain other substances.	**Surgical Mask** Surgical masks are disposable coverings for mouth and nose to protect against infection during surgical procedures.	**Anti Viral Face Mask** An antiviral face mask inactivates some harmful pathogens, including imminent strains of influenza, such as H1N1, avian flu and swine flu. (It contains citric acid, zinc and copper to inactivate flu viruses.)	**Escape Hoods** Smoke escape mask has a filter designed to remove dangerous smoke particles from the air. The price of these kinds of respirators varies greatly! Immediate right is a powered escape mask that provides 30-minute protection for fire, smoke chemical spills, sarin or mustard gas, nuclear contamination or other terrorist threats, so it's an NBC gas mask. The other escape hood is good only for escaping fire
Respirator Types	**NIOSH Gas Mask (N95 and N100)** NIOSH-approved respirators are for use in environments containing certain oil and non-oil based particles. It's an air-purifying respirator that filters particles from the air the user is breathing.	**NBC Gas Mask** This full-face respirator protects against Nuclear, Biological and Chemical substances.			

HEPA & MERV Air Filters

This is a table showing what the different type of HEPA and MERV filters trap.

MERV Rating	Traps Particles Sized 0.3 to 1.0 Microns	Traps Particles Sized 1.0 to 3.0 Microns	Traps Particles Sized 3.0 to 10 Microns	Filter Type and Particles Removed
MERV 1	<20%	<20%	<20%	**Fiberglass and Aluminium Mesh** Pollen, Dust Mites, Spray Paint, Carpet Fibres, Pet Dander
MERV 2	<20%	<20%	<20%	
MERV 3	<20%	<20%	<20%	

MERV 4	<20%	<20%	<20%	Dander
MERV 5	<20%	<20%	20%-34%	**Disposable Filters** Mold Spores, Kitchen Aerosols, Hair Spray, Furniture Polish, Cleaning Sprays
MERV 6	<20%	<20%	35%-49%	
MERV 7	<20%	<20%	50%-69%	
MERV 8	<20%	<20%	70%-85%	
MERV 9	<20%	>50%	85% or better	**Home Box Filters** Lead Dust, Flour, Auto Fumes, Welding Fumes
MERV 10	<20%	50%-64%	85% or better	
MERV 11	<20%	65%-79%	85% or better	
MERV 12	<20%	80%-90%	90% or better	**Commercial Filters** Bacteria, Wildfire Smoke, Respiratory Droplets
MERV 13	>75%	90% or better	90% or better	
MERV 14	75% - 84%	90% or better	90% or better	
MERV 15	85% - 94%	95% or better	90% or better	
MERV 16	95% or better	95% or better	90% or better	
MERV 17	99.97%	99% or better	99% or better	**HEPA & ULPA** Filters Viruses, Carbon Dust
MERV 18	99.997%	99% or better	99% or better	
MERV 19	99.9997%	99% or better	99% or better	
MERV 20	99.99997%	99% or better	99% or better	

2 Body Protection

Protection of the body as an entirety such as body armour, hazmat suits etc.

Traditional Protection	General use; chemical, biological, radiation and physical hazards.
Flame Resistant	Working with water or air reactive chemicals, large volumes of organic solvents, and potentially explosive chemicals.
Barrier	Working with infectious materials.

3 Eye Protection

Protection of the eyes from various elements via any covering medium.

General Safety Glasses	Protects the eyes from dust and small flying particles.
Laser Safety Glasses	Protects the eyes from the lasers power.
Chemical Splash Goggles	Protects against chemicals or infectious substances.
Impact Goggles	Offers protection from flying debris and has ventilation holes in the sides.
Face Shields	Protects from chemical splashes and can be worn with chemical splash goggles.

4 Hearing Protection

Protects the ears from loud noises and sustained noise to prevent ear damage and hearing loss.

Disposable Ear Buds	In-ear buds that reduce the decibel level to protect the ears from damage. Disposed after use.
Reusable Ear Buds	In-ear buds that reduce the decibel level to protect the ears from damage.
Hearing Band	An in-ear band that can be worn around the neck which reduces the decibel level to protect the ears from damage.
Ear Muffs	Over-ear muffs that reduce the decibel level to protect the ears from damage.
Hearing Aid	Not hearing is as dangerous as hearing too loudly but it's often overlooked.

5 Head Protection

Any form of protection of the head excluding respiratory protection such as gas masks.

Hats	A simple piece of clothing to keep sun off the head.				
Helmets	**Bicycle Helmet** Protection from objects falling on the head.	**Construction Helmet** A helmet suspended above the head slightly to cushion the impact of falling beams and other debris.	**Combat Helmet** A metal helmet designed to deflect or stop bullets.		

6 Hand Protection

Protects the hands from injury and often provides specific resistance to various elements.

Disposable Latex For working with biological hazards like blood and bodily fluids.	**Disposable Nitrile** Working with biological hazards and chemical splash hazards.	**Disposable Vinyl** Working with biological hazards.	**Natural Rubber Latex** Working with small volumes of corrosive liquids, organic solvents, flammable compounds	**Nitrile** Using apparatus under pressure, air or water reactive chemicals.	**Butyl** Working with large volumes of organic solvents; small to large volumes of dangerous solvents, acutely toxic or hazardous materials.
Silver Shield Same as butyl and Viton II gloves, added mechanical protection, hazardous material spills.	**Terrycloth Autoclave** Working with hot liquids and equipment, open flames, water bath, oil bath.	**Cryogen** Handling cryogenic liquids.	**Wire Mesh** Working with live animals and exposed to potential cuts.	**Viton II** Same as butyl gloves, plus hazardous material spills.	

7 Foot Protection

Protects the feet from dirt, sticks, rocks, insects and animals.

Boots

Keeps the feet protected from falling objects. They are often steel capped for extra protection.

8 Other Limb Protection

Knee/Elbow Pads Protects the knees from scrapes and falls.	**Gaiters** Protects the legs from thorns and sharp flora additionally offering protection from small animals.	**Riot Shield** For protection from thrown projectiles, debris and bullets.		

9 Skin Protection

Solar Radiation Protection from the UV component of sunlight.	**Insect Repellent** Protection from biting or stinging insects.			

Solar Radiation

- Attempt to schedule work in full sun to take place outside the hours of 10am to 3pm.
- Use shade wherever possible.
- Wear dark, loose and closely woven clothing (long sleeved, button up, collared shirt).
- Wear a 10 cm wide brimmed hat or hat with a neck flap.
- Wear Gloves.
- Put on broad spectrum water resistant SPF30+ sunscreen at least 10-15 minutes before going out in the sun. Re-apply every two hours.
- Drink plenty of water.
- Check your skin regularly for changes.

Insect Repellent

10 Height Protection

Height protection includes protection from falls from any height.

11 Elemental Protection

Air Protection

Includes protection from air pathogens, gases, lack of oxygen, high speed wind etc.

Water Protection

Protection from water and liquids such as chemicals and high pressure water.

Fire Protection

Protection from fire and flames.

Earth Protection

Protection from earth, dirt, earth bacteria etc.

Heat Protection

Protection from heat from sunlight, mechanical equipment, fires etc.

Cold Protection

Protection from cold temperatures, liquid nitrogen etc.

12 Safety

Camping Safety

Sleeping Never sleep in contact with the ground - you will absorb the cold.	**Fire Extinguisher/Blanket** Offers a defence against different types of fires.	**Medical Kit** A medical kit to treat minor injuries sustained. May include some more advanced components.			

Bear Bag

Traditionally a bear bag was simply something to hold your food out of reach of bears. This usually meant finding a way to suspend it from a high branch, and in this instance it's usually sufficient for the bag to be waterproof. There are two options. One is to get a bear canister to keep all of your food in and, in some localities where bears are common, this might even be required by law. The other option is to hang a bear bag. Since I don't have room in my pack for a large bear canister, I always choose the bear bag method. Bears aren't the only wild animals which will be attracted by the smell and come to eat all of your food. There are also animals like raccoons, foxes and rabbits to consider. For this reason, it's best to hang a bear bag even if there isn't a real risk of bears. The bear bag should be hung at least 60m (200ft) downwind from your campsite and the same distance from your kitchen area.

Bear Canister

Bear-resistant food storage containers, also called bear canisters or bear cans, are usually hard-sided containers used by backpackers to protect their food from theft by bears. Bear canisters are seeing increased popularity in areas where bears have become habituated to human presence, and are required in some regions such as Yosemite National Park in the United States. A bear canister typically weighs between 2-4 lb (1-2 kg), and has a storage capacity of 400 - 900 in3 (6 - 15 litres). Hard-sided bear cans employ such materials as polycarbonate, ABS plastic, carbon fibre, and aluminium in their construction. An effective canister must resist both the tremendous strength and high intelligence of an attacking animal. Most containers are too large for a bear to simply pick up and carry away.

The lid of a canister is usually recessed in order to prevent it being pried off, and tool use, or at least an advanced degree of motor skills, is required to remove it. Some bear canisters contain gaskets that block the scent from escaping the container. At least one model of soft-sided "bear bag" is made from Spectra (UHMWPE) fabric.

While a soft-sided container may prevent a bear from eating its contents, the food inside is likely to be reduced to purée in the attempt. A newer model comes with an aluminium stiffener that protects the contents more effectively than the bag alone. An alternative is bear bagging, wherein items attractive to a bear such as food or other perishables are placed in a bag and then raised into the air using a rope — out of reach of a bear. The rationale is that bears, being unable to reach the food, are less drawn to campsites and pose less of a threat to campers and their equipment.

Type of Bag

Your bag needs to be sturdy enough to hold all of your food, and ideally you should be able to seal it fairly well so bugs and birds don't get to the food inside. The best bear bag is a waterproof drawstring bag with a strap on the bottom. You actually hang the bag by the strap so it is upside down. This way no water can drip into it if it rains. If you don't have one of these bags, don't fret. So long as the bag is sturdy and waterproof, you are fine. A heavy-duty shopping bag will work in a pinch. I have a waterproof cover for my backpack, and I use this as my bear bag too.

Hanging

Equipment ● Bear Bag ● 12m (40ft) Rope ● Throw/Rope Bag ● Mini Carabineer ● Small Twig	**Positioning** When properly hung the bag should be about 2m (~6ft) away from the trunk, 2m below the branch, and about 4m (12ft) above the ground.

1. Fill the bear bag with all food items, trash and scented items including chewing gum and flavoured lip gloss.
2. Add rocks to the throw bag and attach carabineer (with rope attached) to the bag's draw string to secure. Find a branch about 6 meters (20 feet) above the ground and toss the throw bag over.
3. Unclip throw bag from the carabineer and clip the carabineer onto the bear bag. Feed the loose ends of the rope through the carabineer and pull loose end to raise the bear bag to the top of the tree branch.
4. Use a carabineer to attach the line to your food bag, then clip the other side of the line into the carabineer. Hoist the bag until it touches the branch.
5. Reach as high as you can and tie a clove hitch around the twig on the loose end of the rope, creating a toggle.
6. Release the loose end of the rope. The bear bag will stop at the toggle.

Food Safety

Cooking Safety

Fire Safety

Heating Safety

Carbon Monoxide
Never use fuel-burning equipment such as gas stoves, heaters, lanterns, and charcoal grills inside a tent, camper, or other enclosed shelter.

Electrical Safety

Navigation Safety

Survival Safety

Baby Safety

Safety relating to babies and children.

Home Safety Checklist

This is a home safety checklist to go through if you have a baby who is about to start crawling. Every home is different. Some items in the following checklist may not apply in your home, or there might be some risks that only apply to your house.

General

☐ Is an emergency evacuation plan (including an agreed meeting spot) in place and is practised regularly?	☐ Has a list of emergency contact numbers been created and placed near each phone?

Throughout the Home

☐Are the floor coverings sound and free of trip hazards?	☐ Are safety barriers installed at the top and bottom of stairs to prevent falls?	☐ Are the railings designed to prevent children climbing?	☐ Has an electrical safety switch been installed and is it operational?
☐ Have safety covers been fitted in unused power outlets?	☐ Have the smoke alarms have been tested within the last month, are operational, and batteries changed once per year?	☐ Are button/lithium batteries and products containing button/lithium batteries out of reach of children, stored securely and always disposed of safely?	☐ Are heaters, open fires and candles screened with a secured guard or inaccessible? Children should be supervised at all times when these are in use.
☐ Are electrical appliances in good working order?	☐ Are all electrical appliances switched off and unplugged when not in use and cords stored out of reach?	☐ Are blind and curtains cords out of children's reach to avoid strangulation?	☐ Are matches, cigarettes and lighters stored out of reach of children?
☐ Are smoke alarms installed as per regulations on each floor and near the kitchen?	☐ Are power boards used instead of adaptors?	☐ Are the power boards overloaded?	☐

Kitchen and Dining

☐ Are knives and other sharp objects stored in a lockable cupboard or out of reach of children?	☐ Is the highchair stable and fitted with a five point safety harness? A five point safety harness should be fastened whenever highchair is in use.	☐ Are cleaning and hazardous products such as medications, chemicals, plastic bags, matches and lighters, batteries, etc. stored in a lockable cupboard or are inaccessible to children?	☐ Do you use rear burners on the stove whenever possible and ensure pot handles are always turned away from the front of the stove?
☐ Is the stove bolted to the wall to prevent tipping forward?	☐ Is the dishwasher kept closed at all times?	☐ Is the microwave positioned out of reach of children?	☐ Are curtains kept away from stove or other appliances?
☐ Is access to the kitchen when cooking restricted by use of a secure safety barrier?	☐ Are safety catches installed on drawers and cupboards containing dangerous items?	☐ Are kettles, toasters and appliance cords kept out of reach of children?	☐ Are non-slip placemats are used instead of table cloths?
☐ Are hot drinks and alcohol placed out of reach of children?	☐ Is a fire blanket/fire extinguisher located in the kitchen?	☐ Is alcohol stored in a child resistant cupboard?	☐

Laundry

☐ Are hazardous substances such as cleaning products stored in a lockable cupboard or inaccessible to children?	☐ Are poisonous substances stored in their original container?	☐ Is the soaking bucket inaccessible to children and have a firm fitting lid?	☐ Is the iron out of reach of children?

☐ Is the lint filter in dryer cleaned regularly?	☐	☐	☐
Living Room			
☐ Is furniture arranged to allow access and to avoid trip hazards and collisions?	☐ Is the furniture positioned away from windows?	☐ Are large items of furniture, such as televisions, bookcases and entertainment units, secured to prevent them falling on children?	☐ Are protective covers placed on sharp corners/ edges of furniture?
☐ Are heaters located at least one (1) metre away from any curtains or other flammable materials?	☐ Is safety glass or safety film installed to low level glass doors and windows?	☐ Are stickers or frosting applied to glass sliding doors to prevent collisions?	☐ Is a separate play space provided for children?
☐ Are toys checked regularly for damage or loose parts?	☐	☐	☐
Bathroom			
☐ Is a hot water temperature device installed so tap water is no hotter than 50°C?	☐ Is the bath water temperature always tested before putting the child in? Starting with cold, then hot, then finishing with cold water?	☐ Are hazardous products such as shampoos, razors and medications stored in a lockable cupboard or inaccessible to children?	☐ Are electrical appliances removed from the bathroom?
☐ Is a non-slip bath mat or floor surface provided?	☐ Are non-slip stickers or a non-slip suction mat used in the base of the bath or shower?	☐ Are children supervised at all times in the bathroom?	☐ Is the room heater out of reach of children (avoid radiating heaters)?
☐ Are bath taps inaccessible to children?	☐	☐	☐
Bedroom			
☐ Is the cot free of soft toys, pillows, bumpers etc.?	☐ Is furniture arranged to avoid trip hazards and collisions?	☐ Does the cot comply with your countries standards for cot rails?	☐ Is the cot mattress firm and does it fit snuggly? 50mm apart?
☐ Is furniture (including cots and beds) positioned away from windows, blind cords, electrical outlets and ceiling fans?	☐ Is the child's bed of safe design? The top section of a bunk bed is NOT recommended for a child of under twelve (12) years of age).	☐ Does the bunk bed comply with your countries standard and not in a room with a ceiling fan?	☐ Are toys stored where children can reach them without climbing?
☐ Are toys in good condition and suitable for the child's age?	☐ Is the change table stable?	☐ Is the change table mat secure?	☐ Are items needed for changing baby located at an arm's reach of the change table?
☐ Is a five point safety harness used when changing baby on the change table?	☐ Is 'low fire danger' nightwear worn?	☐ Are electric blankets checked prior to fitting them to an older child's bed?	☐
Garage and Shed			
☐ Is the garage and shed lockable?	☐ Are poisonous and hazardous substances, such as paint, pesticides and flammable liquids, stored in a lockable cupboard or are inaccessible to children?	☐ Are power tools and hardware etc. inaccessible to children?	☐ Do children have restricted access to the garage and shed?
Outdoors			
☐ Are the wading pools and other water containers emptied immediately after use?	☐ Are play areas fenced securely, checked and maintained regularly and not located near a driveway?	☐ Are fence and gates in good condition and in working order?	☐ Is sunscreen and hat worn when outside?
☐ Is play equipment checked regularly and in good condition?	☐ Are trampoline, swings and climbing items positioned on a soft surface, eg. well maintained grass or mulch?	☐ Is garden free from poisonous or hazardous plants?	☐ Are wrist, knee and elbow guards worn when riding a scooter, inline skates or skateboard etc.?
☐ Are children supervised in the backyard at all times?	☐ Are children restricted from accessing the driveway?	☐ Are helmets worn when riding a tricycle, bike, scooter, inline skates or skateboard etc.?	☐ Are branches and twigs removed from children's eye level?
☐ Are children supervised around pets, especially dogs?	☐ Does pram or stroller comply with your countries standards?	☐ Is five point safety harness on the pram or stroller secured when in use?	☐ Are garden statues and birdbaths cemented in to prevent a crushing hazard?
☐ Is the pool or spa isolated on all 4 sides with a fence and a self-closing gate?	☐	☐	☐

Weapons

Information, tips and handling of modern weapons

"Due to the rising cost of ammunition I'm no longer able to provide a warning shot. Thanks for your understanding."
Unknown

Introduction

This section is based around modern handheld weapons such as pistols, rifles, shotguns, energy weapons, etc and how to handle them.

Purpose	The aim of WEAPONS is to provide detailed information on the most common types of modern guns and ammunition. It focuses on proper handling techniques, safety practises, weapon attachments and weapon maintenance.
Lost?	• For tips on avoiding using your guns, see the SECURITY section. • For a recommendation on guns and ammo counts for your kits, see the GEAR section. • For information on shooting animals humanely, see the FIELD DRESSING section. • If you want information on gunshot wounds, see the INJURY > Foreign Bodies section. • For using weapons defensively, and how far bullets can penetrate different materials, look at the DEFENCE section. • For smithing your own guns and ammo, see the CRAFTING > Blacksmithing section. • For large-scale, or vehicle mounted weapons, see the WARFARE section. • For wars and other gun violence, see the MAN-MADE DISASTERS section.

Contents

1 Gun Safety

Gun safety rules and practice recommendations are intended to avoid accidental discharge or negligent discharge, or the consequences of firearm malfunctions. Their purpose is to eliminate or minimize the risks of unintentional death, injury or property damage caused by improper possession, storage or handling of firearms. There were 47,000 unintentional firearm deaths worldwide in 2013.

WEAPONS Gun Safety Rules and Mindset

Rules and Mindset

Gun safety training seeks to instill a certain mindset and appropriate habits by following specific rules. The mindset is that firearms are inherently dangerous and must always be stored carefully and handled with care. Handlers are taught to treat firearms with respect for their destructive capabilities, and strongly discouraged from playing or toying with firearms, a common cause of accidents. The rules of gun safety follow from this mindset.

Various version of the "Ten Commandments of Gun Safety" have been published. This one is from the Sporting Shooters Association of Australia:

1. Treat every gun with the respect due a loaded gun.
2. Carry only empty guns, taken down or with the action open, into your car, camp and home.
3. Always be sure that the barrel and action are clear of obstructions.
4. Always carry your gun so that you can control the direction of the muzzle.
5. Be sure of your target before you pull the trigger.
6. Never point a gun at anything you do not want to shoot.
7. Never leave your gun unattended unless you unload it first.
8. Never climb a tree or a fence with a loaded gun.
9. Never shoot at a flat, hard surface or the surface of water.
10. Do not mix gunpowder and alcohol.

The National Rifle Association provides a similar set of rules:
1. ALWAYS keep the gun pointed in a safe direction.
2. ALWAYS keep your finger off the trigger until ready to shoot.
3. ALWAYS keep the gun unloaded until ready to use.

The United States Marine Corps uses the following four weapons safety rules:
1. Treat every weapon as if it were loaded
2. Never point the weapon at anything you do not intend to shoot
3. Keep your finger straight and off the trigger until you're ready to fire
4. Keep the weapon on safe until you intend to fire

Blank ammunition, which is a primed casing filled with gunpowder, either crimped or covered with a wad, is dangerous up to 15 feet. In the past, people have injured or killed themselves believing that blanks were not dangerous. Therefore, gun safety rules apply even to guns loaded with blanks.

Treat Firearms As Loaded

This rule is a matter of keeping a vigilant mindset. The purpose is to create safe handling habits, and to discourage presumptive reasoning along the lines of, "I know my gun is unloaded so certain unsafe practices are OK". The proposition "the gun is always loaded" means that, even though it may be known that this is not true of a particular firearm, that knowledge is never trusted or relied upon until definitively proven. Thus even if the firearm turned out to be loaded when the handler thought it was not, treating it as loaded would avoid an "unintentional discharge", and if one should occur anyway, avoiding damage, injury or death.

Many firearm accidents result from the handler mistakenly believing a firearm is emptied, safetied, or otherwise disarmed when in fact it is ready to be discharged. Such misunderstandings can arise from a number of sources.

● Faulty handling of the firearm. A handler may execute the steps of procedures such as loading, firing and emptying in the wrong order or omit steps of the procedures.
● Misunderstandings about a firearm's status. For instance, a handler may think the safety is on when it is not. A round of ammunition may be left in the chamber or in the magazine while the handler thinks it is emptied. The firearm may have been handled by another individual without the handler's knowledge. A handler may receive a firearm and assume it is in a certain state without checking whether that assumption is true. For example, as handlers interact and pass the firearm between them, each avoids over-relying on the "show clear" of the other. Person 1 may misjudge the status; person 2 cannot assume that "it's OK because person 1 already checked it".
● Mechanical failures. Wear, faulty assembly, damage or faulty design of the firearm can cause it not to function as intended. For instance, a safety may have been worn down to a point where it is no longer functioning. Broken or worn parts in the trigger, sear or hammer/striker may have given the firearm a "hair trigger" (a very sensitive trigger). A dented or bent body of the firearm may cause jams or premature discharge of ammunition. Sensitivity to impact may cause a firearm to discharge if dropped or struck against another object. A broken extractor may result in a round remaining in the chamber even when the otherwise proper steps have been taken to unload the weapon.

If a handler always treats firearms as capable of being discharged at any time, the handler is more likely to take precautions to prevent an unintentional discharge and to avoid damage or injury if one does occur.

Point the Muzzle Away

Also known as muzzle discipline, this rule is intended to minimize the potential damage caused by an unintended discharge. While the first rule teaches that a firearm must be assumed to be ready to fire, this second rule goes beyond that and says, "Since the firearm might fire, assume that it will and make sure no harm occurs when it does." A consequence of this rule is that any kind of playing or "toying" with firearms is prohibited. Playfully pointing firearms at people or other non-targets violates this rule and is possibly an extreme endangerment to life and/or property. To discourage this kind of behavior, the rule is sometimes alternately stated, "Never point a firearm at anything unless you intend to destroy it."

Two natural "safe" directions to point the muzzle are up (at the sky) and down (at the ground). Both have their advantages and disadvantages. Firing at the ground may result in a ricochet or cause hazardous fragments to be flung at people or objects. Aiming upward eliminates this risk but replaces it with the risk that the bullet may cause damage when it comes down to the ground again. A bullet fired straight up only returns at the terminal velocity of the bullet. However, a bullet fired at an angle not perfectly vertical will retain its spin and ballistic stability on the way down and can attain much more lethal speeds.

Several accidents have reportedly been caused by discharging firearms into the air; although the evidence in a few such cases has been disputed, a study by the Centers for Disease Control and Prevention found 43 likely cases of injury from falling bullets during 2004 New Year celebrations in Puerto Rico. It is also possible that the muzzle will inadvertently be pointed at a non-target such as someone's head or an aircraft.

In cases where the firearm is being handled indoors, up and down may not be safe directions. For example, a bullet fired upward or downward may travel through the ceiling, floor and plenum between adjacent floors of a multi-story building. In indoor areas where firearms will be handled often, a suitably safe direction should be designated. Firing ranges often designate a direction in which it is safe to point a firearm; almost universally this is downrange into a backstop which is designed to contain bullets and eliminate potential ricochets. In armories or other areas where weapons must be handled, a container filled with sand known as a "clearing barrel" or "clearing can" is often used for this purpose; bullets unintentionally discharged into the barrel will be safely stopped and contained by the sand.

Keep Fingers off the Trigger

Also known as trigger discipline, this rule is intended to prevent an undesired discharge. Normally a firearm is discharged by depressing its trigger. A handler's finger may involuntarily move for any of several reasons: the handler is startled, a lack of full attention on body movements, physiological reasons beyond conscious control such as a spasm, stumbling or falling, or the finger being pushed by something (as when trying to holster a handgun with one's finger on the trigger). Handlers are therefore taught to minimize the harmful effects of such a motion by keeping their finger off and far away from the trigger until the muzzle is pointing at the target and the handler wishes to discharge the firearm.

The trigger guard and the receiver area above the trigger of a firearm presents a natural point for a handler to keep their finger out straight alongside the weapon, so as not to violate this rule. Another recommendation is to keep the trigger finger above the trigger guard, so that there is less chance of the finger involuntarily slipping into the guard when startled. A properly indexed trigger finger also helps remind the person holding the firearm of the direction of the muzzle.

In popular culture, such as movies and TV shows, this rule is often violated, even by characters such as military personnel or law enforcement officers who should be trained in gun safety and thus would logically know better.

Be sure of the Target, and Beyond

This rule is intended to eliminate or minimize collateral damage to non-targets when a firearm is intentionally discharged. Unintended damage may occur if a non-target is misidentified as a target, if the target is missed, or if the bullet hits something or someone other than the intended target.

Handlers are taught that they must positively identify and verify their target. Additionally, they learn that even when firing at a valid target, unintended targets may still be hit, for three reasons:

- The bullet may miss the intended target and hit a non-target around or beyond the target.
- A non-target may pass in front of the target and be hit with a bullet aimed at the target.
- The bullet may pass through the intended target and hit a non-target beyond it, so-called "overpenetration".

Therefore, this rule requires a handler to "always be sure of your target; not just the target itself, but above, below, to the left, to the right, in front of, and behind the target".

This may create situations that present dilemmas for a handler. Such situations are for instance a police officer in a riot with bystanders, a civilian facing a possible intruder at night, or a soldier in a confrontation where civilians are near the enemy. Indecision or misjudgment of the handler's abilities in such a situation may cause undesired outcomes, such as injury to the handler due to hesitation, or the handler violating rules of engagement and causing unintended damage. Hunters are commonly prohibited from shooting across roads and trails, or after dusk and before dawn, due to the risk of inadvertently hitting an unintended target. All discharge of firearms is prohibited in some cities, in part due to the possibility of hitting unseen targets.

Training is used to minimize the risk of such outcomes. Target practice increases the precision with which the handler can discharge the firearm and thus increase the chances that the intended target is hit. Education about terminal ballistics gives the handler knowledge about the characteristics of a bullet after a target is hit. This knowledge coupled with insight into the handler's own capabilities makes it easier for the handler to make appropriate decisions about whether to discharge or not, even if given little time and/or put under severe stress. Ammunition can be chosen to reduce the risk of overpenetration.

Range Safety Rules

Ranges and organized shoots may impose additional safety rules on participants. For example, at its marksmanship clinics, Project Appleseed requires that a range safety officer (RSO) uses a weed trimmer line to check each rifle's bore for obstructions prior to its first use for the day. Six steps are then always followed when a round of shooting is complete and the line is ready to go "cold" to allow posting or checking targets, or when a rifle is ready to be removed from the line:

1) Magazine out;
2) Bolt back;
3) Safety on;
4) Chamber flag in;
5) Ground the rifle;
6) Step back; no one touching the rifle.

Open bolt indicators, or chamber flags, such as the yellow safety flag distributed by the Civilian Marksmanship Program or the green chamber flag distributed by Project Appleseed, may be required to be inserted in the chamber to show the chamber is empty.

Ranges may limit the type of ammunition used, such as prohibiting the use of incendiary, tracer, or armor-piercing rounds, or more powerful rounds than a range is equipped to handle. They may require the use of ear and eye protection. Alcohol is commonly forbidden. Some ranges impose a waiting period for shooters who wish to rent a firearm, or require them to bring a friend, in order to reduce the incidence of suicides. Ranges are advised to designate a range safety officer to enforce these rules.

Ranges must be designed with safety in mind, including the use of proper backstops for the intended type of shooting.

Malfunctions

Firearm malfunctions may be caused by the primer and/or powder, by mechanical failures, or by mishandling.

Failure to Fire Malfunctions

Malfunctions associated with the firing pin of a firearm, or with the primer and/or powder within a cartridge include failures to discharge (misfires, "duds"), delayed discharge (hang fires), and incomplete or insufficient discharge (squibs). A misfire is when the cartridge does not fire after it is struck by the firing pin. A hangfire is when the firing pin strikes the cartridge, but there is a delay of some seconds before the cartridge finally fires. A squib is when an underpowered round is fired, perhaps with an insufficient amount of powder in the case, and the bullet lodges in the bore. If the firearm is fired again, the barrel can peel back, severely damaging the weapon and injuring the shooter.

In each case, the shooter should wait for a period of time, commonly recommended between 25 seconds, up to two minutes, with the firearm pointed in a safe direction, then carefully remove the magazine, extract any mis-fed or misfired cartridge(s), and, with the breech opened carefully, check to ensure there is not a bullet or other obstruction lodged in the bore of the barrel. If there is an obstruction, and a subsequent round is fired, the firearm can fail explosively resulting in serious injury. Misfired rounds should be disposed of properly, usually in a special container for live ammo that failed to fire after ejecting round; such rounds should not be simply disposed of in the trash.

Mechanical Malfunctions

Mechanical malfunctions of firearms include slamfires, out-of-battery discharges, jams, accidental release of the firing pin, and failure of the breech or barrel to contain the propellant.

A slam fire is when a cartridge fires immediately upon being chambered, before a trigger squeeze, and is most often caused by a floating firing pin that becomes obstructed by debris, or by an improperly raised primer that is installed on a cartridge case. A slamfire can also be caused by a softer primer being used than normally recommended, commonly in military firearms, which usually use cartridges with relatively hard primers.

Out-of-battery discharges occur when a cartridge is not correctly secured by the bolt but can be fired by the firearm's firing pin. Out-of-battery discharges can be initiated by either the operator deliberately releasing the firing pin or as a slamfire. Out-of-battery discharges often cause extreme damage to the firearm, particularly on the bolt, firing pin, magazine, and receiver as well as injure the operator and nearby observers. Eye damage and blinding are common injuries caused by out-of-battery firings. Eye protection, such as shooting glasses, are highly recommended for avoiding eye injuries. Out-of-battery discharges can be avoided by careful understanding of the firearm's operating mechanism.

Types of jams include failures to feed, extract, or eject a cartridge; failure to fully cycle after firing; and failure of a recoil- or gas-operated firearm to lock back when empty (largely a procedural hazard, as a "slide lock" is a visual cue that the firearm's ammunition supply is empty). When a jam occurs, the handler should exercise extreme caution as a cartridge whose primer has been struck and which has been deformed in a jam can discharge unexpectedly (in a "hang-fire"). One method of quickly clearing a jammed semi-automatic weapon is tap rack bang.

Firearms may also fire unintentionally for several reasons, including dropping the weapon or when a firearm receives any hard mechanical shocks. Similarly, unintentional firing may occur due to faulty triggers, or excessive heat buildup in the chamber which leads to the propellant cooking off. To prevent accidental firing when firearms are dropped or jarred, experts often suggest using modern firearm designs that have safety features such as a transfer bar or a firing pin block which prevent the firing pin from striking the primer unless the trigger is squeezed. For older firearms without these features, experts suggest that they should be carried without a round in the chamber, or with the firing pin resting on an empty chamber in the case of revolvers.

Firearms may undergo catastrophic failure (a "kaBoom" or "kB") due to various causes, some caused by mishandling and others by poor design, weakened parts or the use of ammunition for which the firearm was not designed, but which will chamber and fire nonetheless. Barrels may become blocked by foreign material, such as dirt, snow, or even water. For that reason, the muzzle should never be allowed to rest on the ground or allowed to accumulate precipitation. Another form of mishandling is the use of a cartridge that generates more pressure than the firearm was designed for. This can occur through faulty handloading, or the use of overpressure ammunition (+P or +P+) or magnum loads in firearms not rated for them.

Storage

Proper storage prevents unauthorized use or theft of firearms and ammunition, or damage to them.

Gun Safes

A 'gun safe' or 'gun cabinet' is commonly used to physically prevent access to a firearm. Local laws may require particular standards for the lock, for the strength and burglar resistance of the cabinet, and may even require guns and ammunition to be stored separately.

Disassembly

Access to a functioning firearm can be prevented by keeping the firearm disassembled and the parts stored at separate locations. Sometimes, this rule is codified in law. For example, Swedish law requires owners of firearms either to store the entire firearm in a safe or lockable gun rack, or to lock the "vital piece" (bolt, etc.) away in a safe place.

Locks

There are several types of locks that serve to make it difficult to discharge a firearm. Locks are considered less effective than keeping firearms stored in a lockable safe since locks are more easily defeated than approved safes. An unauthorized handler can bypass the locked firearm at their leisure. Some manufacturers, such as Taurus, build locks into the firearm itself.

California effected regulations in 2000 that forced gun locks to be approved by a firearm safety device laboratory via California Penal Code Section 12088. All gun locks under this code must receive extensive tests including saw, pick, pull, and many other tests in order to be approved for the state of California. If a lock passes the requirements then it is said to be California Department of Justice (CADOJ) approved.

Trigger Locks

Trigger locks prevent trigger manipulation, however they do not guarantee that the firearm absolutely cannot be discharged. Some trigger locks are integrated into the design of the weapon, requiring no external parts besides the key. Generally, two pieces come together from either side behind the trigger and are locked in place, which can be unlocked with a key or combination. This physically prevents the trigger from being depressed to discharge the weapon. Other more commercially common types of trigger locks do not go behind the trigger, but encompass the full area within the trigger guard to making the trigger inaccessible to users. Identilock is a gun attachment that completely covers and prevents access to the trigger, which makes it different from other trigger locks.

There is controversy surrounding manufacturing standards, usage, and legislation of trigger locks. While supporters of trigger locks argue that they will save children from dying in gun accidents, critics point to demonstrations that some models can be removed by children with very little force and common household tools.

Many firearms can go off if the gun is dropped. It is important to make sure to look for firearms that fully disengage the hammer when the safety is put on. A former senior product manager at Master Lock, a trigger lock manufacturer, was quoted as saying "If you put a trigger lock on any loaded gun, you are making the gun more dangerous." Critics also point out that a trigger lock will increase the time it takes a gun owner to respond to a self-defense emergency. In 2008, the U.S. Supreme Court overturned a Washington, D.C. law that required handguns to be locked or otherwise kept inoperative within the home, saying that this "makes it impossible for citizens to use them for the core lawful purpose of self-defense." Although there are no universal standards for the design or testing of trigger locks, some jurisdictions, such as the state of California, maintain a list of approved trigger lock devices. In Canada, a trigger lock is one of the methods prescribed by law to secure a firearm during transport or storage.

Chamber Locks

Chamber locks aim to block ammunition from being chambered, since most firearms typically cannot be discharged unless the ammunition is in the correct position. They are used to prevent live ammunition from being loaded into a firearm by blocking the chamber with a dummy cartridge or a chamber plug, which is sometimes wedged into place with the use of a tool, in essence jamming the gun. Another type is one in which a steel rod locked into the safety cartridge with a key. As long as the rod and safety cartridge are engaged, the dummy round cannot eject nor can live ammunition be loaded into the firearm. Chamber locks work with most firearm types including revolvers, pistols, rifles and shotguns. They are available in any caliber and length, and may include such features as unique keying, rapid removal, and rigorous testing and certification by major state departments such as the California Department of Justice. Some shooting ranges require the handler to insert a temporary chamber plug which often has a brightly colored external tag, to signal the chamber being devoid of ammunition and blocked, whenever the gun is being unused. These are called empty chamber indicators, or simply chamber flags.

Cable Locks

Cable locks are a popular type of lock that usually threads into the receiver through the ejection port of repeating firearms. These locks physically obstruct the movements of the bolt, thereby preventing the cycling of the action, and deny the return to "battery" and the closure of the breech. In many designs of pistol and rifle, they also thread through the magazine well of the gun to prevent the proper insertion of a magazine.

Smart Guns

Personalized guns, or smart guns, are intended to prevent unauthorized use with built-in locks that are released by RFID chips or other proximity devices, fingerprint recognition, magnetic rings, or a microchip implant.

Secondary Dangers

While a firearm's primary danger lies in the discharge of ammunition, there are other ways a firearm may be detrimental to the health of the handler and bystanders.

Noise

When a firearm is discharged it emits a very loud noise, typically close to the handler's ears. This can cause temporary or permanent hearing damage such as tinnitus. Hearing protection such as earplugs, or earmuffs, or both, can reduce the risk of hearing damage. Some earmuffs or headphones made for shooting and similar loud situations use active noise control. Firearms may also have silencers which reduce the sound intensity from the barrel.

Hot Gases and Debris

A firearm emits hot gases, powder, and other debris when discharged. Some weapons, such as semi-automatic and fully automatic firearms, typically eject spent cartridge casings at high speed. Casings are also dangerously hot when ejected. Revolvers store spent casings in the chamber, but may emit a stream of hot gases and possible fine particulate debris laterally from the interface between the revolving chamber and the gun barrel. Any of these may hurt the handler or bystanders through burning or impact damage. Because eyes are particularly vulnerable to this type of damage, eye protection should be worn to reduce the risk of injury. Prescription lenses and various tints to suit different light conditions are available. Some eye protection products are rated to withstand impact from birdshot loads, which offers protection against irresponsible firearms use by other game bird shooters.

Toxins and Pollutants

In recent years the toxic effects of ammunition and firearm cleaning agents have been highlighted.

- Lead ammunition left in nature may become mobilized by acid rain.
- Older ammunition may have mercury-based primers.
- Lead accumulates in shooting range backstops.

Indoor ranges require good ventilation to remove pollutants such as powder, smoke, and lead dust from the air around the shooters. Indoor and outdoor ranges typically require extensive decontamination when they are decommissioned to remove all traces of lead, copper, and powder residues from the area.

Lead, copper and other metals will also be released when a firearm is cleaned. Highly aggressive solvents and other agents used to remove lead and powder fouling may also present a hazard to health. Installing good ventilation, washing hands after handling firearms, and cleaning the space where the firearm was handled lessens the risk of unnecessary exposure.

Unsafe Users

Impaired Users

Firearms should never be handled by persons who are under the influence of alcohol or any drugs which may affect their judgment. Gun safety teachers advocate zero tolerance of their use. In the United States, this recommendation is codified in many states' penal codes as a crime of "carrying under the influence", with penalties similar to DWI/DUI. Other sources of temporary impairment include exhaustion, dehydration, and emotional stress. These can affect reaction time, cognitive processing, sensory perception, and judgment.

Many jurisdictions prohibit the possession of firearms by people deemed generally incapable of using them safely, such as the mentally ill or convicted felons.

Children

Children who are generally considered too young to be allowed to handle firearms at all can be taught a different set of rules:

- Stop.
- Don't touch.
- Leave the area.
- Tell an adult.

The purpose of these rules is to prevent children from inadvertently handling firearms. These rules are part of the Eddie Eagle program developed by the National Rifle Association for preschoolers through 6th graders.

Whether programs like Eddie Eagle are effective has not been conclusively determined. Some studies published in peer-reviewed journals have shown that it is very difficult for young children to control their curiosity even when they have been taught not to touch firearms. Gun access is also a major risk factor for youth suicide. The American Academy of Pediatrics (AAP) advises that keeping a gun in the home, especially a handgun increases the risk of injury and death for children and youth in the home. If families do keep a gun in the home, the AAP advises keeping it unloaded and locked up, with the ammunition locked in a separate location, and the keys to the locked boxes hidden.

Polling shows that over half of parents who do not own a gun have never talked with their children age 5–17 about gun safety. The ASK Campaign (Asking Saves Kids) is based on the fact that many families with children have a gun, and almost half these guns are left unlocked or loaded. The ASK Campaign urges parents to ask their friends, neighbors and family members if they have an unlocked gun in the home before sending their children over to play.

2 Handguns

A handgun is a firearm designed to be usable with only one hand. It is distinguished from a long barreled gun (i.e., carbine, rifle, shotgun, submachine gun, or machine gun) which typically is intended to be held by both hands and braced against the shoulder. Handguns have shorter effective ranges compared to long guns, and are much harder to shoot accurately. While most early handguns are single-shot pistols, the two most common types of handguns used in modern times are revolvers and semi-automatic pistols.

Handgun Types

Handgun	The smallest of all firearms is the handgun. There are two common types of handguns: revolvers and semi-automatic pistols.
Single Shot	Single-shot firearms are firearms that hold only a single round of ammunition, and must be reloaded after each shot.
Revolver	Revolvers have a number of firing chambers or "charge holes" in a revolving cylinder; each chamber in the cylinder is loaded with a single cartridge or charge.
Semi Automatic	Semi-automatic pistols have a single fixed firing chamber machined into the rear of the barrel, and a magazine so they can be used to fire more than one round. Each press of the trigger fires a cartridge, using the energy of the cartridge to activate the mechanism so that the next cartridge may be fired immediately.
Bolt Action	Bolt action is a type of repeater firearm action where the handling of cartridges into and out of the weapon's barrel chamber are operated by manually manipulating the bolt handle, which is most commonly placed on the right-hand side of the weapon (as most users are right-handed).
Fully Automatic	Gun specialists point out that the word automatic is sometimes misunderstood to mean fully automatic fire when used to refer to a self-loading, semi-automatic firearm not capable of fully automatic fire. In this case, automatic refers to the loading mechanism, not the firing capability.
Pocket Pistol	A pocket pistol is any small, pocket-sized semi-automatic pistol, (or less commonly derringer, or small revolver), suitable for concealed carry in either a front or rear pocket of a pair of trousers, or in an exterior coat pocket.
Machine Pistol	A machine pistol is typically a handgun-style machine gun, capable of fully automatic or burst fire, and chambered for pistol cartridges.

Notable Handguns

Smith & Wesson M&P Series	The Smith & Wesson M&P (Military and Police) is a polymer-framed, short recoil operated, locked breech semi-automatic pistol introduced in the summer of 2005 by the American company Smith & Wesson. It uses a Browning-type locking system. While targeted at law enforcement agencies, the M&P is also widely available on the commercial market.
Smith & Wesson Shield	Smith & Wesson's latest addition to the M&P SHIELD lineup is intended to reduce the barriers to shooting a semiautomatic handgun. The M&P 9 SHIELD EZ is touted as easy to use from all perspectives.
Glock G29	The Glock 29 is a 10mm Auto equivalent of the subcompact Glock 26 introduced in 1997 along with the Glock 30 (.45 ACP). The pistol features a 96 mm (3.8 in) barrel and a standard magazine capacity of 10 rounds. Like other subcompact Glock pistols, the Glock 29 functions with the factory magazines from its related full-size model, giving an optional capacity of 15 rounds.
CZ-USA 85 Combat	The CZ 85 Combat is a large frame semi-automatic pistol chambered in 9mm. The 85 Combat is produced by CZ-USA, a Kansas City based subsidiary of the Czech arms manufacturer Česká Zbrojovka Uherský Brod. The 85 Combat is similar to the 85 B, but offers several additional features. The 85 Combat differs from other models in its inclusion of a fully adjustable rear sight, an extended magazine release, an ambidextrous slide stop, and a drop free magazine. Drop free magazines fall free of the gun when the magazine release is pressed, disengaging from the firearm completely.
Dan Wesson Specialist	A full-size 1911, the Specialist is chambered in .45 or 9mm and loaded with features to satisfy a public servant?s special requirements. The forged stainless steel slide wears our popular Clark-style serrated rib with a single amber tritium dot in the rear sight and a green lamp with white target ring in front.
Ruger MK III	The Ruger Mark III is a .22 Long Rifle semi-automatic pistol manufactured by Sturm, Ruger & Company. It replaced the MK II in 2004. The Mark III was succeeded by the MK IV, with production of the Mark III ending on December 8, 2016.
Magnum Research Micro Desert Eagle	Magnum Research made their name with the iconic Desert Eagle, a large, heavy, powerful semi-automatic that shoots cartridges primarily used in revolvers like .357 Magnum, .44 Magnum and .50 AE. And the name is now so iconic and so well known, I guess the company figured, why not slap it on to other products? Like the Micro Desert Eagle in .380 ACP. Even though this gun is very small, fairly light, has a tiny barrel and shoots a marginal cartridge.
Glock G19	The Glock 19 is effectively a reduced-size Glock 17, called the "Compact" by the manufacturer. It was first produced in 1988, primarily for military and law enforcement. The Glock 19's barrel and pistol grip are shorter by about 12 mm (0.5 in) than the Glock 17, and it uses a magazine with a standard capacity of 15 rounds. The pistol is compatible with factory magazines from the Glock 17 and Glock 18, giving the Glock 19 available capacities of: 17 rounds (standard magazine with +2 extension), 10, 17, and 19 (standard Glock 17 magazine with +2), 24 and 26 (standard magazine with +2 extension) and the 31 (standard Glock 18 magazine with +2 removed) and 33 rounds of the Glock 18. To preserve the operational reliability of the short recoil system, the mass of the slide remains the same as in the Glock 17 from which it is derived. With the exception of the slide, frame, barrel, locking block, recoil spring, guide rod, and slide lock spring, all of the other components are interchangeable between the models 17 and 19.
Colt Defender	The Colt Defender™ offers power and performance every time. Now available in 9mm and the classic .45 ACP, this package is an excellent choice for concealed carry. With Novak sights and a Colt Upswept Beavertail Grip Safety, this pistol will provide an exceptional hold and quick target acquisition. The Colt Defender is an accurate and reliable workhorse able to withstand the rigors of everyday carry and numerous trips to the range.
Browning Buckmark	Browning's flagship handgun, the Buck Mark, is the prototype for what a bargain pistol should be. However, just because the price is low, doesn't mean the quality is too. Each of these Rimfire pistols is crafted with some of the finest materials as well as with the latest gunsmithing technology. Many of the Buck Marks are quite heavy, but that's fine considering that it's not intended to be a CCW. Most of the weight is thanks to the aircraft-grade aluminum alloy components. But some models are heavier than others; for instance one of the models has a hefty 5.5" slab bull stainless steel barrel. The most impressive feature of the Buck Marks has to be the variety and quality of their grips. There are several options out there and they are all exceptional –you just have to find the one that fits best to your hands.

Handgun Anatomy

Loading Handguns

Hunting with handguns has grown in popularity in recent years. Many of the fundamentals of rifle firing also apply to shooting handguns.
● Single-action revolvers typically load through a gate on the right side of the frame. To rotate the cylinder, pull the hammer back to half-cock. For a safer carry in the holster or hand, leave an empty chamber in front of the hammer.
● Double-action revolvers have cylinders that fall downward, exposing all chambers for loading.
● Semi-automatics usually fire rounds stored in a magazine that is inserted in the grip or handle.

Firing Handguns

Body position and grip are vital to hitting the target. The hand position on the grip of a pistol is especially critical. Although the grip configuration of the revolver and semi-automatic are different, the gripping procedure is the same.
● Hold the handgun high on the grip so that the recoil is directed back to the hand and arm in a straight line. This allows better repeat shots and more accurate shooting.
● Use a two-handed hold whenever possible, applying pressure from front to rear.

Handgun Modifications

3 Rifles

A rifle is a long-barrelled firearm designed for accurate shooting, with a barrel that has a helical pattern of grooves ("rifling") cut into the bore wall. In keeping with their focus on accuracy, rifles are typically designed to be held with both hands and braced firmly against the shooter's shoulder via a buttstock for stability during shooting. Rifles are used extensively in warfare, law enforcement, hunting and shooting sports.

Rifle Types

A rifle is so named for the spiral fluting (rifling) machined into the inner surface of its barrel, which imparts a self-stabilizing spin to the single bullets it fires.

Lever-action Rifle	Lever action is a type of firearm action which uses a lever located around the trigger guard area (often including the trigger guard itself) to load fresh cartridges into the chamber of the barrel when the lever is worked. This contrasts to bolt-action, pump-action, semi-automatic, or selective-fire weapons. Most lever-action firearms are rifles, but some lever-action shotguns and a few pistols have also been made. The Winchester Model 1873 rifle is one of the most famous lever-action firearms, but many manufacturers—notably Henry and Marlin—also produce lever-action rifles. Even Colt's Mfg. Co. produced the 6403 lever-action Colt-Burgess rifles from 1883 until 1885. Mossberg produces the 464 in centerfire .30-30 and rimfire .22. While the term lever action generally implies a repeating firearm, it is also sometimes—and incorrectly—applied to a variety of single shot or falling block actions that use a lever for cycling, such as the Martini–Henry or the Ruger No. 1.
Bolt-action Rifle	Bolt action is a type of firearm action where the handling of cartridges into and out of the weapon's barrel chamber is operated by manually manipulating the bolt directly via a bolt handle, which is most commonly placed on the right-hand side of the weapon (as most users are right-handed). When the handle is operated, the bolt is unlocked from the receiver and pulled rearward to open the breech allowing the spent cartridge case to be extracted and ejected, the firing pin within the bolt is cocked (either on opening or closing of the bolt depending on the gun design) and engages the sear, then upon the bolt being pushed back, a new cartridge (if available) is loaded into the chamber, and finally the breech is closed tight by the bolt re-locking against the receiver.
Pump-action Rifle	A pump-action or slide-action firearm is one in which a forend can be moved forward and backward in order to eject a spent round of ammunition and to chamber a fresh one. It is much faster than a bolt-action and somewhat faster than a lever-action, as it does not require the trigger hand to be removed from the trigger while reloading. Once fired, the forend is slid rearward by hand and the expended cartridge ejected. It is then reloaded by manually moving the forend to the front.
Assault Rifle	An assault rifle is a selective-fire rifle that uses an intermediate cartridge and a detachable magazine. Assault rifles were first put into mass production and accepted into widespread service during World War II. Though Western nations were slow to accept the assault rifle concept, by the end of the 20th century they had become the standard weapon in most of the world's armies, replacing full-powered rifles and sub-machine guns in most roles. Examples include the StG 44, AK-47 and the M16 rifle.
Battle Rifle	A battle rifle is a military service rifle that is capable of semi or fully automatic fire, and fires a full-powered rifle cartridge. The term "battle rifle" was created largely out of a need to better differentiate the intermediate-power assault rifles (e.g. StG-44, AK-47, M16, AUG) from full-powered automatic rifles (e.g. FG-42, FN FAL, M14, H&K G3) as both classes of firearms have a similar appearance and share many of the same features such as detachable magazines, pistol grips, etc.
Carbine	A carbine is a long gun firearm but instead with a shorter barrel rather than a standard rifle or musket. Most carbines are shortened versions of full-length rifles, shooting the same type of ammunition, while others fire generally lower-powered ammunition, including types designed for pistols. The smaller size and lighter weight of carbines make them easier to handle. They are typically issued to high-mobility troops such as special-operations soldiers and paratroopers, as well as to mounted, artillery, logistics, or other non-infantry personnel whose roles do not require full-sized rifles, although there is a growing tendency for carbines to be issued to front-line soldiers to offset the increasing weight of other issued equipment. An example of this is the US Army's M4 carbine, which is standard issue.
Service Rifle	A service rifle or service weapon (also known as a standard-issue rifle) is a weapon which an armed force issues as standard to its service members. In modern forces, this is typically a versatile and rugged battle rifle, assault rifle, or carbine suitable for use in nearly all environments. Most armies also have service pistols or side arms.
Sniper Rifle	A sniper rifle is a high-precision, long range rifle. Requirements include accuracy, reliability, mobility, concealment and optics for anti-personnel, anti-materiel and surveillance uses of the military sniper. The modern sniper rifle is a portable shoulder-fired weapon system with a choice between bolt-action or semi-automatic action, fitted with a telescopic sight for extreme accuracy and chambered for a high-ballistic performance centerfire cartridge.

4 Shotguns

A shotgun (also known as a scattergun, peppergun, or historically as a fowling piece) is a long-barreled firearm designed to shoot a straight-walled cartridge known as a shotshell, which discharges numerous small spherical projectiles called shot, or a single solid projectile called a slug. Shotguns are most commonly used as smoothbore firearms, meaning that their gun barrels have no rifling on the inner wall, but rifled barrels for shooting sabot slugs (slug barrels) are also available.

WEAPONS Shotguns Shotgun Types

Shotgun Types

Shotguns are predominantly smoothbore firearms designed to fire a number of shot; pellet sizes commonly ranging between 2 mm #9 birdshot and 8.4 mm #00 (double-aught) buckshot.

WEAPONS Shotguns Firing Shotguns Aiming

Firing Shotguns

Shouldering the Shotgun

- When you bring the shotgun to your shoulder, the stock should be brought to your cheek first and then back to your shoulder.
- A common error is lowering the head and cheek to the stock, instead of bringing the stock all the way up to the cheek. When done properly, with your head naturally erect, the gun butt always should come to the same spot on your shoulder.

Aiming the Shotgun

- Because targets usually appear suddenly and move quickly, there's no time to "aim" a shotgun. It's designed to be pointed, with the eye sighting along the top of the barrel or rib.
- The sight is usually a bead on the front of the gun. Your eye must be in line with the barrel, so it's important to position your head properly on the stock.
- When you bring the gun to your face, the stock should fit snugly against your cheek with your eye on that side above the centerline of the gun. If you can't assume that position comfortably, you may need to adjust the "gun fit."

Firing

- Unlike rifle firing, quick trigger action is important when hunting with a shotgun. To fire, quickly slap the trigger with a firm motion, keeping a firm grip on the shotgun while pulling the stock rearward.
- Because the trigger is pulled quickly and the body and gun are typically in motion, breath control isn't necessary.
- Continue the shotgun's swing as you pull the trigger. Stopping the swing as you shoot will cause you to hit behind a moving target.

Unlike rifle firing, quick reflexes and flexibility are essential for effective shotgun shooting. Proper shotgun techniques will help you develop the rapid, fluid response you need to hit your target. A shotgun is almost always shot at a moving target from a standing position. You must be able to swing freely over a wide arc and maintain control. That requires a relaxed, balanced stance.

- Stand with your feet spread about shoulder-width apart and your knees bent slightly so that you are balanced perfectly. Bring your left foot slightly forward (if you're a right-handed shooter), and lean your body in the same direction. The position of the feet is important. The toes of your forward foot should point at about 45 degrees toward the target. Take the time to place your feet properly, even for a quick shot.
- Keeping your knees slightly bent makes it easier to swing with a moving target. The bent leg to the rear supports the movements of your hips, allowing you to swing smoothly.

Shotgun Modifications

5 Carbines

A carbine is a long gun that has a barrel shortened from its original length. Most modern carbines are rifles that are compact versions of a longer rifle or are rifles chambered for less powerful cartridges.

Carbine Types

A carbine is a firearm similar to a rifle in form and intended usage, but generally shorter or smaller than the typical "full-size" hunting or battle rifle of similar time period, and sometimes using a smaller or less-powerful cartridge.

Notable Carbines

Carbine Modifications

6 Machine Guns

A machine gun (MG) is a fully automatic and rifled firearm designed for sustained direct fire with rifle cartridges. Other automatic firearms such as automatic shotguns and automatic rifles (including assault rifles and battle rifles) are typically designed more for firing short bursts rather than continuous fire and are not considered true machine guns.

7 Submachine Guns

A submachine gun (SMG) is a magazine-fed automatic carbine designed to fire handgun cartridges. The term "submachine gun" was coined by John T. Thompson, the inventor of the Thompson submachine gun, to describe its design concept as an automatic firearm with notably less firepower than a machine gun (hence the prefix "sub-"). As a machine gun must fire rifle cartridges to be classified as such, submachine guns are not considered machine guns.

8 Automatic Rifles

An automatic rifle is a type of autoloading rifle that is capable of fully automatic fire. Automatic rifles are generally select-fire weapons capable of firing in semi-automatic and automatic firing modes (some automatic rifles are capable of burst-fire as well). Automatic rifles are distinguished from semi-automatic rifles in their ability to fire more than one shot in succession once the trigger is pulled. Most automatic rifles are further subcategorized as battle rifles or assault rifles.

WEAPONS Energy

10 Energy Weapons

A directed-energy weapon (DEW) is a ranged weapon that damages its target with highly focused energy, including laser, microwaves and particle beams. Potential applications of this technology include weapons that target personnel, missiles, vehicles, and optical devices.

WEAPONS Energy Weapons Rifle Types

Energy Weapon Types

Electrolaser	An electrolaser is a type of electroshock weapon that is also a directed-energy weapon. It uses lasers to form an electrically conductive laser-induced plasma channel (LIPC). A fraction of a second later, a powerful electric current is sent down this plasma channel and delivered to the target, thus functioning overall as a large-scale, high energy, long-distance version of the Taser electroshock gun.
Pulsed Energy Projectile	It involves the emission of an invisible laser pulse which, upon contact with the target, ablates the surface and creates a small amount of exploding plasma. This produces a pressure wave that stuns the target and knocks him off his feet, and electromagnetic radiation that affects nerve cells causing a painful sensation. The technology can also be used as a lethal weapon, and indeed an early name was pulsed impulsive kill laser.

WEAPONS Energy Weapons Active Denial System

Active Denial System

Active Denial System (Millimetre Wave Crowd Control Gun)
The Active Denial System (ADS) is a non-lethal, directed-energy weapon developed by the U.S. military, designed for area denial, perimeter security and crowd control. Informally, the weapon is also called the heat ray since it works by heating the surface of targets, such as the skin of targeted human subjects. Raytheon is currently marketing a reduced-range version of this technology. The ADS was deployed in 2010 with the United States military in the Afghanistan War, but was withdrawn without seeing combat. As of 2014, the ADS was only a vehicle-mounted weapon, though U.S. Marines and police were both working on portable versions. ADS was developed under the sponsorship of the DoD Non-Lethal Weapons Program with the Air Force Research Laboratory as the lead agency. There are reports that Russia and China are developing their own versions of the Active Denial System. The device can be used for targets up to 250 metres (820 ft) away.

Effects
The ADS works by firing a high-powered beam of 95 GHz waves at a target, which corresponds to a wavelength of 3.2 mm. The ADS millimetre wave energy works on a similar principle as a microwave oven, exciting the water and fat molecules in the skin, and instantly heating them via dielectric heating. One significant difference is that a microwave oven uses the much lower frequency (and longer wavelength) of 2.45 GHz. The short millimetre waves used in ADS only penetrate the top layers of skin, with most of the energy being absorbed within 0.4 mm (1⁄64 inch), whereas microwaves will penetrate into human tissue about 17 mm (0.67 inch).

The ADS's effect of repelling humans occurs at slightly higher than 44°C (111°F), though first-degree burns occur at about 51°C (124°F), and second-degree burns occur at about 58°C (136°F). In testing, pea-sized blisters have been observed in less than 0.1% of ADS exposures, indicating that second degree surface burns have been caused by the device. The radiation burns caused are similar to microwave burns, but only on the skin surface due to the decreased penetration of shorter millimetre waves. The surface temperature of a target will continue to rise so long as the beam is applied, at a rate dictated by the target's material and distance from the transmitter, along with the beam's frequency and power level set by the operator.
Most human test subjects reached their pain threshold within 3 seconds, and none could endure more than 5 seconds. Like all focused energy, the beam will irradiate all matter in the targeted area, including everything beyond/behind it that is not shielded, with no possible discrimination between individuals, objects or materials. Anyone incapable of leaving the target area (e.g., physically handicapped, infants, incapacitated, trapped, etc.) would continue to receive radiation until the operator turned off the beam. Reflective materials such as aluminium cooking foil should reflect this radiation and could be used to make clothing that would be protective against this radiation.

Like all focused energy, the beam will irradiate all matter in the targeted area, including everything beyond/behind it that is not shielded, with no possible discrimination between individuals, objects or materials. Anyone incapable of leaving the target area (e.g., physically handicapped, infants, incapacitated, trapped, etc.) would continue to receive radiation until the operator turned off the beam. Reflective materials such as aluminium cooking foil should reflect this radiation and could be used to make clothing that would be protective against this radiation.
Following approximately ten thousand test exposures of volunteers to ADS beams, a Penn State Human Effects Advisory Panel (HEAP) concluded that ADS is a non-lethal weapon that has a high probability of effectiveness with a low probability of injury:
- No significant effects for wearers of contact lenses or other eyewear (including night vision goggles)
- Normal skin applications, such as cosmetics, have little effect on ADS's interaction with skin
- No age-related differences in response to ADS exposures
- No effect on the male reproduction system
- Damage was the occurrence of pea-sized blisters in less than 0.1% of the exposures (6 of 10,000 exposures).

Long Term Effects
Many possible long-term effects have been studied, with the conclusion that no long-term effects are likely at the exposure levels studied. However, overexposures of either operators or targets may cause thermal injury. According to an official military assessment, "In the event of an overexposure to a power density sufficient to produce thermal injury, there is an extremely low probability that scars derived from such injury might later become cancerous. Proper wound management further decreases this probability, as well as the probability of hypertrophic scarring or keloid formation. ADS operators would be exposed to more than the standard maximum permissible exposure (MPE) limits for RF energy, and military use requires an exception to these exposure limits.

Possible Long-Term Effects
● Cancer: A mouse cancer study was performed at two energy levels and exposures with a 94 GHz transmitter: a single 10 second, 1 W/cm2 exposure; and repeated 10 second exposures over 2 week period at 333 mW/cm2. At both energy levels, no increase in skin cancers were observed. No studies of higher energy levels, or longer exposure times have been performed on millimetre-wave systems.
● Cornea damage: Tests on non-human primate eyes have observed no short-term or long-term damage as the blink reflex protects the eye from damage within 0.25 seconds.
● Birth defects: Millimetre waves only penetrate 0.4 mm (1⁄64 inch) into the skin, making direct damage to the testes or ovaries impossible.
● Blisters and scarring: Pea-sized blistering due to second degree burns occurred in a very small minority (less than 0.1%) of tested exposures, which have a remote potential for scarring.

5G Network Risk
Today's cellular and Wi-Fi networks rely on microwaves – a type of electromagnetic radiation utilizing frequencies up to 6 gigahertz (GHz) in order to wirelessly transmit voice and data. This era of wireless frequency is almost over making room for new 5G applications will require using new spectrum bands in much higher frequency ranges above 6 GHz to 100 GHz and beyond, utilizing sub-millimeter and millimetre waves. Millimetre waves are utilized by the U.S. Army in crowd dispersal guns called Active Denial Systems. Dr. Paul Ben-Ishai pointed to research that was commissioned by the U.S. Army to find out why people ran away when the beam touched them.

"If you are unlucky enough to be standing there when it hits you, you will feel like your body is on fire." The U.S. Department of Defence explains how: "The sensation dissipates when the target moves out of the beam. The sensation is intense enough to cause a nearly instantaneous reflex action of the target to flee the beam." It uses radio frequency millimetre waves in the 96GHz range to penetrate the top 1/64 of an inch layer of skin on the targeted individual, instantly producing an intolerable heating sensation that causes them to flee. A lot of respected people have posted warnings about the mass deployment of commercial millimetre-wave technology.

5G networks have divided network services into three categories: enhanced Mobile Broadband (eMBB) or handsets; Ultra-Reliable Low-Latency Communications (URLLC), which includes industrial applications and autonomous vehicles; and Massive Machine Type Communications (MMTC) or sensors. Initial 5G deployments will focus on eMBB and fixed wireless, which makes use of many of the same capabilities as eMBB. 5G will use spectrum in the existing LTE frequency range (600 MHz to 6 GHz) and also in millimetre wave bands (24–86 GHz). 5G technologies have to satisfy ITU IMT-2020 requirements and/or 3GPP Release 15; while IMT-2020 specifies data rates of 20 Gbit/s, 5G speed in sub-6 GHz bands is similar to 4G.

Dazzler
A dazzler is a non-lethal weapon which uses intense directed radiation to temporarily disable its target with flash blindness. Targets can include sensors or human vision.

Particle-Beam Weapon
A particle-beam weapon uses a high-energy beam of atomic or subatomic particles to damage the target by disrupting its atomic and/or molecular structure.

Sonic Weapon
Sonic and ultrasonic weapons (USW) are weapons of various types that use sound to injure, incapacitate, or kill an opponent.

11 Homemade Weapons

12 Ammo

Ammunition (informally ammo) is the material fired, scattered, dropped or detonated from any weapon. Ammunition is both expendable weapons (e.g., bombs, missiles, grenades, land mines) and the component parts of other weapons that create the effect on a target (e.g., bullets and warheads). Nearly all mechanical weapons require some form of ammunition to operate.

The purpose of ammunition is to project a force against a selected target to have an effect (usually, but not always, lethal). The most iconic example of ammunition is the firearm cartridge, which includes all components required to deliver the weapon effect in a single package.

Ammunition comes in a great range of sizes and types and is often designed to work only in specific weapons systems. However, there are internationally recognized standards for certain ammunition types (e.g., 5.56×45mm NATO) that enable their use across different weapons and by different users. There are also specific types of ammunition that are designed to have a specialized effect on a target, such as armor-piercing shells and tracer ammunition, used only in certain circumstances. Ammunition is commonly colored in a specific manner to assist in the identification and to prevent the wrong ammunition types from being used accidentally.

Design
Ammunition design has evolved throughout history as different weapons have been developed and different effects required. Historically, ammunition was of relatively simple design and build (e.g., sling-shot, stones hurled by catapults), but as weapon designs developed (e.g., rifling) and became more refined, the requirement for more specialized ammunition increased. Modern ammunition can vary significantly in quality but is usually manufactured to very high standards.

For example, ammunition for hunting can be designed to expand inside the target, maximizing the damage inflicted by a single round. Anti-personnel shells are designed to fragment into many pieces and can affect a large area. Armor-piercing rounds are specially hardened to penetrate armor, while smoke ammunition covers an area with a fog that screens people from view. More generic ammunition (e.g., 5.56×45mm NATO) can often be altered slightly to give it a more specific effect (e.g., tracer, incendiary), whilst larger explosive rounds can be altered by using different fuzes.

Naming

The measurements in metric are almost always a "diameter to length" ratio. **5.56x45 Means** 5.56mm Wide 45mm Long	Shotshells are measured in "gauge", with a lower number being a larger diameter.			

Terms

These are the terms used for the different types of ammunitions.

Round	A round is a single cartridge containing a projectile, propellant, primer and casing.
Shell	A shell is a form of ammunition that is fired by a large caliber cannon or artillery piece. Before the mid-19th century, these shells were usually made of solid materials and relied on kinetic energy to have an effect. However, since that time, they are more often filled with high-explosives (see artillery).
Shot	A shot refers to a single release of a weapons system. This may involve firing just one round or piece of ammunition (e.g., from a semi-automatic firearm), but can also refer to ammunition types that release a large number of projectiles at the same time (e.g., cluster munitions or shotgun shells).
Dud	A dud refers to loaded ammunition that fails to function as intended, typically failing to detonate on landing. However, it can also refer to ammunition that fails to fire inside the weapon, known as a misfire, or when the ammunition only partially functions, known as a hang fire. Dud ammunition, which is classified as an unexploded ordnance (UXO), is regarded as highly dangerous. In former conflict zones, it is not uncommon for dud ammunition to remain buried in the ground for many years. Large quantities of ammunition from World War I continue to be regularly found in fields throughout France and Belgium and occasionally still claim lives. Although classified as an unexploded ordnance, landmines that have been left behind after conflict are not considered duds as they have not failed to work and may still be fully functioning and simply forgotten.
Bomb	A bomb, or more specifically a guided or unguided bomb (also called an aircraft bomb or aerial bomb), is typically an airdropped, unpowered explosive weapon. Mines and the warheads used in guided missiles and rockets are also referred to as bomb-type ammunition.

Components

The components of ammunition intended for rifles and munitions may be divided into these categories:

Fuze / Primer	The term "fuze" refers to the detonator of an explosive round or shell. The spelling is different in British English and American English (fuse/fuze respectively) and they are unrelated from a fuse (electrical). A fuse was earlier used to ignite the propellant (e.g., such as on a firework) until the advent of more reliable systems such as the primer or igniter that is used in most modern ammunitions. The fuze of a weapon can be used to alter how the ammunition works. For example, a common artillery shell fuze can be set to 'point detonation' (detonation when it hits the target), delay (detonate after it has hit and penetrated the target), time-delay (explode a specified time after firing or impact) and proximity (explode above or next to a target without hitting it, such as for airburst effects or anti-aircraft shells). These allow a single ammunition type to be altered to suit the situation it is required for. There are many designs of a fuze, ranging from simple mechanical to complex radar and barometric systems. Fuzes are usually armed by the acceleration force of firing the projectile, and usually arm several meters after clearing the bore of the weapon. This helps to ensure the ammunition is safer to handle when loading into the weapon and reduces the chance of the detonator firing before the ammunition has cleared the weapon.
Explosive Materials / Propellants	The propellant is the component of ammunition that is activated inside the weapon and provides the kinetic energy required to move the projectile from the weapon to the target. Before the use of gunpowder, this energy would have been produced mechanically by the weapons system (e.g., a catapult or crossbow); in modern times, it is usually a form of chemical energy that rapidly burns to create kinetic force, and an appropriate amount of chemical propellant is packaged with each round of ammunition. In recent years, compressed gas, magnetic energy and electrical energy have been used as propellants.
Projectile	The projectile is the part of the ammunition that leaves the weapon and has the effect on the target. This effect is usually either kinetic (e.g., as with a standard bullet) or through the delivery of explosives.
Cartridge Casing	The cartridge is the container that holds the projectile and propellant. Not all ammunition types have a cartridge case. In its place, a wide range of materials can be used to contain the explosives and parts. With some large weapons, the ammunition components are stored separately until loaded into the weapon system for firing. With small arms, caseless ammunition can reduce the weight and cost of ammunition, and simplify the firing process for increased firing rate, but the maturing technology has functionality issues. Generally brass, nickel, or steel.

Ammo Types

These are the different types of bullets and their purposes.

Handgun Bullets

Jacketed Hollow Point (JHP)	Jacketed Hollow Point (JHP) bullets have full-length jacket with a hollow point. This construction provides deep penetration with controlled expansion, and also enables reliable feeding into the chamber and good function in autoloading pistols. These very accurate bullets are suitable for revolvers, too.
Semi Jacketed Hollow Point (SJHP)	Semi Jacketed Hollow Point (SJ HP) bullets provide optimum expansion with controlled penetration. Due to the partly exposed lead in the nose they are less suitable for pistols and they are mainly used in revolver ammunition.
Semi Jacket Flat Point (SJFP)	Semi Jacketed Flat Point (SJ FP) bullets with flat exposed lead tips are suitable for short range shooting with revolvers. They provide deeper penetration with less expansion than SJ HP bullets, which provide deep penetration with controlled expansion and good functioning in auto loading pistols.
Full Metal Jacket (FMJ)	Full Metal Jacket (FMJ) bullets are general purpose bullets suitable for auto loading pistols. They provide excellent cartridge feeding into the weapon chamber and good penetration. These bullets are good choice for practice shooting.
Flat Point Jacket (FPJ)	Flat Point Jacket (FPJ) bullets are actually FMJ bullets with a flat nose. These bullets are designed to improve the stopping power of the FMJ bullets. They are suitable primarily for revolver ammunition but are also used in pistol ammunition.
Full Metal Spitz (FMS)	Full Metal Spitz (FMS) is our bullet with conical nose used in 357 Magnum and 38 Special cartridges. Main characteristic of this bullet is excellent penetration capability.
Lead Round Nose (LRN)	Lead Round Nose (LRN) bullets are versatile, economical bullets for general purpose, used mainly in revolvers. They are very accurate and especially suitable for practice.
Semi Wad Cutter (SWC)	Semi Wad Cutter (SWC) have higher velocity and power and provide accurate shooting at somewhat longer distances than it is possible with WC bullets.
Wad Cutter (WC)	Wad Cutter (WC) bullets are specially designed lead bullets with excellent accuracy intended for shooting competitions. These cylindrical bullets cut clean holes in target for easy reading of results. Because of low recoil they are suitable for training.

Semi Wad Cutter Hollow Point (SWCHP)	Semi Wad Cutter Hollow Point (SWC HP) with a nose deliver immediate expansion and efficient transfer of energy. They leave clean holes in paper targets.
Total Metal Jacket (TMJ)	Total Metal Jacket (TMJ) bullets are FMJ bullets of special design in which the lead is not exposed. The enclosed base eliminates lead vaporization during firing. These bullets are suitable for indoor shooting.

Rifle Bullets

Soft Point (SP)	The tip of the bullet is left uncoated. (Exposed Lead)
Pointed Soft Point (PSP)	Pointed Soft Point (PSP) bullets have sharp lead nose, which cause the bullets expansion when hitting and aerodynamically shaped ogival part which provide better ballistic coefficient and maximum striking energy at longer ranges.
Soft Point Boat Tail (SPBT) and Pointed Soft Point Boat Tail (PSPBT)	Soft Point Boat Tail (SPBT) and Pointed Soft Point Boat Tail (PSP BT) bullets have specially shaped back part of a reduced diameter, which lowers the air drag. The better ballistic coefficient of these bullets, primary PSP BT bullet, provides successful firing at longer distances, at which the bullet keeps higher striking energy with reduced drift and flatter trajectory.
Soft Point Round Nose (SPRN)	Soft Point Round Nose (SP RN) bullets have a blunt rounded nose and are suitable for short range shooting, especially in bushes (or in woods). The large lead weight exposed in the nose assures high energy impact and bullet mushrooming that is reliable even at smaller velocitiest. These bullets have larger bullet weight for a certain length.
Flat Soft Point (FSP)	Flat Soft Point (FSP) bullets have a flat lead nose of increased diameter. These bullets are suitable for use in the carbines with tubular magazines as they reduce the possibility of primer ignition in the cartridge placed in front due to recoil when firing. They expand reliably and penetrate deeply on light to medium game.
Hollow Soft Point (HSP)	Hollow Soft Point (HSP) bullets have a cavity in the nose which causes expansion and helps mushroooming during penetration.
Hollow Point (HP)	Hollow Point (HP) bullets are designed primary for shooting competition. Due to cavity in the nose, center of gravity is placed back, improving flight stability and accuracy. Hollow point initiates rapid expansion on impact.
Hollow Point Boat Tail (HPBT)	Hollow Point Boat Tail (HPBT) bullets have higher ballistic coefficient because of small meplat, long ogival and boat tail design. These features enable very accurate long range shooting, with flat trajectory and reduced wind drift.
Full Metal Jacket (FMJ)	Full Metal Jacket (FMJ) bullets are nonexpanding bullets with a full-length jacket opened at the base only. Due to their sharp nose, these bullets provide good penetration. They are suitable for target shooting, but also for varmint hunting as they cause minimal tissue damage and leave a small exit hole.
Full Metal Jacket Round Nose (FMJRN)	Full Metal Jacket Round Nose (FMJ RN) with rounded nose is suitable for short range shooting. They provide maximum penetration when hunting dangerous game.
Full Metal Jacket Boat Tail (FMJ BT)	Full Metal Jacket Boat Tail (FMJ BT) bullets are specially shaped bullets to reduce air resistance. The rear cone in combination with aerodynamically shaped ogival part provides high ballistic coefficient, slight velocity drop on trajectory, greater down-range energy and less wind drift as well.

Other Bullets

Semi Jacketed (SJ)	
Armour Piercing (AP)	Has an alloy core, instead of lead.
Boat Tail (BT)	The rear end of the cartridge is tapered to stabilize the projectile in flight.
Tracer Bullet	Tracer ammunition (tracers) are bullets or cannon-caliber projectiles that are built with a small pyrotechnic charge in their base. When fired, the pyrotechnic composition is ignited by the burning powder and burns very brightly, making the projectile trajectory visible to the naked eye during daylight, and very bright during nighttime firing. This allows the shooter to visually trace the flight path of the projectile and thus make necessary ballistic corrections, without having to confirm projectile impacts and without even using the sights of the weapon. Tracer fire can also be used as a marking tool to signal other shooters to concentrate their fire on a particular target during battle.

Ammo Performance

13 Gun Modifications

Firearm modification is commonly done in order to enhance various aspects of the performance of a firearm. Reasons for these modifications can range from cosmetic to functional, and can be simple operations that the owner can perform, or complex operations requiring the services of a gunsmith.

Accessories

Grips

Gun Holders

Gun Sights

A sight is an aiming device used to assist in visually aligning ranged weapons, surveying instruments or optical illumination equipments with the intended target. Sights can be a simple set or system of markers that have to be aligned together with the target (such as iron sights on firearms), or optical devices that allow the user to see a sometimes optically enhanced (e.g. magnified) image of the target aligned in the same focus with an aiming point (e.g. telescopic sights, reflector sights and holographic sights). There are also sights that project an aiming point (or a "hot spot") onto the target itself, such as laser sights and infrared illuminators on some night vision devices.

There are many types of sighting devices. They can be fixed, mechanical, optical, computational, or a mixture of all of these attributes.

Iron Sights	Iron sights operate simply. Most manufacturers install them as "standard"on commercially available rifles and pistols. A rear and front sight make up a set of iron sights. The front sight should be the shooter's focus when aiming; The rear sight is often adjustable to let the shooter account for windage and elevation. While more accurate sights are available, we don't see iron sights falling out of favor any time soon. They are generally low profile, simple to use and maintain, and don't require a power source. Open sights like you would see on a revolver are the more common of the iron sights. There are a ton of open sights out there. You may see any combination of differently shaped rear and front sights.
Telescopic Sight	Also called a scope, a telescopic sight is true to its name — think of it as a little telescope that is put on top of a rifle, or less frequently a pistol. The lens magnifies the distant target for the shooter, and a reticle in the sight's center indicates the point of aim. Naturally, self-defense seldom calls for a scope that can let you hit your target from several hundred feet away. This is why you'll find telescopic sights on the rifles of hunters, snipers, and target shooters. For instance, the optic on the AR-10 featured above can help take down game like deer from longer distances with .308 ammo than a red dot or iron sights would likely allow. A telescopic sight requires more finesse than iron sights when used properly. You have to take time to "sight-in" or zero-in telescopic sights before you use them. This helps ensure the sight reflects an accurate picture of where your shots will land with your specific firearm and ammunition. The primary disadvantage of telescopic sights is that they limit their user's field of vision. However, because telescopic sights require less visual acuity from the shooter than iron sights, they're often easier to use for those of us on the wrong side of 30.
Reflex Sight	A reflex sight is a handy device for quickly lining up a shot on a target at short to medium range. It utilizes reflective glass, may be magnified or non-magnified, and superimposes a reticle over the point of aim. The red dot sight is a commonly used type of reflex sight. It fittingly indicates the point of aim with a single red LED. The accuracy and speed provided by a red dot sight make it a good choice for a novice shooter who would like to quickly become proficient with their firearm. It allows aiming with both eyes open and without shifting focus. A larger diameter reticle makes acquiring a target even easier, but at the expense of obscuring it and making accurate long distance shooting more difficult. The downside to red dot sights is that they need a power source (albeit not a strong one). They also generally require closer positioning to the shooter's face, and good ones aren't cheap.
Laser Sight	You must zero in laser sights like telescopic sights, but once zeroed they permit far faster aiming than iron sights. Laser sights also facilitate with accurate rapid fire. Red lasers are most common because they are economical and require relatively little electricity, but their light is harder to see in bright sunlight. A green laser is preferable when the sun is shining, but it will be costlier. A laser's greatest drawbacks are that it makes its shooter a far more obvious target, is straight and therefore less capable of accommodating dropoff, and needs a significant energy supply. When laser guns become real, perhaps a very weak laser could also come out of the barrel for aiming purposes. We came up with that idea first — Lockheed Martin, please take note.
Red Dot Sights	Red Dot sights use lower magnification and can be incorporated into lower magnification telescopic sights. This type of optic comes either battery-powered or utilizes other sources of light such as fiber optics or luminescent materials. Despite its construction, all red dots provide the same sighting presentation — an illuminated, adjustable dot delivering precise aiming capabilities. Though it uses the "red" moniker, the dot doesn't have to be that color. Some may appear green or adopt other colors. These sights are popular options for short-range shooting due to the dot's ability to been seen in both peripheral vision direct focus. Non-magnifying red dot sights typically appear on pistols, carbines and shorter-range rifles. There are several kinds of red dots to include holographic sights, reflex sights and prism sights.
Holographic Sight	Holographic sights are precise non-magnifying optical sights that use a laser to project a fine reticle in a glass viewer. Battery-powered, they usually come with adjustable brightness settings. Holographic sights offer shooters faster acquisition than standard red dots because it allows the eye to focus on the target and the reticle simultaneously. Additionally, many holographic sights offer a larger view window which helps when shooting. Due to their patented technology and market demand, these optics, like the EOTech XPS2, are typically more expensive.
Prism Sights	Another optic that falls under the red dot catch-all is the prism sight. This type of optic is a compact device that uses a prism to magnify the image. Much like the telescopic sight, it can be adjusted to correct elevation and windage. Due to the compact prism used internally, prism sights are much smaller than telescopic sights. Prism sights usually offer a fixed magnification, typically towards the lower end of the power spectrum. The prism magnification also gives shorter eye relief than telescopic sights, requiring shooters to mount the optic much closer to be used properly.

Lighting

This includes any forms of lighting that can be attached to a gun such as a torch or a laser.

Mounted Torches

Mounted Lasers

Stock

A gunstock or often simply stock, the back portion of which is also known as a shoulder stock, a buttstock or simply a butt, is a part of a long gun that provides structural support, to which the barrel, action, and firing mechanism are attached. The stock also provides a means for the shooter to firmly brace the gun and easily aim with stability by being held against the user's shoulder when shooting the gun, and helps to counter muzzle rise by transmitting recoil straight into the shooter's body.

Stock Accessories

These are any accessories that can be mounted to the stock.

Magazines

A magazine is an ammunition storage and feeding device within or attached to a repeating firearm. Magazines can be removable (detachable) or integral (internal/fixed) to the firearm. The magazine functions by moving the cartridges stored within it into a position where they may be loaded into the barrel chamber by the action of the firearm. The detachable magazine is often colloquially referred to as a clip, although this is technically inaccurate.

Choke

In firearms, a choke is a tapered constriction of a gun barrel at the muzzle end. Chokes are most commonly seen on shotguns, but are also used on some rifles, pistols, or even airguns. Notably, some .22 LR match rifles have a constricted bore diameter near the muzzle.

Monopods & Bipods

A bipod is an attachment, usually to a weapon, that helps support and steady it. The bipod provides significant stability along two axes of motion (side-to-side, and up-and-down).

Recoil Pads

A recoil pad is a piece of rubber, foam, leather, or other soft material usually attached to the buttstock of a rifle or shotgun. Recoil pads may also be worn around the shoulder with straps, placing the soft material between the buttstock and the shoulder of the person firing the gun. The purpose of this device is to provide additional padding between the typically hard buttstock surface and the user's shoulder, to reduce the amount of felt recoil of the firearm, and to prevent slippage on the shooter's clothing while aiming.

Swivels

A swivel is a connection that allows the connected object, such as a gun, chair or swivel caster to rotate horizontally or vertically.

Suppressors

A silencer, also known as a sound suppressor, suppressor or sound moderator, is a muzzle device that reduces the acoustic intensity of the muzzle report (sound of gunfire) and eliminates muzzle flash when a gun (firearm or air gun) is discharged, by modulating the speed and pressure of the gas ejection from the muzzle and hence suppressing the muzzle blast. Like a muzzle brake, a silencer can be a detachable accessory mounted separately onto the muzzle, or an integral part of the barrel.

Silencers

Suppressor Sleeve

Flash Hider

Modifications

Common modifications include:
- Cosmetic and ergonomic modifications
  - Replacement or alteration of grips or stocks
  - Changing of sights, such as the adjustable iron sights or a telescopic sight
  - Adding or removing weight to ease carrying, alter balance, or help moderate recoil
  - Metal engraving or custom woodwork
  - Checkering or stippling wood or metal
  - Altering the metal finish, using techniques such as bluing, electroplating, or parkerizing
  - Use of a shorter barrel to reduce size and weight, or a longer barrel to increase velocity
- Caliber conversions
  - Rechambering or rebarreling for a new caliber, such as conversions made to chamber a wildcat cartridge
  - Use of a caliber conversion sleeve or other readily removable insert to fire a smaller, less expensive cartridge

- Operating mechanism conversions
  - Muzzleloading or paper cartridge to metallic cartridge conversions, such as the Allin conversion or Lund conversion
  - Conversion from fully automatic or select fire to semiautomatic only or manual operation, or vice versa
  - Short recoil to blowback conversions, used in various .22 Long Rifle conversions, such as the Colt Ace and J. A. Ceiner conversion kits.
  - Conversion from handgun to carbine or rifle
  - Addition of a rifled barrel to a shotgun to allow it to better fire shotgun slugs
- Accurizing
- Sporterizing

Legal Issues
Care must be taken when modifying firearms, as some operations may convert a legal firearm into an illegal one. An example of this is the restrictions in the US National Firearms Act, which define restricted classes of firearms. Examples of illegal firearms under this act are:

- Rifles with overall lengths under 26 inches, or barrels under 16 inches in length
- Shotguns with overall lengths under 26 inches, or barrels under 18 inches in length
- Machine guns
- A conversion to a fixed cartridge of over .50 caliber

These restrictions vary from location to location; some areas may restrict magazine capacity or require special safety devices such as loaded chamber indicators, integral locking mechanisms, magazine disconnects. Also commonly required are identifying marks such as serial numbers or firearm microstamping components, removal of which may be illegal Furthermore - conversion of semi-automatic weapons into select-fire weapons has been illegal for non-SOT holding gunsmiths since the passage of the Hughes Amendment in 1986.

Such weapons may be held only by law enforcement and military only except for "dealer samples" left in the hands of SOT holders. Fully automatic weapons converted to semi-automatic only operation are machine guns per the NFA. The BATFE's policy is "Once a machine gun, always a machine gun."

14 Weapon Handling

How to hold, shoot and reload various types of weapons.

Firing Stance

These are different techniques and stances in which you can shoot a weapon.

Standing	With neither arm supported, this is the most difficult position for firing an accurate shot. Rather than trying to hold the barrel steady, which is impossible, try to keep movement of the barrel to as small an area as possible. Smooth, natural motion will produce the best shot.
Sitting	Both arms are supported by your legs. Next to the prone position, this is the steadiest position.
Kneeling	With only one arm braced, the kneeling position is less steady than the prone and sitting positions.
Prone	The prone position is the steadiest of the four positions. Because it's the easiest to hold, it's the best position for mastering the fundamentals of firing—aiming, breath control, trigger squeeze, and follow through.

Firing Styles

These are the different ways you can fire a weapon.

Sighted Fire	
Hip Fire	Shooting a gun without using the sights at all. This is most commonly a video game term, but could apply to real weapons too.
Leading the Target: Swing-Through Method	The two most common methods of leading targets at long distances are swing-through and sustained lead. ● Swing-through is the best technique for the beginning student. ● Point your shotgun at a moving target and swing with it. Increase the speed of the gun so that the muzzle passes the target, and then fire. In other words, literally "swing through" the target and fire at a blank space in front of the target.
Leading the Target: Sustained Lead	The two most common methods of leading targets at long distances are swing-through and sustained lead. ● The sustained lead method is a little more challenging because it requires more experience. ● You estimate the length of the lead necessary to hit the target, and maintain that lead as you swing with the target, fire, and continue the swing.
Snap-Shooting	Snap-shooting is a technique to use if you must make a quick shot and the target is straight ahead at close range. You simply raise the shotgun, and point where you think the target will be when the shot arrives.

Firing Preparation

A list of recommended procedures to complete before firing.

Choosing a Choke

As with firing a rifle, good shotgun marksmanship begins with proper preparation, which includes adjusting your gun and ammunition for maximum performance and mastering shotgun techniques. You also must choose the proper choke.

A choke allows you to fine-tune your shotgun for the type of game you're hunting. Built-in or attached to the muzzle end of the barrel, the choke is a constriction that controls the shot string, thus affecting pellet density at various distances.
The tighter the constriction, the greater the distance that the cluster of pellets stays together. The looser the constriction, the faster the shot pattern spreads.

Here are the four most common chokes, ranging from most open to tightest.
- Cylinder (unchoked)
- Improved Cylinder
- Modified
- Full

Aiming

How to aim a gun properly and safely.

Determine Your Dominant Eye

Just as you have a dominant hand, you also have a dominant eye. You need to aim with the dominant—or master—eye for the most accurate shooting. Usually your dominant eye is the same as your dominant hand, but not always. You should determine which is your dominant eye before you sight-in your rifle or handgun.

To determine your dominant eye:
1. Form a triangular opening with your thumbs and forefingers.
2. Stretch your arms out in front of you.
3. Focus on a distant object while looking through the triangular opening and keeping both eyes open.
4. Bring your hands slowly to your face, keeping sight of the object through the opening; the opening will come to your dominant eye naturally.
5. If you're not sure, close one eye at a time. The weak eye will see the back of your hand; the strong one will be focused on the object in the triangle.

Sighting In

Sight alignment is the process of lining up rear and front sights. The sight picture is the image you see when the sights are aligned correctly with the target. To ensure that the bullet will travel to the target in your sight, it's necessary to sight-in your rifle or handgun.
- With an open sight, you line up the target with the blade or bead of the front sight within the notch of the rear sight.
- With an aperture sight, you line up the target so that the front sight is within the rear peephole.
- With a telescopic sight with a crosshair reticle, you line up the target with the crosshairs of the sight.
- With a telescopic sight with a dot reticle, you line up the target with the dot of the sight. The dot must be centered.

Rifle bullets don't travel in a straight line. They travel in an arc, formed by the pull of gravity. "Sighting-in" is a process of adjusting the sights to hit a target at a specific range. Deer hunters, for example, often sight-in their rifles to hit the bull's-eye at 100 yards. All rifles should be sighted-in before every hunt using the ammunition you plan to use, especially rifles with peep or telescopic sights. Guns you sighted-in prior to your last outing could have been knocked out of alignment by a single jolt. That misalignment could mean the difference between a successful hunt and a disappointing experience.

Other than ensuring accurate shots, sighting-in a rifle has other advantages:
- Forces you to practice
- Makes accurate shooting possible
- Helps identify problems with your firing technique
- Helps determine the farthest range at which you can hit your target
- Improves safety by helping you know where your rifle will fire
- Builds confidence in your shooting ability

Sighting-In Procedure
Fire your rifle from a solid bench rest with the forestock resting on a pad or a sandbag. Don't rest the gun on its barrel—it will shoot higher than normal. Ideally, use an adjustable shooting tripod with sandbags. A spotting scope is also useful.

Sight-in instructions are printed on some targets available from retail outlets or manufacturers. The sighting-in process for most centerfire rifles begins at 25 yards and then should be repeated at 100 yards. The basic steps involve firing at least three shots carefully and consistently at a target. If the bullets form a relatively small group of holes on the target, but not where you were aiming, the sights will have to be adjusted.

Adjusting Your Sight
When adjusting peep or telescopic sights, the rear sights or dials are adjusted by a certain number of minutes-of-angle, or "clicks," in a certain direction. Read the sight's instruction manual to see how much each click changes the sight at 100 yards. The rear sight is moved in the same direction you want your shot to move on the target. Moving shots from side to side is "adjusting for windage." Moving shots up or down is "adjusting for elevation."

Specific instructions about trajectory and what fractions or inches you should be above the bull's-eye at 25, 50, or 100 yards are usually included on sight-in targets. You also might consult a ballistics chart or get help from an experienced shooter.

Firing

Using correct firing techniques will help you steady the rifle for the most accurate shooting. Bear in mind that these are only the basics. Further study will help you understand other factors that can affect your accuracy, such as wind, heat, and parallax.

Firing Principles

Shooting From a Rest
When shooting in the field, the safest and most accurate shots are taken from a rest—a log, large rock, or other stable object. Don't rest the barrel directly on a hard surface, or the rifle will fire higher than normal—put some padding, such as a hat or a jacket, under the rifle.

Breathing
Your breathing can move the rifle just enough to throw off your shot.
- When you're ready to fire, draw a deep breath, and exhale about half of it.
- Then hold your breath as you squeeze the trigger.
- Bear in mind that if you hold your breath too long, your heart beats faster, which increases your pulse and causes the rifle to move. If you notice this happening, take another breath and start over.
- At times the excitement of spotting game will make it more difficult to control your breathing. Try to relax and follow the correct procedure.

Trigger Squeeze
Jerking the trigger or abruptly clenching the trigger hand can move the gun enough to cause a miss.
To squeeze the trigger without jarring the gun, simply apply slow, steady pressure until the gun fires.
Practice makes breath control and proper trigger squeeze habitual.

Follow Through
After the bullet fires, it's important to continue the squeeze or follow through. That prevents you from jerking the gun before the bullet has left the barrel.

Four Fundamentals for Accurate Shooting
1. Aim carefully, aligning your sights.
2. Take a deep breath, and then release about half of it.
3. Squeeze the trigger slowly.
4. Follow through.

Reloading

This section shows you how to reload the most common types of guns.

15 Maintenance

Maintenance

Firearm maintenance (or gun care for short) is a series of periodic preventive maintenance procedures aiming to ensure the proper function of a firearm, often with the use of a variety of specialized tools and chemical solutions. Typically such maintenance is performed by the owner of the firearm using either simple methods such as cleaning the firearm with oil or other cleaning solutions, or more sophisticated practices such as lubricating moving parts with oil/grease and recoating exposed surfaces with protective finishes such as varnishing or bluing.

When a firearm presents with physical damage related to the ordinary use of the firearm, or when a firearm malfunctions in a life-threatening manner, a professional gunsmith should perform advanced maintenance to determine if the firearm is repairable and/or safe to shoot anymore.

An inadequately maintained firearm will often accumulate excessive fouling and dirt within the barrel and receiver, which not only can clog up the rifling and decrease the firearm's accuracy and precision, but can also interfere with the proper operation of the action and lead to potentially dangerous malfunctions. Furthermore, some of the foulings and dirts are either corrosive themselves, or capable of making the firearm vulnerable to rusting and wears, and thus can lead to irreversible damages to the firearm over time.

The consequences of neglecting proper maintenance can be serious. For instance, during the Vietnam War, the newly issued M16A1 assault rifle was distributed to US troops with marketing literature from Colt Firearms claiming that the weapon was self-cleaning, which implied to many to mean that it did not have to be routinely maintained. However, this misapprehension compounded the rifle's design flaws and made the weapon notorious for repeated failures in combat, which led to needless casualties among US forces. Once the problem was acknowledged by the US military, the weapon was not only subject to upgrades, but US troops were also trained in proper maintenance of the weapon and supplied with cleaning kits and an illustrated booklet on the subject by Will Eisner.

The ordinary firing action releases fine particles of gunpowder, metals (mostly lead and copper from the bullet moving over the riflings) and other contaminates into the inner spaces of a firearm, which may cause malfunctions or in rarer cases of extreme buildup may raise the barrel pressure too high causing the firearm to explode (catastrophic failure) upon being fired. It has been widely reported that firearms without a spring to control the inertia of the firing pin require constant cleaning of the bolt assembly, as extremely dangerous phenomena such as slamfire may occur. Slamfire is a malfunction in which a firearm which is normally semi-automatic may temporarily and involuntarily become fully automatic, firing repeatedly — without another pull of the trigger — until the firearm is out of ammunition or jams.

Every major firearms manufacturer provides detailed information on the proper methods used to disassemble, clean and then reassemble a firearm they produced. This information is usually packaged with the firearm. In the event that this information is not present with the firearm at the point of purchase, it is advisable to ask the manufacturer where this information may be obtained. For safety reasons the manufacturer's directions for cleaning, maintenance and care should always be followed.

There are many different types of weapon and firearm cleaning kits available on for sale. These kits will give you the necessary tools and materials to properly clean your firearm safely and effectively. These kits help keep your firearm stay maintained and properly lubricated, making the firearm last longer without failure.

Firearms produce massive momentary forces upon firing a bullet. A typical 9mm projectile produces a maximum of 34,084 psi (2,350.0 bar) of pressure in the instant of firing. The amount of pressure a firearm may endure for the first few milliseconds after the cartridge fires can be over 2,300 times more than the normal atmospheric pressure. Therefore, it is important for the safety of the shooter, and the longevity of a firearm that it is properly lubricated as per the manufacturer's specifications.

When in an extreme and life-threatening situation such as preparing for combat, the manufacturer's recommended lubricants may not be available to soldiers, or others who may enter these scenarios.

If there is time to perform firearm maintenance before a life-threatening emergency (such as daily cleaning of a rifle in a combat zone) it may become necessary to use other sources of lubrication, as a firearm will function better with some lubricant than it will with none. One United States Marine Corps sergeant recounts that synthetic motor oil performed better than standard military issued lubricant in extreme conditions. However it is advisable to immediately return to the standard recommendation of the firearm manufacturer when conditions allow.

It is critically important that a firearm is free of ammunition before beginning maintenance. The National Rifle Association teaches gun owners that "before cleaning your gun, make absolutely sure that it is unloaded. The gun's action should be open during the cleaning process. Also, be sure that no ammunition is present in the cleaning area". When reassembling a firearm after it has been cleaned, it is very important to know how to put the weapon back together properly. Failure to reassemble your firearm properly could lead to malfunction when firing and could lead to injury.

Maintenance Tips

Clean your gun after every use. A good-quality firearm is a significant investment, whether you're using it for sport, hunting, or home defense. Make sure you give it the attention it deserves whenever you get back from a round of firing it. The whole cleaning process, start to finish, only takes 20 or 30 minutes. It's worth it to do it regularly. You might even consider getting out old guns from the back of the closet and doing them all at once while you've got the materials out.

Consider investing in a barrel snake and/or ultrasonic cleaners. Like everything else, gun cleaning technology is cutting edge. For rifles and shotguns, barrel snakes are long multi-purpose cleaners that make the job much quicker and easier, some featuring lights on the end that allow you to see the interior of the barrel much more easily. It cuts down on time and makes the job more efficient.

Store your guns unloaded in a cool and dry environment. To ensure the longest life for your gun, don't store them anywhere they'll be significantly affected by the elements. Keep them indoors, in temperature-controlled environments. Consider investing in trigger locks to keep your gun safe and tamper proof. Soft or hard cases are available for guns, anywhere as cheap as $15 or $20. If you have a higher budget, there are also lockable gun cabinets and safes made for the purpose of storing guns in a controlled and locked environment.

Cleaning

Properly inspecting and regularly cleaning your guns will keep them functioning effectively and firing safely. Because of the tiny explosion in the chamber every time you pull the trigger, residue and sediment are left on the inside of the barrel, making it essential that you take the time to clean it regularly to avoid dangerous malfunctions. You should clean a gun after every time you fire it, and particularly after target practice when you are firing lots of rounds.

Get a cleaning kit. Whether you purchase a pre-assmebled cleaning kit from a sporting goods store or you assemble the necessary components individually, you'll need a few basic things to have in your arsenal of cleaning supplies. A basic set includes:
- Cleaning solvent
- Lubricant, or gun oil
- A bore brush
- A patch holder and patches
- Cleaning rod
- A nylon cleaning brush
- Flashlight
- Cotton swabs
- Microfiber cloths for polishing

Unload your gun. Always take the time to properly unload your gun and double-check to make sure that it's unloaded every time you pick it up to clean it. Remember that your gun may still have a round ready to fire after you remove the magazine, so check and remove this round. After opening the chamber, look through the barrel from back to front. Confirm that no round remains inside, either in the chamber or stuck in the barrel. No gun can be considered unloaded until you have looked through the barrel.

Disassemble your gun only as much as the manufacturer recommends. Check the owner's manual for disassembly instructions to prepare the gun for cleaning. This will allow you to access all parts that become dirty from firing.
- Semi-automatic pistols and rifles will generally be stripped into their major components: barrel, slide, guide rod, frame and magazine. Revolvers, shotguns, and most other sorts of guns will not need to be stripped to clean them.
- Field stripping is not necessary to clean the gun thoroughly. Don't take apart your gun more than you have to unless it requires repair. Likewise, some guns can't be stripped at all and it won't be necessary to do anything but open the chamber to clean it.

Always clean your gun in a well-ventilated area. Find a a place with good air circulation to clean your guns. Solvent fumes are noxious and can make you sick. Likewise, the solvent and lubricant used just flat-out smell foul if you try to clean your guns indoors, so keep your family happy and don't stink up the joint. Cover your work surface with plastic bags, newspaper, or old towels you've saved for the purpose. Head out to the garage and put the door up, or clean your guns on a bright and dry day to get them cleaned properly.

Clean out the barrel with cleaning rod and patches. Soak the bore, or inside of the barrel, using a cleaning rod, patch holder and the right size cotton patches for your gun. Work from the back of the bore if you can. If not, use a muzzle guard. The muzzle guard keeps the cleaning rod from banging against the muzzle, which can cause your gun to malfunction. To thoroughly clean the barrel out, push a solvent-soaked patch through the bore until it exits the other end. Remove the patch, don't pull it back through. Pulling it back through will just redeposit all the gunk you clean off.

Alternate the bore brush and patches to thoroughly scrub the barrel. Remove the patch holder and attach the bore brush. Run the bore brush back and forth along the full length of the bore 3 or 4 times to loosen any debris. Next, reattach the patch holder and run solvent-soaked cotton patches through the bore. Remove them when they exit the front. Repeat this process until a patch comes out clean. Run one more dry patch through to dry it out and inspect it closely for any build-up you may have missed.

Lubricate the barrel. Attach the cotton mop to the cleaning rod. Apply a few drops of gun conditioner or lubricant to the cotton mop and run it through the bore to leave a light coating of gun oil on the inside. Clean and lubricate the action with solvent. Apply solvent to the gun brush and brush all parts of the action. Wipe them dry with a clean cloth. Next, lubricate the moving parts of the action lightly. A light coating helps prevent rust. A heavy coating gets gummy and attracts debris, so only use a small amount.

Wipe down the rest of your gun with a luster cloth. This is a flannel cloth that comes pre-treated with a silicon lubricant. It will remove any remaining debris, including acid from fingerprints, and add shine. If you don't have a particular cloth designated for cleaning guns, old t-shirts and pairs of socks work really well for the purpose. Use something you've got lying around and won't need to reuse.

Warfare

The components and aim of large scale warfare

"The object of war is not to die for your country
but to make the other bastard die for theirs."
George S. Patton

Introduction

This section covers the types of equipment, traps, units, vehicles, aircraft and ships you may see during a war. Knowing what each looks like and does can help you hide from them and give you foreknowledge what's likely to come.

Purpose	The aim of WARFARE is to give the reader a grasp of modern weapons and vehicles in the 21st century, where military units are perpetually alert and ready to strike. It starts off by covering land, sea, air and space materiel such as tanks, submarines, bombers and hypersonic missiles. Warfare also covers intelligence agencies, espionage and the different kinds of covert operations run across the world. Finally it covers electronic warfare such as drones, UAVs and robots and then moves to the traps and explosives currently in-use around the world so the reader can identify them if the need arises. By the end you should be able to easily identify the different assets of war and be able to understand each one's purpose and capability for the use of escaping the destruction it's designed to inflict.

Contents

1 Personnel

Any types of people employed by the army or special agencies to perform certain tasks.

Army Personnel

The Army calls its jobs military occupational specialties, or MOS. Each of the MOS requires advanced individual training and specialization. Army jobs can be divided into two basic categories: those that participate in combat missions and those that support the soldiers who are in combat roles. The Army has around 190 MOSs available for enlisted soldiers. Similar specialties are divided into "branches" or "fields." Below are the Army enlisted job fields.

Native Language Speaker	These soldiers are recruited for their native language abilities, and perform translation and interpreter duties in many foreign languages and cultures.	
Infantry	Infantry is the oldest and largest branch in the US Army combat arms, with its soldiers trained to use small arms, anti-armour or indirect fire weapons such as mortars during combat missions.	• Infantryman (Rifleman) • Indirect Fire Infantryman (Mortarman)

Intelligence Officers

Secret Agents

Intelligence Agent

Provides access to sensitive information through the use of special privileges. If used in corporate intelligence gathering, this may include gathering information of a corporate business venture or stock portfolio. In economic intelligence, "Economic Analysts may use their specialized skills to analyse and interpret economic trends and developments, assess and track foreign financial activities, and develop new econometric and modelling methodologies." This may also include information of trade or tariff.

Access Agent

Provides access to other potential agents by providing profiling information that can help lead to recruitment into an intelligence service.

Agent of Influence

Provides political influence in an area of interest, possibly including publications needed to further an intelligence service agenda. The use of the media to print a story to mislead a foreign service into action, exposing their operations while under surveillance.

Agent Provocateur

An agent provocateur (French for "inciting agent") is a person who commits or who acts to entice another person to commit an illegal or rash act or falsely implicate them in partaking in an illegal act, so as to ruin the reputation or entice legal action against the target or a group they belong to. An agent provocateur may be a member of a law enforcement agency acting out of their own sense of duty or under orders, or other entity. They may target any group, such as a peaceful protest or demonstration, a union, a political party or a company. Prevention of infiltration by agents provocateurs, is part of the duty of demonstration marshals, also called stewards, deployed by organizers of large or controversial assemblies. An agent provocateur may be a police officer or a secret agent of police who encourages suspects to carry out a crime under conditions where evidence can be obtained; or who suggests the commission of a crime to another, in hopes they will go along with the suggestion and be convicted of the crime. A political organization or government may use agents provocateurs against political opponents. The provocateurs try to incite the opponent to do counter-productive or ineffective acts to foster public disdain or provide a pretext for aggression against the opponent. Historically, labour spies, hired to infiltrate, monitor, disrupt, or subvert union activities, have used agent provocateur tactics. Agent provocateur activities raise ethical and legal issues. In common law jurisdictions, the legal concept of entrapment may apply if the main impetus for the crime was the provocateur.

Facilities Agent

Provides access to buildings, such as garages or offices used for staging operations, resupply, etc.

Principal Agent

Functions as a handler for an established network of agents, usually considered "blue chip."

Confusion Agent

In espionage, a confusion agent is an individual who is dispatched for the primary purpose of confounding the intelligence or counterintelligence apparatus of another country, rather than for the purpose of collecting and transmitting information. Such an individual may provide misleading information, among other confusion tactics.

Sleeper Agent

A sleeper agent is a spy who is placed in a target country or organization not to undertake an immediate mission but to act as a potential asset if activated. Even if unactivated, the "sleeper agent" is still an asset and is still playing an active role in sedition, treason or espionage by virtue of agreeing to act if activated. Sleeper agents are popular plot devices in fiction, particularly in espionage fiction and science fiction. This common use in fiction is directly related to and results from repeated instances of real-life "sleeper agents" participating in spying, espionage, sedition, treason, and assassinations.

There are sleeper agents, most being portrayed unrealistically in movies and books. In espionage, a sleeper agent is one who has infiltrated into the target country and has "gone to sleep", sometimes for many years. The agent does nothing to communicate with the sponsor or any existing agents or to obtain information beyond what is in public sources. The agent can also be referred to as a 'deep cover' agent. The agent acquires jobs and identities, ideally ones that will prove useful in the future, and attempts to blend into everyday life as a normal citizen. Counter-espionage agencies in the target country cannot, in practice, closely watch all those who might possibly have been recruited some time before. In a sense, the best sleeper agents are those who do not need to be paid by the sponsor, as they are able to earn enough money to finance themselves. That avoids any possibly traceable payments from abroad. In such cases, it is possible that the sleeper agent might be successful enough to become what is sometimes termed an "agent of influence". Sleeper agents who have been discovered have often been natives of the target country who moved elsewhere in early life and were co-opted (perhaps for ideological or ethnic reasons) before returning to the target country. That is valuable to the sponsor as the sleeper's language and other skills can be those of a 'native' and thus less likely to trigger suspicion. Choosing and inserting sleeper agents has often posed difficulties, as it is uncertain that the target will be appropriate some years in the future. If the sponsor government and its policies change after the sleeper has been inserted, the sleeper might be found to have been planted in the wrong target.

Illegal Agent

Double Agent

WARFARE Personnel Secret Agent

In the field of counterintelligence, a double agent (also double secret agent) is an employee of a secret intelligence service for one country, whose primary purpose is to spy on a target organization of another country, but who, in fact, has been discovered by the target organization and is now spying on their own country's organization for the target organization. Double agentry may be practiced by spies of the target organization who infiltrate the controlling organization or may result from the turning (switching sides) of previously loyal agents of the controlling organization by the target. The threat of execution is the most common method of turning a captured agent (working for an intelligence service) into a double agent (working for a foreign intelligence service) or a double agent into a re-doubled agent. It is unlike a defector, who is not considered an agent as agents are in place to function for an intelligence service and defectors are not, but some consider that defectors in place are agents until they have defected. Double agents are often used to transmit disinformation or to identify other agents as part of counter-espionage operations. They are often very trusted by the controlling organization since the target organization will give them true, but useless or even counterproductive, information to pass along.

WARFARE Personnel Secret Agents

Redoubled Agent

A re-doubled agent is an agent who gets caught as a double agent and is forced to mislead the foreign intelligence service. F.M. Begoum describes the redoubled agent as "one whose duplicity in doubling for another service has been detected by his original sponsor and who has been persuaded to reverse his affections again".

WARFARE Personnel Secret Agents

Unwitting Double Agent

Offers or is forced to recruit as a double or redoubled agent and in the process is recruited by either a third-party intelligence service or his own government without the knowledge of the intended target intelligence service or the agent. This can be useful in capturing important information from an agent that is attempting to seek allegiance with another country. The double agent usually has knowledge of both intelligence services and can identify operational techniques of both, thus making third-party recruitment difficult or impossible. The knowledge of operational techniques can also affect the relationship between the operations officer (or case officer) and the agent if the case is transferred by an operational targeting officer to a new operations officer, leaving the new officer vulnerable to attack. This type of transfer may occur when an officer has completed his term of service or when his cover is blown.

Triple Agent

A triple agent is a spy who pretends to be a double agent for one side, while he or she is truthfully a double agent for the other side. Unlike a re-doubled agent, who changes allegiance due to being compromised, a triple agent is usually considered to have always been loyal to their original side. It may also refer to a spy who works for three opposing sides, such that each side thinks the spy works for them alone.

WARFARE Hierarchy

2 Hierarchy

Military organization or military organisation is the structuring of the armed forces of a state so as to offer such military capability as a national defence policy may require. In some countries paramilitary forces are included in a nation's armed forces, though not considered military. Armed forces that are not a part of military or paramilitary organizations, such as insurgent forces, often mimic military organizations, or use ad hoc structures, while formal military organization tends to use hierarchical forms.

WARFARE Hierarchy Army Hierarchy

Army Hierarchy

The following table gives an overview of some of the terms used to describe army hierarchy in armed forces across the world. Whilst it is recognized that there are differences between armies of different nations, many are modelled on the British or American models, or both. However, many military units and formations go back in history for a long time, and were devised by various military thinkers throughout European history. For example, the modern Corps was first introduced in France about 1805 by Napoleon as a more flexible tactical grouping of two or more divisions during the Napoleonic Wars. They have become part of the organization of most armies around the world.

Symbol	Name	Nature	Strength	Constituent Units	Commander or Leader
XXXXXX	region, theatre	Command	1,000,000–10,000,000	4+ army groups	general, army general, five-star general or field marshal
XXXXX	army group, front	Command	400,000–1,000,000	2+ armies	general, army general, five-star general or field marshal
XXXX	army	Command	100,000–200,000	2–4 corps	general, army general, four-star general or colonel general
XXX	corps	Formation	20,000–50,000	2+ divisions	lieutenant general, corps general or three-star general
XX	division, legion	Formation	6,000–20,000	2–4 brigades or regiments	major general, divisional general or two-star general
X	brigade	Formation	3,000–5,000	2+ regiments, 3–6 battalions or Commonwealth regiments	brigadier, brigadier general, brigade general, or one-star general (sometimes colonel)
III	regiment or group	Unit	1,000–3,000	2+ battalions or U.S. Cavalry squadrons	colonel
II	battalion, U.S. Cavalry squadron, Commonwealth armoured regiment or Argentine Army regiment/artillery group/battalion, German Abteilung, artillery or cavalry division in some languages, cohort	Unit	300–1,000	2–6 companies, batteries, U.S. Cavalry troops, or Commonwealth squadrons, Argentine squadrons/companies	lieutenant colonel
I	infantry company, artillery battery, U.S. Cavalry troop, Commonwealth armour or combat engineering squadron or Argentine cavalry squadron or engineering company	Subunit	80–250	2–8 platoons or Commonwealth troops	chief warrant officer, captain or major
•••	platoon or Commonwealth troop	Sub-subunit	26–55	2+ Section, or vehicles	warrant officer, first or second lieutenant
••	section or patrol	-	12–24	1–2+ squads or 3–6 fireteams	sergeant or staff sergeant

•	squad or crew	-	8–12	2–3 fireteams or 1+ cell	corporal or sergeant
Ø	fireteam or cell	-	4-Mar	n/a	lance corporal to sergeant
Ø	fire and manoeuvre team	-	3-Feb	n/a	any/private first class

Rungs may be skipped in this ladder: for example, typically NATO forces skip from battalion to brigade. Likewise, only large military powers may have organizations at the top levels and different armies and countries may also use traditional names, creating considerable confusion: For example, a British or Canadian armoured regiment (battalion) is divided into squadrons (companies) and troops (platoons), whereas an American cavalry squadron (battalion) is divided into troops (companies) and platoons. Army, army group, region, and theatre are all large formations that vary significantly between armed forces in size and hierarchy position. While divisions were the traditional level at which support elements (field artillery, hospital, logistics and maintenance, etc.) were added to the unit structure, since World War II, many brigades now have such support units, and since the 1980s, regiments also have been receiving support elements.

A regiment with such support elements is called a regimental combat team in US military parlance, or a battle group in the UK and other forces. During World War II the Red Army used the same basic organizational structure. However, in the beginning many units were greatly underpowered and their size was actually one level below on the ladder that is usually used elsewhere; for example, a division in the early-WWII Red Army would have been about the size of most nations' regiments or brigades. At the top of the ladder, what other nations would call an army group, the Red Army called a front. By contrast, during the same period the German Wehrmacht Army Groups, particularly on the Eastern Front, such as Army Group Centre significantly exceeded the above numbers, and were more cognate with the Soviet Strategic Directions.

Naval Hierarchy

Naval organization at the flotilla level and higher is less commonly abided by, as ships operate in smaller or larger groups in various situations that may change at a moment's notice. However, there is some common terminology used throughout navies to communicate the general concept of how many vessels might be in a unit. Navies are generally organized into groups for a specific purpose, usually strategic, and these organizational groupings appear and disappear frequently based on the conditions and demands placed upon a navy. This contrasts with army organization where units remain static, with the same men and equipment, over long periods of time.

Unit Name	Vessel Types	No. of Vessels	Officer in Command
Navy or Admiralty	All vessels in a navy	2+ Fleets	Fleet Admiral, Admiral of the Fleet, Grand Admiral or Admiral
Fleet	All vessels in an ocean or general region	2+ Battle Fleets or Task Forces	Admiral or Vice Admiral
Battle Fleet or Task Force	A large number of vessels of all types	2+ Task Groups	Vice Admiral
Task Group	A collection of complementary vessels	2+ Task Units or Squadrons	Rear Admiral (upper half) or Rear Admiral
Squadron or Task Unit	Usually capital ships	A small number of vessels	Rear Admiral (lower half), Commodore, or Flotilla Admiral
Flotilla or Task Unit	Usually not capital ships	A small number of vessels, usually of the same or similar types	Rear Admiral (lower half), Commodore, or Flotilla Admiral
Task Element	A single vessel	One	Captain or Commander

The five-star ranks of Admiral of the Fleet and Fleet Admiral have largely been out of regular use since the 1990s, with the exception of ceremonial or honorary appointments. Currently, all major navies are commanded by an admiral (four-star rank) or vice-admiral (three-star rank) depending on relative size. Smaller naval forces, such as the RNZN, or those navies that are effectively coastguards, are commanded by a rear-admiral (two-star rank), commodore (one-star rank) or even a captain. Aircraft carriers are typically commanded by a captain. Submarines and destroyers are typically commanded by a captain or commander. Corvettes, the smallest class of warship, are commanded by officers with the rank of commander or lieutenant-commander.

Auxiliary ships, including gunboats, minesweepers, patrol boats, military riverine craft, tenders and torpedo boats are usually commanded by lieutenants, sub-lieutenants or warrant officers. Usually, the smaller the vessel, the lower the rank of the ship's commander. For example, patrol boats are often commanded by ensigns, while frigates are rarely commanded by an officer below the rank of commander. Historical navies were far more rigid in structure. Ships were collected in divisions, which in turn were collected in numbered squadrons, which comprised a numbered fleet. Permission for a vessel to leave one unit and join another would have to be approved on paper. The modern U.S. Navy is primarily based on a number of standard groupings of vessels, including the carrier strike group and the Expeditionary Strike Group. Additionally, Naval organization continues aboard a single ship. The complement forms three or four departments (such as tactical and engineering), each of which has a number of divisions, followed by work centres.

Air Force Hierarchy

The organizational structures of air forces vary between nations: some air forces (such as the United States Air Force and the Royal Air Force) are divided into commands, groups and squadrons; others (such as the Soviet Air Force) have an Army-style organizational structure. The modern Royal Canadian Air Force uses Air Division as the formation between wings and the entire air command. Like the RAF, Canadian wings consist of squadrons.

Symbol	Unit Name (USAF/RAF/Other Air Forces)	No. of Personnel	No. of Aircraft	No. of Subordinate Units (USAF/RAF)	Officer in Command (USAF/RAF)
XXXXXX +	Air Force	Entire air force	Entire air force	All Major Commands / Commands	GAF / MRAF or Air Chf Mshl
XXXXX	Major Command/Command or Tactical Air Force / Russian Air army	Varies	Varies	By Region or Duty (subordinate units varies)	Gen/Air Chf Mshl or Air Mshl
XX	Numbered Air Force/No RAF equivalent/Aviation Division /Air Division/Air Brigade	By Region (subordinate units varies)	Varies	2+ Wings/Groups	Maj-Gen or Lt-Gen / N/A
X	Wing/Group (inc. EAGs)/Russian aviation brigade	1,000–5,000	48–100	2+ Groups/Wings	Brig-Gen/AVM or Air Cdre
III	Group/Wing (inc. EAWs) or Station/Russian aviation regiment	300–1,000	17–48	3–4 Squadrons/3–10 Flights	Col/Gp Capt or Wg Cdr
II	Squadron	100–300	7–16	3–4 Flights	Lt Col or Maj/Wg Cdr or Sqn Ldr
•••	Flight	20–100	4–6	2 Sections plus maintenance and support crew	Capt/Sqn Ldr or Flt Lt
••	Element or Section	5–20	n/a–2	n/a	Junior Officer or Senior NCO

•	Detail	2–4	n/a	n/a	Junior NCO

Task Force

A task force is a unit or formation created as a temporary grouping for a specific operational purpose. Aside from administrative hierarchical forms of organization that have evolved since the early 17th century in Europe, fighting forces have been grouped for specific operational purposes into mission-related organizations such as the German Kampfgruppe or the U.S. Combat Team (Army) and Task Force (Navy) during the Second World War, or the Soviet Operational manoeuvre group during the Cold War. In the British and Commonwealth armies the battlegroup became the usual grouping of companies during the Second World War and the Cold War. Within NATO, a Joint Task Force (JTF) would be such a temporary grouping that includes elements from more than one armed service, a Combined Task Force (CTF) would be such a temporary grouping that includes elements from more than one nation, and a Combined Joint Task Force (CJTF) would be such a temporary grouping that includes elements of more than one armed service and more than one nation.

3 Land Materiel

Materiel, refers to supplies, equipment, and weapons in military supply chain management, and typically supplies and equipment only in a commercial supply chain context.

Armoured Fighting Vehicles

An armoured fighting vehicle (AFV) is an armed combat vehicle protected by armour, generally combining operational mobility with offensive and defensive capabilities. AFVs can be wheeled or tracked. Main battle tanks, armoured cars, armoured self-propelled guns, and armoured personnel carriers are all examples of AFVs. Armoured fighting vehicles are classified according to their intended role on the battlefield and characteristics. The classifications are not absolute; two countries may classify the same vehicle differently, and the criteria change over time. For example, relatively lightly armed armoured personnel carriers were largely superseded by infantry fighting vehicles with much heavier armament in a similar role. Successful designs are often adapted to a wide variety of applications. For example, the MOWAG Piranha, originally designed as an APC, has been adapted to fill numerous roles such as a mortar carrier, infantry fighting vehicle, and assault gun.

Tank

Tank Classifications
Over time, tanks tended to be designed with heavier armour and weapons, increasing the weight of all tanks, so these classifications are relative to the average for the nation's tanks for any given period. An older tank design might be reclassified over time, such as a tank being first deployed as a medium tank, but in later years relegated to light tank roles. Tanks were also classified by roles that were independent of size, such as cavalry tank, cruiser tank, fast tank, infantry tank, tank destroyer, "assault" tank, or "breakthrough" tank. Military theorists initially tended to assign tanks to traditional military infantry, cavalry, and artillery roles, but later developed more specialized roles unique to tanks. In modern use, the heavy tank has fallen out of favour, being supplanted by more heavily armed and armoured descendant of the medium tanks – the universal main battle tank. The light tank has, in many armies, lost favour to cheaper, faster, lighter armoured cars; however, light tanks (or similar vehicles with other names) are still in service with a number of forces as reconnaissance vehicles, most notably the Russian Marines with the PT-76, the British Army with the Scimitar, and the Chinese Army with the Type 63.

Light Tanks	Smaller tanks with thinner armour and lower-powered guns, allowing for better tactical mobility and ease of strategic transport. These are intended for armoured reconnaissance, skirmishing, artillery observation, expeditionary warfare and supplementing airborne or naval landings. Light tanks are typically cheaper to build and maintain, but fare poorly against heavier tanks. They may be held in reserve for exploiting any breakthroughs in enemy lines, with the goal of disrupting communications and supply lines.
Medium Tanks	Mid-sized tanks with adequate armour and guns, and fair mobility, allowing for a balance of fighting abilities, mobility, cost, and transportability.
Heavy Tanks	Larger tanks with thick armour and more powerful guns, but less mobile and more difficult to transport. They were intended to be more than a match for typical enemy medium tanks, easily penetrating their armour while being much less susceptible to their attacks. Heavy tanks cost more to both build and maintain.

Main Battle Tank
Modern main battle tanks or "universal tanks" incorporate recent advances in automotive, artillery, armour, and electronic technology to combine the best characteristics of the historic medium and heavy tanks into a single, all around type. They are also the most expensive to mass-produce. A main battle tank is distinguished by its high level of firepower, mobility and armour protection relative to other vehicles of its era. It can cross comparatively rough terrain at high speeds, but its heavy-dependency on fuel, maintenance, and ammunition makes it logistically demanding. It has the heaviest armour of any AFVs on the battlefield, and carries a powerful precision-guided munition weapon systems that may be able to engage a wide variety of both ground targets and air targets. Despite significant advances in anti-tank warfare, it still remains the most versatile and fearsome land-based weapon-systems of the 21st-century, valued for its shock action and high survivability.

Tankette
A tankette is a tracked armed and armoured vehicle resembling a small "ultra-light tank" or "super-light tank" roughly the size of a car, mainly intended for light infantry support or scouting. They were one or two-man vehicles armed with a machine gun. Colloquially it may also simply mean a "small tank". Tankettes were designed and built by several nations between the 1920s and 1940s. They were very popular with smaller countries. Some saw some combat (with limited success) in World War II. However, the vulnerability of their light armour eventually caused the concept to be abandoned.

Super-Heavy Tank
The term "super-heavy tank" has been used to describe armoured fighting vehicles of extreme size, generally over 75 tonnes. Programs have been initiated on several occasions with the aim of creating an invincible siegeworks/breakthrough vehicle for penetrating enemy formations and fortifications without fear of being destroyed in combat. Examples were designed in World War I and World War II (such as the Panzer VIII Maus), along with a few in the Cold War. However, few working prototypes were built and there are no clear evidence any of these vehicles saw combat, as their immense size would have made most designs impractical.

Flame Tank
A flame tank is an otherwise-standard tank equipped with a flamethrower, most commonly used to supplement combined arms attacks against fortifications, confined spaces, or other obstacles. The type only reached significant use in the Second World War, during which the United States, Soviet Union, Germany, Italy, Japan and the United Kingdom (including members of the British Commonwealth) all produced flamethrower-equipped tanks. Usually, the flame projector replaced one of the tank's machineguns, however, some flame projectors replaced the tank's main gun. Fuel for the flame weapon was generally carried inside the tank, although a few designs mounted the fuel externally, such as the armoured trailer used on the Churchill Crocodile. Flame tanks have been superseded by thermobaric weapons such as the Russian TOS-1.

WARFARE

Automated Fighting Vehicles

Tank

Infantry Tank
The idea for this tank was developed during World War I by British and French. The infantry tank was designed to work in concert with infantry in the assault, moving mostly at a walking pace, and carrying heavy armour to survive defensive fire. Its main purpose was to suppress enemy fire, crush obstacles such as barbed-wire entanglements, and protect the infantry on their advance into and through enemy lines by giving mobile overwatch and cover. The French Renault FT was the first iteration of this concept. The British and French retained the concept between the wars and into the Second World War era. Because infantry tanks did not need to be fast, they could carry heavy armour. One of the best-known infantry tanks was the Matilda II of World War II. Other examples include the French R-35, the British Valentine, and the British Churchill.

Cruiser Tank
A cruiser tank, or cavalry tank, was designed to move fast and exploit penetrations of the enemy front. The idea originated in "Plan 1919", a British plan to break the trench deadlock of World War I in part via the use of high-speed tanks. The first cruiser tank was the British Whippet. Between the wars, this concept was implemented in the "fast tanks" pioneered by J. Walter Christie. These led to the Soviet BT tank series and the British cruiser tank series. During World War II, British cruiser tanks were designed to complement infantry tanks, exploiting gains made by the latter to attack and disrupt the enemy rear areas. In order to give them the required speed, cruiser designs sacrificed armour and armament compared to the infantry tanks. Pure British cruisers were generally replaced by more capable medium tanks such as the US Sherman and, to a lesser extent, the Cromwell by 1943. The Soviet fast tank (bistrokhodniy tank, or BT tank) classification also came out of the infantry/cavalry concept of armoured warfare and formed the basis for the British cruisers after 1936. The T-34 was a development of this line of tanks as well, though their armament, armour, and all-round capability places them firmly in the medium tank category.

Armoured Car

The armoured car is a wheeled, often lightly armoured, vehicle adapted as a fighting machine. Its earliest form consisted of a motorised ironside chassis fitted with firing ports. By World War I, this had evolved into a mobile fortress equipped with command equipment, searchlights, and machine guns for self-defence. It was soon proposed that the requirements for the armament and layout of armoured cars be somewhat similar to those on naval craft, resulting in turreted vehicles. The first example carried a single revolving cupola with a Vickers gun; modern armoured cars may boast heavier armament – ranging from twin machine guns to large calibre cannon. Some multi-axled wheeled fighting vehicles can be quite heavy, and superior to older or smaller tanks in terms of armour and armament. Others are often used in military marches and processions, or for the escorting of important figures. Under peacetime conditions, they form an essential part of most standing armies. Armoured car units can move without the assistance of transporters and cover great distances with fewer logistical problems than tracked vehicles. During World War II, armoured cars were used for reconnaissance alongside scout cars. Their guns were suitable for some defence if they encountered enemy armoured vehicles, but they were not intended to engage enemy tanks. Armoured cars have since been used in the offensive role against tanks with varying degrees of success, most notably during the South African Border War, Toyota War, the Invasion of Kuwait, and other lower-intensity conflicts.

Aerosani
An aerosani is a type of propeller-driven snowmobile, running on skis, used for communications, mail deliveries, medical aid, emergency recovery and border patrolling in northern Russia, as well as for recreation. Aerosanis were used by the Soviet Red Army during the Winter War and World War II. The first aerosanis may have been built by young Igor Sikorsky in 1909–10, before he built multi-engine airplanes and helicopters. They were very light plywood vehicles on skis, propelled by old airplane engines and propellers.

Scout Car
A scout car is a military armoured reconnaissance vehicle, capable of off-road mobility and often carrying mounted weapons such as machine guns for offensive capabilities and crew protection. They often only carry an operational crew aboard, which differentiates them from wheeled armoured personnel carriers (APCs) and Infantry Mobility Vehicles (IMVs), but early scout cars, such as the open-topped US M3 Scout Car could carry a crew of seven. The term is often used synonymously with the more general term armoured car, which also includes armoured civilian vehicles. They are also differentiated by being designed and built for purpose, as opposed to improvised "technicals" which might serve in the same role.

Reconnaissance Vehicle
A reconnaissance vehicle, also known as a scout vehicle, is a military vehicle used for forward reconnaissance. Both tracked and wheeled reconnaissance vehicles are in service. In some nations, light tanks such as the M551 Sheridan and AMX-13 are also used by scout platoons. Reconnaissance vehicles are usually designed with a low profile or small size and are lightly armoured, relying on speed and cover to escape detection. Their armament ranges from a medium machine gun to a large cannon. Modern examples are often fitted with ATGMs and a wide range of sensors. Some armoured personnel carriers and infantry mobility vehicle, such as the M113, TPz Fuchs, and Cadillac Gage Commando double in the reconnaissance role.

Internal Security Vehicle
An internal security vehicle (ISV), also known as an armoured security vehicle (ASV), is a combat vehicle used for suppressing civilian unrest. Security vehicles are typically armed with a turreted heavy machine gun and auxiliary medium machine gun. The vehicle is designed to minimize firepower dead space and the vehicles weapons can be depressed to a maximum of 12°. Non-lethal water cannons and tear gas cannons can provide suppressive fire in lieu of unnecessary deadly fire. The vehicle must be protected against weapons typical of riots. Protection from incendiary devices is achieved though coverage of the air intake and exhaust ports as well as a strong locking mechanism on the fuel opening. Turret and door locks prevent access to the interior of the vehicle by rioters. Vision blocks, ballistic glass and window shutters and outside surveillance cameras allow protected observation from within the vehicle. Wheeled 4x4 and 6x6 configurations are typical of security vehicles. Tracked security vehicles are often cumbersome and leave negative political connotations for being perceived as an imperial invading force.

Improvised Fighting Vehicle
An improvised fighting vehicle is a combat vehicle resulting from modifications to a civilian or military non-combat vehicle in order to give it a fighting capability. Such modifications usually consist of the grafting of armour plating and weapon systems. Various militaries have procured such vehicles, ever since the introduction of the first automobiles into military service. During the early days, the absence of a doctrine for the military use of automobiles or of an industry dedicated to producing them, lead to much improvisation in the creation of early armoured cars, and other such vehicles. Later, despite the advent of arms industries in many countries, several armies still resorted to using ad hoc contraptions, often in response to unexpected military situations, or as a result of the development of new tactics for which no available vehicle was suitable. The construction of improvised fighting vehicles may also reflect a lack of means for the force that uses them. This is especially true in developing countries, where various armies and guerrilla forces have used them, as they are more affordable than military-grade combat vehicles. Modern examples include military gun truck used by units of regular armies or other official government armed forces, based on a conventional cargo truck, that is able to carry a large weight of weapons and armour. They have mainly been used by regular armies to escort military convoys in regions subject to ambush by guerrilla forces. "Narco tanks", used by Mexican drug cartels in the Mexican Drug War, are built from such trucks, which combines operational mobility, tactical offensive, and defensive capabilities.

Troop Carriers (APC)

Troop-carrying AFVs are divided into three main types – armoured personnel carriers (APCs), infantry fighting vehicles (IFVs) and infantry mobility vehicles (IMV). The main difference between the three is their intended role – the APC is designed purely to transport troops and is armed for self-defence only – whereas the IFV is designed to provide close-quarters and anti-armour fire support to the infantry it carries. IMV is a wheeled armoured personnel carrier serving as a military patrol, reconnaissance or security vehicle.

Armoured Personnel Carrier
Armoured personnel carriers (APCs) are intended to carry infantry quickly and relatively safely to the point where they are deployed. In the Battle of Amiens, 8 August 1918, the British Mk V* (Mark Five Star) tank carried a small number of machine gunners as an experiment, but the men were debilitated by the conditions inside the vehicle. Later that year the first purpose-built APC, the British Mk IX (Mark Nine), appeared. In 1944, the Canadian general Guy Simonds ordered the conversion of redundant armoured vehicles to carry troops (generically named "Kangaroos"). This proved highly successful, even without training, and the concept was widely used in the 21st Army Group. Post-war, specialised designs were built, such as the Soviet BTR-60 and US M113.

WARFARE Automated Fighting Vehicles Troop Carriers (APC)

Infantry Fighting Vehicle
An infantry fighting vehicle (IFV), also known as a mechanized infantry combat vehicle (MICV), is a type of armoured fighting vehicle used to carry infantry into battle and provide direct fire support. The first example of an IFV was the West German Schützenpanzer Lang HS.30 which served in the Bundeswehr from 1958 until the early 1980s. IFVs are similar to armoured personnel carriers (APCs) and infantry carrier vehicles (ICVs), designed to transport a section or squad of infantry (generally between five and ten men) and their equipment. They are differentiated from APCs— which are purely "troop-transport" vehicles armed only for self-defence— because they are designed to give direct fire support to the dismounted infantry and so usually have significantly enhanced armament. IFVs also often have improved armour and some have firing ports (allowing the infantry to fire personal weapons while mounted). They are typically armed with an autocannon of 20 to 40 mm calibre, 7.62mm machine guns, anti-tank missiles (ATGMs) and/or surface-to-air missiles (SAMs). IFVs are usually tracked, but some wheeled vehicles fall into this category. IFVs are generally less heavily armed and armoured than main battle tanks. They sometimes carry anti-tank missiles to protect and support infantry against armoured threats, such as the NATO TOW missile and Soviet Bastion, which offer a significant threat to tanks. Specially equipped IFVs have taken on some of the roles of light tanks; they are used by reconnaissance organizations, and light IFVs are used by airborne units which must be able to fight without the heavy firepower of tanks.

Infantry Mobility Vehicle
An infantry mobility vehicle (IMV) or protected patrol vehicle (PPV) is a wheeled armoured personnel carrier (APC) serving as a military patrol, reconnaissance or security vehicle. Examples include the ATF Dingo, AMZ Dzik, AMZ Tur, Mungo ESK, and Bushmaster IMV. This term also applies to the vehicles currently being fielded as part of the MRAP program. IMVs were developed in response to the threats of modern counter insurgency warfare, with an emphasis on Ambush Protection and Mine-Resistance. Similar vehicles existed long before the term IMV was coined, such as the French VAB and South African Buffel. The term is coming more into use to differentiate light 4x4 wheeled APCs from the traditional 8x8 wheeled APCs. It is a neologism for what might have been classified in the past as an armoured scout car, such as the BRDM, but the IMV is distinguished by having a requirement to carry dismountable infantry. The up-armoured M1114 Humvee variant can be seen as an adaptation of the unarmoured Humvee to serve in the IMV role.

WARFARE Automated Fighting Vehicles Amphibious Vehicles

Amphibious Vehicles

Many modern military vehicles, ranging from light wheeled command and reconnaissance, through armoured personnel carriers and tanks, are manufactured with amphibious capabilities. Contemporary wheeled armoured amphibians include the French Véhicule de l'Avant Blindé and Véhicule Blindé Léger. The latter is a small, lightly armoured 4x4 all-terrain vehicle that is fully amphibious and can swim at 5.4 km/h. The VAB (Véhicule de l'Avant Blindé - "Armoured Vanguard Vehicle") is a fully amphibious armoured personnel carrier powered in the water by two water jets, that entered service in 1976 and produced in numerous configurations, ranging from basic personnel carrier, anti-tank missile platform. During the Cold War the Soviet bloc states developed a number of amphibious APCs, fighting vehicles and tanks, both wheeled and tracked. Most of the vehicles the Soviets designed were amphibious, or could ford deep water. Wheeled examples are the BRDM-1 and BRDM-2 4x4 armoured scout cars, as well as the BTR-60, BTR-70, BTR-80 and BTR-94 8x8 armoured personnel carriers and the BTR-90 infantry fighting vehicle.

The US Marine Corps currently uses the AAV7-A1 Assault Amphibious Vehicle, which was to be succeeded by the Expeditionary Fighting Vehicle, which was capable of planing on water and can achieve water speeds of 37–46 km/h. The EFV project has been cancelled. A significant amount of tracked armoured vehicles that are primarily intended for land-use, have some amphibious cability, tactically useful inland, reducing dependence on bridges. They use their tracks, sometimes with added propeller or water jets for propulsion. As long as the banks have a shallow enough slopes to enter or leave the water they can cross rivers and water obstacles. Some heavy tanks can operate amphibiously with a fabric skirt to add buoyancy. The Sherman DD tank used in the Normandy landings had this setup. When in water the waterproof float screen was raised and propellers deployed. Some modern vehicles use a similar skirt.

WARFARE Automated Fighting Vehicles Armoured Engineering Vehicle

Armoured Engineering Vehicle

Modern engineering AFV's utilize chassis based on main battle tank platforms: these vehicles are as well armoured and protected as tanks, designed to keep up tanks, conduct obstacle breaching operations to help tanks get to wherever it needs to be, perform utility functions necessary to expedite mission objectives of tanks, and to conduct other earth-moving and engineering work on the battlefield. These vehicles go by different names depending upon the country of use or manufacture. In the United States the term "combat engineer vehicle (CEV)" is used, in the United Kingdom the term "Armoured Vehicle Royal Engineers (AVRE)" is used, while in Canada and other commonwealth nations the term "armoured engineer vehicle (AEV)" is used. There is no set template for what such a vehicle will look like, yet likely features include a large dozer blade or mine ploughs, a large calibre demolition cannon, augers, winches, excavator arms and cranes, or lifting booms. Although the term "armoured engineer vehicle" is used specifically to describe these multi-purpose tank-based engineering vehicles, that term is also used more generically in British and Commonwealth militaries to describe all heavy tank-based engineering vehicles used in the support of mechanized forces. Thus, "armoured engineer vehicle" used generically would refer to AEV, AVLB, Assault Breachers, and so on. Good examples of this type of vehicle include the UK Trojan AVRE, the Russian IMR, and the US M728 Combat Engineer Vehicle.

Breaching Vehicle
A breaching vehicle is especially designed to clear pathways for troops and other vehicles through minefields and along roadside bombs and Improvised Explosive Devices. These vehicles are equipped with mechanical or other means for the breaching of man made obstacles. Common types of breaching vehicles include mechanical flails, mine plough vehicles, and mine roller vehicles.

Armoured Bulldozer
The armoured bulldozer is a basic tool of combat engineering. These combat engineering vehicles combine the earth moving capabilities of the bulldozer with armour which protects the vehicle and its operator in or near combat. Most are civilian bulldozers modified by addition of vehicle armour/military equipment, but some are tanks stripped of armament and fitted with a dozer blade. Some tanks have bulldozer blades while retaining their armament, but this does not make them armoured bulldozers as such, because combat remains the primary role – earth moving is a secondary task.

Armoured Recovery Vehicle
An armoured recovery vehicle (ARV) is a type of vehicle recovery armoured fighting vehicle used to repair battle- or mine-damaged as well as broken-down armoured vehicles during combat, or to tow them out of the danger zone for more extensive repairs. To this end the term "Armoured Repair and Recovery Vehicle" (ARRV) is also used. ARVs are normally built on the chassis of a main battle tank (MBT), but some are also constructed on the basis of other armoured fighting vehicles, mostly armoured personnel carriers (APCs). ARVs are usually built on the basis of a vehicle in the same class as they are supposed to recover; a tank-based ARV is used to recover tanks, while an APC-based one recovers APCs, but does not have the power to tow a much heavier tank.

Armoured Vehicle-Launched Bridge
An armoured vehicle-launched bridge (AVLB) is a combat support vehicle, sometimes regarded as a subtype of combat engineering vehicle, designed to assist militaries in rapidly deploying tanks and other armoured fighting vehicles across rivers. The AVLB is usually a tracked vehicle converted from a tank chassis to carry a folding metal bridge instead of weapons. The AVLB's job is to allow armoured or infantry units to cross water, when a river too deep for vehicles to wade through is reached, and no bridge is conveniently located (or sufficiently sturdy, a substantial concern when moving 60-ton tanks). The bridge layer unfolds and launches its cargo, providing a ready-made bridge across the obstacle in only minutes. Once the span has been put in place, the AVLB vehicle detaches from the bridge, and moves aside to allow traffic to pass. Once all of the vehicles have crossed, it crosses the bridge itself and reattaches to the bridge on the other side. It then retracts the span ready to move off again. A similar procedure can be employed to allow crossings of small chasms or similar obstructions. AVLBs can carry bridges of 60 feet (18 metres) or greater in length. By using a tank chassis, the bridge layer is able to cover the same terrain as main battle tanks, and the provision of armour allows them to operate even in the face of enemy fire. However, this is not a universal attribute: some exceptionally sturdy 6x6 or 8x8 truck chassis have lent themselves to bridge-layer applications.

Combat Engineer Section Carriers
The combat engineer section carriers are used to transport sappers (combat engineers) and can be fitted with a bulldozer's blade and other mine-breaching devices. They are often used as APCs because of their carrying ability and heavy protection. They are usually armed with machine guns and grenade launchers and usually tracked to provide enough tractive force to push blades and rakes. Some examples are the U.S. M113 APC, IDF Puma, Nagmachon, Husky, and U.S. M1132 ESV (a Stryker variant).

Air Defence Vehicles

An anti-aircraft vehicle, also known as a self-propelled anti-aircraft weapon (SPAA) or self-propelled air defence system (SPAD), is a mobile vehicle with a dedicated anti-aircraft capability. The Russian equivalent of SPAAG is ZSU (from zenitnaya samokhodnaya ustanovka – "anti-aircraft self-propelled mount"). Specific weapon systems used include machine guns, autocannons, larger guns, or missiles, and some mount both guns and longer-ranged missiles. Platforms used include both trucks and heavier combat vehicles, such as APCs and tanks, which add protection from aircraft, artillery, and small arms fire for front line deployment. Anti-aircraft guns are usually mounted in a quickly traversing turret with a high rate of elevation, for tracking fast-moving aircraft. They are often in dual or quadruple mounts, allowing a high rate of fire. Today, missiles (generally mounted on similar turrets) have largely supplanted anti-aircraft guns.

Self-Propelled Artillery

Self-propelled artillery vehicles give mobility to artillery. Within the term are covered self-propelled guns (or howitzers) and rocket artillery. They are highly mobile, usually based on tracked chassis carrying either a large howitzer or other field gun or alternatively a mortar or some form of rocket or missile launcher. They are usually used for long-range indirect bombardment support on the battlefield. In the past, self-propelled artillery has included direct-fire "Gun Motor Carriage" vehicles, such as assault guns and tank destroyers (also known as self-propelled anti-tank guns).

These have been heavily armoured vehicles, the former providing danger-close fire-support for infantry and the latter acting as specialized anti-tank vehicles. Modern self-propelled artillery vehicles may superficially resemble tanks, but they are generally lightly armoured, too lightly to survive in direct-fire combat. However, they protect their crews against shrapnel and small arms and are therefore usually included as armoured fighting vehicles. Many are equipped with machine guns for defence against enemy infantry. The key advantage of self-propelled over towed artillery is that it can be brought into action much faster. Before towed artillery can be used, it has to stop, unlimber and the guns set up.

To move position, the guns must be limbered up again and brought — usually towed — to the new location. By comparison, self-propelled artillery in combination with modern communications, can stop at a chosen location and begin firing almost immediately, then quickly move on to a new position. This ability is very useful in a mobile conflict and particularly on the advance. Conversely, towed artillery was and remains cheaper to build and maintain. It is also lighter and can be taken to places that self-propelled guns cannot reach, so despite the advantages of the self-propelled artillery, towed guns remain in the arsenals of many modern armies.

Assault Gun
An assault gun is a gun or howitzer mounted on a motor vehicle or armoured chassis, designed for use in the direct fire role in support of infantry when attacking other infantry or fortified positions. Historically, the custom-built fully armoured assault guns usually mounted the gun or howitzer in a fully enclosed casemate on a tank chassis. The use of a casemate instead of a gun turret limited these weapons' field of fire, but allowed a larger gun to be fitted relative to the chassis, more armour to be fitted for the same weight, and provided a cheaper construction. In most cases, these turretless vehicles also presented a lower profile as a target for the enemy.

Mortar Carrier
A mortar carrier is a self-propelled artillery vehicle carrying a mortar as its primary weapon. Mortar carriers cannot be fired while on the move and some must be dismounted to fire. In U.S. Army doctrine, mortar carriers provide close and immediate indirect fire support for manoeuvre units while allowing for rapid displacement and quick reaction to the tactical situation. The ability to relocate not only allows fire support to be provided where it is needed faster, but also allows these units to avoid counter-battery fire. Mortar carriers have traditionally avoided direct contact with the enemy. Many units report never using secondary weapons in combat. Prior to the Iraq War, American 120 mm mortar platoons reorganized from six M1064 mortar carriers and two M577 fire direction centres (FDC) to four M1064 and one FDC. The urban environment of Iraq made it difficult to utilize mortars. New technologies such as mortar ballistic computers and communication equipment and are being integrated. Modern era combat is becoming more reliant on direct fire support from mortar carrier machine guns.

Multiple Rocket Launcher
A multiple rocket launcher is a type of unguided rocket artillery system. Like other rocket artillery, multiple rocket launchers are less accurate and have a much lower (sustained) rate of fire than batteries of traditional artillery guns. However, they have the capability of simultaneously dropping many hundreds of kilograms of explosive, with devastating effect. The Korean Hwacha is an example of an early weapon system with a resemblance to the modern-day multiple rocket launcher. The first modern multiple rocket launcher was the German Nebelwerfer of the 1930s, a small towed artillery piece. Only later in World War II did the Allies deploy similar weapons in the form of the Land Mattress. The first self-propelled multiple rocket launchers – and arguably the most famous – were the Soviet BM-13 Katyushas, first used during World War II and exported to Soviet allies afterwards. They were simple systems in which a rack of launch rails was mounted on the back of a truck. This set the template for modern multiple rocket launchers. The Americans mounted tubular launchers atop M4 Sherman tanks to create the T34 Calliope rocket launching tank, only used in small numbers, as their closest equivalent to the Katyusha.

Tank Destroyer
Tank destroyers and tank hunters are armed with an anti-tank gun or missile launcher, and are designed specifically to engage enemy armoured vehicles. Many have been based on a tracked tank chassis, while others are wheeled. Since World War II, main battle tanks have largely replaced gun-armed tank destroyers; although lightly armoured anti tank guided missile (ATGM) carriers are commonly used for supplementary long-range anti-tank engagements.

In post-Cold War conflict, the resurgence of expeditionary warfare has seen the emergence of gun-armed wheeled vehicles, sometimes called "protected gun systems", which may bear a superficial resemblance to tank destroyers, but are employed as direct fire support units typically providing support in low intensity operations such as Iraq and Afghanistan. These have the advantage of easier deployment, as only the largest air transports can carry a main battle tank, and their smaller size makes them more effective in urban combat. Many forces' IFVs carry anti-tank missiles in every infantry platoon, and attack helicopters have also added anti-tank capability to the modern battlefield.

But there are still dedicated anti-tank vehicles with very heavy long-range missiles, or intended for airborne use. There have also been dedicated anti-tank vehicles built on ordinary armoured personnel carrier or armoured car chassis. Examples include the U.S. M901 ITV (Improved TOW Vehicle) and the Norwegian NM142, both on an M113 chassis, several Soviet ATGM launchers based on the BRDM reconnaissance car, the British FV438 Swingfire and FV102 Striker and the German Raketenjagdpanzer series built on the chassis of the HS 30 and Marder IFV.

Armoured Train

An armoured train is a railway train protected with armour. Armoured trains usually include railroad cars armed with artillery and machine guns. They were mostly used during the late 19th and early 20th century, when they offered an innovative way to quickly move large amounts of firepower. Most countries discontinued their use – road vehicles became much more powerful and offered more flexibility, and train tracks proved too vulnerable to sabotage as well as to attacks from the air. However, the Russian Federation used improvised armoured trains in the Second Chechen War of 1999–2009.

Carriage Roles

Artillery	Fielding a mixture of guns, machine guns and rocket launchers. See also railway guns.

Infantry	Designed to carry infantry units, may also mount machine guns.
Machine Gun	Dedicated to machine guns.
Anti-Aircraft	Equipped with anti-aircraft weapons.
Command	Similar to infantry wagons, but designed to be a train command centre.
Anti-Tank	Equipped with anti-tank guns, usually in a tank gun turret.
Platform	Unarmoured, used for any purpose from the transport of ammunition or vehicles, through track repair or derailing protection to railroad ploughs for track destruction.
Troop Sleepers	A railroad passenger car which had been constructed to serve as something of a mobile barracks (essentially, a sleeping car) for transporting troops over distances sufficient to require overnight accommodations.
Tank Transport	A light tank on a flatbed car which could be quickly offloaded by means of a ramp and used away from the range of the main railway line to chase down enemy partisans.
Missile Transport	The USSR had railway-based RT-23 Molodets ICBMs by the late 1980s (to reduce the chances of a first strike succeeding in destroying the launchers for a retaliatory strike). The US at one time proposed having a railway-based system for the MX Missile program but this never got past the planning stage.

Design
Different types of armour were used to protect from attack by tanks. In addition to various metal plates, concrete and sandbags were used in some cases for improvised armoured trains. Armoured trains were sometimes escorted by a kind of rail-tank called a draisine. One such example was the 'Littorina' armoured trolley which had a cab in the front and rear, each with a control set so it could be driven down the tracks in either direction. Littorina mounted two dual 7.92mm MG13 machine gun turrets from Panzer I light tanks.

Reconnaissance Vehicles

A reconnaissance vehicle, also known as a scout vehicle, is a military vehicle used for forward reconnaissance. Both tracked and wheeled reconnaissance vehicles are in service. In some nations, light tanks such as the M551 Sheridan and AMX-13 have also been used by scout platoons. Reconnaissance vehicles are usually designed with a low profile or small size and are lightly armoured, relying on speed and cover to escape detection. Their armament ranges from a medium machine gun to a large cannon. Modern examples are often fitted with ATGMs and a wide range of sensors.

Role
Reconnaissance of enemy positions can involve firing upon the enemy in hopes of receiving return fire that gives away the enemy's position. This can make the reconnaissance vehicle vulnerable to return fire that may destroy the vehicle before the enemy's position can be relayed. Dismounted operations by armed scouts include observation post manning, reconnaissance of areas not traversable by vehicle, and marking enemy mine fields. CBRN reconnaissance vehicles can also detect weapons of mass destruction. They accompany regular reconnaissance vehicles and are fully protected against airborne threats.

Military Engineering Vehicles

A military engineering vehicle is a vehicle built for the construction work or for the transportation of combat engineers on the battlefield. These vehicles may be modified civilian equipment or purpose-built military vehicles.

Civilian and Militarized Heavy Equipment

Military engineering can employ a wide variety of heavy equipment in the same or similar ways to how this equipment is used outside the military. Bulldozers, cranes, graders, excavators, dump trucks, loaders, and backhoes all see extensive use by military engineers. Military engineers may also use civilian heavy equipment which was modified for military applications. Typically, this involves adding armour for protection from battlefield hazards such as artillery, unexploded ordnance, mines, and small arms fire. Often this protection is provided by armour plates and steel jackets. Some examples of armoured civilian heavy equipment are the IDF Caterpillar D9, American D7 TPK, Canadian D6 armoured bulldozer, cranes, graders, excavators, and M35 2-1/2 ton cargo truck. Militarized heavy equipment may also take on the form of traditional civilian equipment designed and built to unique military specifications. These vehicles typically sacrifice some depth of capability from civilian models in order to gain greater speed and independence from prime movers. Examples of this type of vehicle include high speed backhoes such as the Australian Army's High Mobility Engineering Vehicle (HMEV) from Thales or the Canadian Army's Multi-Purpose Engineer Vehicle (MPEV) from Arva.

Armoured Engineering Vehicle

Typically based on the platform of a main battle tank, these vehicles go by different names depending upon the country of use or manufacture. In the US the term "combat engineer vehicle (CEV)" is used, in the UK the term "Armoured Vehicle Royal Engineers (AVRE)" is used, while in Canada and other commonwealth nations the term "armoured engineer vehicle (AEV)" is used. There is no set template for what such a vehicle will look like, yet likely features include a large dozer blade or mine ploughs, a large calibre demolition cannon, augers, winches, excavator arms and cranes or lifting booms. These vehicles are designed to directly conduct obstacle breaching operations and to conduct other earth-moving and engineering work on the battlefield. Good examples of this type of vehicle include the UK Trojan AVRE, the Russian IMR, and the US M728 Combat Engineer Vehicle. Although the term "armoured engineer vehicle" is used specifically to describe these multi-purpose tank based engineering vehicles, that term is also used more generically in British and Commonwealth militaries to describe all heavy tank based engineering vehicles used in the support of mechanized forces. Thus, "armoured engineer vehicle" used generically would refer to AEV, AVLB, Assault Breachers, and so on.

Armoured Earth Mover

Lighter and less multi-functional than the CEVs or AEVs described above, these vehicles are designed to conduct earth-moving work on the battlefield. These vehicles have greater high speed mobility than traditional heavy equipment and are protected against the effects of blast and fragmentation. Good examples are the American M9 ACE and the UK FV180 Combat Engineer Tractor.

Breaching Vehicle

These vehicles are equipped with mechanical or other means for the breaching of man made obstacles. Common types of breaching vehicles include mechanical flails, mine plough vehicles, and mine roller vehicles. In some cases, these vehicles will also mount Mine-clearing line charges. Breaching vehicles may be either converted armoured fighting vehicles or purpose built vehicles. In larger militaries, converted AFV are likely to be used as assault breachers while the breached obstacle is still covered by enemy observation and fire, and then purpose built breaching vehicles will create additional lanes for following forces. Good examples of breaching vehicles include the USMC M1 Assault Breacher Vehicle, the UK Aardvark JSFU, and the Singaporean Trailblazer.

WARFARE

Military Engineering Vehicles

Bridging Vehicles

Several types of military bridging vehicles have been developed. An armoured vehicle-launched bridge (AVLB) is typically a modified tank hull converted to carry a bridge into battle in order to support crossing ditches, small waterways, or other gap obstacles. Another type of bridging vehicle is the truck launched bridge. The Soviet TMM bridging truck could carry and launch a 10-meter bridge that could be daisy-chained with other TMM bridges to cross larger obstacles. More recent developments have seen the conversion of AVLB and truck launched bridge with launching systems that can be mounted on either tank or truck for bridges that are capable of supporting heavy main battle tanks. Earlier examples of bridging vehicles include a type in which a converted tank hull is the bridge. On these vehicles, the hull deck comprises the main portion of the tread way while ramps extend from the front and rear of the vehicle to allow other vehicles to climb over the bridging vehicle and cross obstacles. An example of this type of armoured bridging vehicle was the Churchill Ark used in the Second World War.

Combat Engineer Section Carriers

Another type of CEVs are armoured fighting vehicles which are used to transport sappers (combat engineers) and can be fitted with a bulldozer's blade and other mine-breaching devices. They are often used as APCs because of their carrying ability and heavy protection. They are usually armed with machine guns and grenade launchers and usually tracked to provide enough tractive force to push blades and rakes. Some examples are the U.S. M113 APC, IDF Puma, Nagmachon, Husky, and U.S. M1132 ESV (a Stryker variant).

Military Ferries and Amphibious Crossing Vehicles

One of the major tasks of military engineering is crossing major rivers. Several military engineering vehicles have been developed in various nations to achieve this task. One of the more common types is the amphibious ferry such as the M3 Amphibious Rig. These vehicles are self-propelled on land, they can transform into raft type ferries when in the water, and often multiple vehicles can connect to form larger rafts or floating bridges. Other types of military ferries, such as the Soviet Plavayushij Transportyor - Srednyj, are able to load while still on land and transport other vehicles cross country and over water. In addition to amphibious crossing vehicles, military engineers may also employ several types of boats. Military assault boats are small boats propelled by oars or an outboard motor and used to ferry dismounted infantry across water.

Anti-Aircraft

Anti-aircraft warfare or counter-air defence is defined by NATO as "all measures designed to nullify or reduce the effectiveness of hostile air action". They include surface based, subsurface (submarine launched), and air-based weapon systems, associated sensor systems, command and control arrangements and passive measures (e.g. barrage balloons). It may be used to protect naval, ground, and air forces in any location. However, for most countries the main effort has tended to be 'homeland defence'. NATO refers to airborne air defence as counter-air and naval air defence as anti-aircraft warfare. Missile defence is an extension of air defence as are initiatives to adapt air defence to the task of intercepting any projectile in flight. In some countries, such as Britain and Germany during the Second World War, the Soviet Union, NATO, and the United States, ground-based air defence and air defence aircraft have been under integrated command and control. However, while overall air defence may be for homeland defence including military facilities, forces in the field, wherever they are, invariably deploy their own air defence capability if there is an air threat. A surface-based air defence capability can also be deployed offensively to deny the use of airspace to an opponent. Until the 1950s, guns firing ballistic munitions ranging from 7.62 mm to 152.4 mm were the standard weapons; guided missiles then became dominant, except at the very shortest ranges (as with close-in weapon systems, which typically use rotary autocannons or, in very modern systems, surface-to-air adaptations of short range air-to-air missiles).

Artillery

Artillery is a class of heavy military weapons built to fire munitions far beyond the range and power of infantry's small arms. Early artillery development focused on the ability to breach defensive walls, and fortifications, and led to heavy, fairly immobile siege engines. As technology improved, lighter, more mobile field artillery developed for battlefield use. This development continues today; modern self-propelled artillery vehicles are highly mobile weapons of great versatility providing the largest share of an army's total firepower. In its earliest sense, the word artillery referred to any group of soldiers primarily armed with some form of manufactured weapon or armour. Since the introduction of gunpowder and cannon, the word "artillery" has largely meant cannon, and in contemporary usage, it usually refers to shell-firing guns, howitzers, mortars, rockets and guided missiles. In common speech, the word artillery is often used to refer to individual devices, along with their accessories and fittings, although these assemblages are more properly called "equipments". However, there is no generally recognised generic term for a gun, howitzer, mortar, and so forth: the United States uses "artillery piece", but most English-speaking armies use "gun" and "mortar". The projectiles fired are typically either "shot" (if solid) or "shell" (if not). "Shell" is a widely used generic term for a projectile, which is a component of munitions. By association, artillery may also refer to the arm of service that customarily operates such engines. In some armies one arm has operated field, coastal, anti-aircraft artillery and anti-tank artillery, in others these have been separate arms and in some nations coastal has been a naval or marine responsibility.

Artillery

In the 20th century technology based target acquisition devices, such as radar, and systems, such as sound ranging and flash spotting, emerged to acquire targets, primarily for artillery. These are usually operated by one or more of the artillery arms. The widespread adoption of indirect fire in the early 20th century introduced the need for specialist data for field artillery, notably survey and meteorological, in some armies provision of these are the responsibility of the artillery arm. Artillery originated for use against ground targets—against infantry, cavalry and other artillery. An early specialist development was coastal artillery for use against enemy ships. The early 20th century saw the development of a new class of artillery for use against aircraft: anti-aircraft guns. Artillery is arguably the most lethal form of land-based armament currently employed, and has been since at least the early Industrial Revolution. The majority of combat deaths in the Napoleonic Wars, World War I, and World War II were caused by artillery. In 1944, Joseph Stalin said in a speech that artillery was "the God of War".

Artillery Piece
Although not called as such, machines performing the role recognizable as artillery have been employed in warfare since antiquity. Historical references show artillery was first employed by the Roman legions at Syracuse in 399 BC. Until the introduction of gunpowder into western warfare, artillery was dependent upon mechanical energy which not only severely limited the kinetic energy of the projectiles, it also required the construction of very large engines to store sufficient energy. A 1st-century BC Roman catapult launching 6.55 kg (14.4 lb) stones achieved a kinetic energy of 16,000 joules, compared to a mid-19th-century 12-pounder gun, which fired a 4.1 kg (9.0 lb) round, with a kinetic energy of 240,000 joules, or a late 20th century US battleship that fired a 1,225 kg (2,701 lb) projectile from its main battery with an energy level surpassing 350,000,000 joules.

Precision-Guided Artillery
Modern artillery is most obviously distinguished by its long range, firing an explosive shell or rocket and a mobile carriage for firing and transport. However, its most important characteristic is the use of indirect fire, whereby the firing equipment is aimed without seeing the target through its sights. Indirect fire emerged at the beginning of the 20th century and was greatly enhanced by the development of predicted fire methods in World War I. However, indirect fire was area fire; it was and is not suitable for destroying point targets; its primary purpose is area suppression. Nevertheless, by the late 1970s precision-guided munitions started to appear, notably the US 155 mm Copperhead and its Soviet 152 mm Krasnopol equivalent that had success in Indian service. These relied on laser designation to 'illuminate' the target that the shell homed onto.

WARFARE Artillery Ammunition

However, in the early 21st Century, the Global Positioning System (GPS) enabled relatively cheap and accurate guidance for shells and missiles, notably the US 155 mm Excalibur and the 227 mm GMLRS rocket. The introduction of these led to a new issue, the need for very accurate three dimensional target coordinates—the mensuration process. Weapons covered by the term 'modern artillery' include "cannon" artillery (such as howitzer, mortar, and field gun) and rocket artillery. Certain smaller-calibre mortars are more properly designated small arms rather than artillery, albeit indirect-fire small arms. This term also came to include coastal artillery which traditionally defended coastal areas against seaborne attack and controlled the passage of ships.

With the advent of powered flight at the start of the 20th century, artillery also included ground-based anti-aircraft batteries. The term "artillery" has traditionally not been used for projectiles with internal guidance systems, preferring the term "missilery", though some modern artillery units employ surface-to-surface missiles. Advances in terminal guidance systems for small munitions has allowed large-calibre guided projectiles to be developed, blurring this distinction.

Ammunition

One of the most important roles of logistics is the supply of munitions as a primary type of artillery consumable, their storage (ammunition dump, arsenal, magazine) and the provision of fuses, detonators and warheads at the point where artillery troops will assemble the charge, projectile, bomb or shell.

A round of artillery ammunition comprises four components:
- Fuze
- Projectile
- Propellant
- Primer

Fuzes

Fuzes are the devices that initiate an artillery projectile, either to detonate its high explosive (HE) filling or eject its cargo (illuminating flare or smoke canisters being examples). The official military spelling is "fuze". Broadly there are four main types:
- Impact (including graze and delay)
- Mechanical time including airburst
- Proximity sensor including airburst
- Electronic time including airburst

Most artillery fuzes are nose fuzes. However, base fuzes have been used with armour piercing shells and for squash head (HESH or HEP) anti-tank shells. At least one nuclear shell and its non-nuclear spotting version also used a multi-deck mechanical time fuze fitted into its base. Impact fuzes were, and in some armies remain, the standard fuze for HE projectiles. Their default action is normally 'superquick', some have had a 'graze' action which allows them to penetrate light cover and others have 'delay'.

Delay fuzes allow the shell to penetrate the ground before exploding. Armour- or concrete-piercing fuzes are specially hardened. During World War I and later, ricochet fire with delay or graze fuzed HE shells, fired with a flat angle of descent, was used to achieve airburst. HE shells can be fitted with other fuzes. Airburst fuzes usually have a combined airburst and impact function. However, until the introduction of proximity fuzes, the airburst function was mostly used with cargo munitions—for example, shrapnel, illumination, and smoke. The larger calibers of anti-aircraft artillery are almost always used airburst. Airburst fuzes have to have the fuze length (running time) set on them.

This is done just before firing using either a wrench or a fuze setter pre-set to the required fuze length. Early airburst fuzes used igniferous timers which lasted into the second half of the 20th century. Mechanical time fuzes appeared in the early part of the century. These required a means of powering them. The Thiel mechanism used a spring and escapement (i.e. 'clockwork'), Junghans used centrifugal force and gears, and Dixi used centrifugal force and balls. From about 1980, electronic time fuzes started replacing mechanical ones for use with cargo munitions.

Proximity fuzes have been of two types: photo-electric or radar. The former was not very successful and seems only to have been used with British anti-aircraft artillery 'unrotated projectiles' (rockets) in World War II. Radar proximity fuzes were a big improvement over the mechanical (time) fuzes which they replaced. Mechanical time fuzes required an accurate calculation of their running time, which was affected by non-standard conditions. With HE (requiring a burst 20 to 30 feet (9.1 m) above the ground), if this was very slightly wrong the rounds would either hit the ground or burst too high. Accurate running time was less important with cargo munitions that burst much higher. The first radar proximity fuzes (codenamed 'VT') were invented by the British and developed by the US and initially used against aircraft in World War II.

Their ground use was delayed for fear of the enemy recovering 'blinds' (artillery shells which failed to detonate) and copying the fuze. The first proximity fuzes were designed to detonate about 30 feet (9.1 m) above the ground. These air-bursts are much more lethal against personnel than ground bursts because they deliver a greater proportion of useful fragments and deliver them into terrain where a prone soldier would be protected from ground bursts. However, proximity fuzes can suffer premature detonation because of the moisture in heavy rain clouds. This led to 'controlled variable time' (CVT) after World War II.

These fuzes have a mechanical timer that switched on the radar about 5 seconds before expected impact, they also detonated on impact. The proximity fuze emerged on the battlefields of Europe in late December 1944. They have become known as the U.S. Artillery's "Christmas present", and were much appreciated when they arrived during the Battle of the Bulge. They were also used to great effect in anti-aircraft projectiles in the Pacific against kamikaze as well as in Britain against V-1 flying bombs.

Electronic multi-function fuzes started to appear around 1980. Using solid-state electronics they were relatively cheap and reliable, and became the standard fitted fuze in operational ammunition stocks in some western armies. The early versions were often limited to proximity airburst, albeit with height of burst options, and impact. Some offered a go/no-go functional test through the fuze setter. Later versions introduced induction fuze setting and testing instead of physically placing a fuze setter on the fuze. The latest, such as Junghan's DM84U provide options giving, superquick, delay, a choice of proximity heights of burst, time and a choice of foliage penetration depths. A new type of artillery fuze will appear soon. In addition to other functions these offer some course correction capability, not full precision but sufficient to significantly reduce the dispersion of the shells on the ground.

Projectile

The projectile is the munition or "bullet" fired downrange. This may or may not be an explosive device. Traditionally, projectiles have been classified as "shot" or "shell", the former being solid and the latter having some form of "payload". Shells can also be divided into three configurations: bursting, base ejection or nose ejection. The latter is sometimes called the shrapnel configuration. The most modern is base ejection, which was introduced in World War I. Both base and nose ejection are almost always used with airburst fuzes. Bursting shells use various types of fuze depending on the nature of the payload and the tactical need at the time.

Payloads have included:
Bursting: High-explosive, white phosphorus ("Willie Pete" or "Wilson Picket"), coloured marker, chemical, nuclear devices; high explosive anti-tank (HEAT) and canister may be considered special types of bursting shell.
Nose Ejection: Shrapnel, star, incendiary and flechette (a more modern version of shrapnel).
Base Ejection: Dual purpose improved conventional munitions (DPICM)-bomblets, which arm themselves and function after a set number of rotations after having been ejected from the projectile (this produces unexploded sub-munitions, or "duds", which remain dangerous), scatterable mines, illuminating, coloured flare, smoke, incendiary, propaganda, chaff (foil to jam radars) and modern exotics such as electronic payloads and sensor-fuzed munitions.

Stabilization

Rifled	Traditionally, artillery projectiles have been spin-stabilised, meaning that they spin in flight so that gyroscopic forces prevent them from tumbling. Spin is induced by gun barrels having rifling which engages a soft metal band around the projectile, called a "driving band" (UK) or "rotating band" (U.S.). The driving band is usually made of copper, but synthetic materials have also been used.
Smoothbore/Fin-Stabilized	In modern artillery, smoothbore tubes have been used mostly by mortars. These projectiles use fins in the airflow at their rear to maintain correct orientation. The primary benefits over rifled barrels is reduced barrel wear, longer ranges that can be achieved (due to the reduced loss of energy to friction and gas escaping around the projectile via the rifling) and larger explosive cores for a given calibre artillery due to less metal needing to be used to form the case of the projectile because of less force applied to the shell from the non-rifled sides of the barrel of smooth bore guns.
Rifled/Fin-Stabilized	A combination of the above can be used, where the barrel is rifled, but the projectile also has deployable fins for stabilization, guidance or gliding.

Propellant

Most forms of artillery require a propellant to propel the projectile at the target. Propellant is always a low explosive, this means it deflagrates instead of detonating, as with high explosives. The shell is accelerated to a high velocity in a very short time by the rapid generation of gas from the burning propellant. This high pressure is achieved by burning the propellant in a contained area, either the chamber of a gun barrel or the combustion chamber of a rocket motor. Until the late 19th century, the only available propellant was black powder. Black powder had many disadvantages as a propellant; it has relatively low power, requiring large amounts of powder to fire projectiles, and created thick clouds of white smoke that would obscure the targets, betray the positions of guns, and make aiming impossible.

In 1846, nitrocellulose (also known as guncotton) was discovered, and the high explosive nitroglycerin was discovered at much the same time. Nitrocellulose was significantly more powerful than black powder, and was smokeless. Early guncotton was unstable, however, and burned very fast and hot, leading to greatly increased barrel wear. Widespread introduction of smokeless powder would wait until the advent of the double-base powders, which combine nitrocellulose and nitroglycerin to produce powerful, smokeless, stable propellant.

Many other formulations were developed in the following decades, generally trying to find the optimum characteristics of a good artillery propellant; low temperature, high energy, non-corrosive, highly stable, cheap, and easy to manufacture in large quantities. Broadly, modern gun propellants are divided into three classes: single-base propellants which are mainly or entirely nitrocellulose based, double-base propellants composed of a combination of nitrocellulose and nitroglycerin, and triple base composed of a combination of nitrocellulose and nitroglycerin and Nitroguanidine.

Artillery shells fired from a barrel can be assisted to greater range in three ways:
- Rocket-assisted projectiles (RAP) enhance and sustain the projectile's velocity by providing additional 'push' from a small rocket motor that is part of the projectile's base.
- Base bleed uses a small pyrotechnic charge at the base of the projectile to introduce sufficient combustion products into the low-pressure region behind the base of the projectile responsible for a large proportion of the drag.
- Ramjet-assisted, similar to rocket-assisted, but using a ramjet instead of a rocket motor; it is anticipated that a ramjet-assisted 120-mm mortar shell could reach a range of 22 mi (35 km).

Propelling charges for tube artillery can be provided in one of two ways: either as cartridge bags or in metal cartridge cases. Generally, anti-aircraft artillery and smaller-calibre (up to 3" or 76.2 mm) guns use metal cartridge cases that include the round and propellant, similar to a modern rifle cartridge. This simplifies loading and is necessary for very high rates of fire. Bagged propellant allows the amount of powder to be raised or lowered, depending on the range to the target. It also makes handling of larger shells easier. Each requires a totally different type of breech to the other. A metal case holds an integral primer to initiate the propellant and provides the gas seal to prevent the gases leaking out of the breech; this is called obturation. With bagged charges, the breech itself provides obturation and holds the primer. In either case, the primer is usually percussion, but electrical is also used, and laser ignition is emerging. Modern 155 mm guns have a primer magazine fitted to their breech.

Artillery ammunition has four classifications according to use:

Service	Ammunition used in live fire training or for wartime use in a combat zone. Also known as "warshot" ammunition.
Practice	Ammunition with a non- or minimally-explosive projectile that mimics the characteristics (range, accuracy) of live rounds for use under training conditions. Practice artillery ammunition often utilizes a coloured-smoke-generating bursting charge for marking purposes in place of the normal high-explosive charge.
Dummy	Ammunition with an inert warhead, inert primer, and no propellant; used for training or display.
Blank	Ammunition with live primer, greatly reduced propellant charge (typically black powder), and no projectile; used for training, demonstration or ceremonial use.

Field Artillery System

Because field artillery mostly uses indirect fire the guns have to be part of a system that enables them to attack targets invisible to them in accordance with the combined arms plan. The main functions in the field artillery system are:
- Communications
- Command: authority to allocate resources;
- Target acquisition: detect, identify and deduce the location of targets;
- Control: authority to decide which targets to attack and allot fire units to the attack;
- Computation of firing data – to deliver fire from a fire unit onto its target;
- Fire units: guns, launchers or mortars grouped together;
- Specialist services: produce data to support the production of accurate firing data;
- Logistic services: to provide combat supplies, particularly ammunition, and equipment support.

All these calculations to produce a quadrant elevation (or range) and azimuth were done manually using instruments, tablulated, data of the moment, and approximations until battlefield computers started appearing in the 1960s and 1970s. While some early calculators copied the manual method (typically substituting polynomials for tabulated data), computers use a different approach. They simulate a shell's trajectory by 'flying' it in short steps and applying data about the conditions affecting the trajectory at each step. This simulation is repeated until it produces a quadrant elevation and azimuth that lands the shell within the required 'closing' distance of the target coordinates. NATO has a standard ballistic model for computer calculations and has expanded the scope of this into the NATO Armaments Ballistic Kernel (NABK) within the SG2 Shareable (Fire Control) Software Suite (S4).

Classifications

Artillery types can be categorised in several ways, for example by type or size of weapon or ordnance, by role or by organizational arrangements.

Heavy Artillery	Capable of firing a long distance to bombard its target.
Field Artillery	Mobile weapons used to support armies in the field. Subcategories include:

Infantry Support Guns	Directly support infantry units.
Mountain Guns	Lightweight weapons that can be moved through difficult terrain.
Field Guns	Capable of long range fire.
Howitzers	Capable of high angle fire, they are most often employed for indirect-fire.
Gun Howitzers	Capable of high or low angle fire with a long barrel.
Mortars	Typically short-barreled, high-trajectory weapons designed primarily for an indirect-fire role.
Anti-Tank Artillery	Weapons, usually mobile, designed for attacking tanks.
Anti-Aircraft Artillery	Weapons, usually mobile, designed for attacking aircraft from the ground. Some guns were suitable for dual-role anti-aircraft and field (anti-tank) use. The World War II German 88 mm gun was a famous example.
Rocket Artillery	Rocket-launched instead of shot or shell.
Railway Gun	Large-calibre weapons that are mounted on, transported by and fired from specially-designed railway wagons.
Naval Artillery	Guns mounted on warships and used either against other ships or in support of ground forces. The crowning achievement of naval artillery was the battleship, but the advent of airpower and missiles have rendered this type of artillery largely obsolete. They are typically longer-barreled, low-trajectory, high-velocity weapons designed primarily for a direct-fire role.
Coastal Artillery	Fixed-position weapons dedicated to defence of a particular location, usually a coast (for example, the Atlantic Wall in World War II) or harbour. Not needing to be mobile, coastal artillery used to be much larger than equivalent field artillery pieces, giving them longer range and more destructive power. Modern coastal artillery (for example, Russia's "Bereg" system) is often self-propelled, (allowing it to avoid counter-battery fire) and fully integrated, meaning that each battery has all of the support systems that it requires (maintenance, targeting radar, etc.) organic to its unit.
Other Categories	Modern field artillery can also be split into two other subcategories: towed and self-propelled. As the name suggests, towed artillery has a prime mover, usually an artillery tractor or truck, to move the piece, crew, and ammunition around. Towed artillery is in some cases equipped with an APU for small displacements. Self-propelled artillery is permanently mounted on a carriage or vehicle with room for the crew and ammunition and is thus capable of moving quickly from one firing position to another, both to support the fluid nature of modern combat and to avoid counter-battery fire. It includes mortar carrier vehicles, many of which allow the mortar to be removed from the vehicle and used dismounted, potentially in terrain in which the vehicle cannot navigate, or in order to avoid detection.

Equipment Types

The three main types of artillery "gun" are guns, howitzers, and mortars. During the 20th century, guns and howitzers have steadily merged in artillery use, making a distinction between the terms somewhat meaningless. By the end of the 20th century, true guns with calibers larger than about 60 mm had become very rare in artillery use, the main users being tanks, ships, and a few residual anti-aircraft and coastal guns. The term "cannon" is a United States generic term that includes guns, howitzers, and mortars; it is not used in other English speaking armies. The traditional definitions differentiated between guns and howitzers in terms of maximum elevation (well less than 45° as opposed to close to or greater than 45°), number of charges (one or more than one charge), and having higher or lower muzzle velocity, sometimes indicated by barrel length. These three criteria give eight possible combinations, of which guns and howitzers are but two. However, modern "howitzers" have higher velocities and longer barrels than the equivalent "guns" of the first half of the 20th century. True guns are characterized by long range, having a maximum elevation significantly less than 45°, a high muzzle velocity and hence a relatively long barrel, smooth bore (no rifling) and a single charge.

The latter often led to fixed ammunition where the projectile is locked to the cartridge case. There is no generally accepted minimum muzzle velocity or barrel length associated with a gun. Howitzers can fire at maximum elevations at least close to 45°; elevations up to about 70° are normal for modern howitzers. Howitzers also have a choice of charges, meaning that the same elevation angle of fire will achieve a different range depending on the charge used. They have rifled bores, lower muzzle velocities and shorter barrels than equivalent guns. All this means they can deliver fire with a steep angle of descent. Because of their multi-charge capability, their ammunition is mostly separate loading (the projectile and propellant are loaded separately). That leaves six combinations of the three criteria, some of which have been termed gun howitzers. A term first used in the 1930s when howitzers with a relatively high maximum muzzle velocities were introduced, it never became widely accepted, most armies electing to widen the definition of "gun" or "howitzer". By the 1960s, most equipments had maximum elevations up to about 70°, were multi-charge, had quite high maximum muzzle velocities and relatively long barrels.

Equipment types

Mortars are simpler. The modern mortar originated in World War I and there were several patterns. After that war, most mortars settled on the Stokes pattern, characterized by a short barrel, smooth bore, low muzzle velocity, elevation angle of firing generally greater than 45°, and a very simple and light mounting using a "baseplate" on the ground. The projectile with its integral propelling charge was dropped down the barrel from the muzzle to hit a fixed firing pin. Since that time, a few mortars have become rifled and adopted breech loading. There are other recognized typifying characteristics for artillery. One such characteristic is the type of obturation used to seal the chamber and prevent gases escaping through the breech. This may use a metal cartridge case that also holds the propelling charge, a configuration called "QF" or "quickfiring" by some nations. The alternative does not use a metal cartridge case, the propellant being merely bagged or in combustible cases with the breech itself providing all the sealing. This is called "BL" or "breech loading" by some nations.

A second characteristic is the form of propulsion. Modern equipment can either be towed or self-propelled (SP). A towed gun fires from the ground and any inherent protection is limited to a gun shield. Towing by horse teams lasted throughout World War II in some armies, but others were fully mechanized with wheeled or tracked gun towing vehicles by the outbreak of that war. The size of a towing vehicle depends on the weight of the equipment and the amount of ammunition it has to carry. A variation of towed is portee, where the vehicle carries the gun which is dismounted for firing. Mortars are often carried this way. A mortar is sometimes carried in an armoured vehicle and can either fire from it or be dismounted to fire from the ground. Since the early 1960s it has been possible to carry lighter towed guns and most mortars by helicopter.

Even before that, they were parachuted or landed by glider from the time of the first airborne trials in the USSR in the 1930s. In an SP equipment, the gun is an integral part of the vehicle that carries it. SPs first appeared during World War I, but did not really develop until World War II. They are mostly tracked vehicles, but wheeled SPs started to appear in the 1970s. Some SPs have no armour and carry little or no ammunition. Armoured SPs usually carry a useful ammunition load. Early armoured SPs were mostly a "casemate" configuration, in essence an open top armoured box offering only limited traverse. However, most modern armoured SPs have a full enclosed armoured turret, usually giving full traverse for the gun. Many SPs cannot fire without deploying stabilizers or spades, sometimes hydraulic. A few SPs are designed so that the recoil forces of the gun are transferred directly onto the ground through a baseplate.

A few towed guns have been given limited self-propulsion by means of an auxiliary engine. Two other forms of tactical propulsion were used in the first half of the 20th century: Railways or transporting the equipment by road, as two or three separate loads, with disassembly and re-assembly at the beginning and end of the journey. Railway artillery took two forms, railway mountings for heavy and super-heavy guns and howitzers and armoured trains as "fighting vehicles" armed with light artillery in a direct fire role. Disassembled transport was also used with heavy and super heavy weapons and lasted into the 1950s.

Application of Fire

There are several dimensions to this subject. The first is the notion that fire may be against an opportunity target or may be prearranged. If it is the latter it may be either on-call or scheduled. Prearranged targets may be part of a fire plan. Fire may be either observed or unobserved, if the former it may be adjusted, if the latter then it has to be predicted. Observation of adjusted fire may be directly by a forward observer or indirectly via some other target acquisition system. NATO also recognises several different types of fire support for tactical purposes:

Application of Fire

Counterbattery Fire	Delivered for the purpose of destroying or neutralizing the enemy's fire support system.
Counterpreparation Fire	Intensive prearranged fire delivered when the imminence of the enemy attack is discovered.
Covering Fire	Used to protect troops when they are within range of enemy small arms.
Defensive Fire	Delivered by supporting units to assist and protect a unit engaged in a defensive action.
Final Protective Fire	An immediately available prearranged barrier of fire designed to impede enemy movement across defensive lines or areas.
Harassing Fire	A random number of shells are fired at random intervals, without any pattern to it that the enemy can predict. This process is designed to hinder enemy forces' movement, and, by the constantly imposed stress, threat of losses and inability of enemy forces to relax or sleep, lowers their morale.
Interdiction Fire	Placed on an area or point to prevent the enemy from using the area or point.
Preparation Fire	Delivered before an attack to weaken the enemy position.

These purposes have existed for most of the 20th century, although their definitions have evolved and will continue to do so, lack of suppression in counterbattery is an omission. Broadly they can be defined as either:

Deep Supporting Fire	Directed at objectives not in the immediate vicinity of own force, for neutralizing or destroying enemy reserves and weapons, and interfering with enemy command, supply, communications and observation; or
Close Supporting Fire	Placed on enemy troops, weapons or positions which, because of their proximity present the most immediate and serious threat to the supported unit.

Two other NATO terms also need definition:

Neutralization Fire	Delivered to render a target temporarily ineffective or unusable; and
Suppression Fire	That degrades the performance of a target below the level needed to fulfil its mission. Suppression is usually only effective for the duration of the fire.

The tactical purposes also include various "mission verbs", a rapidly expanding subject with the modern concept of "effects based operations". Targeting is the process of selecting target and matching the appropriate response to them taking account of operational requirements and capabilities. It requires consideration of the type of fire support required and the extent of coordination with the supported arm. It involves decisions about:

- What effects are required, for example, neutralization or suppression;
- The proximity of and risks to own troops or non-combatants;
- What types of munitions, including their fuzing, are to be used and in what quantities;
- When the targets should be attacked and possibly for how long;
- What methods should be used, for example, converged or distributed, whether adjustment is permissible or surprise essential, the need for special procedures such as precision or danger close
- How many fire units are needed and which ones they should be from those that are available (in range, with the required munitions type and quantity, not allotted to another target, have the most suitable line of fire if there is a risk to own troops or non-combatants);

The targeting process is the key aspect of tactical fire control. Depending on the circumstances and national procedures it may all be undertaken in one place or may be distributed. In armies practicing control from the front, most of the process may be undertaken by a forward observer or other target acquirer. This is particularly the case for a smaller target requiring only a few fire units. The extent to which the process is formal or informal and makes use of computer based systems, documented norms or experience and judgement also varies widely armies and other circumstances.

Surprise may be essential or irrelevant. It depends on what effects are required and whether or not the target is likely to move or quickly improve its protective posture. During World War II UK researchers concluded that for impact fuzed munitions the relative risk were as follows:

- Men standing – 1
- Men lying – 1/3
- Men firing from trenches – 1/15–1/50
- Men crouching in trenches – 1/25–1/100

Airburst munitions significantly increase the relative risk for lying men, etc. Historically most casualties occur in the first 10–15 seconds of fire, i.e. the time needed to react and improve protective posture, however, this is less relevant if airburst is used.

There are several ways of making best use of this brief window of maximum vulnerability:

- Ordering the guns to fire together, either by executive order or by a "fire at" time. The disadvantage is that if the fire is concentrated from many dispersed fire units then there will be different times of flight and the first rounds will be spread in time. To some extent a large concentration offsets the problem because it may mean that only one round is required from each gun and most of these could arrive in the 15 second window.
- Burst fire, a rate of fire to deliver three rounds from each gun within 10 or 15 seconds, this reduces the number of guns and hence fire units needed, which means they may be less dispersed and have less variation in their times of flight. Smaller calibre guns, such as 105 mm, have always been able to deliver three rounds in 15 seconds, larger calibers firing fixed rounds could also do it but it wasn't until the 1970s that a multi-charge 155 mm howitzer, FH-70 first gained the capability.
- Multiple round simultaneous impact (MRSI), where a single weapon or multiple individual weapons fire multiple rounds at differing trajectories so that all rounds arrive on target at the same time.
- Time on target, fire units fire at the time less their time of flight, this works well with prearranged scheduled fire but is less satisfactory for opportunity targets because it means delaying the delivery of fire by selecting a 'safe' time that all or most fire units can achieve. It can be used with both the previous two methods.

Counter-Battery Fire

Modern counter-battery fire developed in World War I, with the objective of defeating the enemy's artillery. Typically such fire was used to suppress enemy batteries when they were or were about to interfere with the activities of friendly forces (such as to prevent enemy defensive artillery fire against an impending attack) or to systematically destroy enemy guns. In World War I the latter required air observation. The first indirect counter-battery fire was in May 1900 by an observer in a balloon. Enemy artillery can be detected in two ways, either by direct observation of the guns from the air or by ground observers (including specialist reconnaissance), or from their firing signatures. This includes radars tracking the shells in flight to determine their place of origin, sound ranging detecting guns firing and resecting their position from pairs of microphones or cross-observation of gun flashes using observation by human observers or opto-electronic devices, although the widespread adoption of 'flashless' propellant limited the effectiveness of the latter.

Once hostile batteries have been detected they may be engaged immediately by friendly artillery or later at an optimum time, depending on the tactical situation and the counter-battery policy. Air strike is another option. In some situations the task is to locate all active enemy batteries for attack using a counter-battery fire at the appropriate moment in accordance with a plan developed by artillery intelligence staff. In other situations counter-battery fire may occur whenever a battery is located with sufficient accuracy. Modern counter-battery target acquisition uses unmanned aircraft, counter-battery radar, ground reconnaissance and sound-ranging. Counter-battery fire may be adjusted by some of the systems, for example the operator of an unmanned aircraft can 'follow' a battery if it moves. Defensive measures by batteries include frequently changing position or constructing defensive earthworks, the tunnels used by North Korea being an extreme example. Counter-measures include air defence against aircraft and attacking counter-battery radars physically and electronically.

Field Artillery Team

Field Artillery Team' is a US term and the following description and terminology applies to the US, other armies are broadly similar but differ in significant details. Modern field artillery (post–World War I) has three distinct parts: the forward observer (or FO), the fire direction centre (FDC) and the actual guns themselves. The forward observer observes the target using tools such as binoculars, laser rangefinders, designators and call back fire missions on his radio, or relays the data through a portable computer via an encrypted digital radio connection protected from jamming by computerized frequency hopping. A lesser known part of the team is the FAS or Field Artillery Survey team which setups up the "Gun Line" for the cannons. Today most artillery battalions use a(n) "Aiming Circle" which allows for faster setup and more mobility. FAS teams are still used for checks and balances purposes and if a gun battery has issues with the "Aiming Circle" a FAS team will do it for them.

The FO can communicate directly with the battery FDC, of which there is one per each battery of 4–8 guns. Otherwise the several FOs communicate with a higher FDC such as at a Battalion level, and the higher FDC prioritizes the targets and allocates fires to individual batteries as needed to engage the targets that are spotted by the FOs or to perform preplanned fires. The Battery FDC computes firing data—ammunition to be used, powder charge, fuse settings, the direction to the target, and the quadrant elevation to be fired at to reach the target, what gun will fire any rounds needed for adjusting on the target, and the number of rounds to be fired on the target by each gun once the target has been accurately located—to the guns. Traditionally this data is relayed via radio or wire communications as a warning order to the guns, followed by orders specifying the type of ammunition and fuse setting, direction, and the elevation needed to reach the target, and the method of adjustment or orders for fire for effect (FFE). However, in more advanced artillery units, this data is relayed through a digital radio link. Other parts of the field artillery team include meteorological analysis to determine the temperature, humidity and pressure of the air and wind direction and speed at different altitudes. Also radar is used both for determining the location of enemy artillery and mortar batteries and to determine the precise actual strike points of rounds fired by battery and comparing that location with what was expected to compute a registration allowing future rounds to be fired with much greater accuracy.

Time on Target
A technique called Time on Target was developed by the British Army in North Africa at the end of 1941 and early 1942 particularly for counter-battery fire and other concentrations, it proved very popular. It relied on BBC time signals to enable officers to synchronize their watches to the second because this avoided the need to use military radio networks and the possibility of losing surprise, and the need for field telephone networks in the desert. With this technique the time of flight from each fire unit (battery or troop) to the target is taken from the range or firing tables, or the computer and each engaging fire unit subtracts its time of flight from the TOT to determine the time to fire. An executive order to fire is given to all guns in the fire unit at the correct moment to fire. When each fire unit fires their rounds at their individual firing time all the opening rounds will reach the target area almost simultaneously. This is especially effective when combined with techniques that allow fires for effect to be made without preliminary adjusting fires.

MRSI (Multiple Rounds Simultaneous Impact)
A modern version of the earlier "time on target" is a concept in which fire from different weapons was timed to arrive on target at the same time. It is possible for artillery to fire several shells per gun at a target and have all of them arrive simultaneously, which is called MRSI (Multiple Rounds Simultaneous Impact). This is because there is more than one trajectory for the rounds to fly to any given target: typically one is below 45 degrees from horizontal and the other is above it, and by using different size propelling charges with each shell, it is possible to create multiple trajectories. Because the higher trajectories cause the shells to arc higher into the air, they take longer to reach the target and so if the shells are fired on these trajectories for the first volleys (starting with the shell with the most propellant and working down) and then after the correct pause more volleys are fired on the lower trajectories, the shells will all arrive at the same time. This is useful because many more shells can land on the target with no warning. With traditional volleys along the same trajectory, anybody at the target area may have time (however long it takes to reload and re-fire the guns) to take cover between volleys. However, guns capable of burst fire can deliver several rounds in 10 seconds if they use the same firing data for each, and if guns in more than one location are firing on one target they can use Time on Target procedures so that all their shells arrive at the same time and target.
To engage targets using MRSI requires two things, firstly guns with the requisite rate of fire and sufficiently different size propelling charges, secondly a fire control computer that has been designed to compute such missions and the data handling capability that allows all the firing data to be produced, sent to each gun and then presented to the gun commander in the correct order. The number of rounds that can be delivered in MRSI depends primarily on the range to the target and the rate of fire, for maximum rounds the range is limited to that of lowest propelling charge that will reach the target. Examples of guns with a rate of fire that makes them suitable for MRSI includes UK's AS-90, South Africa's Denel G6-52 (which can land six rounds simultaneously at targets at least 25 km (16 mi) away), Germany's Panzerhaubitze 2000 (which can land five rounds simultaneously at targets at least 17 km (11 mi) away), and Slovakia's 155 mm SpGH ZUZANA model 2000.

The Archer project (developed by BAE-Systems in Sweden) is a 155 mm howitzer on a wheeled chassis which is claimed to be able to deliver up to six shells on target simultaneously from the same gun. The 120 mm twin barrel AMOS mortar system, joint developed by Hägglunds (Sweden) and Patria (Finland), is capable of 7 + 7 shells MRSI. The United States Crusader program (now cancelled) was slated to have MRSI capability. It is unclear how many fire control computers have the necessary capabilities. Two-round MRSI firings were a popular artillery demonstration in the 1960s, where well trained detachments could show off their skills for spectators.

Air Burst
The destructiveness of artillery bombardments can be enhanced when some or all of the shells are set for airburst, meaning that they explode in the air above the target instead of upon impact. This can be accomplished either through time fuzes or proximity fuzes. Time fuses use a precise timer to detonate the shell after a preset delay. This technique is tricky and slight variations in the functioning of the fuse can cause it to explode too high and be ineffective, or to strike the ground instead of exploding above it. Since December 1944 (Battle of the Bulge), proximity fuzed artillery shells have been available that take the guesswork out of this process. These embody a miniature, low powered radar transmitter in the fuse to detect the ground and explode them at a predetermined height above it. The return of the weak radar signal completes an electrical circuit in the fuze which explodes the shell. The proximity fuse itself was developed by the British to increase the effectiveness of anti-aircraft warfare. This is a very effective tactic against infantry and light vehicles, because it scatters the fragmentation of the shell over a larger area and prevents it from being blocked by terrain or entrenchments that do not include some form of robust overhead cover. Combined with TOT or MRSI tactics that give no warning of the incoming rounds, these rounds are especially devastating because many enemy soldiers are likely to be caught in the open. This is even more so if the attack is launched against an assembly area or troops moving in the open rather than a unit in an entrenched tactical position.

4 Sea Materiel

Aircraft Carrier

An aircraft carrier is a warship that serves as a seagoing airbase, equipped with a full-length flight deck and facilities for carrying, arming, deploying, and recovering aircraft. Typically, it is the capital ship of a fleet, as it allows a naval force to project air power worldwide without depending on local bases for staging aircraft operations. Carriers have evolved since their inception in the early twentieth century from wooden vessels used to deploy balloons to nuclear-powered warships that carry numerous fighters, strike aircraft, helicopters, and other types of aircraft. While heavier aircraft such as fixed-wing gunships and bombers have been launched from aircraft carriers, it is currently not possible to land them. By its diplomatic and tactical power, its mobility, its autonomy and the variety of its means, the aircraft carrier is often the centrepiece of modern combat fleets. Tactically or even strategically, it replaced the battleship in the role of flagship of a fleet. One of its great advantages is that, by sailing in international waters, it does not interfere with any territorial sovereignty and thus obviates the need for overflight authorizations from third party countries, reduce the times and transit distances of aircraft and therefore significantly increase the time of availability on the combat zone. There is no single definition of an "aircraft carrier", and modern navies use several variants of the type. These variants are sometimes categorized as sub-types of aircraft carriers, and sometimes as distinct types of naval aviation-capable ships. Aircraft carriers may be classified according to the type of aircraft they carry and their operational assignments.

Admiral Sir Mark Stanhope, RN, former First Sea Lord (head) of the Royal Navy, has said, "To put it simply, countries that aspire to strategic international influence have aircraft carriers." Henry Kissinger, while United States Secretary of State, also said: "An aircraft carrier is 100,000 tons of diplomacy". As of April 2019, there are 41 active aircraft carriers in the world operated by thirteen navies. The United States Navy has 11 large nuclear-powered fleet carriers—carrying around 80 fighter jets each—the largest carriers in the world; the total combined deckspace is over twice that of all other nations combined. As well as the aircraft carrier fleet, the U.S. Navy has nine amphibious assault ships used primarily for helicopters, although these also carry up to 20 vertical or short take-off and landing (V/STOL) fighter jets and are similar in size to medium-sized fleet carriers. China, France, India, Russia, and the UK each operate a single large/medium-size carrier, with capacity from 30 to 60 fighter jets. Italy operates two light fleet carriers and Spain operates one. Helicopter carriers are operated by Japan (4), France (3), Australia (2), Egypt (2), Brazil (1), South Korea (1), and Thailand (1). Future aircraft carriers are under construction or in planning by Brazil, China, India, Russia, the United Kingdom, and the United States.

Types of Carriers

Amphibious Assault Ship	An amphibious assault ship is a type of amphibious warfare ship employed to land and support ground forces on enemy territory by an amphibious assault. The design evolved from aircraft carriers converted for use as helicopter carriers (and as a result, are often mistaken for conventional fixed-wing aircraft carriers). Modern ships support amphibious landing craft, with most designs including a well deck. Coming full circle, some amphibious assault ships also support V/STOL fixed-wing aircraft, now having a secondary role as aircraft carriers.
Anti-Submarine Warfare Carrier	An anti-submarine warfare carrier (ASW carrier) (US hull classification symbol CVS) is a type of small aircraft carrier whose primary role is as the nucleus of an anti-submarine warfare hunter-killer group. This type of ship came into existence during the Cold War as a development of the escort carriers used in the ASW role in the North Atlantic during World War II.
Balloon Carrier / Balloon Tenders	A balloon carrier or balloon tender was a ship equipped with a balloon, usually tied to the ship by a rope or cable, and usually used for observation. During the second half of the 19th century and the early 20th century, these ships were built to have the furthest possible view of the surrounding waters. After several experiments, the type became formalized in the early 1900s, but was soon to be superseded by the development of seaplane carriers and regular aircraft carriers at the beginning of World War I.
Escort Carrier	The escort carrier or escort aircraft carrier (US hull classification symbol CVE), also called a "jeep carrier" or "baby flattop" in the United States Navy (USN) or "Woolworth Carrier" by the Royal Navy, was a small and slow type of aircraft carrier used by the Royal Navy, the United States Navy, the Imperial Japanese Navy and Imperial Japanese Army Air Force in World War II. They were typically half the length and a third the displacement of larger fleet carriers. While they were slower, carried fewer planes and were less well armed and armoured, escort carriers were cheaper and could be built quickly, which was their principal advantage.
Fleet Carrier	A fleet carrier is an aircraft carrier designed to operate with the main fleet of a nation's navy. The term was developed during World War II, to distinguish it from the escort carrier and other lesser types. In addition to many medium-sized carriers, supercarriers, as well as some light carriers, are also classed as fleet carriers.
Flight Deck Cruiser	The flight-deck cruiser was a proposed type of aircraft cruiser, warships combining features of aircraft carriers and light cruisers designed by the United States Navy during the period between World War I and World War II. Several designs were proposed for the type, but none was approved for construction. The final design was developed just before World War II, and the entry of the United States into the war saw the project come to an end.
Helicopter Carrier	A helicopter carrier is a type of aircraft carrier whose primary purpose is to operate helicopters. A helicopter carrier has a large flight deck that occupies a large part of the ship, which can extend the full length of the ship like HMS Ocean of the Royal Navy (RN), or only partway, usually aft, as in the Soviet Navy's Moskva class, the Chinese Navy's Type 0891A or the RN's RFA Argus. It often also has a hangar deck for the storage of aircraft.
Light Aircraft Carrier	A light aircraft carrier, or light fleet carrier, is an aircraft carrier that is smaller than the standard carriers of a navy. The precise definition of the type varies by country; light carriers typically have a complement of aircraft only one-half to two-thirds the size of a full-sized fleet carrier. A light carrier was similar in concept to an escort carrier in most respects, however light carriers were intended for higher speeds to be deployed alongside fleet carriers, while escort carriers usually defended convoys and provided air support during amphibious operations.
Sea Control Ship	The Sea Control Ship (SCS) was a small aircraft carrier developed and conceptualized by the United States Navy under Chief of Naval Operations Elmo Zumwalt during the 1970s. Currently the term refers to naval vessels that can perform similar duties. The SCS was intended as an escort vessel, providing air support for convoys. It was cancelled after budgetary cuts to the US Navy. The SCS was to be equipped with a mix of Rockwell XFV-12 fighter aircraft and anti-submarine warfare helicopters. It was tasked with carrying out anti-submarine warfare operations.
Seaplane Tender and Seaplane Carriers	A seaplane tender is a boat or ship that supports the operation of seaplanes. Some of these vessels, the seaplane carriers, could not only carry seaplanes but also provided all the facilities needed for their operation; these ships are regarded by some as the first aircraft carriers and appeared just before the First World War.
Aircraft Cruiser	The aircraft cruiser (also known as aviation cruiser or cruiser-carrier) is a warship that combines the features of the aircraft carrier and a surface warship such as a cruiser or battleship. A more modern derivative of the aircraft cruiser is the helicopter cruiser which could typically operate at least 4 or more helicopters including medium and heavy lift varieties. This is in contrast to surface warships such as cruisers, destroyers, and frigates which have basic aviation facilities, including a hanger and landing pad, that are sufficient only for 1–2 light/medium helicopters.

Hull Classification

CV - Generic aircraft carrier CVA - Attack carrier CVB - Large aircraft carrier (retired) CVAN - Nuclear-powered attack carrier CVE - Escort carrier	CVG - Flight deck cruiser (proposed) CVHA - Aircraft carrier, Helicopter Assault (retired) CVHE - Aircraft carrier, Helicopter, Escort (retired) CVV - Aircraft Carrier (Medium) (proposed) CVL - Light aircraft carrier CVN - Nuclear-powered aircraft carrier	CVS - Anti-submarine warfare carrier LHA - Landing Helicopter Assault, a type of amphibious assault ship LHD - Landing Helicopter Dock, a type of amphibious assault ship 'LPH - Landing Platform Helicopter, a type of amphibious assault ship

Structure

Carriers are large and long ships, although there is a high degree of variation depending on their intended role and aircraft complement. The size of the carrier has varied over history and among navies, to cater to the various roles that global climates have demanded from naval aviation. Regardless of size, the ship itself must house their complement of aircraft, with space for launching, storing, and maintaining them. Space is also required for the large crew, supplies (food, munitions, fuel, engineering parts), and propulsion. US aircraft carriers are notable for having nuclear reactors powering their systems and propulsion. This makes the carrier reasonably tall.

The top of the carrier is the flight deck, where aircraft are launched and recovered. On the starboard side of this is the island, where air-traffic control and the bridge are located. The constraints of constructing a flight deck affect the role of a given carrier strongly, as they influence the weight, type, and configuration of the aircraft that may be launched. For example, assisted launch mechanisms are used primarily for heavy aircraft, especially those loaded with air-to-ground weapons. CATOBAR is most commonly used on USN fleet carriers as it allows the deployment of heavy jets with full loadouts, especially on ground-attack missions.

STOVL is used by other navies because it is cheaper to operate and still provides good deployment capability for fighter aircraft. Due to the busy nature of the flight deck, only 20 or so aircraft may be on it at any one time. A hangar storage several decks below the flight deck is where most aircraft are kept, and aircraft are taken from the lower storage decks to the flight deck through the use of an elevator. The hangar is usually quite large and can take up several decks of vertical space. Munitions are commonly stored on the lower decks because they are highly explosive. Usually this is below the water line so that the area can be flooded in case of emergency.

Flight Deck

As "runways at sea", aircraft carriers have a flat-top flight deck, which launches and recovers aircraft. Aircraft launch forward, into the wind, and are recovered from astern. The flight deck is where the most notable differences between a carrier and a land runway are found. Creating such a surface at sea poses constraints on the carrier. For example, the fact that it is a ship means that a full-length runway would be costly to construct and maintain. This affects take-off procedure, as a shorter runway length of the deck requires that aircraft accelerate more quickly to gain lift. This either requires a thrust boost, a vertical component to its velocity, or a reduced take-off load (to lower mass). The differing types of deck configuration, as above, influence the structure of the flight deck. The form of launch assistance a carrier provides is strongly related to the types of aircraft embarked and the design of the carrier itself.

There are two main philosophies in order to keep the deck short: add thrust to the aircraft, such as using a Catapult Assisted Take-Off (CATO-); and changing the direction of the airplanes' thrust, as in Vertical and/or Short Take-Off (V/STO-). Each method has advantages and disadvantages of its own:

● Catapult assisted take-off but arrested recovery (CATOBAR): A steam- or electric-powered catapult is connected to the aircraft, and is used to accelerate conventional aircraft to a safe flying speed. By the end of the catapult stroke, the aircraft is airborne and further propulsion is provided by its own engines. This is the most expensive method as it requires complex machinery to be installed under the flight deck, but allows for even heavily loaded aircraft to take off.
● Short take-off but arrested recovery (STOBAR) depends on increasing the net lift on the aircraft. Aircraft do not require catapult assistance for take off; instead on nearly all ships of this type an upwards vector is provided by a ski-jump at the forward end of the flight deck, often combined with thrust vectoring by the aircraft. Alternatively, by reducing the fuel and weapon load, an aircraft is able to reach faster speeds and generate more upwards lift and launch without a ski-jump or catapult.

● Short take-off vertical-landing (STOVL): On aircraft carriers, non-catapult-assisted, fixed-wing short takeoffs are accomplished with the use of thrust vectoring, which may also be used in conjunction with a runway "ski-jump". Use of STOVL tends to allow aircraft to carry a larger payload as compared to during VTOL use, while still only requiring a short runway. The most famous examples are the Hawker Siddeley Harrier and the Sea Harrier. Although technically VTOL aircraft, they are operationally STOVL aircraft due to the extra weight carried at take-off for fuel and armaments. The same is true of the F-35B Lightning II, which demonstrated VTOL capability in test flights but is operationally STOVL.
● Vertical take-off and landing (VTOL): Aircraft are specifically designed for the purpose of using very high degrees of thrust vectoring (e.g. if the thrust to weight-force ratio is greater than 1, it can take off vertically), but are usually slower than conventionally propelled aircraft.

On the recovery side of the flight deck, the adaptation to the aircraft loadout is mirrored. Non-VTOL or conventional aircraft cannot decelerate on their own, and almost all carriers using them must have arrested-recovery systems to recover their aircraft. Aircraft that are landing extend a tailhook that catches on arrestor wires stretched across the deck to bring themselves to a stop in a short distance.

Operations

Carriers steam at speed, up to 35 knots (65 km/h; 40 mph) into the wind during flight deck operations to increase wind speed over the deck to a safe minimum. This increase in effective wind speed provides a higher launch airspeed for aircraft at the end of the catapult stroke or ski-jump, as well as making recovery safer by reducing the difference between the relative speeds of the aircraft and ship. Since the early 1950s on conventional carriers it has been the practice to recover aircraft at an angle to port of the axial line of the ship. The primary function of this angled deck is to allow aircraft that miss the arresting wires, referred to as a bolter, to become airborne again without the risk of hitting aircraft parked forward. The angled deck allows the installation of one or two "waist" catapults in addition to the two bow cats. An angled deck also improves launch and recovery cycle flexibility with the option of simultaneous launching and recovery of aircraft.

Deck Structures

The superstructure of a carrier (such as the bridge, flight control tower) are concentrated in a relatively small area called an island, a feature pioneered on HMS Hermes in 1923. While the island is usually built on the starboard side of the flight deck, the Japanese aircraft carriers Akagi and Hiryū had their islands built on the port side. Very few carriers have been designed or built without an island. The flush deck configuration proved to have significant drawbacks, primary of which was management of the exhaust from the power plant. Fumes coming across the deck were a major issue in USS Langley. In addition, lack of an island meant difficulties managing the flight deck, performing air traffic control, a lack of radar housing placements and problems with navigating and controlling the ship itself. Another deck structure that can be seen is a ski-jump ramp at the forward end of the flight deck. This was first developed to help launch STOVL aircraft take off at far higher weights than is possible with a vertical or rolling take-off on flat decks. Originally developed by the Royal Navy, it since has been adopted by many navies for smaller carriers. A ski-jump ramp works by converting some of the forward rolling movement of the aircraft into vertical velocity and is sometimes combined with the aiming of jet thrust partly downwards. This allows heavily loaded and fuelled aircraft a few more precious seconds to attain sufficient air velocity and lift to sustain normal flight.

National Fleets (Longest Carriers)

The U.S. Navy has the largest carriers in the world, and currently has eleven in service. The UK operates one 65,000 tonne STOVL carrier. The navies of China, France, India, and Russia each operate a single medium-sized fleet carrier. The US has nine similarly sized Amphibious Warfare Ships. There are three small light carriers in use capable of operating both fixed-wing aircraft and helicopters, Italy operates two, and Spain one.

United States	China	Russia	England	India	France

Anti-Submarine Warfare Carrier

An anti-submarine warfare carrier (ASW carrier) (US hull classification symbol CVS) is a type of small aircraft carrier whose primary role is as the nucleus of an anti-submarine warfare hunter-killer group. This type of ship came into existence during the Cold War as a development of the escort carriers used in the ASW role in the North Atlantic during World War II. After World War II, the main naval threat to most Western nations was confrontation with the Soviet Union. The Soviets ended the war with a small navy and took the route of asymmetric confrontation against Western surface ship superiority by investing heavily in submarines both for attack and later fielding submarine-launched missiles. Several nations who purchased British and US surplus light carriers were most easily able to accommodate slow-moving, less expensive, and easy-to-land anti-submarine aircraft from the 1960s forward, such as the S-2 Tracker, which flew from the decks of US, Canadian, Australian, Dutch, Argentine, and Brazilian carriers, or Alizé, which flew from French and Indian ships, allowing these ships to still remain useful especially in the framework of NATO even as newer fighter and strike aircraft were becoming too heavy for the equipment designed for World War II aircraft.

Improvement in long-range shore-based patrol and conventional ship-based ASW helicopter capability combined with the increasing difficulty maintaining surplus WWII carriers led to most of these ships being retired or docked by smaller nations from the 1970s to the mid-1980s. This trend in ASW force draw-down only accelerated with the massive reduction in the operational Soviet/Russian submarine fleet, which rarely went to sea in large numbers in the 1990s. Ships that could be called dedicated ASW carriers are now only found within the Japan MSDF, which operates helicopters and no fixed-wing carrier-based aircraft of any kind. Even the United States Navy, the last nation to regularly operate a dedicated fixed-wing carrier-based ASW aircraft, the S-3 Viking, on its mixed-role super carriers had already removed most ASW equipment in the 1990s from this aircraft and has now removed this type from service as of January 2009 without replacement. The Argentine Navy, currently without much hope of a replacement CATOBAR carrier of its own, trained several times a year landings and takeoffs of their S-2 Turbo Trackers aboard the Brazilian aircraft carrier São Paulo until this carrier was also retired. Much easier to operate from small decks than fixed-wing aircraft were ASW helicopters, which flew from the decks of nearly all allied conventional carriers to this day and most LPH or STOVL carriers operated by the Soviet, Spanish, Italian, Japanese, British, and Thai navies.

Air-Cushioned Landing Craft

An air-cushioned landing craft, also called an LCAC (landing craft, air cushioned) is a modern variation on the amphibious landing boat. The majority of these craft are small- to mid-sized multi-purpose hovercraft, also known as "over the beach" ("OTB") craft. This allows troops and material to access more than 70 percent of the world's coastline, while only approximately 15 percent of that coastline is available to conventional boat-type landing craft. Typical barriers to conventional landing craft are soft sandy beaches, marshes, swampland, and loose surfaces. Air cushion technology has vastly increased the landing capability of the craft, providing greater speed and flexibility over traditional landing craft. Like the mechanized landing craft, they are usually equipped with mounted machine guns; they also support grenade launchers and heavy weapons.

Amphibious Assault Ship

An amphibious assault ship (also commando carrier or an amphibious assault carrier) is a type of amphibious warfare ship employed to land and support ground forces on enemy territory by an amphibious assault. The design evolved from aircraft carriers converted for use as helicopter carriers (and as a result, are often mistaken for conventional fixed-wing aircraft carriers). Modern ships support amphibious landing craft, with most designs including a well deck. Coming full circle, some amphibious assault ships also support V/STOL fixed-wing aircraft, now having a secondary role as aircraft carriers. The role of the amphibious assault ship is fundamentally different from that of a standard aircraft carrier: its aviation facilities have the primary role of hosting helicopters to support forces ashore rather than to support strike aircraft. However, some are capable of serving in the sea-control role, embarking aircraft like Harrier fighters for combat air patrol and helicopters for anti-submarine warfare or operating as a safe base for large numbers of STOVL fighters conducting air support for an expeditionary unit ashore. Most of these ships can also carry or support landing craft, such as air-cushioned landing craft (hovercraft) or LCUs. The largest fleet of these types is operated by the United States Navy, including the Wasp class dating back to 1989 and the very similar America-class ships that debuted in 2014. Amphibious assault ships are also operated by the French Navy, the Italian Navy, the Republic of Korea Navy, the Royal Australian Navy, the Brazilian Navy, and the Spanish Navy. The term amphibious assault ship is often used interchangeably with other ship classifications. It applies to all large-deck amphibious ships such as the Landing Platform Helicopter (LPH), Landing Helicopter Assault (LHA), and Landing Helicopter Dock (LHD).

Battlecruiser

The battlecruiser, or battle cruiser, was a type of capital ship of the first half of the 20th century. They were similar in displacement, armament and cost to battleships, but differed slightly in form and balance of attributes. Battlecruisers typically carried slightly thinner armour and a lighter main gun battery than contemporary battleships, installed on a longer hull with much higher engine power in order to attain faster speeds. The first battlecruisers were designed in the United Kingdom in the first decade of the century, as a development of the armoured cruiser, at the same time as the dreadnought succeeded the pre-dreadnought battleship.

The goal of the design was to outrun any ship with similar armament, and chase down any ship with lesser armament; they were intended to hunt down slower, older armoured cruisers and destroy them with heavy gunfire while avoiding combat with the more powerful but slower battleships. However, as more and more battlecruisers were built, they were increasingly used alongside the better-protected battleships.

Battlecruisers served in the navies of the UK, Germany, the Ottoman Empire, Australia and Japan during World War I, most notably at the Battle of the Falkland Islands and in the several raids and skirmishes in the North Sea which culminated in a pitched fleet battle, the Battle of Jutland. British battlecruisers in particular suffered heavy losses at Jutland, where their crews' poor fire safety & ammunition handling practices left them vulnerable to catastrophic magazine explosions following hits to their main turrets from large-calibre shells. This dismal showing led to a persistent general belief that battlecruisers were too thinly armoured to function successfully.

By the end of the war, capital ship design had developed with battleships becoming faster and battlecruisers becoming more heavily armoured, blurring the distinction between a battlecruiser and a fast battleship. The Washington Naval Treaty, which limited capital ship construction from 1922 onwards, treated battleships and battlecruisers identically, and the new generation of battlecruisers planned was scrapped under the terms of the treaty.

Improvements in armour design and propulsion created the 1930s "fast battleship" with the speed of a battlecruiser and armour of a battleship, making the battlecruiser in the traditional sense effectively an obsolete concept. Thus from the 1930s on, only the Royal Navy continued to use "battlecruiser" as a classification for the World War I–era capital ships that remained in the fleet; while Japan's battlecruisers remained in service, they had been significantly reconstructed and were re-rated as full-fledged fast battleships.

Battlecruisers were put into action again during World War II, and only one survived to the end. There was also renewed interest in large "cruiser-killer" type warships, but few were ever begun, as construction of battleships and battlecruisers was curtailed in favour of more-needed convoy escorts, aircraft carriers, and cargo ships. In the post–Cold War era, the Soviet Kirov class of large guided missile cruisers have also been termed "battlecruisers".

Battleship

WARFARE Sea Materiel Battleship

A battleship is a large armoured warship with a main battery consisting of large calibre guns. During the late 19th and early 20th centuries the battleship was the most powerful type of warship, and a fleet of battleships was considered vital for any nation that desired to maintain command of the sea. The term battleship came into formal use in the late 1880s to describe a type of ironclad warship, now referred to by historians as pre-dreadnought battleships. In 1906, the commissioning of HMS Dreadnought into the United Kingdom's Royal Navy heralded a revolution in battleship design. Subsequent battleship designs, influenced by HMS Dreadnought, were referred to as "dreadnoughts", though the term eventually became obsolete as they became the only type of battleship in common use. Battleships were a symbol of naval dominance and national might, and for decades the battleship was a major factor in both diplomacy and military strategy. A global arms race in battleship construction began in Europe in the 1890s and culminated at the decisive Battle of Tsushima in 1905, the outcome of which significantly influenced the design of HMS Dreadnought. The launch of Dreadnought in 1906 commenced a new naval arms race.

Three major fleet actions between steel battleships took place: the long range gunnery duel at the Battle of the Yellow Sea in 1904, the decisive Battle of Tsushima in 1905, both, during the Russo-Japanese War, and the inconclusive Battle of Jutland (1916) during the First World War. Jutland was the largest naval battle and the only full-scale clash of dreadnaughts of the war, it was the last major battle fought primarily by battleships in naval history. The Naval Treaties of the 1920s and 1930s limited the number of battleships, though technical innovation in battleship design continued. Both the Allied and Axis powers built battleships during World War II, though the increasing importance of the aircraft carrier meant that the battleship played a less important role than had been expected. The value of the battleship has been questioned, even during their heyday. There were few of the decisive fleet battles that battleship proponents expected, and used to justify the vast resources spent on building battlefleets. Even in spite of their huge firepower and protection, battleships were increasingly vulnerable to much smaller and relatively inexpensive weapons: initially the torpedo and the naval mine, and later aircraft and the guided missile.

WARFARE Sea Materiel CAM Ship

CAM Ship

CAM ships were World War II-era British merchant ships used in convoys as an emergency stop-gap until sufficient escort carriers became available. CAM ship is an acronym for catapult aircraft merchant ship. They were equipped with a rocket-propelled catapult launching a single Hawker Hurricane, dubbed a "Hurricat" or "Catafighter" to destroy or drive away an attacking bomber. Normally the Hurricane fighter would be lost when the pilot then bailed out or ditched in the ocean near the convoy. CAM ships continued to carry their normal cargoes after conversion. The concept was developed and tested by the five fighter catapult ships, commissioned as warships and commanded and crewed by the Royal Navy - but the CAM ships were merchant vessels, commanded and crewed by the Merchant Navy.

WARFARE Sea Materiel Corvette

Corvette

A corvette is a small warship. It is traditionally the smallest class of vessel considered to be a proper (or "rated") warship. The warship class above the corvette is that of the frigate, while the class below was historically that of the sloop-of-war. The modern types of ship below a corvette are coastal patrol craft and fast attack craft. In modern terms, a corvette is typically between 500 tons and 2,000 tons although recent designs may approach 3,000 tons, which might instead be considered a small frigate.

The word "corvette" is first found in Middle French, a diminutive of the Dutch word corf, meaning a small ship, from the Latin corbis, meaning "basket". The rank "corvette captain", equivalent in many navies to "lieutenant commander", derives from the name of this type of ship. The rank is the most junior of three "captain" ranks in several European (e.g., France, Spain, Italy, Croatia) and South American (e.g., Argentina, Chile) navies, because a corvette, as the smallest class of rated warship, was traditionally the smallest class of vessel entitled to a commander of a "captain" rank.

WARFARE Sea Materiel Cruiser

Cruiser

A cruiser is a type of warship. Modern cruisers are generally the largest ships in a fleet after aircraft carriers and amphibious assault ships, and can usually perform several roles. The term has been in use for several hundred years, and has had different meanings throughout this period. During the Age of Sail, the term cruising referred to certain kinds of missions – independent scouting, commerce protection, or raiding – fulfilled by a frigate or sloop-of-war, which were the cruising warships of a fleet. In the later 20th century, the obsolescence of the battleship left the cruiser as the largest and most powerful surface combatant after the aircraft carrier.

The role of the cruiser varied according to ship and navy, often including air defence and shore bombardment. During the Cold War, the Soviet Navy's cruisers had heavy anti-ship missile armament designed to sink NATO carrier task forces via saturation attack. The U.S. Navy built guided-missile cruisers upon destroyer-style hulls (some called "destroyer leaders" or "frigates" prior to the 1975 reclassification) primarily designed to provide air defence while often adding anti-submarine capabilities, being larger and having longer-range surface-to-air missiles (SAMs) than early Charles F. Adams guided-missile destroyers tasked with the short-range air defence role.

WARFARE Sea Materiel Cruiser

By the end of the Cold War, the line between cruisers and destroyers had blurred, with the Ticonderoga-class cruiser using the hull of the Spruance-class destroyer but receiving the cruiser designation due to their enhanced mission and combat systems. Indeed, the newest U.S. and Chinese destroyers are more heavily armed than some of the cruisers that they succeeded. Currently only two nations operate cruisers: the United States and Russia, and in both cases the vessels are primarily armed with guided missiles. BAP Almirante Grau was the last gun cruiser in service, serving with the Peruvian Navy until 2017.

WARFARE Sea Materiel Cruiser Armoured Cruiser

Armoured Cruiser

The armoured cruiser was a type of warship of the late 19th and early 20th centuries. It was designed like other types of cruisers to operate as a long-range, independent warship, capable of defeating any ship apart from a battleship and fast enough to outrun any battleship it encountered. Varying in size, it was distinguished from other types of cruiser by its belt armour—thick iron (or later steel) plating on much of the hull to protect the ship from shellfire much like that on battleships. The first armoured cruiser, the Imperial Russian Navy's General-Admiral, was launched in 1873 and combined sail and steam propulsion. By the 1890s cruisers had abandoned sail and took on a modern appearance. For many decades naval technology had not advanced far enough for designers to produce a cruiser which combined an armoured belt with the long range and high speed required to fulfil its mission; for this reason, many navies preferred to build protected cruisers in the 1880s and early 1890s. It was often possible to build cruisers which were faster and better all-round using this type of ship, which relied on a lighter armoured deck to protect the vital parts of the ship; however, by the late 1880s the development of rapid-fire cannon and high-explosive shells made the reintroduction of side armour a necessity. The invention of face-hardened armour in the mid-1890s offered effective protection with less weight than previously. Schematic of armoured cruiser. Red lines: armoured upper and middle decks and side belt. Grey areas: lateral protective coal bunkers. The machinery was arranged in the protected internal void above the double-bottom.

Light Cruiser

WARFARE Sea Materiel Cruiser Light Cruiser

A light cruiser is a type of small- or medium-sized warship. The term is a shortening of the phrase "light armoured cruiser", describing a small ship that carried armour in the same way as an armoured cruiser: a protective belt and deck. Prior to this smaller cruisers had been of the protected cruiser model, possessing armoured decks only. While lighter and smaller than other contemporary ships they were still true cruisers, retaining the extended radius of action and self-sufficiency to act independently across the world. Through their history they served in a variety of roles, primarily as convoy escorts and destroyer command ships, but also as scouts and fleet support vessels for battle fleets. BAP Almirante Grau of the Peruvian Navy was the last light cruiser in service, being retired in 2017. Another four are preserved as museum ships: HMS Belfast in London, HMS Caroline in Belfast, USS Little Rock in Buffalo, New York, and Mikhail Kutuzov at Novorossiysk. Similar ships include the protected cruisers Aurora (St. Petersburg) and USS Olympia (Philadelphia, Pennsylvania), and the bow of the Puglia (Italy). In the United States Navy, light cruisers have the hull classification symbol CL. Both heavy cruisers and light cruisers were classified under a common CL/CA sequence after 1931, hence there are some missing hull numbers, see List of United States Navy cruisers. After the development of seaborne guided missiles in the 1950s, all remaining cruisers armed solely with guns, regardless of calibre were redesignated as "Gun Cruisers" (hull classification symbol CA), with guided missile cruisers (which generally carry some gun armament) gaining the new hull classification symbol CG. By the 1975 fleet realignment, all gun cruisers were out of the fleet.

Destroyer

WARFARE Sea Materiel Destroyer

In naval terminology, a destroyer is a fast, manoeuvrable long-endurance warship intended to escort larger vessels in a fleet, convoy or battle group and defend them against smaller powerful short-range attackers. They were originally developed in the late 19th century by Fernando Villaamil for the Spanish Navy as a defence against torpedo boats, and by the time of the Russo-Japanese War in 1904, these "torpedo boat destroyers" (TBDs) were "large, swift, and powerfully armed torpedo boats designed to destroy other torpedo boats". Although the term "destroyer" had been used interchangeably with "TBD" and "torpedo boat destroyer" by navies since 1892, the term "torpedo boat destroyer" had been generally shortened to simply "destroyer" by nearly all navies by the First World War.

Before World War II destroyers were light vessels with little endurance for unattended ocean operations; typically a number of destroyers and a single destroyer tender operated together. After the war, the advent of the guided missile allowed destroyers to take on the surface combatant roles previously filled by battleships and cruisers. This resulted in larger and more powerful guided missile destroyers more capable of independent operation.

At the start of the 21st century, destroyers are the global standard for surface combatant ships, with only two nations (United States and Russia) operating the heavier class cruisers, with no battleships or true battlecruisers remaining. Modern guided missile destroyers are equivalent in tonnage but vastly superior in firepower to cruisers of the World War II era, and are capable of carrying nuclear tipped cruise missiles. At 510 feet (160 m) long, a displacement of 9,200 tons, and with armament of more than 90 missiles, guided missile destroyers such as the Arleigh Burke-class are actually larger and more heavily armed than most previous ships classified as guided missile cruisers.

Dreadnought

WARFARE Sea Materiel Dreadnought

The dreadnought was the predominant type of battleship in the early 20th century. The first of its kind, the Royal Navy's HMS Dreadnought, made such a strong impression on people's minds when launched in 1906 that similar battleships built subsequently were referred to generically as "dreadnoughts", and earlier battleships became known as "pre-dreadnoughts". Dreadnought's design had two revolutionary features: an "all-big-gun" armament scheme, with more heavy-calibre guns than previous ships, and steam turbine propulsion. As dreadnoughts became a symbol of national power, the arrival of these new warships was a crucial catalyst in the intensifying naval arms race between the United Kingdom and Germany.

With the launch of a single ship, Dreadnought, the scales of naval power were reset overnight. As a result, dreadnought races sprang up around the world, including in South America, during the lead up to World War I. Successive designs increased rapidly in size and made use of improvements in armament, armour, and propulsion throughout the dreadnought era. Within five years, new battleships had outclassed Dreadnought. These more powerful vessels were known as "super-dreadnoughts". Most of the original dreadnoughts were scrapped after the end of World War I under the terms of the Washington Naval Treaty, but many of the newer super-dreadnoughts continued to be used throughout World War II.

The only surviving dreadnought is USS Texas, located near the San Jacinto Battleground State Historic Site. Dreadnought-building consumed vast resources in the early 20th century, but there was only one battle between large dreadnought fleets. In the 1916 Battle of Jutland, the British and German navies clashed with no decisive result. The term "dreadnought" gradually dropped from use after World War I, especially after the Washington Naval Treaty, as virtually all remaining battleships shared dreadnought characteristics; the term can also be used to describe battlecruisers, the other type of ship resulting from the dreadnought revolution.

Escort Aircraft Carrier

WARFARE Sea Materiel Escort Aircraft Carrier

The escort carrier or escort aircraft carrier (US hull classification symbol CVE), also called a "jeep carrier" or "baby flattop" in the United States Navy (USN) or "Woolworth Carrier" by the Royal Navy, was a small and slow type of aircraft carrier used by the Royal Navy, the United States Navy, the Imperial Japanese Navy and Imperial Japanese Army Air Force in World War II. They were typically half the length and a third the displacement of larger fleet carriers. While they were slower, carried fewer planes and were less well armed and armoured, escort carriers were cheaper and could be built quickly, which was their principal advantage. Escort carriers could be completed in greater numbers as a stop-gap when fleet carriers were scarce.

However, the lack of protection made escort carriers particularly vulnerable and several were sunk with great loss of life. The light carrier (hull classification symbol CVL) was a similar concept to escort carriers in most respects, but were capable of higher speeds to allow operation alongside fleet carriers. Most often built on a commercial ship hull, escort carriers were too slow to keep up with the main forces consisting of fleet carriers, battleships, and cruisers. Instead, they were used to escort convoys, defending them from enemy threats such as submarines and planes.

In the invasions of mainland Europe and Pacific islands, escort carriers provided air support to ground forces during amphibious operations. Escort carriers also served as backup aircraft transports for fleet carriers and ferried aircraft of all military services to points of delivery. In the Battle of the Atlantic, escort carriers were used to protect convoys against U-boats. Initially escort carriers accompanied the merchant ships and helped to fend off attacks from aircraft and submarines. As numbers increased later in the war, escort carriers also formed part of hunter-killer groups that sought out submarines instead of being attached to a particular convoy.

In the Pacific theatre, CVEs provided air support of ground troops in the Battle of Leyte Gulf. They lacked the speed and weapons to counter enemy fleets, relying on the protection of a Fast Carrier Task Force. However, at the Battle off Samar, one U.S. task force of escort carriers managed to successfully defend itself against a much larger Japanese force of battleships and cruisers. The Japanese met a furious defence of carrier aircraft, screening destroyers, and destroyer escorts, proving that CVEs could appear to have the same striking power as full CVs.

Frigate

A frigate is a type of warship, having various sizes and roles over the last few centuries. In the 17th century, a frigate was any warship built for speed and manoeuvrability, the description often used being "frigate-built". These could be warships carrying their principal batteries of carriage-mounted guns on a single deck or on two decks (with further smaller carriage-mounted guns usually carried on the forecastle and quarterdeck of the vessel). The term was generally used for ships too small to stand in the line of battle, although early line-of-battle ships were frequently referred to as frigates when they were built for speed.

In the 18th century, frigates were usually as long as a ship of the line and were square-rigged on all three masts (full-rigged), but were faster and with lighter armament, used for patrolling and escort. In the definition adopted by the British Admiralty, they were rated ships of at least 28 guns, carrying their principal armaments upon a single continuous deck – the upper deck – while ships of the line possessed two or more continuous decks bearing batteries of guns. In the late 19th century (beginning about 1858 with the construction of prototypes by the British and French navies), the armoured frigate was a type of ironclad warship that for a time was the most powerful type of vessel afloat.

The term "frigate" was used because such ships still mounted their principal armaments on a single continuous upper deck. In modern navies, frigates are used to protect other warships and merchant-marine ships, especially as anti-submarine warfare (ASW) combatants for amphibious expeditionary forces, underway replenishment groups, and merchant convoys. Ship classes dubbed "frigates" have also more closely resembled corvettes, destroyers, cruisers and even battleships. Some European navies such as the French, German or Spanish ones use the term "frigate" for both their destroyers and frigates. The rank "frigate captain" derives from the name of this type of ship.

Fast Attack Craft

A fast attack craft (FAC) is a small, fast, agile and offensive warship armed with anti-ship missiles, gun or torpedoes. FACs are usually operated in close proximity to land as they lack both the sea keeping and all-round defensive capabilities to survive in blue water. The size of the vessel also limits the fuel, stores and water supplies. In size they are usually between 50–800 tonnes and can reach speeds of 25–50 knots. A fast attack craft's main advantage over other warship types is its affordability.

Many FACs can be deployed at a relatively low cost, allowing a navy which is at a disadvantage to effectively defend itself against a larger adversary. A small boat, when equipped with the same weapons as its larger counterpart, can pose a serious threat to even the largest of capital ships. Their major disadvantages are poor seagoing qualities, cramped quarters and poor ability to defend themselves against aerial threat.

Gunboat

A gunboat is a naval watercraft designed for the express purpose of carrying one or more guns to bombard coastal targets, as opposed to those military craft designed for naval warfare, or for ferrying troops or supplies. In the later 19th century and early 20th century, "gunboat" was the common name for smaller armed vessels. These could be classified, from the smallest to the largest, into river gunboats, river monitors, coastal-defence gunboats (such as SMS Panther), and full-fledged monitors for coastal bombardments. In the 1870s and 1880s Britain took to building so called "flat-iron" (or Rendel) gunboats for coastal defence. When there would be few opportunities to re-coal, vessels carrying a full sailing rig continued in use as gunboats; HMS Gannet, a sloop preserved at Chatham Historic Dockyard in the United Kingdom, exemplifies this type of gunboat.

Hospital Ship

A hospital ship is a ship designated for primary function as a floating medical treatment facility or hospital. Most are operated by the military forces (mostly navies) of various countries, as they are intended to be used in or near war zones. Although attacking a hospital ship is a war crime, belligerent navies have the right to board such ships for inspections. In the nineteenth century redundant warships were used as moored hospitals for seamen.

Hospital ships were covered under the Hague Convention X of 1907. Article four of the Hague Convention X outlined the restrictions for a hospital ship:
● Ship must be clearly marked and lighted as a hospital ship
● The ship should give medical assistance to wounded personnel of all nationalities
● The ship must not be used for any military purpose
The ship must not interfere with or hamper enemy combatant vessels
● Belligerents, as designated by the Hague Convention, can search any hospital ship to investigate violations of the above restrictions
● Belligerents will establish the location of a hospital ship

According to the San Remo Manual on International Law Applicable to Armed Conflicts at Sea, a hospital ship violating legal restrictions must be duly warned and given a reasonable time limit to comply. If a hospital ship persists in violating restrictions, a belligerent is legally entitled to capture it or take other means to enforce compliance. A non-complying hospital ship may only be fired on under the following conditions:
● Diversion or capture is not feasible
● No other method to exercise control is available
● The violations are grave enough to allow the ship to be classified as a military objective
● The damage and casualties will not be disproportionate to the military advantage.

In all other circumstances, attacking a hospital ship is a war crime.

Ironclad

An ironclad is a steam-propelled warship protected by iron or steel armour plates used in the early part of the second half of the 19th century. The ironclad was developed as a result of the vulnerability of wooden warships to explosive or incendiary shells. The first ironclad battleship, Gloire, was launched by the French Navy in November 1859. The British Admiralty had been considering armoured warships since 1856 and prepared a draft design for an armoured corvette in 1857; in early 1859 the Royal Navy started building two iron-hulled armoured frigates, and by 1861 had made the decision to move to an all-armoured battle fleet. After the first clashes of ironclads (both with wooden ships and with one another) took place in 1862 during the American Civil War, it became clear that the ironclad had replaced the unarmoured ship of the line as the most powerful warship afloat. This type of ship would come to be very successful in the American Civil War.

Ironclads were designed for several roles, including as high seas battleships, coastal defence ships, and long-range cruisers. The rapid development of warship design in the late 19th century transformed the ironclad from a wooden-hulled vessel that carried sails to supplement its steam engines into the steel-built, turreted battleships and cruisers familiar in the 20th century. This change was pushed forward by the development of heavier naval guns (the ironclads of the 1880s carried some of the heaviest guns ever mounted at sea at the time), more sophisticated steam engines, and advances in metallurgy which made steel shipbuilding possible. The quick pace of change meant that many ships were obsolete as soon as they were finished, and that naval tactics were in a state of flux. Many ironclads were built to make use of the ram or the torpedo, which a number of naval designers considered the important weapons of naval combat. There is no clear end to the ironclad period, but towards the end of the 1890s the term ironclad dropped out of use. New ships were increasingly constructed to a standard pattern and designated battleships or armoured cruisers.

Landing Craft

WARFARE Sea Materiel Landing Craft

Landing craft are small and medium seagoing watercraft such as boats, and barges, used to convey a landing force (infantry and vehicles) from the sea to the shore during an amphibious assault. The term excludes landing ships, which are larger. Production of landing craft peaked during World War II, with a significant number of different designs produced in large quantities by the United Kingdom and United States. Because of the need to run up onto a suitable beach, World War II landing craft were flat-bottomed, and many designs had a flat front, often with a lowerable ramp, rather than a normal bow. This made them difficult to control and very uncomfortable in rough seas. The control point (too rudimentary to call a bridge on LCA and similar craft) was normally at the extreme rear of the vessel, as were the engines. In all cases, they were known by an abbreviation derived from the official name rather than by the full title.

Littoral Combat Ship

WARFARE Sea Materiel Littoral Combat Ship

The Littoral combat ship (LCS) is a set of two classes of relatively small surface vessels designed for operations near shore by the United States Navy. It was "envisioned to be a networked, agile, stealthy surface combatant capable of defeating anti-access and asymmetric threats in the littorals." Littoral combat ships are the American equivalent of corvettes. The Freedom class and the Independence class are the first two LCS variants. Each is slightly smaller than the U.S. Navy's Oliver Hazard Perry-class frigate but larger than Cyclone-class patrol ships. They have the capabilities of a small assault transport, including a flight deck and hangar for housing two SH-60 or MH-60 Seahawk helicopters, a stern ramp for operating small boats, and the cargo volume and payload to deliver a small assault force with fighting vehicles to a roll-on/roll-off port facility.

Standard armaments include Mk 110 57 mm guns and RIM-116 Rolling Airframe Missiles. They are also equipped with autonomous air, surface, and underwater vehicles. Possessing lower air defence and surface warfare capabilities than destroyers, the LCS concept emphasizes speed, flexible mission modules and a shallow draft. The first littoral combat ship, USS Freedom, was commissioned on 8 November 2008 in Veteran's Park, Milwaukee, Wisconsin. The second ship, and first of the trimaran-based USS Independence, was commissioned on 16 January 2010, in Mobile, Alabama.

The concept behind the littoral combat ship, as described by former Secretary of the Navy Gordon R. England, is to "create a small, fast, manoeuvrable and relatively inexpensive member of the DD(X) family of ships." The ship is easy to reconfigure for different roles, including anti-submarine warfare, mine countermeasures, anti-surface warfare, intelligence, surveillance and reconnaissance, homeland defence, maritime intercept, special operations, and logistics. Due to its modular design, the LCS will be able to replace slower, more specialized ships such as minesweepers and larger amphibious-type assault ships. Most of the mission modules' functions are performed by carried vehicles such as helicopters or unmanned vehicles such as the Spartan Scout, AN/WLD-1 RMS Remote Minehunting System and MQ-8B Fire Scout as part of the Navy's goal to "unman the front lines".

Performing functions such as sonar sweeps for mines or submarines as well as launching torpedoes against hostile submarines at a distance from the ship is less risky. Placing sensors on remote vehicles allows the LCS to exploit concepts such as bistatic sonar. DARPA's Tactically Exploited Reconnaissance Node (TERN) program aims to build a Medium-altitude long-endurance unmanned aerial vehicle (MALE UAV) that can operate from LCS-2 and can carry a payload of 600 pounds (270 kg) out to an operational radius of 600–900 nautical miles (1,100–1,700 km).

Mine Planter

WARFARE Sea Materiel Mine Planter

Mine planter and the earlier "torpedo planter" was a term used for mine warfare ships into the early days of World War I. In later terminology, particularly in the United States, a mine planter was a ship specifically designed to install controlled mines or contact mines in coastal fortifications. This type of ship diverged in both function and design from a ship operating as a naval minelayer. Though the vessel may be seagoing it is not designed to lay large numbers of mines in open sea. A mine planter was designed to place controlled minefields in exact locations so that they might be fired individually or as a group from shore when observers noted a target to be at or near a designated mine's position. The terms and types of specialized ship existed from the 1860s where "torpedoes" were made famous in the American Civil War until the demise of large, fixed coastal fortifications brought on by the changes of World War II. The earliest mines were the "torpedoes" associated with harbour defences. Thus the vessels required to place the torpedoes were termed torpedo planters with the equipment evolving with the mines.

Minesweeper

WARFARE Sea Materiel Minesweeper

A minesweeper is a small naval warship designed to engage in minesweeping. Using various mechanisms intended to counter the threat posed by naval mines, waterways are kept clear for safe shipping. Minesweepers are equipped with mechanical or electrical devices, known as "sweeps", for disabling mines. The modern minesweeper is designed to reduce the chances of it detonating mines itself; it is soundproofed to reduce its acoustic signature and often constructed using wood, fiberglass or non-ferrous metal, or is degaussed to reduce its magnetic signature. Mechanical sweeps are devices designed to cut the anchoring cables of moored mines, and preferably attach a tag to help the subsequent localization and neutralization. They are towed behind the minesweeper, and use a towed body (e.g. oropesa, paravane) to maintain the sweep at the desired depth and position. Influence sweeps are equipment, often towed, that emulate a particular ship signature, thereby causing a mine to detonate. The most common such sweeps are magnetic and acoustic generators.

There are two modes of operating an influence sweep: MSM (mine setting mode) and TSM (target simulation mode or target setting mode). MSM sweeping is founded on intelligence on a given type of mine, and produces the output required for detonation of this mine. If such intelligence is unavailable, the TSM sweeping instead reproduces the influence of the friendly ship that is about to transit the area. TSM sweeping thus clears mines directed at this ship without knowledge of the mines. However, mines directed at other ships might remain. The minesweeper differs from a minehunter; the minehunter actively detects and neutralises individual mines. Minesweepers are in many cases complementary to minehunters, depending on the operation and the environment; a minesweeper is, in particular, better suited to clearing open-water areas with large numbers of mines. Both kinds of ships are collectively called mine countermeasure vessels (MCMV), a term also applied to a vessel that combines both roles. The first such ship was HMS Wilton, also the first warship to be constructed from fiberglass.

Missile Boat

WARFARE Sea Materiel Missile Boat

A missile boat or missile cutter is a small fast warship armed with anti-ship missiles. Being smaller than other warships such as destroyers and frigates, missile boats are popular with nations interested in forming a navy at lower cost. They are similar in concept to the torpedo boats of World War II; in fact, the first missile boats were modified torpedo boats with the torpedo tubes replaced by missile tubes. The doctrine behind the use of missile boats is based on the principle of mobility over defence and firepower. The advent of proper guided missile and electronic countermeasure technologies gave birth to the idea that warships could now be designed to outmanoeuvre their enemies and conceal themselves while carrying powerful weapons. Previously, increasing the potency of naval artillery required larger projectiles, which required larger and heavier guns, which in turn called for larger ships to carry these guns and their ammunition and absorb their recoil. This trend culminated in the giant battleships of World War II. The ability to deploy anti-ship guided self-propelled warheads from small, manoeuvrable platforms partially negated the advantages provided by the earlier and larger warships.

Missile boats, when equipped with sophisticated anti-ship missiles, and especially when used in a swarm, can pose a significant threat to even the largest of capital ships, and do so at much greater ranges than is possible with torpedoes. Iran and North Korea have some of the largest numbers of missile boats in operation today. North Korea alone operates more than 300, while Iran has been developing "swarm boats" to be used as harassing vessels in the heavily contested littoral waters of the Persian Gulf. To counter the threat, the US Navy has been developing an ASUW Littoral Defensive Anti-Surface Warfare doctrine, along with vessels such as the littoral combat ship. The People's Liberation Army Navy of China also has a large fleet of missile craft, which include Type 22 missile boats, Type 037IG Houxin-class missile boats and Type 037II Houjian-class missile boats, with a total of 109 units.

Monitor (Warship)

WARFARE Sea Materiel Monitor

A monitor was a relatively small warship which was neither fast nor strongly armoured but carried disproportionately large guns. They were used by some navies from the 1860s, during the First World War and with limited use in the Second World War. During the Vietnam War they were used by the United States Navy. The Brazilian Navy's Parnaíba is the last monitor in service. The original monitor was designed in 1861 by John Ericsson, who named it USS Monitor. They were designed for shallow waters and served as coastal ships. The term "monitor" also encompassed more flexible breastwork monitors, and was sometimes used as a generic term for any turreted ship. The term "monitor" also encompasses the strongest of riverine warcraft, known as river monitors. In the early 20th century, the term "monitor" was revived for shallow-draught armoured shore bombardment vessels, particularly those of the Royal Navy: the Lord Clive-class monitors carried guns firing heavier shells than any other warship ever has, seeing action (albeit briefly) against German targets during World War I. The Lord Clive vessels were scrapped in the 1920s.

Patrol Boat

WARFARE Sea Materiel Patrol Boat

A patrol boat (also referred to as a patrol craft, patrol ship or patrol vessel) is a relatively small naval vessel generally designed for coastal defence duties. There have been many designs for patrol boats. They may be operated by a nation's navy, coast guard, police force or customs and may be intended for marine (blue water) or estuarine or river ("brown water") environments. They are commonly found engaged in various border protection roles, including anti-smuggling, anti-piracy, fisheries patrols, and immigration law enforcement. They are also often called upon to participate in rescue operations. Vessels of this type include the original yacht (from Dutch/Low German jacht meaning hunting or hunt), a light, fast-sailing vessel used by the Dutch navy to pursue pirates and other transgressors around and into shallow waters. They may be broadly classified as inshore patrol vessels (IPVs) and offshore patrol vessels (OPVs). They are warships typically smaller in size than a corvette and can include fast attack craft, torpedo boats and missile boats, although some are as large as a frigate. The offshore patrol vessels are usually the smallest ship in a navy's fleet that is large and seaworthy enough to patrol off-shore in the open ocean. In larger militaries, such as in the United States military, offshore patrol vessels usually serve in the coast guard, but many smaller nations navies operate these type of ships.

Torpedo Boat

WARFARE Sea Materiel Torpedo Boat

A torpedo boat is a relatively small and fast naval ship designed to carry torpedoes into battle. The first designs rammed enemy ships with explosive spar torpedoes, and later designs launched self-propelled Whitehead torpedoes. They were created to counter battleships and other slow and heavily armed ships by using speed, agility, and the power of their torpedo weapons. A number of inexpensive torpedo boats attacking en masse could overwhelm a larger ship's ability to fight them off using its large but cumbersome guns. An inexpensive fleet of torpedo boats could pose a threat to much larger and more expensive fleets of capital ships, albeit only in the coastal areas to which their small size and limited fuel load restricted them. The introduction of fast torpedo boats in the late 19th century was a serious concern to the era's naval strategists. In response, navies operating large ships introduced smaller ships to counter torpedo boats, mounting light quick-firing guns. These ships, which came to be called "torpedo boat destroyers" and later simply "destroyers", became larger and took on more roles, making torpedo attacks as well as defending against them, and eventually defending against submarines and aircraft. The destroyer eventually became the predominant type of surface warship in the guided missile age. In the modern era, the old concept of a very small, fast, and cheap surface combatant with powerful offensive weapons is taken up by the "fast attack craft".

Patrol Torpedo (PT) Boat

WARFARE Sea Materiel Patrol Torpedo (PT) Boat

A PT boat (short for patrol torpedo boat) was a torpedo-armed fast attack vessel (MTB) used by the United States Navy in World War II. It was small, fast, and inexpensive to build, valued for its manoeuvrability and speed but hampered at the beginning of the war by ineffective torpedoes, limited armament, and comparatively fragile construction that limited some of the variants to coastal waters. The PT boat was very different from the first generation of torpedo boat, which had been developed at the end of the 19th century and featured a displacement hull form. These first generation torpedo boats rode low in the water, displaced up to 300 tons, and had a top speed of 25 to 27 kn (29 to 31 mph; 46 to 50 km/h). During World War I Italy, the US and UK developed the first high-performance motor torpedo boats (often with top speeds over 40 kn (46 mph; 74 km/h)) and corresponding torpedo tactics, but these projects were all quickly disbanded with the Armistice. World War II PT boats continued to exploit some of the advances in planing hull design borrowed from offshore powerboat racing and were able to grow in size due to advancements in engine technology.

During World War II, PT boats engaged enemy warships, transports, tankers, barges, and sampans. As gunboats they could be effective against enemy small craft, especially armoured barges used by the Japanese for inter-island transport. Several saw service with the Philippine Navy, where they were named "Q-boats", most probably after President Manuel L. Quezon. Primary anti-ship armament was four 2,600 pound (1,179 kg) Mark 8 torpedoes. Launched by 21-inch Mark 18 (530 mm) torpedo tubes, each bore a 466-pound (211 kg) TNT warhead and had a range of 16,000 yards (14,630 m) at 36 knots (66 km/h). Two twin M2 .50 cal (12.7 mm) machine guns were mounted for anti-aircraft defence and general fire support. Some boats shipped a 20 mm Oerlikon cannon. Propulsion was via a trio of Packard 4M-2500 and later 5M-2500 supercharged gasoline-fuelled, liquid-cooled marine engines. Nicknamed "the mosquito fleet" – and "devil boats" by the Japanese – the PT boat squadrons were hailed for their daring and earned a durable place in the public imagination that remains strong into the 21st century.

Q-Ship

WARFARE Sea Materiel Q-

Q-ships, also known as Q-boats, decoy vessels, special service ships, or mystery ships, were heavily armed merchant ships with concealed weaponry, designed to lure submarines into making surface attacks. This gave Q-ships the chance to open fire and sink them. They were used by the British Royal Navy (RN) and the German Kaiserliche Marine during the First World War and by the RN, the Kriegsmarine and the United States Navy during the Second World War (1939–45).

Seaplane Tender

WARFARE Sea Materiel Seaplane Tender

A seaplane tender is a boat or ship that supports the operation of seaplanes. Some of these vessels, the seaplane carriers, could not only carry seaplanes but also provided all the facilities needed for their operation; these ships are regarded by some as the first aircraft carriers and appeared just before the First World War. In maritime parlance a tender is a vessel that is used to support the operation of other vessels. In British usage, the term tender was used for small craft, with the term depot ship being used for large sea going vessels. Flying boats and float planes even when based at home in ports and harbour had a need for small support vessels to operate. British tenders were small craft of launch to pinnace size. These were used to ferry crews, stores and supplies between shore and the aircraft, to maintain the buoys used to mark out "taxiways" and "runways" and to keep these clear of debris to prevent foreign object damage, and in the case of emergency to act as rescue craft and airport crash tenders. All those functions that on land would require wheeled ground support equipment had a need for a watercraft equivalent. When deploying flying boat squadrons, bases could rapidly be established in areas lacking infrastructure by sending in addition to small craft tenders, flying boat depot ships, these ships could carry out the function of barracks, workshops and control towers, i.e. those functions which in a land based airfield would be fulfilled by buildings.

Submarine

RFARE Sea Materiel arine

WARFARE Sea Materiel Submarine

A submarine (or simply sub) is a watercraft capable of independent operation underwater. It differs from a submersible, which has more limited underwater capability. It is also sometimes used historically or colloquially to refer to remotely operated vehicles and robots, as well as medium-sized or smaller vessels, such as the midget submarine and the wet sub. Although experimental submarines had been built before, submarine design took off during the 19th century, and they were adopted by several navies. Submarines were first widely used during World War I (1914–1918), and are now used in many navies large and small. Military uses include attacking enemy surface ships (merchant and military), attacking other submarines, aircraft carrier protection, blockade running, ballistic missile submarines as part of a nuclear strike force, reconnaissance, conventional land attack (for example using a cruise missile), and covert insertion of special forces. Civilian uses for submarines include marine science, salvage, exploration and facility inspection and maintenance. Submarines can also be modified to perform more specialized functions such as search-and-rescue missions or undersea cable repair. Submarines are also used in tourism, and for undersea archaeology. Most large submarines consist of a cylindrical body with hemispherical (or conical) ends and a vertical structure, usually located amidships, which houses communications and sensing devices as well as periscopes. In modern submarines, this structure is the "sail" in American usage and "fin" in European usage.

A "conning tower" was a feature of earlier designs: a separate pressure hull above the main body of the boat that allowed the use of shorter periscopes. There is a propeller (or pump jet) at the rear, and various hydrodynamic control fins. Smaller, deep-diving and specialty submarines may deviate significantly from this traditional layout. Submarines use diving planes and also change the amount of water and air in ballast tanks to change buoyancy for submerging and surfacing. Submarines have one of the widest ranges of types and capabilities of any vessel. They range from small autonomous examples and one- or two-person vessels that operate for a few hours, to vessels that can remain submerged for six months—such as the Russian Typhoon class, the biggest submarines ever built. Submarines can work at greater depths than are survivable or practical for human divers. Modern deep-diving submarines derive from the bathyscaphe, which in turn evolved from the diving bell.

WARFARE Sea Materiel Submarine

All surface ships, as well as surfaced submarines, are in a positively buoyant condition, weighing less than the volume of water they would displace if fully submerged. To submerge hydrostatically, a ship must have negative buoyancy, either by increasing its own weight or decreasing its displacement of water. To control their displacement, submarines have ballast tanks, which can hold varying amounts of water and air. For general submersion or surfacing, submarines use the forward and aft tanks, called Main Ballast Tanks (MBT), which are filled with water to submerge or with air to surface. Submerged, MBTs generally remain flooded, which simplifies their design, and on many submarines these tanks are a section of interhull space. For more precise and quick control of depth, submarines use smaller Depth Control Tanks (DCT) – also called hard tanks (due to their ability to withstand higher pressure), or trim tanks. The amount of water in depth control tanks can be controlled to change depth or to maintain a constant depth as outside conditions (chiefly water density) change. Depth control tanks may be located either near the submarine's centre of gravity, or separated along the submarine body to prevent affecting trim. When submerged, the water pressure on a submarine's hull can reach 4 MPa (580 psi) for steel submarines and up to 10 MPa (1,500 psi) for titanium submarines like K-278 Komsomolets, while interior pressure remains relatively unchanged. This difference results in hull compression, which decreases displacement. Water density also marginally increases with depth, as the salinity and pressure are higher. This change in density incompletely compensates for hull compression, so buoyancy decreases as depth increases.

WARFARE Sea Materiel Submarine

A submerged submarine is in an unstable equilibrium, having a tendency to either sink or float to the surface. Keeping a constant depth requires continual operation of either the depth control tanks or control surfaces. Submarines in a neutral buoyancy condition are not intrinsically trim-stable. To maintain desired trim, submarines use forward and aft trim tanks. Pumps can move water between the tanks, changing weight distribution and pointing the sub up or down. A similar system is sometimes used to maintain stability. The hydrostatic effect of variable ballast tanks is not the only way to control the submarine underwater. Hydrodynamic manoeuvring is done by several surfaces, which can be moved to create hydrodynamic forces when a submarine moves at sufficient speed. The stern planes, located near the propeller and normally horizontal, serve the same purpose as the trim tanks, controlling the trim, and are commonly used, while other control surfaces may not be present on all submarines. The fairwater planes on the sail and/or bow planes on the main body, both also horizontal, are closer to the centre of gravity, and are used to control depth with less effect on the trim. When a submarine performs an emergency surfacing, all depth and trim methods are used simultaneously, together with propelling the boat upwards. Such surfacing is very quick, so the sub may even partially jump out of the water, potentially damaging submarine systems.

WARFARE Sea Materiel Submarine

Hull

Modern submarines are cigar-shaped. This design, visible in early submarines, is sometimes called a "teardrop hull". It reduces the hydrodynamic drag when submerged, but decreases the sea-keeping capabilities and increases drag while surfaced. Since the limitations of the propulsion systems of early submarines forced them to operate surfaced most of the time, their hull designs were a compromise. Because of the slow submerged speeds of those subs, usually well below 10 kt (18 km/h), the increased drag for underwater travel was acceptable. Late in World War II, when technology allowed faster and longer submerged operation and increased aircraft surveillance forced submarines to stay submerged, hull designs became teardrop shaped again to reduce drag and noise. USS Albacore (AGSS-569) was a unique research submarine that pioneered the American version of the teardrop hull form (sometimes referred to as an "Albacore hull") of modern submarines. On modern military submarines the outer hull is covered with a layer of sound-absorbing rubber, or anechoic plating, to reduce detection. The occupied pressure hulls of deep diving submarines such as DSV Alvin are spherical instead of cylindrical. This allows a more even distribution of stress at the great depth. A titanium frame is usually affixed to the pressure hull, providing attachment for ballast and trim systems, scientific instrumentation, battery packs, syntactic flotation foam, and lighting.

WARFARE Sea Materiel Submarine

A raised tower on top of a submarine accommodates the periscope and electronics masts, which can include radio, radar, electronic warfare, and other systems including the snorkel mast. In many early classes of submarines (see history), the control room, or "conn", was located inside this tower, which was known as the "conning tower". Since then, the conn has been located within the hull of the submarine, and the tower is now called the "sail". The conn is distinct from the "bridge", a small open platform in the top of the sail, used for observation during surface operation. Modern submarines and submersibles, as well as the oldest ones, usually have a single hull. Large submarines generally have an additional hull or hull sections outside. This external hull, which actually forms the shape of submarine, is called the outer hull (casing in the Royal Navy) or light hull, as it does not have to withstand a pressure difference. Inside the outer hull there is a strong hull, or pressure hull, which withstands sea pressure and has normal atmospheric pressure inside. As early as World War I, it was realized that the optimal shape for withstanding pressure conflicted with the optimal shape for sea keeping and minimal drag, and construction difficulties further complicated the problem. This was solved either by a compromise shape, or by using two hulls; internal for holding pressure, and external for optimal shape.

WARFARE Sea Materiel Submarine

Until the end of World War II, most submarines had an additional partial cover on the top, bow and stern, built of thinner metal, which was flooded when submerged. Germany went further with the Type XXI, a general predecessor of modern submarines, in which the pressure hull was fully enclosed inside the light hull, but optimized for submerged navigation, unlike earlier designs that were optimized for surface operation. The pressure hull is generally constructed of thick high-strength steel with a complex structure and high strength reserve, and is separated with watertight bulkheads into several compartments. There are also examples of more than two hulls in a submarine, like the Typhoon class, which has two main pressure hulls and three smaller ones for control room, torpedoes and steering gear, with the missile launch system between the main hulls. The dive depth cannot be increased easily. Simply making the hull thicker increases the weight and requires reduction of on-board equipment weight, ultimately resulting in a bathyscaphe. This is acceptable for civilian research submersibles, but not military submarines.

WARFARE Sea Materiel Submarine

Propulsion

The first submarines were propelled by humans. The first mechanically driven submarine was the 1863 French Plongeur, which used compressed air for propulsion. Anaerobic propulsion was first employed by the Spanish Ictineo II in 1864, which used a solution of zinc, manganese dioxide, and potassium chlorate to generate sufficient heat to power a steam engine, while also providing oxygen for the crew. A similar system was not employed again until 1940 when the German Navy tested a hydrogen peroxide-based system, the Walter turbine, on the experimental V-80 submarine and later on the naval U-791 and type XVII submarines. Until the advent of nuclear marine propulsion, most 20th-century submarines used batteries for running underwater and gasoline (petrol) or diesel engines on the surface, and for battery recharging. Early submarines used gasoline, but this quickly gave way to kerosene (paraffin), then diesel, because of reduced flammability. Diesel-electric became the standard means of propulsion. The diesel or gasoline engine and the electric motor, separated by clutches, were initially on the same shaft driving the propeller. This allowed the engine to drive the electric motor as a generator to recharge the batteries and also propel the submarine. The clutch between the motor and the engine would be disengaged when the submarine dived, so that the motor could drive the propeller. The motor could have multiple armatures on the shaft, which could be electrically coupled in series for slow speed and in parallel for high speed (these connections were called "group down" and "group up", respectively).

Nuclear Power
Steam power was resurrected in the 1950s with a nuclear-powered steam turbine driving a generator. By eliminating the need for atmospheric oxygen, the time that a submarine could remain submerged was limited only by its food stores, as breathing air was recycled and fresh water distilled from seawater. More importantly, a nuclear submarine has unlimited range at top speed. This allows it to travel from its operating base to the combat zone in a much shorter time and makes it a far more difficult target for most anti-submarine weapons. Nuclear-powered submarines have a relatively small battery and diesel engine/generator power plant for emergency use if the reactors must be shut down. Nuclear power is now used in all large submarines, but due to the high cost and large size of nuclear reactors, smaller submarines still use diesel-electric propulsion. The ratio of larger to smaller submarines depends on strategic needs. The US Navy, French Navy, and the British Royal Navy operate only nuclear submarines, which is explained by the need for distant operations. Other major operators rely on a mix of nuclear submarines for strategic purposes and diesel-electric submarines for defence. Most fleets have no nuclear submarines, due to the limited availability of nuclear power and submarine technology.

Armament
The success of the submarine is inextricably linked to the development of the torpedo, invented by Robert Whitehead in 1866. His invention is essentially the same now as it was 140 years ago. Only with self-propelled torpedoes could the submarine make the leap from novelty to a weapon of war. Until the perfection of the guided torpedo, multiple "straight-running" torpedoes were required to attack a target. With at most 20 to 25 torpedoes stored on board, the number of attacks was limited. To increase combat endurance most World War I submarines functioned as submersible gunboats, using their deck guns against unarmed targets, and diving to escape and engage enemy warships. The importance of guns encouraged the development of the unsuccessful Submarine Cruiser such as the French Surcouf and the Royal Navy's X1 and M-class submarines. With the arrival of Anti-submarine warfare (ASW) aircraft, guns became more for defence than attack. A more practical method of increasing combat endurance was the external torpedo tube, loaded only in port. The ability of submarines to approach enemy harbours covertly led to their use as minelayers. Minelaying submarines of World War I and World War II were specially built for that purpose. Modern submarine-laid mines, such as the British Mark 5 Stonefish and Mark 6 Sea Urchin, can be deployed from a submarine's torpedo tubes.

Sensors
A submarine can have a variety of sensors, depending on its missions. Modern military submarines rely almost entirely on a suite of passive and active sonars to locate targets. Active sonar relies on an audible "ping" to generate echoes to reveal objects around the submarine. Active systems are rarely used, as doing so reveals the sub's presence. Passive sonar is a set of sensitive hydrophones set into the hull or trailed in a towed array, normally trailing several hundred feet behind the sub. The towed array is the mainstay of NATO submarine detection systems, as it reduces the flow noise heard by operators. Hull mounted sonar is employed in addition to the towed array, as the towed array can't work in shallow depth and during manoeuvring. In addition, sonar has a blind spot "through" the submarine, so a system on both the front and back works to eliminate that problem. As the towed array trails behind and below the submarine, it also allows the submarine to have a system both above and below the thermocline at the proper depth; sound passing through the thermocline is distorted resulting in a lower detection range. Submarines also carry radar equipment to detect surface ships and aircraft. Submarine captains are more likely to use radar detection gear than active radar to detect targets, as radar can be detected far beyond its own return range, revealing the submarine. Periscopes are rarely used, except for position fixes and to verify a contact's identity. Civilian submarines, such as the DSV Alvin or the Russian Mir submersibles, rely on small active sonar sets and viewing ports to navigate. The human eye cannot detect sunlight below about 300 feet (91 m) underwater, so high intensity lights are used to illuminate the viewing area.

Navigation
Early submarines had few navigation aids, but modern subs have a variety of navigation systems. Modern military submarines use an inertial guidance system for navigation while submerged, but drift error unavoidably builds over time. To counter this, the crew occasionally uses the Global Positioning System to obtain an accurate position. The periscope—a retractable tube with a prism system that provides a view of the surface—is only used occasionally in modern submarines, since the visibility range is short. The Virginia-class and Astute-class submarines use photonics masts rather than hull-penetrating optical periscopes. These masts must still be deployed above the surface, and use electronic sensors for visible light, infrared, laser range-finding, and electromagnetic surveillance. One benefit to hoisting the mast above the surface is that while the mast is above the water the entire sub is still below the water and is much harder to detect visually or by radar.

Communication
Military submarines use several systems to communicate with distant command centres or other ships. One is VLF (very low frequency) radio, which can reach a submarine either on the surface or submerged to a fairly shallow depth, usually less than 250 feet (76 m). ELF (extremely low frequency) can reach a submarine at greater depths, but has a very low bandwidth and is generally used to call a submerged sub to a shallower depth where VLF signals can reach. A submarine also has the option of floating a long, buoyant wire antenna to a shallower depth, allowing VLF transmissions by a deeply submerged boat. By extending a radio mast, a submarine can also use a "burst transmission" technique. A burst transmission takes only a fraction of a second, minimizing a submarine's risk of detection. To communicate with other submarines, a system known as Gertrude is used. Gertrude is basically a sonar telephone. Voice communication from one submarine is transmitted by low power speakers into the water, where it is detected by passive sonars on the receiving submarine. The range of this system is probably very short, and using it radiates sound into the water, which can be heard by the enemy.

Life Support Systems
With nuclear power or air-independent propulsion, submarines can remain submerged for months at a time. Conventional diesel submarines must periodically resurface or run on snorkel to recharge their batteries. Most modern military submarines generate breathing oxygen by electrolysis of water (using a device called an "Elektrolytic Oxygen Generator"). Atmosphere control equipment includes a CO2 scrubber, which uses an amine absorbent to remove the gas from air and diffuse it into waste pumped overboard. A machine that uses a catalyst to convert carbon monoxide into carbon dioxide (removed by the CO2 scrubber) and bonds hydrogen produced from the ship's storage battery with oxygen in the atmosphere to produce water, is also used. An atmosphere monitoring system samples the air from different areas of the ship for nitrogen, oxygen, hydrogen, R-12 and R-114 refrigerants, carbon dioxide, carbon monoxide, and other gases. Poisonous gases are removed, and oxygen is replenished by use of an oxygen bank located in a main ballast tank. Some heavier submarines have two oxygen bleed stations (forward and aft). The oxygen in the air is sometimes kept a few percent less than atmospheric concentration to reduce fire danger. Fresh water is produced by either an evaporator or a reverse osmosis unit. The primary use for fresh water is to provide feedwater for the reactor and steam propulsion plants. It is also available for showers, sinks, cooking and cleaning once propulsion plant needs have been met.

Seawater is used to flush toilets, and the resulting "black water" is stored in a sanitary tank until it is blown overboard using pressurized air or pumped overboard by using a special sanitary pump. The blackwater–discharge system is difficult to operate, and the German Type VIIC boat U-1206 was lost with casualties because of human error while using this system. Water from showers and sinks is stored separately in "grey water" tanks and discharged overboard using drain pumps. Trash on modern large submarines is usually disposed of using a tube called a Trash Disposal Unit (TDU), where it is compacted into a galvanized steel can. At the bottom of the TDU is a large ball valve. An ice plug is set on top of the ball valve to protect it, the cans atop the ice plug. The top breech door is shut, and the TDU is flooded and equalized with sea pressure, the ball valve is opened and the cans fall out assisted by scrap iron weights in the cans. The TDU is also flushed with seawater to ensure it is completely empty and the ball valve is clear before closing the valve.

Submarine Aircraft Carrier

A submarine aircraft carrier is a submarine equipped with aircraft for observation or attack missions. These submarines saw their most extensive use during World War II, although their operational significance remained rather small. The most famous of them were the Japanese I-400-class submarines and the French submarine Surcouf, although small numbers of similar craft were built for other nations' navies as well. Most operational submarine aircraft carriers, with the exception of the I-400 and AM classes, used their aircraft for reconnaissance and observation. This is in contrast to the typical surface aircraft carrier, whose main function is serving as a base for offensive aircraft. No submarine aircraft carriers remain in use, but the concept reappears periodically. The ability to make a stealth attack has an allure, but sustained air operations largely negate the advantage of being submersible, and the size limitations preclude sizable sustained aerial operations. Furthermore, any submarine large enough to be useful would be vulnerable to detection and counterattack. Combined with the cost for such a specialized vessel, it is unlikely that any navy would consider their construction worthwhile. In addition, submarine launchable cruise missiles increasingly incorporate limited surveillance capabilities, allowing them to serve as both strike weapons and disposable reconnaissance drones; this further reduces the value of operating aircraft from submarines.

U-Boat

U-boat is an anglicised version of the German word U-Boot, a shortening of Unterseeboot, literally "underseaboat." While the German term refers to any submarine, the English one (in common with several other languages) refers specifically to military submarines operated by Germany, particularly in the First and Second World Wars. Although at times they were efficient fleet weapons against enemy naval warships, they were most effectively used in an economic warfare role (commerce raiding) and enforcing a naval blockade against enemy shipping. The primary targets of the U-boat campaigns in both wars were the merchant convoys bringing supplies from Canada and other parts of the British Empire, and from the United States to the United Kingdom and (during the Second World War) to the Soviet Union and the Allied territories in the Mediterranean. German submarines also destroyed Brazilian merchant ships during World War II, causing Brazil to declare war on the Axis powers in 1944.

Submarine Chaser

A submarine chaser is a small and fast naval vessel that is specifically intended for anti-submarine warfare. Many of the American submarine chasers used in World War I found their way to Allied nations by way of Lend-Lease in World War II. U.S. Navy submarine chasers were designed specifically to destroy German submarines in World War I, and Japanese and German submarines in World War II. The small 110-foot (34 m) SC-1-class submarine chasers of the design used in World War I carried the hull designator SC (for Submarine Chaser). Their main weapon was the depth charge. They also carried machine guns and anti-aircraft guns. The similar-sized SC-497-class was built for World War II. Also in World War II, larger 173-foot (53 m) PC-461-class submarine chasers used the PC hull classification symbol (for Patrol, Coastal).

Survey Ship

A survey vessel is any type of ship or boat that is used for mapping. It is a type of research vessel.

The task of survey vessels is to map the bottom, benthic zone, full water column, and surface for the purpose of:
- Hydrography
- General oceanography
- Marine habitats
- Salvage
- Dredging
- Marine archaeology

Typically, modern survey vessels are equipped with one or more of the following equipment:
- GPS positioning and logging
- Single beam sonar
- Multibeam sonar
- Side-scan sonar
- Towed magnetometer
- Subsurface profiler
- Grab sampler
- Bottom coring device
- DCHP
- CTD
- Inertial Measurement Unit

Troopship

A troopship (also troop ship or troop transport or trooper) is a ship used to carry soldiers, either in peacetime or wartime. Operationally, standard troopships – often drafted from commercial shipping fleets – cannot land troops directly on shore, typically loading and unloading at a seaport or onto smaller vessels, either tenders or barges. Attack transports, a variant of ocean-going troopship adapted to transporting invasion forces ashore, carry their own fleet of landing craft. Landing ships beach themselves and bring their troops directly ashore.

5 Air Materiel

A military aircraft is any fixed-wing or rotary-wing aircraft that is operated by a legal or insurrectionary armed service of any type. Military aircraft can be either combat or non-combat:

- Combat aircraft are designed to destroy enemy equipment using their own aircraft ordnance. Combat aircraft are typically developed and procured only by military forces.
- Non-combat aircraft are not designed for combat as their primary function, but may carry weapons for self-defence. These mainly operate in support roles, and may be developed by either military forces or civilian organizations.

Combat aircraft, or "Warplanes", are divided broadly into multi-role, fighters, bombers, attackers, and electronic warfare support. Variations exist between them, including fighter-bombers, such as the MiG-23 ground-attack aircraft and the Soviet Ilyushin Il-2 Shturmovik. Also included among combat aircraft are long-range maritime patrol aircraft, such as the Hawker Siddeley Nimrod and the S-3 Viking that are often equipped to attack with anti-ship missiles and anti-submarine weapons.

Fighter Aircraft

The primary role of fighters is destroying enemy aircraft in air-to-air combat, as part of both offensive and defensive counter air operations. Many fighters also possess a degree of ground attack capability, allowing them to perform surface attack and close air support missions. In addition to their counter air duties they are tasked to perform escort mission for bombers or other aircraft. Fighters are capable of carrying a variety of weapons, including machine guns, cannons, rockets, guided missiles, and bombs. Many modern fighters can attack enemy fighters from a great distance, before the enemy even sees or detects them. Examples of fighters include the F-22 Raptor, F-15 Eagle, and Su-27.

Fighter Aircraft

A fighter aircraft is a military aircraft designed primarily for air-to-air combat against other aircraft, as opposed to bombers and attack aircraft, whose main mission is to attack ground targets. The hallmarks of a fighter are its speed, manoeuvrability, and small size relative to other combat aircraft. Many fighters have secondary ground-attack capabilities, and some are designed as dual-purpose fighter-bombers; often aircraft that do not fulfil the standard definition are called fighters. This may be for political or national security reasons, for advertising purposes, or other reasons. A fighter's main purpose is to establish air superiority over a battlefield. Since World War I, achieving and maintaining air superiority has been considered essential for victory in conventional warfare. The success or failure of a belligerent's efforts to gain air superiority hinges on several factors including the skill of its pilots, the tactical soundness of its doctrine for deploying its fighters, and the numbers and performance of those fighters. Because of the importance of air superiority, since the early days of aerial combat armed forces have constantly competed to develop technologically superior fighters and to deploy these fighters in greater numbers, and fielding a viable fighter fleet consumes a substantial proportion of the defence budgets of modern armed forces.

Fifth Generation Jet Fighters (2005 to the present)
Currently the cutting edge of fighter design, fifth-generation fighters are characterized by being designed from the start to operate in a network-centric combat environment, and to feature extremely low, all-aspect, multi-spectral signatures employing advanced materials and shaping techniques. They have multifunction AESA radars with high-bandwidth, low-probability of intercept (LPI) data transmission capabilities. The Infra-red search and track sensors incorporated for air-to-air combat as well as for air-to-ground weapons delivery in the 4.5th generation fighters are now fused in with other sensors for Situational Awareness IRST or SAIRST, which constantly tracks all targets of interest around the aircraft so the pilot need not guess when he glances. These sensors, along with advanced avionics, glass cockpits, helmet-mounted sights (not currently on F-22), and improved secure, jamming-resistant LPI datalinks are highly integrated to provide multi-platform, multi-sensor data fusion for vastly improved situational awareness while easing the pilot's workload. Avionics suites rely on extensive use of very high-speed integrated circuit (VHSIC) technology, common modules, and high-speed data buses. Overall, the integration of all these elements is claimed to provide fifth-generation fighters with a "first-look, first-shot, first-kill capability".

A key attribute of fifth-generation fighters is a small radar cross-section. Great care has been taken in designing its layout and internal structure to minimize RCS over a broad bandwidth of detection and tracking radar frequencies; furthermore, to maintain its VLO signature during combat operations, primary weapons are carried in internal weapon bays that are only briefly opened to permit weapon launch. Furthermore, stealth technology has advanced to the point where it can be employed without a trade-off with aerodynamics performance, in contrast to previous stealth efforts. Some attention has also been paid to reducing IR signatures, especially on the F-22. Detailed information on these signature-reduction techniques is classified, but in general includes special shaping approaches, thermoset and thermoplastic materials, extensive structural use of advanced composites, conformal sensors, heat-resistant coatings, low-observable wire meshes to cover intake and cooling vents, heat ablating tiles on the exhaust troughs (seen on the Northrop YF-23), and coating internal and external metal areas with radar-absorbent materials and paint (RAM/RAP). The AESA radar offers unique capabilities for fighters (and it is also quickly becoming essential for Generation 4.5 aircraft designs, as well as being retrofitted onto some fourth-generation aircraft).

In addition to its high resistance to ECM and LPI features, it enables the fighter to function as a sort of "mini-AWACS," providing high-gain electronic support measures (ESM) and electronic warfare (EW) jamming functions. Other technologies common to this latest generation of fighters includes integrated electronic warfare system (INEWS) technology, integrated communications, navigation, and identification (CNI) avionics technology, centralized "vehicle health monitoring" systems for ease of maintenance, fibre optics data transmission, stealth technology and even hovering capabilities. Manoeuvre performance remains important and is enhanced by thrust-vectoring, which also helps reduce take-off and landing distances.

Supercruise may or may not be featured; it permits flight at supersonic speeds without the use of the afterburner – a device that significantly increases IR signature when used in full military power. Such aircraft are sophisticated and expensive. The fifth generation was ushered in by the Lockheed Martin/Boeing F-22 Raptor in late 2005. The U.S. Air Force originally planned to acquire 650 F-22s, but now only 187 will be built. As a result, its unit flyaway cost (FAC) is around US$150 million. To spread the development costs – and production base – more broadly, the Joint Strike Fighter (JSF) program enrols eight other countries as cost- and risk-sharing partners.

Altogether, the nine partner nations anticipate procuring over 3,000 Lockheed Martin F-35 Lightning II fighters at an anticipated average FAC of $80–85 million. The F-35, however, is designed to be a family of three aircraft, a conventional take-off and landing (CTOL) fighter, a short take-off and vertical landing (STOVL) fighter, and a Catapult Assisted Take Off But Arrested Recovery (CATOBAR) fighter, each of which has a different unit price and slightly varying specifications in terms of fuel capacity (and therefore range), size and payload. Other countries have initiated fifth-generation fighter development projects, with Russia's Sukhoi Su-57 and Mikoyan LMFS. In December 2010, it was discovered that China is developing the 5th generation fighter Chengdu J-20. The J-20 took its maiden flight in January 2011.

The Shenyang J-31 took its maiden flight on 31 October 2012. Japan is exploring its technical feasibility to produce fifth-generation fighters. India is developing the Advanced Medium Combat Aircraft (AMCA), a medium weight stealth fighter jet designated to enter into serial production by late 2030s. India also had initiated a joint fifth generation heavy fighter with Russia called the FGFA. As of 2018 May, the project is suspected to have not yielded desired progress or results for India and has been put on hold or dropped altogether. Other countries considering fielding an indigenous or semi-indigenous advanced fifth generation aircraft include Korea, Sweden and Turkey.

Sixth Generation Jet Fighters

As of November 2018, France, Germany, Japan, Russia, the United Kingdom and the United States have announced the development of a sixth-generation aircraft program. France and Germany will develop a joint sixth-generation fighter to replace their current fleet of Dassault Rafales, Eurofighter Typhoons, and Panavia Tornados by 2035. The overall development will be led by a collaboration of Dassault and Airbus, while the engines will reportedly be jointly developed by Safran and MTU Aero Engines. Thales and MBDA are also seeking a stake in the project. Spain is reportedly planning to join the programme in the later stages and is expected to sign a letter of intent in early 2019. Currently at the concept stage, the first sixth-generation jet fighter is expected to enter service in the United States Air Force and United States Navy in 2025–30 period. The USAF seeks a new fighter for the 2030–50 period named the "Next Generation Tactical Aircraft" ("Next Gen TACAIR"). The US Navy looks to replace its F/A-18E/F Super Hornets beginning in 2025 with the Next Generation Air Dominance air superiority fighter. The United Kingdom's proposed stealth fighter is being developed by a European consortium called Team Tempest, consisting of BAE Systems, Rolls-Royce, Leonardo S.p.A. and MBDA. The aircraft is intended to enter service in 2035.

Fighter Weapons

Throughout the history of air combat, fighters which, by surprise or manoeuvre, attain a good firing position have achieved the kill about one third to one half the time, no matter what weapons were carried. The only major historic exception to this has been the low effectiveness shown by guided missiles in the first one to two decades of their existence. From WWI to the present fighter aircraft have featured machine guns and automatic cannons as weapons, and they are still considered as essential back-up weapons today. The power of air-to-air guns has increased greatly over time, and has kept them relevant in the guided missile era. In WWI two rifle calibre machine guns was the typical armament producing a weight of fire of about 0.4 kg (0.88 lb) per second. The standard WWII American fighter armament of six 0.50-cal (12.7mm) machine guns fired a bullet weight of approximately 3.7 kg/sec (8.1 lbs/sec), at a muzzle velocity of 856 m/s (2,810 ft/s). British and German aircraft tended to use a mix of machine guns and autocannon, the latter firing explosive projectiles. The modern M61 Vulcan 20 mm rotating barrel Gatling gun that is standard on current American fighters fires a projectile weight of about 10 kg/s (22 lb/s), nearly three times that of six 0.50-cal machine guns, with higher velocity of 1,052 m/s (3450 ft/s) supporting a flatter trajectory, and with exploding projectiles.

Modern fighter gun systems also feature ranging radar and lead computing electronic gun sights to ease the problem of aim point to compensate for projectile drop and time of flight (target lead) in the complex three dimensional manoeuvring of air-to-air combat. However, getting in position to use the guns is the challenge. The range of guns is longer than in the past but still quite limited compared to missiles, with modern gun systems having a maximum effective range of approximately 1,000 meters. High probability of kill also requires firing to usually occur from the rear hemisphere of the target. Despite these limits, when pilots are well trained in air-to-air gunnery and these conditions are satisfied, gun systems are tactically effective and highly cost efficient. The cost of a gun firing pass is far less than firing a missile, and the projectiles are not subject to the thermal and electronic countermeasures than can sometimes defeat missiles. When the enemy can be approached to within gun range, the lethality of guns is approximately a 25% to 50% chance of "kill per firing pass". The range limitations of guns, and the desire to overcome large variations in fighter pilot skill and thus achieve higher force effectiveness, led to the development of the guided air-to-air missile. There are two main variations, heat-seeking (infrared homing), and radar guided.

Radar missiles are typically several times heavier and more expensive than heat-seekers, but with longer range, greater destructive power, and ability to track through clouds. The highly successful AIM-9 Sidewinder heat-seeking (infrared homing) short-range missile was developed by the United States Navy in the 1950s. These small missiles are easily carried by lighter fighters, and provide effective ranges of approximately 10 to 35 km (~6 to 22 miles). Beginning with the AIM-9L in 1977, subsequent versions of Sidewinder have added all-aspect capability, the ability to use the lower heat of air to skin friction on the target aircraft to track from the front and sides.

The latest (2003 service entry) AIM-9X also features "off-boresight" and "lock on after launch" capabilities, which allow the pilot to make a quick launch of a missile to track a target anywhere within the pilot's vision. The AIM-9X development cost was U.S. $3 billion in mid to late 1990s dollars, and 2015 per unit procurement cost is $0.6 million each. The missile weighs 85.3 kg (188 lbs), and has a maximum range of 35 km (22 miles) at higher altitudes. Like most air-to-air missiles, lower altitude range can be as limited as only about one third of maximum due to higher drag and less ability to coast downward.

The effectiveness of heat-seeking missiles was only 7% early in the Vietnam War, but improved to approximately 15%–40% over the course of the war. The AIM-4 Falcon used by the USAF had kill rates of approximately 7% and was considered a failure. The AIM-9B Sidewinder introduced later achieved 15% kill rates, and the further improved AIM-9D and J models reached 19%. The AIM-9G used in the last year of the Vietnam air war achieved 40%. Israel used almost totally guns in the 1967 Six-Day War, achieving 60 kills and 10 losses. However, Israel made much more use of steadily improving heat-seeking missiles in the 1973 Yom Kippur War.

In this extensive conflict Israel scored 171 of out of 261 total kills with heat-seeking missiles (65.5%), 5 kills with radar guided missiles (1.9%), and 85 kills with guns (32.6%). The AIM-9L Sidewinder scored 19 kills out of 26 fired missiles (73%) in the 1982 Falklands War. But, in a conflict against opponents using thermal countermeasures, the United States only scored 11 kills out of 48 fired (Pk = 23%) with the follow-on AIM-9M in the 1991 Gulf War. Radar guided missiles fall into two main missile guidance types. In the historically more common semi-active radar homing case the missile homes in on radar signals transmitted from launching aircraft and reflected from the target.

This has the disadvantage that the firing aircraft must maintain radar lock on the target and is thus less free to manoeuvre and more vulnerable to attack. A widely deployed missile of this type was the AIM-7 Sparrow, which entered service in 1954 and was produced in improving versions until 1997. In more advanced active radar homing the missile is guided to the vicinity of the target by internal data on its projected position, and then "goes active" with an internally carried small radar system to conduct terminal guidance to the target. This eliminates the requirement for the firing aircraft to maintain radar lock, and thus greatly reduces risk. A prominent example is the AIM-120 AMRAAM, which was first fielded in 1991 as the AIM-7 replacement, and which has no firm retirement date as of 2016. The current AIM-120D version has a maximum high altitude range of greater than 160 km (>99 miles), and cost approximately $2.4 million each (2016). As is typical with most other missiles, range at lower altitude may be as little as one third that of high altitude. In the Vietnam air war radar missile kill reliability was approximately 10% at shorter ranges, and even worse at longer ranges due to reduced radar return and greater time for the target aircraft to detect the incoming missile and take evasive action. At one point in the Vietnam war, the U.S. Navy fired 50 AIM-7 Sparrow radar guided missiles in a row without a hit. Between 1958 and 1982 in five wars there were 2,014 combined heat-seeking and radar guided missile firings by fighter pilots engaged in air-to-air combat, achieving 528 kills, of which 76 were radar missile kills, for a combined effectiveness of 26%.

However, only four of the 76 radar missile kills were in the beyond-visual-range mode intended to be the strength of radar guided missiles. The United States invested over $10 billion in air-to-air radar missile technology from the 1950s to the early 1970s. Amortized over actual kills achieved by the U.S. and its allies, each radar guided missile kill thus cost over $130 million. The defeated enemy aircraft were for the most part older MiG-17s, −19s, and −21s, with new cost of $0.3 million to $3 million each. Thus, the radar missile investment over that period far exceeded the value of enemy aircraft destroyed, and furthermore had very little of the intended BVR effectiveness.

However, continuing heavy development investment and rapidly advancing electronic technology led to significant improvement in radar missile reliabilities from the late 1970s onward. Radar guided missiles achieved 75% Pk (9 kills out of 12 shots) in operations in the Gulf War in 1991. The percentage of kills achieved by radar guided missiles also surpassed 50% of total kills for the first time by 1991. Since 1991, 20 of 61 kills worldwide have been beyond-visual-range using radar missiles. Discounting an accidental friendly fire kill, in operational use the AIM-120D (the current main American radar guided missile) has achieved 9 kills out of 16 shots for a 56% Pk. Six of these kills were BVR, out of 13 shots, for a 46% BVR Pk. Though all these kills were against less capable opponents who were not equipped with operating radar, electronic countermeasures, or a comparable weapon themselves, the BVR Pk was a significant improvement from earlier eras.

However, a current concern is electronic countermeasures to radar missiles, which are thought to be reducing the effectiveness of the AIM-120D. Some experts believe that as of 2016 the European Meteor missile, the Russian K-37M, and the Chinese PL-15 are more resistant to countermeasures and more effective than the AIM-120D. Now that higher reliabilities have been achieved, both types of missiles allow the fighter pilot to often avoid the risk of the short-range dogfight, where only the more experienced and skilled fighter pilots tend to prevail, and where even the finest fighter pilot can simply get unlucky.

Taking maximum advantage of complicated missile parameters in both attack and defence against competent opponents does take considerable experience and skill, but against surprised opponents lacking comparable capability and countermeasures, air-to-air missile warfare is relatively simple. By partially automating air-to-air combat and reducing reliance on gun kills mostly achieved by only a small expert fraction of fighter pilots, air-to-air missiles now serve as highly effective force multipliers.

Air Superiority Fighter

An air superiority fighter, is a type of fighter aircraft designed for entering and seizing control of enemy airspace as a means of establishing complete dominance over the enemy's air force (air supremacy). Air superiority fighters are designed primarily to effectively engage enemy fighters, more than other types of aircraft, although some may have a secondary role for air-to-ground strikes. During World War II and through the Korean War, fighters were classified by their role: heavy fighter, interceptor, escort fighter, night fighter, and so forth. With the development of guided missiles in the 1950s, design diverged between fighters optimized to fight in the beyond visual range (BVR) regime (interceptors), and fighters optimized to fight in the within visual range (WVR) regime (air superiority fighters). In the United States, the influential proponents of BVR developed fighters with no forward-firing gun, such as the original F-4 Phantom II, as it was thought that they would never need to resort to WVR combat. These aircraft would sacrifice high manoeuvrability, and instead focus on other performance characteristics, as they presumably would never engage in a dogfight with enemy fighters.

After lessons learned from combat experiences involving modern military air capacity, the U.S. Navy's VFAX/VFX and U.S. Air Force's F-X (Fighter Experimental) reassessed their tactical direction which resulted in the U.S. Navy's F-14 Tomcat and US Air Force's F-15 Eagle. The two designs were built to achieve air superiority and significant consideration was given during the development of both aircraft to allow them to excel at the shorter ranges of fighter combat. Both aircraft also serve as interceptors due to their high maximum speed. By contrast, the Soviets (and the succeeding Russian Federation) developed and continue to operate separate types of air superiority (MiG-29, Su-27) and interceptor (MiG-25, MiG-31) fighters. For the US Navy, the F-14 Tomcat was initially deployed solely as an air superiority fighter (plus fleet defence interceptor and tactical aerial reconnaissance). By contrast, the multirole F/A-18 Hornet was designed as strike fighter while having only enough of an edge to defend itself against enemy fighters if needed.

While the F-14 had an undeveloped secondary ground attack capability, the Navy did not want to risk it in the air-to-ground role at the time, due to its lack of proper defensive electronic countermeasures (DECM) and radar homing and warning (RHAW) for overland operations, as well as the fighter's high cost. In the 1990s, the US Navy added LANTIRN pods to its F-14s and deployed them on precision ground-attack missions. The F-15 Eagle was envisioned originally as an air superiority fighter and interceptor under the mantra "not a pound for air-to-ground". However, the F-15C can carry "dumb" and GPS guided bombs, such capabilities which were first used by Israeli Air Force. In fact, the basic airframe proved versatile enough to produce a very capable strike fighter, the F-15E Strike Eagle. While designed for ground attack, it retains the air-to-air lethality of the original F-15. Similarly, the F-16 Fighting Falcon was also originally designed as an air superiority fighter but has since evolved into a successful all-weather multirole aircraft. Since the 1990s, with air superiority fighters such as the F-14 and F-15 pressed into the strike role and/or having a strike derivative, the lines between air superiority fighters and multirole fighters has blurred somewhat. With the retirement of the F-14 Tomcat, the US Navy has pressed its F/A-18 Hornet and its upsized derivative, the F/A-18E/F Super Hornet, into the air superiority role, despite the Hornets being originally designed as multirole strike fighters.

Interceptor Aircraft

An interceptor aircraft, or simply interceptor, is a type of fighter aircraft designed specifically to attack enemy aircraft, particularly bombers and reconnaissance aircraft, as they approach. There are two general classes of interceptor: relatively lightweight aircraft built for high performance, and heavier aircraft designed to fly at night or in adverse weather and operate over longer ranges. For daytime operations, conventional fighters normally fill the interceptor role, as well as many other missions. Daytime interceptors have been used in a defensive role since the World War I era, but are perhaps best known from several major actions during World War II, notably the Battle of Britain where the Supermarine Spitfire and Hawker Hurricane developed a good reputation. Few aircraft can be considered dedicated daytime interceptors. Exceptions include the Messerschmitt Me 163B—the only rocket-powered, manned military aircraft ever to see combat—and to a lesser degree designs like the Mikoyan-Gurevich MiG-15, which had heavy armament specifically intended for anti-bomber missions.

Night fighters and bomber destroyers are, by definition, interceptors of the heavy type, although initially they were rarely referred to as such. In the early Cold War era the combination of jet-powered bombers and nuclear weapons created air forces' demand for highly capable interceptors; it is during this period that the term is perhaps most recognized and used. Examples of classic interceptors of this era include the F-106 Delta Dart, Sukhoi Su-15, and English Electric Lightning. Through the 1960s and 1970s, the rapid improvements in design led to most air-superiority and multirole fighters, such as the Grumman F-14 Tomcat and McDonnell Douglas F-15 Eagle, having the performance to take on the interceptor role, and the strategic threat moved from bombers to intercontinental ballistic missiles (ICBMs). Dedicated interceptor designs became rare, with the only widely used examples designed after the 1960s being the Tornado F3, Mikoyan MiG-25 "Foxbat", Mikoyan MiG-31 "Foxhound", and the Shenyang J-8 "Finback".

WARFARE Air Materiel Fighter Aircraft Interceptor Aircraft

Point Defence Interceptors
In the spectrum of various interceptors, one design approach especially shows sacrifices necessary to achieve decisive benefit in a chosen aspect of performance. A "Point defence interceptor" is of a lightweight design, intended to spend most of its time on the ground located at the defended target, and able to launch on demand, climb to altitude, manoeuvre and then attack the bomber in a very short time, before the bomber can deploy its weapons. At the end of Second World War, the Luftwaffe's most critical requirement was for interceptors as the Commonwealth and American air forces pounded German targets night and day.

As the bombing effort grew, notably in early 1944, the Luftwaffe introduced a rocket-powered design, the Messerschmitt Me 163 Komet, in the very-short-range interceptor role. The engine allowed about 7 minutes of powered flight, but offered such tremendous performance that they could fly right by the defending fighters. The Me 163 required an airbase, however, which were soon under constant attack. Following the Emergency Fighter Program, the Germans developed even odder designs, such as the Bachem Ba 349 Natter, which launched vertically and thus eliminated the need for an airbase.

In general all these initial German designs proved difficult to operate, often becoming death traps for their pilots, and had little effect on the bombing raids. Rocket-boosted variants of both of Germany's jet fighters; the Me 262 in its "C" subtype series, all nicknamed "home protector" (Heimatschützer, in four differing formats) and the planned He 162E subtype, using one of the same BMW 003R turbojet/rocket "mixed-power" engine as the Me 262C-2b Heimatschützer II used a pair of, had airworthy prototypes built, but were never produced in quantity.

In the initial stage of Cold War, bombers were expected to attack flying higher and faster, even at transonic speeds. Initial transonic and supersonic fighters had modest internal fuel tanks in their slim fuselages, but a very high fuel consumption. This led fighter prototypes emphasizing acceleration and operational ceiling, with a sacrifice on the loiter time, essentially limiting them to point defence role. Such were the mixed jet/rocket power Republic XF-91 or Saunders Roe SR.53.

The Soviet and Western trials with zero-length launch were also related. None of these found practical use. Designs that depended solely on jet engines achieved more success with the F-104 Starfighter (initial A version) and the English Electric Lightning. The role of manned point defence designs was reassigned to unmanned interceptors—surface-to-air missiles (SAMs)—which first reached an adequate level in 1954–1957. SAM advancements ended the concept of massed high-altitude bomber operations, in favour of penetrators (and later cruise missiles) flying a combination of techniques colloquially known as "flying below the radar". By flying terrain masking low-altitude nap-of-the-earth flight profiles the effective range, and therefore reaction time, of ground-based radar was limited to at best the radar horizon. In the case of ground radar systems this can be countered by placing radar systems on mountain tops to extend the radar horizon, or through placing high performance radars in interceptors or in AWACs aircraft used to direct point defence interceptors.

Area Defence
As capabilities continued to improve – especially through the widespread introduction of the jet engine and the adoption of high speed, low level flight profiles, the time available between detection and interception dropped. Most advanced point defence interceptors combined with long-range radars were struggling to keep the reaction time down enough to be effective. Fixed times, like the time needed for the pilot to climb into the cockpit, became an increasing portion of the overall mission time, there were few ways to reduce this. During the Cold War in times of heightened tensions, quick reaction alert (QRA) aircraft were kept piloted, fully fuelled and armed, with the engines running at idle on the runway ready to take off. The aircraft being kept topped up with fuel via hoses from underground fuel tanks. If a possible intruder was identified, the aircraft would be ready to take off as soon as the external fuel lines were detached. However, keeping QRA aircraft at this state of readiness was physically and mentally draining to the pilots and was expensive in terms of fuel. As an alternative, longer-range designs with extended loiter times were considered. These area defence interceptors or area defence fighters were in general larger designs intended to stay on lengthy patrol and protect a much larger area from attack, depending on greater detection capabilities, both in the aircraft themselves and operating with AWACS, rather than high speed to reach targets.

The exemplar of this concept was the Tupolev Tu-28. The later Panavia Tornado ADV was able to achieve long range in a smaller airframe through the use of more efficient engines. Rather than focusing on acceleration and climb rate, the design emphasis is on range and missile carrying capacity, which together translate into combat endurance, look-down/shoot-down radars good enough to detect and track fast moving interdictors against ground clutter, and the capability to provide guidance to air-to-air missiles (AAM) against these targets. High speed and acceleration was put into long-range and medium-range AAMs, and agility into short range dog fighting AAMs, rather than into the aircraft themselves. They were first to introduce all-weather avionics, assuring successful operations during night, rain, snow, or fog. Countries that were strategically dependent on surface fleet, most notably US and UK, maintained also fleet defence fighters, such as the F-14 Tomcat.

Fighter-Bomber

A fighter-bomber is a fighter aircraft that has been modified, or used primarily, as a light bomber or attack aircraft. It differs from bomber and attack aircraft primarily in its origins, as a fighter that has been adapted into other roles, whereas bombers and attack aircraft are developed specifically for bombing and attack roles. Although still used, the term fighter-bomber has less significance since the introduction of rockets and guided missiles into aerial warfare. Modern aircraft with similar duties are now typically called multirole combat aircraft or strike fighters.

Development
Prior to World War II, general limitations in available engine and aeronautical technology required that each proposed military aircraft have its design tailored to a specific prescribed role. Engine power grew dramatically during the early period of the war, roughly doubling between 1939 and 1943. The Bristol Blenheim, a typical light bomber of the opening stages of the war, was originally designed in 1934 as a fast civil transport to meet a challenge by Lord Rothermere, owner of the Daily Mail. It had two Bristol Mercury XV radial engines of 920 hp each, a crew of three, and its payload was just 1,200 lbs of bombs. The Blenheim suffered disastrous losses over France in 1939 when it encountered Messerschmitt Bf 109s, and light bombers were quickly withdrawn. In contrast, the Vought F4U Corsair fighter—which entered service in December 1942—had in common with its eventual U.S. Navy stablemate, the Grumman F6F Hellcat and the massive, seven-ton USAAF Republic P-47 Thunderbolt—a single Pratt & Whitney R-2800 Double Wasp radial engine of 2,000 hp in a much smaller, simpler and less expensive single-seat aircraft, and was the first aircraft design to ever fly with the Double Wasp engine in May 1940.

With less airframe and crew to lift, the Corsair's ordnance load was either four High Velocity Aircraft Rockets or 2,000 lbs of bombs; a later version could carry eight rockets or 4,000 lbs of bombs. The massive, powerful 18-cylinder Double Wasp engine weighed almost a ton—half as much again as the V12 Rolls-Royce Merlin and twice as much as the 9-cylinder Bristol Mercury that powered some heavy fighters. Increased engine power meant that many existing fighter designs could carry useful bomb loads, and adapt to the fighter-bomber role. Notable examples include the Focke-Wulf Fw 190, Hawker Typhoon and Republic P-47 Thunderbolt. Various bombing tactics and techniques could also be used: some designs were intended for high-level bombing, others for low-level semi-horizontal bombing, or even for low-level steep dive bombing as exemplified by the Blackburn Skua and North American A-36 Apache. Larger twin-engined aircraft were also used in the fighter-bomber role, especially where longer ranges were needed for naval strikes. Examples include the Lockheed P-38 Lightning, the Bristol Beaufighter (developed from a torpedo bomber), and de Havilland Mosquito (developed from an unarmed fast bomber). The Beaufighter MkV had a Boulton-Paul turret with four 0.303 in (7.7 mm) machine guns mounted aft of the cockpit but only two were built. Bristol's Blenheim was even pushed into service as a fighter during the Battle of Britain but it was not fast enough. Equipped with an early Airborne Interception (AI) radar set, however, it proved to be an effective night fighter.

Strike Fighter

In current military parlance, a strike fighter is a multirole combat aircraft designed to operate primarily as an attack aircraft, while also incorporating certain performance characteristics of a fighter for air-to-air combat. As a category, it is distinct from fighter-bombers. It is closely related to the concept of interdictor aircraft, but it puts more emphasis on air-to-air combat capabilities as a multirole combat aircraft. Examples of contemporary American strike fighters are the McDonnell Douglas F-15E Strike Eagle, Boeing F/A-18E/F Super Hornet, and Lockheed Martin F-35 Lightning II. Beginning in the 1940s, the term "strike fighter" was occasionally used in navies to refer to fighter aircraft capable of performing air-to-surface strikes, such as the Westland Wyvern, Blackburn Firebrand and Blackburn Firecrest.

The term entered normal use in the United States Navy by the end of the 1970s, becoming the official description of the new McDonnell Douglas F/A-18 Hornet. In 1983, the U.S. Navy even renamed each existing Fighter Attack Squadron to Strike Fighter Squadron to emphasize the air-to-surface mission (as the "Fighter Attack" designation was confused with the "Fighter" designation, which flew pure air-to-air missions). This name quickly spread to non-maritime use. When the F-15E Strike Eagle came into service, it was originally called a "dual role fighter", but it instead quickly became known as a "strike fighter". In 1995, the U.S. military's Joint Advanced Strike Technology program changed its name to the Joint Strike Fighter program. The project consequently resulted in the development of the F-35 Lightning II family of fifth generation multirole fighters to perform ground attack, reconnaissance, and air defence missions with stealth capability.

Bomber Aircraft

Bombers are normally larger, heavier, and less manoeuvrable than fighter aircraft. They are capable of carrying large payloads of bombs, torpedoes or cruise missiles. Bombers are used almost exclusively for ground attacks and not fast or agile enough to take on enemy fighters head-to-head. A few have a single engine and require one pilot to operate and others have two or more engines and require crews of two or more. A limited number of bombers, such as the B-2 Spirit, have stealth capabilities that keep them from being detected by enemy radar. An example of a conventional modern bomber would be the B-52 Stratofortress. An example of a World War II bomber would be a B-17 Flying Fortress. Bombers include light bombers, medium bombers, heavy bombers, dive bombers, and torpedo bombers.

Bomber

A bomber is a combat aircraft designed to attack ground and naval targets by dropping air-to-ground weaponry (such as bombs), firing torpedoes and bullets, or deploying air-launched cruise missiles.

Classification	
Strategic	Strategic bombing is done by heavy bombers primarily designed for long-range bombing missions against strategic targets such as supply bases, bridges, factories, shipyards, and cities themselves, to diminish the enemy's ability to wage war by limiting access to resources through crippling infrastructure or reducing industrial output. Current examples include the strategic nuclear-armed bombers: B-2 Spirit, B-52 Stratofortress, Tupolev Tu-95 'Bear', and Tupolev Tu-22M 'Backfire'; historically notable examples are the: Gotha G.IV, Avro Lancaster, Heinkel He 111, Junkers Ju 88, Boeing B-17 Flying Fortress, Consolidated B-24 Liberator, Boeing B-29 Superfortress, and Tupolev Tu-16 'Badger'.
Tactical	Tactical bombing, aimed at countering enemy military activity and in supporting offensive operations, is typically assigned to smaller aircraft operating at shorter ranges, typically near the troops on the ground or against enemy shipping. This role is filled by tactical bomber class, which crosses and blurs with various other aircraft categories: light bombers, medium bombers, dive bombers, interdictors, fighter-bombers, attack aircraft, multirole combat aircraft, and others.

Modern Era
At present, the U.S. and Russia are involved in developing replacements for their legacy bomber fleets, the USAF with the Northrop Grumman B-21 and the Russian Air Force with the PAK DA. A 1999 USAF report calls for the US bomber fleet to remain in service until the late 2030s-early 2040s, and the B-21 is scheduled to reach deployment in the 2020s. The U.S. is also considering another bomber in 2037. The B-21, however, required to provide an answer to the fifth generation defence systems (such as SA-21 Growlers, bistatic radar and active electronically scanned array radar). Also, it has been chosen to be able to stand against rising superpowers and other countries with semi-advanced military capability. Finally, a third reason is the role of long-term air support for areas with a low threat level (Iraq, Afghanistan), the latter referred to as close air support for the global war on terror (CAS for GWOT). The B-21 would thus be able to stay for extended periods on a same location (called persistence).

Strategic Bomber

A strategic bomber is a medium to long range penetration bomber aircraft designed to drop large amounts of air-to-ground weaponry onto a distant target for the purposes of debilitating the enemy's capacity to wage war. Unlike tactical bombers, penetrators, fighter-bombers, and attack aircraft, which are used in air interdiction operations to attack enemy combatants and military equipment, strategic bombers are designed to fly into enemy territory to destroy strategic targets (e.g., infrastructure, logistics, military installations, factories, cities, and civilians). In addition to strategic bombing, strategic bombers can be used for tactical missions. There are currently three countries that operate strategic bombers: the United States, Russia, and China. The modern strategic bomber role appeared after strategic bombing was widely employed, and atomic bombs were first used in combat during World War II. Nuclear strike missions (i.e., delivering nuclear-armed missiles or bombs) can potentially be carried out by most modern fighter-bombers and strike fighters, even at intercontinental range, with the use of aerial refuelling, so any nation possessing this combination of equipment and techniques theoretically has such capability. Primary delivery aircraft for a modern strategic bombing mission need not always necessarily be a heavy bomber type, and any modern aircraft capable of nuclear strikes at long range is equally able to carry out tactical missions with conventional weapons. An example is France's Mirage IV, a small strategic bomber replaced in service by the ASMP-equipped Mirage 2000N fighter-bomber and Rafale multirole fighter.

Post Cold War
Today the French Republic has limited its strategic armaments to a squadron of four nuclear-powered ballistic missile submarines, with 16 SLBM tubes apiece. France also maintains an active force of supersonic fighter-bombers carrying stand-off nuclear missiles such as the ASMP, with Mach 3 speed and a range of 500 kilometres. These missiles can be delivered by the Dassault Mirage 2000N and Rafale fighter-bombers; the Rafale is also capable of refuelling others in flight using a buddy refuelling pod. Newer strategic bombers such as the Rockwell International B-1B Lancer, the Tupolev Tu-160, and the Northrop Grumman B-2 Spirit designs incorporate various levels of stealth technology in an effort to avoid detection, especially by radar networks.

Despite these advances earlier strategic bombers, for example the B-52 (last produced in 1962) or the Tupolev Tu-95 remain in service and can also deploy the latest air-launched cruise missiles and other "stand-off" or precision guided weapons such as the JASSM and the JDAM. The Russian Air Force's new Tu-160 strategic bombers are expected to be delivered on a regular basis over the course of 10 to 20 years. In addition, the current Tu-95 and Tu-160 bombers will be periodically updated, as was done during the 1990s with the Tu-22M bombers.

Strategic bombers of the Cold War were primarily armed with nuclear weapons. During the post-1940s Indochina Wars, and also since the end of the Cold War, modern bombers originally intended for strategic use have been exclusively employed using non-nuclear, high explosive weapons. During the Vietnam War, Operation Menu, Operation Freedom Deal, Gulf War, military action in Afghanistan, and the 2003 invasion of Iraq, American B-52s and B-1s were mostly employed in tactical roles. During the Soviet-Afghan war in 1979–88, Soviet Air Forces Tu-22Ms carried out several mass air raids in various regions of Afghanistan.

Nomenclature
Bombers listed below were used in the main or represented a shift in long-range bomber design (Maximum bomb load). In practice, bomb loads carried are dependent on factors such as the distance to target and the individual type, size or weight of bombs used. Nomenclature for size classification of aircraft types used in strategic bombing varies, particularly since the time of World War II due to sequential technological advancements and changes in aerial warfare strategy and tactics. The B-29, for example was a benchmark aircraft of the heavy bomber type at end of World War II due to its size, range and load carrying ability; as the Cold War began, it became an intercontinental range strategic bomber with the development of new techniques, such as aerial refuelling (which also greatly extended the range of other medium- to long-range bombers, fighter-bombers and attack aircraft). During the 1950s the U.S. Strategic Air Command also briefly brought back the out-dated term "medium bomber" to distinguish its Boeing B-47 Stratojets from somewhat larger contemporary Boeing B-52 Stratofortress "heavy bombers" in bombardment wings; older B-29 and B-50 heavy bombers were also redesignated as "medium" during this period.

SAC's nomenclature here was purely semantic and bureaucratic, however as both the B-47 and B-52 strategic bombers were much larger and had far greater performance and load-carrying ability than any of the World War II-era heavy or medium bombers. Other aircraft such as the twin-jet U.S. FB-111, Douglas A-3 Skywarrior and France's Dassault Mirage IV had nominal warloads of less than 20,000 lb (9,100 kg), and were significantly smaller in size and gross weight compared with their strategic bomber contemporaries, based on which they might be classified as medium bombers. In the nuclear strike role, France would replace its Mirage IVs beginning in the late 1980s with the even smaller, single-engine Mirage 2000N fighter-bomber, a further example of advancing technologies and changing tactics in military aviation and aircraft design. France's newer twin-engine Dassault Rafale multirole fighter also has nuclear strike capability.

Carpet Bombing
Carpet bombing, also known as saturation bombing, is a large aerial bombing done in a progressive manner to inflict damage in every part of a selected area of land. The phrase evokes the image of explosions completely covering an area, in the same way that a carpet covers a floor. Carpet bombing is usually achieved by dropping many unguided bombs. The term obliteration bombing is sometimes used to describe especially intensified bombing with the intention of destroying a city or a large part of the city. The term area bombing refers to indiscriminate bombing of an area and also encompasses cases of carpet bombing, including obliteration bombing. It was used in that sense especially during World War II. Carpet bombing of cities, towns, villages, or other areas containing a concentration of civilians is considered a war crime as of the 1977 Protocol I of the Geneva Conventions.

High Level Bombing
High level bombing (also called high-altitude bombing) is a tactic of dropping bombs from bomber aircraft in level flight at high altitude. The term is used in contrast to both World War II-era dive bombing and medium or low level bombing. Prior to the modern age of precision-guided munitions (PGMs), high level bombing was primarily used for strategic bombing—inflicting mass damage on the enemy's economy and population—not for attacks on specific military targets. High level bombing missions have been flown by many different types of aircraft, including medium bombers, heavy bombers, strategic bombers and fighter-bombers.

The choice to use high level bombing as an offensive tactic of aerial warfare is dependent not only upon the inherent accuracy and effectiveness of the bombing aircraft and their delivered ordnance on the target, but also upon a target's air defence capabilities. From the 1940s onward, radar in particular became a powerful new defensive early warning tool, and a serious threat to attacking aircraft when they flew at higher altitudes towards their target.

Bombing from medium to high altitudes, especially in the post-World War II era with sophisticated surface-to-air missiles, interceptor aircraft and radars exposes attacking bomber aircraft to greater risks of detection, interception and destruction. During World War II, various methods were employed to protect high level bombers from flak, fighter aircraft and radar detection, including defensive armament, escort fighters, chaff and electronic jamming. Modern stealth aircraft technologies, for example, can alleviate some risks inherent to high level bombing missions, but are not a guarantee of success or permanent solution for the attackers.

Strategic Bombing
Strategic bombing is a military strategy used in total war with the goal of defeating the enemy by destroying its morale or its economic ability to produce and transport materiel to the theatres of military operations, or both. It is a systematically organized and executed attack from the air which can utilize strategic bombers, long- or medium-range missiles, or nuclear-armed fighter-bomber aircraft to attack targets deemed vital to the enemy's war-making capability. One of the strategies of war is to demoralize the enemy, so that peace or surrender becomes preferable to continuing the conflict. Strategic bombing has been used to this end. The phrase "terror bombing" entered the English lexicon towards the end of World War II and many strategic bombing campaigns and individual raids have been described as terror bombing by commentators and historians. Because the term has pejorative connotations, some, including the Allies of World War II, have preferred to use euphemisms such as "will to resist" and "morale bombings". The theoretical distinction between tactical and strategic air warfare was developed between the two world wars. Some leading theorists of strategic air warfare during this period were the Italian Giulio Douhet, the Trenchard school in the United Kingdom, and General Billy Mitchell in the United States. These theorists were highly influential, both on the military justification for an independent air force (such as the Royal Air Force) and in influencing political thoughts on a future war as exemplified by Stanley Baldwin's 1932 comment that the bomber will always get through.

Defensive measures against air raids include:
- Attempting to shoot down attackers using fighter aircraft and anti-aircraft guns or surface-to-air missiles
- The use of air raid shelters to protect the population
- Air raid sirens
- Employment of Air Raid Wardens
- Setting up organizations like the British ARP (Air Raid Precautions)
- Blackouts - extinguishing all lights at night to make bombing less accurate

Tactical Bombing
Tactical bombing is aerial bombing aimed at targets of immediate military value, such as combatants, military installations, or military equipment. This is in contrast to strategic bombing, or attacking enemy cities and factories to cripple future military production and enemy civilians' will to support the war effort, in order to debilitate the enemy's long-term capacity to wage war. A tactical bomber is a bomber aircraft with an intended primary role of tactical bombing. Tactical bombing is employed for two primary assignments.

Aircraft providing close air support attack targets in nearby proximity to friendly ground forces, acting in direct support of the ground operations (as a "flying artillery"). Air interdiction, by contrast, attacks tactical targets that are distant from or otherwise not in contact with friendly units. Tactical bombing was the first type of aerial bombing mission. It began in World War I when pilots dropped small bombs over the side of their open cockpits onto enemy troops below. One of the earliest examples of tactical bombing was at the Battle of Neuve Chapelle in 1915 when the Royal Flying Corps dropped bombs on German rail communications.

By the time of World War II a number of specialized aircraft were developed to fulfil this role, including various fighter-bombers. During the Korean War tactical bombing missions were sometimes carried out by older piston-powered fighters such as the Vought F4U Corsair. In the Vietnam War, missions were frequently directed by forward air controllers (FACs) flying small propeller-driven planes. The FAC would mark targets with smoke, often in coordination with infantry on the ground. Bombers orbiting overhead would then fly in to hit the target. In the modern era, precision-guided munitions ("smart bombs") can be directed with extreme accuracy.

Heavy Bomber

Heavy bombers are bomber aircraft capable of delivering the largest payload of air-to-ground weaponry (usually bombs) and longest range of their era. Archetypal heavy bombers have therefore usually been among the largest and most powerful military aircraft at any point in time. In the second half of the 20th century, heavy bombers were largely superseded by strategic bombers, which were often smaller in size, but were capable of delivering nuclear weapons. Because of advances in aircraft design and engineering — especially in powerplants and aerodynamics — the size of payloads carried by heavy bombers have increased at rates greater than increases in the size of their airframes. The largest bombers of World War I, the four engine aircraft built by the Zeppelin-Staaken company in Germany, could carry a payload of up to 4,400 pounds (2,000 kg) of bombs. By the middle of World War II even a single-engine fighter-bomber could carry a 2,000-pound (910 kg) bomb load, and such aircraft were taking over from light and medium bombers in the tactical bombing role.

Advancements in four-engine aircraft design enabled heavy bombers to carry even larger payloads to targets thousands of kilometres away. For instance, the Avro Lancaster (introduced in 1942) routinely delivered payloads of 14,000 pounds (6,400 kg) (and sometimes up to 22,000 lb/10,000 kg) and had a range of 2,530 miles (4,070 km). The B-29 (1944) delivered payloads in excess of 20,000 pounds (9,100 kg) and had a range of 3,250 miles (5,230 km). By the early 1960s, the jet-powered Boeing B-52 Stratofortress, travelling at speeds of up to 650 miles per hour (1,050 km/h) (i.e., more than double that of a Lancaster), could deliver a payload of 70,000 pounds (32,000 kg), over a combat radius of 4,480 miles (7,210 km). During World War II, mass production techniques made available large, long-range heavy bombers in such quantities as to allow strategic bombing campaigns to be developed and employed.

This culminated in August 1945, when B-29s of the United States Army Air Forces dropped atomic bombs over Hiroshima and Nagasaki in Japan, contributing significantly to the end of hostilities. The arrival of nuclear weapons and guided missiles permanently changed the nature of military aviation and strategy. After the 1950s intercontinental ballistic missiles and ballistic missile submarines began to supersede heavy bombers in the strategic nuclear role. Along with the emergence of more accurate precision-guided munitions ("smart bombs") and nuclear-armed missiles, which could be carried and delivered by smaller aircraft, these technological advancements eclipsed the heavy bomber's once-central role in strategic warfare by the late 20th century. Heavy bombers have, nevertheless, been used to deliver conventional weapons in several regional conflicts since World War II (e.g., B-52s in the Vietnam War). Heavy bombers are now operated only by the air forces of the United States, Russia and China. They serve in both strategic and tactical bombing roles.

After World War II, the name strategic bomber came into use, for aircraft that could carry aircraft ordnances over long distances behind enemy lines. They were supplemented by smaller fighter-bombers with less range and lighter bomb load, for tactical strikes. Later these were called strike fighters, attack aircraft and multirole combat aircraft. When North Korea attacked South Korea in 1950 the USAF responded with daylight bomber raids on supply lines through North Korea. B-29 Superfortresses flew from Japan on behalf of the United Nations. But the supply to North Korea's army from the Soviet Union was physically and politically out of reach. There were no worthwhile strategic targets in North Korea. The Soviet mentored Northern forces easily routed the South Korean army. The distance to North Korea was too great for fighter escorts based in Japan. So the B-29s flew alone. In November, Mikoyan-Gurevich MiG-15s flown by Soviet pilots started to intercept the US bombers, over North Korea.

The MiG-15 was specifically designed to master US heavy bombers, with nuclear weapons. It could out-perform any fighter deployed by United Nations air forces until the capable F-86 Sabre was produced in greater numbers and brought to Korea. After 28 B-29s were lost, the bombers were restricted to night interdiction and concentrated on destroying supply routes, including the bridges over the Yalu river into China. By the 1960s, manned heavy bombers could not match the intercontinental ballistic missile in the strategic nuclear role. More accurate precision-guided munitions ("smart bombs"), nuclear-armed missiles or bombs were able to be carried by smaller aircraft such as fighter-bombers and multirole fighters. Despite these technological innovations and new capabilities of other contemporary military aircraft, large strategic bombers such as the B-1, B-52 and B-2 have been retained for the role of carpet bombing in several conflicts. The most prolific example (in terms of total bomb tonnage) is the U.S. Air Force B-52 Stratofortress during the 1960s–early 1970s Vietnam War era, in Operation Menu, Operation Freedom Deal, and Operation Linebacker II.

In 1987 the Soviet Tu-160 — the heaviest supersonic bomber/aircraft ever built — entered service; it can carry twelve long-range cruise missiles. The 2010 New START agreement between the United States of America and the Russian Federation defined a "heavy bomber" by two characteristics:
● Range greater than 8,000 kilometres (5,000 mi)
● Equipped for long-range nuclear "air-launched cruise missiles" (ALCMs), defined as an air-to-surface cruise missile of a type flight-tested from an aircraft or deployed on a bomber after 1986.

Medium Bomber

A medium bomber is a military bomber aircraft designed to operate with medium-sized bombloads over medium range distances; the name serves to distinguish this type from larger heavy bombers and smaller light bombers. Mediums generally carried about two tons of bombs, compared to light bombers that carried one ton, and heavies that carried four or more. The term was used prior to and during World War II, based on available parameters of engine and aeronautical technology for bomber aircraft designs at that time. After the war, medium bombers were replaced in world air forces by more advanced and capable aircraft.

History
Subsequent to World War II, only the U.S. Strategic Air Command ever used the term "medium bomber" in the 1950s to distinguish its Boeing B-47 Stratojets from somewhat larger contemporary Boeing B-52 Stratofortress "heavy bombers" in bombardment wings (older B-29 and B-50 heavy bombers were also redesignated as "medium" during this period). This nomenclature was purely semantic and bureaucratic, however as both the B-47 and B-52 strategic bombers were much larger and had far greater performance and load-carrying ability than any of the World War II-era heavy or medium bombers. Similarly, the Royal Air Force referred at times to its V bomber force as medium bombers, but this was in terms of range rather than load-carrying capacity. Although the term is no longer used, development of aircraft that fulfil a 'medium bomber' mission in all but name continued and these have been employed in various post-World War II conflicts; examples include dedicated tactical bombers such as the Su-24 and F-111 which have greater payload and range capability than fighter-bombers, but less than heavier strategic bombers.

Interdictor

An interdictor is a type of attack aircraft that operates far behind enemy lines, with the express intent of interdicting the enemy's military targets, most notably those involved in logistics. The interdiction prevents or delays enemy forces and supplies from reaching the battlefront; the term has generally fallen from use. The strike fighter is a closely related concept, but puts more emphasis on air-to-air combat capabilities as a multirole combat aircraft. Larger versions of the interdictor concept are generally referred to as penetrators.

In the post-war era, the RAF introduced interdictor variants of their English Electric Canberra jet bomber, the aircraft being available as the strategic bombing role had been taken over by the new V bombers. An early interdictor was the F-111, an aircraft able to operate at long distances from its base. The Panavia Tornado was built for a similar purpose, although operating over shorter ranges in the European theatre. The Soviet Sukhoi Su-24/Sukhoi Su-34, Chinese Xian JH-7 and the aborted British BAC TSR-2 are similar interdictor designs.

Attack Aircraft

Attack aircraft can be used to provide support for friendly ground troops. Some are able to carry conventional or nuclear weapons far behind enemy lines to strike priority ground targets. Attack helicopters attack enemy armour and provide close air support for ground troops. An example historical ground-attack aircraft is the Soviet Ilyushin Il-2 Shturmovik. Several types of transport airplanes have been armed with sideways firing weapons as gunships for ground attack. These include the AC-47 and AC-130 aircraft.

Attack Aircraft

An attack aircraft, strike aircraft, or attack bomber, is a tactical military aircraft that has a primary role of carrying out airstrikes with greater precision than bombers, and is prepared to encounter strong low-level air defences while pressing the attack. This class of aircraft is designed mostly for close air support and naval air-to-surface missions, overlapping the tactical bomber mission. Designs dedicated to non-naval roles are often known as ground-attack aircraft. Fighter aircraft often carry out the attack role, although they would not be considered attack aircraft per se, although fighter-bomber conversions of those same aircraft would be considered part of the class. Strike fighters, which have effectively replaced the fighter-bomber and light bomber concepts, also differ little from the broad concept of an attack aircraft. The dedicated attack aircraft as a separate class existed primarily during and after World War II. The precise implementation varied from country to country, and was handled by a wide variety of designs.

In the United States and Britain attack aircraft were generally light bombers or medium bombers, sometimes carrying heavier forward-firing weapons like the North American B-25G Mitchell and de Havilland Mosquito Tsetse. In Germany and the USSR, where they were known as Schlachtflugzeug ("battle aircraft") or sturmovik ("storm trooper") respectively, this role was carried out by purpose-designed and heavily armoured aircraft such as the Henschel Hs 129 and Ilyushin Il-2. The Germans and Soviets also used light bombers in this role: cannon-armed versions of the Junkers Ju 87 Stuka greatly outnumbered the Hs 129, while the Petlyakov Pe-2 was used for this role in spite of not being specifically designed for it. In the latter part of World War II the fighter-bomber began to take over many attack roles, a transition that continued in the post-war era. Jet-powered examples were relatively rare but not unknown, such as the Blackburn Buccaneer. The U.S. Navy continued to introduce new aircraft in their A-series, but these were mostly similar to light and medium bombers. The need for a separate attack aircraft category was greatly diminished by the introduction of precision-guided munitions which allowed almost any aircraft to carry out this role while remaining safe at high altitude.

Attack helicopters also have overtaken many remaining roles that could only be carried out at lower altitudes. Since the 1960s, only two dedicated attack aircraft designs have been widely introduced, the American Fairchild Republic A-10 Thunderbolt II and Soviet Sukhoi Su-25 Frogfoot. One anomaly belonging to this class is the Lockheed AC-130, which features as its primary armament high-calibre artillery guns adapted for aircraft use including the 105 mm M102 howitzer. A variety of light attack aircraft have also been introduced in the post-World War II era, usually based on adapted trainers or other light fixed-wing aircraft. These have been used in counter-insurgency operations.

Recent History
On 17 January 1991, Task Force Normandy began its attack on two Iraqi anti-aircraft missile sites. TF Normandy, under the command of LTC Richard A. "Dick" Cody, consisted of nine AH-64 Apaches, one UH-60 Black Hawk and four Air Force MH-53J Pave Low helicopters. The purpose of this mission was to create a safe corridor through the Iraqi air defence system. The attack was a huge success and cleared the way for the beginning of the Allied bombing campaign. One concern involving the Apache arose when a unit of these helicopters was very slow to deploy during U.S. military involvement in Kosovo. According to the Army Times, the Army is shifting its doctrine to favour ground-attack aircraft over attack helicopters for deep strike attack missions because ground-attack helicopters have proved to be highly vulnerable to small-arms fire; the U.S. Marine Corps has noted similar problems. In the late 1960s the United States Air Force requested a dedicated close air support (CAS) plane that became the Fairchild Republic A-10 Thunderbolt II.

The A-10 was originally conceived as an anti-armour weapon (the A-X program requirements specifically called for an aircraft mounting a large rotary cannon to destroy massed Warsaw Pact armoured forces) with limited secondary capability in the interdiction and tactical bombing roles. Today it remains the only dedicated fixed-wing ground-attack aircraft in any U.S. military service. Overall U.S. experience in the Gulf War, Kosovo War, Afghanistan and Iraq War has resulted in renewed interest in such aircraft. The U.S. Air Force is currently researching a replacement for the A-10 and started the OA-X program to procure a light attack aircraft. The Soviets' similar Sukhoi Su-25 (Frogfoot) found success in the "flying artillery" role with many air forces. The UK has completely retired the BAE Harrier II in 2011, expecting to obtain the F-35 in the near future; it retains its fleet of Panavia Tornado dedicated attack-reconnaissance aircraft and Eurofighter Typhoon multirole fighters.

Gunship

A gunship is a military aircraft armed with heavy guns, primarily intended for attacking ground targets. In modern usage the term "gunship" refers to fixed-wing aircraft aircraft having laterally-mounted heavy armaments (i.e. firing to the side) to attack ground or sea targets. These gunships were configured to circle the target instead of performing strafing runs. Such aircraft have their armament on one side harmonized to fire at the apex of an imaginary cone formed by the aircraft and the ground when performing a pylon turn (banking turn). The term "helicopter gunship" is commonly used to describe armed helicopters.

Fixed-Wing Aircraft
In the more modern, post-World War II fixed-wing aircraft category, a gunship is an aircraft having laterally-mounted heavy armaments (i.e. firing to the side) to attack ground or sea targets. These gunships were configured to circle the target instead of performing strafing runs. Such aircraft have their armament on one side harmonized to fire at the apex of an imaginary cone formed by the aircraft and the ground when performing a pylon turn (banking turn). The Douglas AC-47 Spooky was the first notable modern gunship. In 1964, during the Vietnam War, the popular Douglas C-47 Skytrain transport was successfully modified into a gunship by the United States Air Force with three side-firing Miniguns for circling attacks. At the time the aircraft was known as a "Dragonship", "Puff, the Magic Dragon" or "Spooky" (officially designated FC-47, later corrected to AC-47). Its three 7.62 mm miniguns could selectively fire either 50 or 100 rounds per second. Cruising in an overhead left-hand orbit at 120 knots air speed at an altitude of 3,000 feet (910 m), the gunship could put a bullet or glowing red tracer (every fifth round) into every square yard of a football field-sized target in potentially less than 10 seconds.

And, as long as its 45-flare and 24,000-round basic load of ammunition held out, it could do this intermittently while loitering over the target for hours. The less known Fairchild AC-119G Shadow were twin-engine piston-powered gunships developed by the United States during the Vietnam War. Armed with four 7.62 mm GAU-2/A Miniguns and two 20 mm (0.787 in) M61 Vulcan six-barrel rotary cannons, they replaced the Douglas AC-47 Spooky and operated alongside the early versions of the AC-130 Spectre gunship. It was the later and larger Lockheed AC-130 Gunship II that became the modern, post–World War II origin of the term gunship in military aviation. These heavily armed aircraft used a variety of weapon systems, including 7.62 mm GAU-2/A Miniguns, 20 mm (0.787 in) M61 Vulcan six-barrel rotary cannons, 25 mm (0.984 in) GAU-12/U Equalizer five-barreled rotary cannons, 30 mm Mk44 Bushmaster II chain guns, 40 mm (1.58 in) L/60 Bofors autocannons, and 105 mm (4.13 in) M102 howitzers.

The Douglas AC-47 Spooky, the Fairchild AC-119, and the AC-130 Spectre/Spooky, were vulnerable, and meant to operate only after achieving air superiority. Smaller gunship designs such as the Fairchild AU-23 Peacemaker and the Helio AU-24 Stallion were also designed by the United States during the Vietnam War. These aircraft were meant to be cheap and easy to fly and maintain, and were to be given to friendly governments in Southeast Asia to assist with counter-insurgency operations, eventually seeing service with the Khmer National Air Force, Royal Thai Air Force, and Republic of Vietnam Air Force as well as limited use by the United States Air Force. Renewed interest in the concept of gunships has resulted in the development of a gunship variant of the Alenia C-27J Spartan. Although the United States Air Force decided not to procure the AC-27J, other nations including Italy have chosen the aircraft for introduction. Additionally, in 2013 the US Air Force Special Operations Command reportedly tested a gunship version of the C-145A Skytruck armed with a GAU-18 twin-mount .50-calibre machine gun system.

Helicopter Gunships
Early helicopter gunships also operated in the side-firing configuration, an early example being the Aérospatiale Alouette III. During the Overseas wars in Africa in the 1960s, the Portuguese Air Force experimented to install M3 Browning .50 calibre machine guns in a side-firing twin-mounting configuration in some of its Alouette III helicopters. Later, the .50 calibre machine guns were replaced by a MG 151 20mm cannon in a single mounting. These helicopters were known in Portuguese service as "helicanhões" (heli-cannons) and were used in the escort of unarmed transport helicopters in air assault operations and in the fire support to the troops in the ground. The South African and Rhodesian air forces later used armed Alouette III in similar configurations as the Portuguese, respectively in the South African Border and Rhodesian Bush wars. During the Algerian War, the French operated Sikorsky H-34 "Pirate" armed with a German 20mm MG151 cannon and two .50 machine guns.

During the early days of the Vietnam War, USMC H-34s were among the first helicopter gunships in theatre, fitted with the Temporary Kit-1 (TK-1), comprising two M60C machine guns and two 19-shot 2.75 inch rocket pods. The operations were met with mixed enthusiasm, and the armed H-34s, known as "Stingers" were quickly phased out. The TK-1 kit would form the basis of the TK-2 kit used later on the UH-1E helicopters of the USMC. The U.S. Army also experimented with H-34 gunships armed M2 .50 calibre machine-guns and 2.75-inch rockets. In September 1971, a CH-34 was armed with two M2 .50 calibre machine guns, four M1919 .30 calibre machine guns, forty 2.75-inch rockets, two 5-inch high velocity aerial rockets (HV AR), plus two additional .30 calibre machine guns in the left side aft windows and one .50 calibre machine gun in the right side cargo door. The result was the world's most heavily armed helicopter at the time.

Also, during the Vietnam War, the ubiquitous Bell UH-1 Iroquois helicopters were modified into gunships by mounting the U.S. Helicopter Armament Subsystems—these were forward-firing weapons, such as machine guns, rockets, and autocannons, that began to appear in 1962–1963. Rotary-wing aircraft (helicopters) can use a variety of combat manoeuvres to approach a target. In their case, the term gunship is synonymous with heavily armed helicopter. Specifically, dedicated attack helicopters such as the Bell AH-1 Cobra also fit this meaning. In any case, the gunship armaments include machine guns, rockets, autocannons, missiles, etc. The Soviet Mil Mi-24 (NATO code name: Hind) is a large, heavily armed and armoured helicopter gunship and troop transport. It was introduced in the 1970s and operated by the pre-1991 Soviet Air Force and its successors post-1991, and more than 30 other nations. Its armaments include machine guns, rockets, cannons, missiles, etc. Its fuselage is heavily armoured and is designed to withstand .50 calibre (12.7 mm) machine gun fire. Its armoured cockpits and titanium rotor head are able to withstand 20 mm cannon hits.

Electronic Warfare Aircraft

An electronic-warfare aircraft is a military aircraft equipped for electronic warfare (EW), that is, degrading the effectiveness of enemy radar and radio systems by using radar jamming and deception methods. A recent example would be the Boeing EA-18G Growler, which is a modified version of the Boeing F/A-18F Super Hornet. In 1943, British Avro Lancaster aircraft were equipped with chaff in order to blind enemy air defence radars. They were supplemented by specially-equipped aircraft flown by No. 100 Group RAF, which operated modified Halifaxes, Liberators and Fortresses carrying various jammers such as Carpet, Airborne Cigar, Mandrel, Jostle, and Piperack.

Maritime Patrol Aircraft

A maritime patrol aircraft (MPA), also known as a patrol aircraft, maritime reconnaissance aircraft, or by the older American term patrol bomber, is a fixed-wing aircraft designed to operate for long durations over water in maritime patrol roles — in particular anti-submarine warfare (ASW), anti-ship warfare (AShW), and search and rescue (SAR). Some patrol aircraft were designed for this purpose, like the Kawasaki P-1. Many others are modified designs of pre-existing aircraft, such as the Boeing P-8 Poseidon, which is based on the Boeing 737-800 airliner.

Armament and Countermeasures
The earliest patrol aircraft carried bombs and machine guns. Between the wars the British experimented with equipping their patrol aircraft with the COW 37 mm gun. During World War II, depth charges that could be set to detonate at specific depths, and later when in proximity with large metal objects replaced "anti-submarine" bombs that detonated on contact. Patrol aircraft also carried defensive armament which was necessary when patrolling areas close to enemy territory such as Allied operations in the Bay of Biscay targeting U-boats starting out from their base. As a result of Allied successes with patrol aircraft against U-boats, the Germans introduced U-flak (submarines equipped with more antiaircraft weaponry) to escort U-boats out of base and encouraged commanders to remain on the surface and fire back at attacking craft rather than trying to escape by diving. The advantage was short lived as the submarine was defenceless if it tried to dive for long enough for the aircraft to make its attack, effectively preventing it from diving until a surface ship could arrive to destroy it. Equipping submarines with radar-warning devices and the snorkel made them harder to find. To counter the German long-range patrol aircraft that targeted merchant convoys, the Royal Navy introduced the "CAM ship", which was a merchant vessel equipped with a lone fighter plane which could be launched once to engage the enemy planes. Then the small escort carriers of WW II became available to cover the deep oceans, and the land air bases in the Azores became available in mid-1943 from Portugal.

Sensors
Maritime patrol aircraft are typically fitted with a wide range of sensors:
● Radar to detect surface shipping movements. Radar can also detect a submarine snorkel or periscope, and the wake it creates.
● Magnetic anomaly detector (MAD) to detect the iron in a submarine's hull. The MAD sensor is typically mounted on an extension from the tail or is trailed behind the aircraft on a cable to minimize interference from the metal in the rest of the aircraft;
● Sonobuoys - self-contained sonar transmitter/receivers dropped into the water to transmit data back to the aircraft for analysis;
● ELINT sensors to monitor communications and radar emissions;
● Infrared cameras (sometimes referred to as FLIR for forward looking infrared) for detecting exhaust streams and other sources of heat and are useful in monitoring shipping movements and fishing activity.
● Visual inspection using the aircrew's eyes, in some cases aided by searchlights or flares.

A modern military maritime patrol aircraft typically carries a dozen or so crew members, including relief flight crews, to effectively operate the equipment for 12 hours or more at a time.

Multirole Combat Aircraft

Many combat aircraft today have a multirole ability. Normally only applying to fixed-wing aircraft, this term signifies that the plane in question can be a fighter or a bomber, depending on what the mission calls for. An example of a multirole design is the F-15E Strike Eagle, F/A-18 Hornet, F-35 Lightning II. A World War II example would be the P-38 Lightning.

Multirole Combat Aircraft

A multirole combat aircraft (MRCA) is a combat aircraft intended to perform different roles in combat. A multirole fighter is a multirole combat aircraft which is, at the same time, also a fighter aircraft; in other words, an aircraft whose various roles include, among others, the role of air-to-air combat. The term "Multirole" had originally been reserved for aircraft designed with the aim of using a common airframe for multiple tasks where the same basic airframe is adapted to a number of differing roles.

The main motivation for developing multirole aircraft is cost reduction in using a common airframe. More roles can be added, such as aerial reconnaissance, forward air control, and electronic-warfare aircraft. Attack missions include the subtypes air interdiction, suppression of enemy air defence (SEAD), and close air support (CAS). Multirole has also been applied to one aircraft with both major roles, a primary air-to-air combat role, and a secondary role like air-to-surface attack.

However, those designed with an emphasis on aerial combat are usually regarded as air superiority fighters and usually deployed solely in that role, even though they are theoretically capable of ground attack. A good example is the F-14 Tomcat versus the F/A-18 Hornet; the F-14 was envisioned originally for air superiority and fleet interception defence with some variants later receiving secondary ground attack capability, while the F/A-18 was designed from the onset for air-to-surface strikes with a limited capacity to defend itself from other aircraft. In another instance, the Eurofighter Typhoon and Dassault Rafale are classified as multirole fighters; however the Typhoon is frequently considered an air superiority fighter due to its higher dogfighting prowess while its built-in strike capability has a lighter bomb load compared to contemporaries, compared to the more balanced Rafale which sacrifices air-to-air ability for a heavier payload.

Swing-Role
Some aircraft, like the Saab JAS 39 Gripen, are called swing-role, to emphasize the ability of a quick role change, either at short notice, or even within the same mission. According to the Military Dictionary: "the ability to employ a multi-role aircraft for multiple purposes during the same mission." According to BAE Systems, "an aircraft that can accomplish both air-to-air and air-to-surface roles on the same mission and swing between these roles instantly offers true flexibility. This reduces cost, increases effectiveness and enhances interoperability with allied air forces". "(Swing-role) capability also offers considerable cost-of-ownership benefits to operational commanders." Although the term "multirole aircraft" may be relatively novel, certain airframes in history have proven versatile to multiple roles. In particular, the Junkers Ju 88 was renowned in Germany for being a "jack-of-all-trades", capable of performing as a bomber, dive bomber, night fighter, and so on, much as the British de Havilland Mosquito did as a fast bomber/strike aircraft, reconnaissance, and night fighter. The US joint forces F-4 Phantom II built by McDonnell-Douglas also fits the definition of a multi-role aircraft in its various configurations of the basic airframe design. The various F-4 Phantom II configurations were used in air-to air, fighter bomber, reconnaissance, and suppression of enemy air defences (SEAD) mission roles to name a few.

The first use of the term was by the multinational European project named Multi-Role Combat Aircraft, which was formed in 1968 to produce an aircraft capable of tactical strike, aerial reconnaissance, air defence, and maritime roles. The design was aimed to replace a multitude of different types in the cooperating air forces. The project produced the Panavia Tornado, which used the same basic design to undertake a variety of roles, the Tornado IDS (Interdictor/Strike) variant and later the Panavia Tornado ADV (Air Defence Variant). By contrast, the F-15 Eagle which was another fighter aircraft of that era was designed for air superiority and interception, with the mantra "not a pound for ground" (although the F-15C did have a rarely-used secondary ground attack capability), but that program eventually evolved into the F-15E Strike Eagle interdictor/strike derivative which retained the air-to-air combat lethality of earlier F-15s. The newest fighter jet that fits the definition of 'multi-role' is the Lockheed Martin F-35 Lightning II/Joint Strike Fighter, designed to perform stealth-based ground/naval strike, fighter, reconnaissance and electronic warfare roles. Like a modern-day F-4, 3 variants of this aircraft fulfil the various strike and air defence roles among its joint service requirements: the standard variant is intended to eventually replace the F-16 and A-10 in the USAF and other Western air forces, a STOVL version intended to replace the Harrier in US Marine Corps, British Royal Air Force and Royal Navy service, and a carrier variant intended to eventually replace the older F/A-18C/D for the US Navy and other F-18 operators. The F-35's design goal can be compared to its larger and more air superiority-focused cousin, the F-22 Raptor.

Fighter-Bomber

A fighter-bomber is a fighter aircraft that has been modified, or used primarily, as a light bomber or attack aircraft. It differs from bomber and attack aircraft primarily in its origins, as a fighter that has been adapted into other roles, whereas bombers and attack aircraft are developed specifically for bombing and attack roles. Although still used, the term fighter-bomber has less significance since the introduction of rockets and guided missiles into aerial warfare. Modern aircraft with similar duties are now typically called multirole combat aircraft or strike fighters.

Second World War

When war broke out in Europe, Western Allied Air Forces employed light twin-engined bombers in the tactical role for low level attack. These were found to be extremely vulnerable both to ground fire and to single engine fighters. The German and Japanese Air Forces had chosen dive bombers which were similarly vulnerable. The Ilyushin Il-2 is a heavily armoured two seat single-engine ground attack aircraft. It first flew a month later although few had reached the Soviet Air Force in time for Operation Barbarossa. Naval forces chose both torpedo and dive bombers. None of these could be considered as fighter bombers as they could not combat fighters. The Bristol Blenheim and Douglas A-20 Havoc (which the RAF called Boston) were used as night fighters during the Blitz, as they could carry the heavy early airborne radars. In 1934, the British Air Ministry called for a carrier aircraft which could combine the roles of dive bomber and fighter, to save limited space on small carriers.

The Blackburn Skua was not expected to encounter land-based fighters but was to intercept long-range bombers attacking the fleet and also to sink ships. As a two-seater it could not fight the Messerschmitt Bf 109 on equal terms. But the second seat carried a radio operator with a homing device that could find the carrier even when it had moved, in foul North Sea weather. It achieved one of the first kills of the war, when three from HMS Ark Royal downed a German Dornier Do 18 flying boat over the North Sea. During the Battle of Britain, the Luftwaffe conducted fighter-bomber attacks on the United Kingdom from September to December 1940. A larger fighter-bomber campaign was conducted against the UK from March 1942 until June 1943. These operations were successful in tying down Allied resources at a relatively low cost to the Luftwaffe, but the British Government regarded the campaign as a nuisance given the small scale of the individual raids.

Post-War

Fighter-bombers became increasingly important in the 1950s and 1960s, as new jet engines dramatically improved the power of even the smallest fighter designs. Many aircraft initially designed as fighters or interceptors found themselves in the fighter-bomber role at some point in their career. Notable among these is the Lockheed F-104 Starfighter, first designed as a high-performance day fighter and then adapted to the nuclear strike role for European use. Another such aircraft was the Indian HAL HF-24 Marut. It was used during the Indo-Pak war of 1971, and only three aircraft were lost to ground fire. One aerial kill recorded by Marut flown by Squadron Leader K.K. Bakshi of 220 Squadron shot down a PAF F-86 Sabre on 7 Dec 71 (Flag Officer Hamid Khwaja of 15 Squadron PAF). Other U.S. examples include the North American F-100 Super Sabre and (perhaps most famously) the McDonnell Douglas F-4 Phantom II, each of which were widely used during the Vietnam War.

Strike Fighter

In current military parlance, a strike fighter is a multirole combat aircraft designed to operate primarily as an attack aircraft, while also incorporating certain performance characteristics of a fighter for air-to-air combat. As a category, it is distinct from fighter-bombers. It is closely related to the concept of interdictor aircraft, but it puts more emphasis on air-to-air combat capabilities as a multirole combat aircraft. Examples of contemporary American strike fighters are the McDonnell Douglas F-15E Strike Eagle, Boeing F/A-18E/F Super Hornet, and Lockheed Martin F-35 Lightning II.

Military Transport Aircraft

Military transport aircraft or military cargo aircraft are typically fixed wing and rotary wing cargo aircraft which are used to airlift troops, weapons and other military equipment by a variety of methods to any area of military operations around the surface of the planet, usually outside the commercial flight routes in uncontrolled airspace. Originally derived from bombers, military transport aircraft were used for delivering airborne forces during World War II and towing military gliders. Some military transport aircraft are tasked to perform multi-role duties such as aerial refuelling and rescue missions, tactical, operational and strategic airlifts onto unprepared runways, or those constructed by engineers.

Fixed-Wing

Fixed-wing transport aircraft are defined in terms of their range capability as strategic airlift or tactical airlift to reflect the needs of the land forces which they most often support. These roughly correspond to the commercial flight length distinctions: Eurocontrol defines short-haul routes as shorter than 1,500 km (810 nmi), long-haul routes as longer than 4,000 km (2,200 nmi) and medium-haul between. A more specialised role of a cargo aircraft is that of transporting fuel in support of other aircraft with more limited flight endurance such as fighters or helicopters. Smaller cargo aircraft, known as "utility", are often used to transport military communications equipment as temporary or permanent platforms, and in the command role by providing airborne command post or as an air ambulance.

Rotary Wing

Military transport helicopters are used in places where the use of conventional aircraft is impossible. For example, the military transport helicopter is the primary transport asset of US Marines deploying from LHDs and LHA. The landing possibilities of helicopters are almost unlimited, and where landing is impossible, for example densely packed jungle, the ability of the helicopter to hover allows troops to deploy by abseiling and roping. Transport helicopters are operated in assault, medium and heavy classes. Air assault helicopters are usually the smallest of the transport types, and designed to move an infantry squad or section and their equipment. Helicopters in the assault role are generally armed for self-protection both in transit and for suppression of the landing zone. This armament may be in the form of door gunners, or the modification of the helicopter with stub wings and pylons to carry missiles and rocket pods. For example, the Sikorsky S-70, fitted with the ESSM (External Stores Support System), and the Hip E variant of the Mil Mi-8 can carry as much disposable armament as some dedicated attack helicopters.

The assault helicopter can be thought of as the modern successor to the military glider. Finally, there is the generic term utility helicopter, which generally refers to medium-lift designs. Not all militaries are able to operate a full range of transport helicopters, so the medium transport type is probably the most useful compromise and probably the most common specialist transport type. Medium transport helicopters are generally capable of moving up to a platoon of infantry and are capable of being able to transport towed artillery or light vehicles either internally or as underslung roles. Unlike the assault helicopter they are usually not expected to land directly in a contested landing zone, but are used to reinforce and resupply landing zones taken by the initial assault wave. Examples include the unarmed versions of the Mil Mi-8, Super Puma, and CH-46 Sea Knight. Heavy lift helicopters are the largest and most capable of the transport types, currently limited in service to the CH-53 Sea Stallion and related CH-53E Super Stallion, CH-47 Chinook, Mil Mi-26, and Aérospatiale Super Frelon.

Capable of lifting up to 80 troops and moving small Armoured fighting vehicles (usually as slung loads but also internally), these helicopters operate in the tactical transport role in much the same way as small fixed wing turboprop air-lifters. The lower speed, range and increased fuel consumption of helicopters are more than compensated by their ability to operate virtually anywhere.

Airborne Early Warning and Control

An airborne early warning and control (AEW&C) system is an airborne radar picket system designed to detect aircraft, ships and vehicles at long ranges and perform command and control of the battlespace in an air engagement by directing fighter and attack aircraft strikes. AEW&C units are also used to carry out surveillance, including over ground targets and frequently perform C2BM (command and control, battle management) functions similar to an Air Traffic Controller given military command over other forces. When used at altitude, the radar on the aircraft allows the operators to detect and track targets and distinguish between friendly and hostile aircraft much farther away than a similar ground-based radar. Like a ground-based radar, it can be detected by opposing forces, but because of its mobility, it is much less vulnerable to counter-attack. AEW&C aircraft are used for both defensive and offensive air operations, and are to the NATO and US forces trained or integrated Air Forces what the combat information centre is to a US Navy warship, plus a highly mobile and powerful radar platform. The system is used offensively to direct fighters to their target locations, and defensively, directing counterattacks on enemy forces, both air and ground. So useful is the advantage of command and control from a high altitude, the United States Navy operates Northrop Grumman E-2 Hawkeye AEW&C aircraft off its Supercarriers to augment and protect its carrier Command Information Centres (CICs).

The designation airborne early warning (AEW) was used for earlier similar aircraft, such as the Fairey Gannet AEW.3 and Lockheed EC-121 Warning Star, and continues to be used by the RAF for its Sentry AEW1, while AEW&C (airborne early warning and control) emphasizes the command and control capabilities that may not be present on smaller or simpler radar picket aircraft. AWACS (Airborne Warning and Control System) is the name of the specific system installed in the E-3 and Japanese Boeing E-767 AEW&C airframes, but is often used as a general synonym for AEW&C. Modern AEW&C systems can detect aircraft from up to 400 km (220 nmi) away, well out of range of most surface-to-air missiles. One AEW&C aircraft flying at 9,000 m (30,000 ft) can cover an area of 312,000 km2 (120,000 sq mi). Three such aircraft in overlapping orbits can cover the whole of Central Europe. AEW&C systems communicate with friendly aircraft, vectoring fighters towards bogeys, providing data on threats and targets, help extend their sensor range and make offensive aircraft more difficult to track, since they no longer need to keep their own radar active to detect threats.

Current Systems

Many countries have developed their own AEW&C systems, although the Boeing E-3 Sentry and Northrop Grumman E-2 Hawkeye are the most common systems worldwide. The E-3 Sentry was built by the Boeing Defence and Space Group (now Boeing Defence, Space & Security) and was based on the Boeing 707-320 aircraft. Sixty-five E-3s were built and it is operated by the United States, NATO, the United Kingdom, France, and Saudi Arabia. The specially designed Grumman E-2 Hawkeye entered service in 1965 and has been operated by eight different nations. Over 168 have been produced so far and new versions continue to be developed, making it the most widely used AEW system. For the Japan Air Self-Defence Force, the E-3 technology has been fitted into the Boeing E-767. After World War 2, the United Kingdom deployed a substantial AEW capability with American Douglas AD-4W Skyraiders, designated Skyraider AEW.1, which in turn were replaced by the Fairey Gannet AEW.3, using the same AN/APS-20 radar.

With the retirement of the conventional aircraft carriers, the Gannet was withdrawn and the Royal Air Force (RAF) installed the radars from the Gannets on Avro Shackleton MR.2 airframes, redesignated Shackleton AEW.2. To replace the Shackleton AEW.2, an AEW variant of the Hawker Siddeley Nimrod, known as the Nimrod AEW3, was ordered in 1974. However, after a protracted and problematic development, this was cancelled in 1986, and seven E-3Ds, designated Sentry AEW.1 in RAF service, were purchased instead. The Russian Air Force is currently using around 15–20 Beriev A-50 and A-50U "Shmel" in the AEW role. The "Mainstay" is based on the Ilyushin Il-76 airframe, with a large non-rotating disk radome on the rear fuselage. These replaced the 12 Tupolev Tu-126 that filled the role previously. The A-50 and A-50U will eventually be replaced by the Beriev A-100, which features an AESA array in the radome and is based on the updated Il-476.

In May 1997, Russia and Israel agreed to jointly fulfil an order from China to develop and deliver an early warning system. China reportedly ordered one Phalcon for $250 million, which entailed retrofitting a Russian-made Ilyushin-76 cargo plane with advanced Elta electronic, computer, radar and communications systems. Beijing was expected to acquire several Phalcon AEW systems, and reportedly could buy at least three more (and possibly up to eight) of these systems, the prototype of which was planned for testing beginning in 2000. Finally, in July 2000 the United States pressured Israel to back out of the $1 billion agreement to sell China four Phalcon phased-array radar systems. Following the cancelled A-50I/Phalcon deal, China turned to indigenous solutions. The Phalcon radar and other electronic systems were taken off from the unfinished Il-76, and the airframe was handed to China via Russia in 2002. The Chinese AWACS has a unique phased array radar (PAR) carried in a round radome. Unlike the US AWACS aircraft, which rotate their rotodomes to give a 360 degree coverage, the radar antenna of the Chinese AWACS does not rotate.

Instead, three PAR antenna modules are placed in a triangular configuration inside the round radome to provide a 360 degree coverage. The installation of equipment at the Il-76 began in late 2002 aircraft by Xian aircraft industries (Xian Aircraft Industry Co.). The first flight of an airplane KJ-2000 made in November 2003. All four machines will be equipped with this type. The last to be introduced into service the Chinese Air Force until the end of 2007. In 2003, the Indian Air Force (IAF) and Defence Research and Development Organisation (DRDO) began a study of requirements for developing an Airborne Early Warning and Control (AWAC) system. In 2015, DRDO delivered 3 AWACs, called Netra, to the air force with indigenous radar systems built on the Brazilian Embraer EMB-145 air frame. Netra gives a 240-degree coverage of airspace. The Emb-145 also has air-to-air refuelling capability for longer surveillance time. The Indian Air Force also operates three Israeli EL/W-2090 systems (Il-76/Phalcon system deal cancelled for China), the first of which first arrived on May 25, 2009. India subsequently signed with Israel to pick up the A-50I instead of China, therefore, A50I adopted the 3-radar arrangement designed by Chinese team. The DRDO is now developing a more advanced AWACS with a longer range and with a 360-degree coverage akin to the Phalcon system, based on the Airbus A-330 airframe.

Helicopter AEW Systems

The British Sea King ASaC7 naval helicopter was operated from Invincible-class aircraft carriers. The creation of Sea King ASaC7, and earlier AEW.2 and AEW.5 was the consequence of lessons learnt by the Royal Navy during the 1982 Falklands War when the lack of AEW coverage for the task force was a major tactical handicap, and left them vulnerable to low level attack. The Spanish Navy fields the SH-3 Sea King in the same role, operated from the LPH Juan Carlos I. The AgustaWestland EH-101A AEW of the Italian Navy is operated from the aircraft carriers Cavour and Garibaldi. In 2018 the British will replace their Sea Kings with a modular "Crowsnest" system that can be fitted to any of their Merlin HM2 fleet. The Russian-built Kamov Ka-31 is deployed by the Indian Navy on the aircraft carrier INS Vikramaditya and Talwar-class frigates and will be deployed on the Vikrant-class aircraft carriers. The Russian Navy has two Ka-31R variants, at least one of which was deployed on their aircraft carrier Kuznetsov in 2016. It is fitted with E-801M Oko (Eye) airborne electronic warfare radar that can track 20 targets simultaneously, detecting aircraft up to 150 km (90 mi) away, and surface warships up to 200 km (120 mi) distant.

Airborne Warning and Control System (AWACS)

Boeing produces a specific system with a rotating radar dome 'rotodome' radome designed and built by Boeing (Defence & Space Group) using Westinghouse (now Northrop Grumman) radar. It is mounted on either the E-3 Sentry aircraft (Boeing 707) or more recently the Boeing E-767 (Boeing 767), the latter only being used by the Japan Air Self-Defence Force. When AWACS first entered service it represented a major advance in capability, being the first AEW to use a pulse-Doppler radar, which allowed it to track targets normally lost in ground clutter. Previously, low-flying aircraft could only be readily tracked over water.

Reconnaissance Aircraft

A reconnaissance aircraft is a military surveillance aircraft designed or adapted to perform aerial reconnaissance. Their roles include collection of imagery intelligence (such as photography), signals intelligence, and measurement and signature intelligence. In addition to general intelligence gathering, modern technology has also enabled some aircraft and UAVs to carry out real-time surveillance. In years prior to the development and common use of sophisticated electronic sensors (such as radar) and image recording devices, reconnaissance aircraft were also relied upon by military forces for distant visual observation and scouting of enemy movement. An example is the PBY Catalina maritime patrol flying boat used by the Allies in World War II: a flight of U.S. Navy Catalinas spotted part of the Japanese fleet approaching Midway Island, beginning the Battle of Midway. Since the Cold War much of the strategic reconnaissance aircraft role has passed over to satellites, and the tactical role to unmanned aerial vehicles (UAVs). This has been proven in successful uses by Israel, and by the United States in Desert Storm operations.

Surveillance Aircraft

A surveillance aircraft is an aircraft used for surveillance—collecting information over time. They are operated by military forces and other government agencies in roles such as intelligence gathering, battlefield surveillance, airspace surveillance, observation (e.g. artillery spotting), border patrol and fishery protection. This article concentrates on aircraft used in those roles, rather than for traffic monitoring, law enforcement and similar activities. Surveillance aircraft usually carry no armament, or only limited defensive armament. A surveillance aircraft does not necessarily require high-performance capability or stealth characteristics. It may be a modified civilian aircraft. Surveillance aircraft have also included moored balloons (e.g. TARS) and unmanned aerial vehicles (UAVs). Reconnaissance aircraft are a type of surveillance aircraft. The terms “surveillance” and “reconnaissance” have sometimes been used interchangeably, but, in the military context, a distinction can be drawn between surveillance, which monitors a changing situation in real time, and reconnaissance, which captures a static picture for analysis. Surveillance is sometimes grouped with Intelligence, Target acquisition and Reconnaissance under the title ISTAR. Observation was the term used for surveillance when the main sensor was the human eye.

Roles	
Maritime Patrol	Maritime patrol aircraft are typically large, slow machines capable of flying continuously for many hours, with a wide range of sensors. Such aircraft include the Hawker-Siddeley Nimrod, the Breguet Atlantique, the Tupolev Tu-95, the Lockheed P-2 Neptune and the Lockheed P-3 Orion/CP-140 Aurora.
Law Enforcement	Predator UAVs have been used by the US for border patrol.
Battlefield and Airspace Surveillance	

Current Use
Unmanned (UAV) surveillance aircraft have been deployed or are under development in many countries, including Israel, the UK, the United States, Canada, China, India, South Africa and Pakistan. Unmanned surveillance UAVs include both airships—such as Sky Sentinel and HiSentinel 80—and airplanes. Most air forces around the world lack dedicated surveillance planes. Several countries adapt aircraft for electronic intelligence (ELINT) gathering. The Beech RC-12 Super King Air and Boeing RC-135 Rivet Joint are examples of this activity.

UAVs

An unmanned aerial vehicle (UAV), commonly known as a drone, is an aircraft without a human pilot aboard. UAVs are a component of an unmanned aircraft system (UAS); which include a UAV, a ground-based controller, and a system of communications between the two. The flight of UAVs may operate with various degrees of autonomy: either under remote control by a human operator or autonomously by on-board computers. Compared to manned aircraft, UAVs were originally used for missions too "dull, dirty or dangerous" for humans. While they originated mostly in military applications, their use is rapidly expanding to commercial, scientific, recreational, agricultural, and other applications, such as policing, peacekeeping, and surveillance, product deliveries, aerial photography, agriculture, smuggling, and drone racing. Civilian UAVs now vastly outnumber military UAVs, with estimates of over a million sold by 2015.

Experimental Aircraft

An experimental aircraft is an aircraft that has not yet been fully proven in flight. Often, this implies that new aerospace technologies are being tested on the aircraft, though the label is more broad. The term "experimental aircraft" is usually used to refer to aircraft flown with an experimental certificate. In the United States, this includes most homebuilt aircraft; many of which are based on conventional designs and hence are experimental only in name. The term "research aircraft", by contrast, generally denotes aircraft modified to perform scientific studies, such as weather research or geophysical surveying, similar to a research vessel.

ICBM

An intercontinental ballistic missile (ICBM) is a guided ballistic missile with a minimum range of 5,500 kilometres (3,400 mi) primarily designed for nuclear weapons delivery (delivering one or more thermonuclear warheads). Similarly, conventional, chemical, and biological weapons can also be delivered with varying effectiveness, but have never been deployed on ICBMs. Most modern designs support multiple independently targetable re-entry vehicles (MIRVs), allowing a single missile to carry several warheads, each of which can strike a different target. Early ICBMs had limited precision, which made them suitable for use only against the largest targets, such as cities. They were seen as a "safe" basing option, one that would keep the deterrent force close to home where it would be difficult to attack. Attacks against military targets (especially hardened ones) still demanded the use of a more precise, manned bomber. Second- and third-generation designs (such as the LGM-118 Peacekeeper) dramatically improved accuracy to the point where even the smallest point targets can be successfully attacked. ICBMs are differentiated by having greater range and speed than other ballistic missiles: intermediate-range ballistic missiles (IRBMs), medium-range ballistic missiles (MRBMs), short-range ballistic missiles (SRBMs) and tactical ballistic missiles (TBMs). Short and medium-range ballistic missiles are known collectively as theatre ballistic missiles.

Modern ICBMs typically carry multiple independently targetable re-entry vehicles (MIRVs), each of which carries a separate nuclear warhead, allowing a single missile to hit multiple targets. MIRV was an outgrowth of the rapidly shrinking size and weight of modern warheads and the Strategic Arms Limitation Treaties which imposed limitations on the number of launch vehicles (SALT I and SALT II). It has also proved to be an "easy answer" to proposed deployments of Anti-ballistic missile (ABM) systems—it is far less expensive to add more warheads to an existing missile system than to build an ABM system capable of shooting down the additional warheads; hence, most ABM system proposals have been judged to be impractical. The first operational ABM systems were deployed in the U.S. during the 1970s. Safeguard ABM facility was located in North Dakota and was operational from 1975 to 1976. The USSR deployed its ABM-1 Galosh system around Moscow in the 1970s, which remains in service. Israel deployed a national ABM system based on the Arrow missile in 1998, but it is mainly designed to intercept shorter-ranged theatre ballistic missiles, not ICBMs. The Alaska-based United States national missile defence system attained initial operational capability in 2004.

Flight Phases
The following flight phases can be distinguished:
- Boost phase: 3 to 5 minutes; it is shorter for a solid-fuel rocket than for a liquid-propellant rocket; depending on the trajectory chosen, typical burnout speed is 4 km/s (2.5 mi/s), up to 7.8 km/s (4.8 mi/s); altitude at the end of this phase is typically 150 to 400 km (93 to 249 mi).
- Midcourse phase: approx. 25 minutes—sub-orbital spaceflight with a flight path being a part of an ellipse with a vertical major axis; the apogee (halfway through the midcourse phase) is at an altitude of approximately 1,200 km (750 mi); the semi-major axis is between 3,186 and 6,372 km (1,980 and 3,959 mi); the projection of the flight path on the Earth's surface is close to a great circle, slightly displaced due to earth rotation during the time of flight; the missile may release several independent warheads and penetration aids, such as metallic-coated balloons, aluminium chaff, and full-scale warhead decoys.
- Re-entry/terminal phase (starting at an altitude of 100 km, 62 mi): 2 minutes – impact is at a speed of up to 7 km/s (4.3 mi/s) (for early ICBMs less than 1 km/s (0.62 mi/s)); see also manoeuvrable re-entry vehicle

ICBMs usually use the trajectory which optimizes range for a given amount of payload (the minimum-energy trajectory); an alternative is a depressed trajectory, which allows less payload, shorter flight time, and has a much lower apogee.

Deployability
- In missile silos, which offer some protection from military attack (including, the designers hope, some protection from a nuclear first strike)
- On submarines: submarine-launched ballistic missiles (SLBMs); most or all SLBMs have the long range of ICBMs (as opposed to IRBMs)
- On heavy trucks; this applies to one version of the Topol which may be deployed from a self-propelled mobile launcher, capable of moving through roadless terrain, and launching a missile from any point along its route
- Mobile launchers on rails

The last three kinds are mobile and therefore hard to find. During storage, one of the most important features of the missile is its serviceability. One of the key features of the first computer-controlled ICBM, the Minuteman missile, was that it could quickly and easily use its computer to test itself. After launch, a booster pushes the missile and then falls away. Most modern boosters are solid-fuelled rocket motors, which can be stored easily for long periods of time. Early missiles used liquid-fuelled rocket motors. Many liquid-fuelled ICBMs could not be kept fuelled all the time as the cryogenic fuel liquid oxygen boiled off and caused ice formation, and therefore fuelling the rocket was necessary before launch. This procedure was a source of significant operational delay, and might allow the missiles to be destroyed by enemy counterparts before they could be used. To resolve this problem the United Kingdom invented the missile silo that protected the missile from a first strike and also hid fuelling operations underground.

Once the booster falls away, the remaining "bus" releases several warheads, each of which continues on its own unpowered ballistic trajectory, much like an artillery shell or cannonball. The warhead is encased in a cone-shaped re-entry vehicle and is difficult to detect in this phase of flight as there is no rocket exhaust or other emissions to mark its position to defenders. The high speeds of the warheads make them difficult to intercept and allow for little warning, striking targets many thousands of kilometres away from the launch site (and due to the possible locations of the submarines: anywhere in the world) within approximately 30 minutes. As the nuclear warhead re-enters the Earth's atmosphere its high speed causes compression of the air, leading to a dramatic rise in temperature which would destroy it if it were not shielded in some way.

Deployability

As a result, warhead components are contained within an aluminium honeycomb substructure, sheathed in a pyrolytic carbon-epoxy synthetic resin composite material heat shield. Warheads are also often radiation-hardened (to protect against nuclear-tipped ABMs or the nearby detonation of friendly warheads), one neutron-resistant material developed for this purpose in the UK is three-dimensional quartz phenolic. Circular error probable is crucial, because halving the circular error probable decreases the needed warhead energy by a factor of four. Accuracy is limited by the accuracy of the navigation system and the available geodetic information.

Land-Based ICBMs

Russia, the United States, China, North Korea and India are the only countries currently known to possess land-based ICBMs, Israel has also tested ICBMs but is not open about actual deployment. The United States currently operates 405 ICBMs in three USAF bases. The only model deployed is LGM-30G Minuteman-III. All previous USAF Minuteman II missiles were destroyed in accordance with START II, and their launch silos have been sealed or sold to the public. The powerful MIRV-capable Peacekeeper missiles were phased out in 2005. China has developed several long range ICBMs, like the DF-31. The Dongfeng 5 or DF-5 is a 3-stage liquid fuel ICBM and has an estimated range of 13,000 kilometres. The DF-5 had its first flight in 1971 and was in operational service 10 years later. One of the downsides of the missile was that it took between 30 and 60 minutes to fuel. The Dong Feng 31 (a.k.a. CSS-10) is a medium-range, three-stage, solid-propellant intercontinental ballistic missile, and is a land-based variant of the submarine-launched JL-2. Israel is believed to have deployed a road mobile nuclear ICBM, the Jericho III, which entered service in 2008. It is possible for the missile to be equipped with a single 750 kg (1,650 lb) nuclear warhead or up to three MIRV warheads. It is believed to be based on the Shavit space launch vehicle and is estimated to have a range of 4,800 to 11,500 km (3,000 to 7,100 mi). In November 2011 Israel tested an ICBM believed to be an upgraded version of the Jericho III.

Submarine-Launched

A submarine-launched ballistic missile (SLBM) is a ballistic missile capable of being launched from submarines. Modern variants usually deliver multiple independently targetable re-entry vehicles (MIRVs) each of which carries a nuclear warhead and allows a single launched missile to strike several targets. Submarine-launched ballistic missiles operate in a different way from submarine-launched cruise missiles. Modern submarine-launched ballistic missiles are closely related to intercontinental ballistic missiles (with ranges of over 5,500 kilometres (3,000 nmi), and in many cases SLBMs and ICBMs may be part of the same family of weapons.

Anti-Ballistic Missile

An anti-ballistic missile (ABM) is a surface-to-air missile designed to counter ballistic missiles (see missile defence). Ballistic missiles are used to deliver nuclear, chemical, biological, or conventional warheads in a ballistic flight trajectory. The term "anti-ballistic missile" is a generic term conveying a system designed to intercept and destroy any type of ballistic threat, however it is commonly used for systems specifically designed to counter intercontinental ballistic missiles (ICBMs). There are only three systems in the world that can intercept ICBMs. Besides them, some smaller systems exist (tactical ABMs), that generally cannot intercept intercontinental strategic missiles, even if within range—an incoming ICBM simply moves too fast for these systems.

● The Russian A-135 anti-ballistic missile system is used for the defence of Moscow. It became operational in 1995 and was preceded by the A-35 anti-ballistic missile system. The system uses Gorgon and Gazelle missiles with nuclear warheads to intercept incoming ICBMs.
● The U.S. Ground-Based Midcourse Defence System (GMD), formerly known as National Missile Defence (NMD), was first tested in 1997 and had its first successful intercept test in 1999. Instead of using an explosive charge, it launches a hit-to-kill kinetic projectile to intercept an ICBM. The current GMD system is intended to shield the United States mainland against a limited nuclear attack by a rogue state such as North Korea. GMD does not have the ability to protect against an all-out nuclear attack from Russia, as there are currently 44 ground-based interceptors deployed against crossing projectiles headed toward the homeland. (This does not include the THAAD, or Aegis, or Patriot defences against directly incoming projectiles.)
● The Israeli Arrow 3 system entered operational service in 2017. It is designed for exo-atmosphere interception of ballistic missiles during the spaceflight portion of their trajectory, including those of ICBMs. It may also act as an anti-satellite weapon.

United States

In several tests, the U.S. military have demonstrated the feasibility of destroying long and short range ballistic missiles. Combat effectiveness of newer systems against 1950s tactical ballistic missiles seems very high, as the MIM-104 Patriot (PAC-1 and PAC-2) had a 100% success rate in Operation Iraqi Freedom. The U.S. Navy Aegis combat system uses RIM-161 Standard Missile 3, which hit a target going faster than ICBM warheads. These systems, as opposed to U.S. GMD system, are not capable of a mid-course intercept of an ICBM. The U.S. Terminal High Altitude Area Defence (THAAD) system began production in 2008. Its stated range as a short to intermediate ballistic missile interceptor means that it is not designed to hit midcourse ICBMs, which can reach terminal phase speeds of mach 8 or greater.

But for terminal phase, a THAAD interceptor's speed can reach mach 8, and THAAD has repeatedly proven it can intercept descending exoatmospheric missiles in a ballistic trajectory. The United States Army released information as early as 2004 about their plans to develop a command system that was intended to replace Raytheon's Patriot missile (SAM) engagement control station along with seven other forms of defence command systems.

The system, the Integrated Air and Missile Battle Command System (IBCS), is an anti-ballistic missile defence system designed to shoot down short, medium, and intermediate range ballistic missiles in their terminal phase by intercepting with a hit-to-kill approach. A prime contractor was announced in 2010; by May 2015, a first flight test integrated a networked IBCS 280 engagement operations centre with radar sensor and interceptor launchers. This test demonstrated a missile kill with the first interceptor. By Army doctrine, two interceptors were launched against that missile. By November 2016, IBCS tests demonstrated sensor fusion from disparate data streams,:minute 2:28 identification and tracking of targets, selection of appropriate kill vehicles, and interception of the targets.

Israel

Arrow 2	The Arrow project was begun after the U.S. and Israel agreed to co-fund it on 6 May 1986. The Arrow ABM system was designed and constructed in Israel with financial support by the United States by a multibillion-dollar development program called "Minhelet Homa" (Wall Administration) with the participation of companies like Israel Military Industries, Tadiran and Israel Aerospace Industries.
Arrow 3	The Arrow 3 system is capable of exo-atmosphere interception of ballistic missiles, including of ICBMs. It also acts as an anti-satellite weapon. Lieutenant General Patrick J. O'Reilly, Director of the US Missile Defence Agency, said: "The design of Arrow 3 promises to be an extremely capable system, more advanced than what we have ever attempted in the U.S. with our programs."

WARFARE | A | A

David's Sling	David's Sling, is an Israel Defence Forces military system being jointly developed by the Israeli defence contractor Rafael Advanced Defence Systems and the American defence contractor Raytheon, designed to intercept tactical ballistic missiles, as well as medium- to long-range rockets and slower-flying cruise missiles, such as those possessed by Hezbollah, fired at ranges from 40 km to 300 km. It is designed with the aim of intercepting the newest generation of tactical ballistic missiles, such as Iskander.

6 Space Warfare

Space warfare is combat that takes place in outer space. The scope of space warfare therefore includes ground-to-space warfare, such as attacking satellites from the Earth; space-to-space warfare, such as satellites attacking satellites; and space-to-ground warfare, such as satellites attacking Earth-based targets.

As of 2020 no actual warfare has ever taken place in space, though a number of tests and demonstrations have been performed. International treaties are in place that regulate conflicts in space and limit the installation of space weapon systems, especially nuclear weapons.

History

1960s

Early efforts to conduct space warfare were directed at space-to-space warfare, as ground-to-space systems were considered to be too slow and too isolated by Earth's atmosphere and gravity to be effective at the time. The history of active space warfare development goes back to the 1960s when the Soviet Union began the Almaz project, a project designed to give them the ability to do on-orbit inspections of satellites and destroy them if needed. Similar planning in the United States took the form of the Blue Gemini project, which consisted of modified Gemini capsules that would be able to deploy weapons and perform surveillance.

One early test of electronic space warfare, the so-called Starfish Prime test, took place in 1962, when the United States exploded a ground-launched nuclear weapon in space to test the effects of an electromagnetic pulse. The result was a deactivation of many then-orbiting satellites, both American and Soviet. The deleterious and unfocused effects of the EMP test led to the banning of nuclear weapons in space in the Outer Space Treaty of 1967.

In the early 1960s the U.S. military produced a film called Space and National Security which depicted space warfare.

1970s–1990s

Through the 1970s, the Soviet Union continued their project and test-fired a cannon to test space station defense. This was considered too dangerous to do with a crew on board, however, so the test was conducted after the crew had returned to Earth.

A USAF F-15 Eagle launching an ASM-135 ASAT (anti-satellite) missile in 1985.
A 1976 Soviet report suggested that the design of the space shuttle had been guided by a requirement to deliver a payload- such as a bomb- over Russia and return to land after a single orbit. This may have been a confusion based on requirements 3A and 3B for the shuttle's design, which required the craft to be able to deploy or retrieve an object from a polar orbit in a single pass.

Both the Soviets and the United States developed anti-satellite weaponry designed to shoot down satellites. While early efforts paralleled other space-to-space warfare concepts, the United States was able in the 1980s to develop ground-to-space laser anti-satellite weapons. None of these systems are known to be active today; however, a less powerful civilian version of the ground-to-space laser system is commonly used in the astronomical technique of adaptive optics.

Since 2000

The U.S. developed an interceptor missile, the SM-3, testing it by hitting ballistic test targets while they were in space. On February 21, 2008, the U.S. used a SM-3 missile to destroy a spy satellite, USA-193, while it was 247 kilometers (133 nautical miles) above the Pacific Ocean. Japan fields the U.S.-made SM-3 missile, and there have been plans to base the land-based version in Romania and Vietnam.

In March 2019, India shot down a satellite orbiting in a Low Earth orbit using an ASAT missile during an operation code named Mission Shakti, thus making its way to the list of space warfare nations, establishing the Defense Space Agency the following month, followed by its first-ever simulated space warfare exercise on 25 July which would inform a joint military space doctrine.

In July 2019 Emmanuel Macron "called for a space high command to protect" France's satellites. This was followed by a plan released by military officials. French Defense Minister, Florence Parly, announced a space weapons program that would move the country's space surveillance strategy towards active protection of its assets in space, e.g. satellites. The projects outlined include: patrolling nano-satellites swarms, ground-based laser systems to blind spying satellites, and machine guns mounted on satellites.

Theoretical Space Weaponry

Ballistic Warfare

In the late 1970s and through the 1980s the Soviet Union and the United States theorized, designed and in some cases tested a variety of weaponry designed for warfare in outer space. Space warfare was seen primarily as an extension of nuclear warfare, and so many theoretical systems were based around the destruction or defense of ground and sea-based missiles.

Space-based missiles were not attempted due to the Outer Space Treaty, which banned the use, testing or storage of nuclear weapons outside the Earth's atmosphere. When the U.S. gained "interest in utilizing space-based lasers for ballistic missile defense", two facts emerged. One being that the ballistic missiles are fragile and two, chemical lasers project missile killing energy (3,000 kilometers). This meant that lasers could be put into space to intercept a Ballistic missile.

Systems proposed ranged from measures as simple as ground and space-based anti-missiles to railguns, space based lasers, orbital mines and similar weaponry. Deployment of these systems was seriously considered in the mid-1980s under the banner of the Strategic Defense Initiative announced by Ronald Reagan in 1983, using the term "evil empire" to describe the Soviets (hence the popular nickname "Star Wars").

If the Cold War had continued, many of these systems could potentially have seen deployment: the United States developed working railguns, and a laser that could destroy missiles at range, though the power requirements, range, and firing cycles of both were impractical. Weapons like the space-based laser was rejected, not just by the government, but by Universities, moral thinkers, and religious people because it would have increased the waging of the arms race and questioned the United States' role in the Cold War.

Electronic Warfare

With the end of the Cold War and continued development of satellite and electronics technology, attention was focused on space as a supporting theatre for conventional warfare. Currently, military operations in space primarily concern either the vast tactical advantages of satellite-based surveillance, communications, and positioning systems or mechanisms used to deprive an opponent of said tactical advantages.

Accordingly, most space-borne proposals which would traditionally be considered "weapons" (a communications or reconnaissance satellite may be useful in warfare but isn't generally classified as a weapon) are designed to jam, sabotage, and outright destroy enemy satellites, and conversely to protect friendly satellites against such attacks. To this end, the US (and presumably other countries) is researching groups of small, highly mobile satellites called "microsats" (about the size of a refrigerator) and "picosats" (approximately 1 cubic foot (≈27 litres) in volume) nimble enough to maneuver around and interact with other orbiting objects to repair, sabotage, hijack, or simply collide with them.

Kinetic Bombardment

Another theorized use involves the extension of conventional weaponry into orbit for deployment against ground targets. Though international treaties ban the deployment of nuclear missiles outside the atmosphere, other categories of weapons are largely unregulated. Traditional ground-based weapons are generally not useful in orbital environments, and few if any would survive re-entry even if they were, but as early as the 1950s, the United States has toyed with kinetic bombardment, i.e. orbiting magazines of non-explosive projectiles to be dropped onto hardened targets from low Earth orbit.

Kinetic weapons have always been widespread in conventional warfare—bullets, arrows, swords, clubs, etc.—but the energy a projectile would gain while falling from orbit would make such a weapon rival all but the most powerful explosives. A direct hit would presumably destroy all but the most hardened targets without the need for nuclear weapons.

Such a system would involve a 'spotter' satellite, which would identify targets from orbit with high-power sensors, and a nearby 'magazine' satellite to de-orbit a long, needle-like tungsten dart onto it with a small rocket motor or just dropping a very big rock from orbit (such as an asteroid). This would be more useful against a larger but less hardened target (such as a city). Though a common device in science fiction, there is no publicly available evidence that any such systems have actually been deployed by any nation.

Directed-Energy Weapons

Weapon systems that fall under this category include lasers, linear particle accelerators or particle-beam based weaponry, microwaves and plasma-based weaponry. Particle beams involve the acceleration of charged or neutral particles in a stream towards a target at extremely high velocities, the impact of which creates a reaction causing immense damage. Most of these weapons are theoretical or impractical to implement currently, aside from lasers which are starting to be used in terrestrial warfare. That said, directed-energy weapons are more practical and more effective in a vacuum (i.e. space) than in the Earth's atmosphere, as in the atmosphere the particles of air interfere with and disperse the directed energy. Nazi Germany had a project for such a weapon, considered a wunderwaffe, the sun gun, which would have been an orbital concave mirror able to concentrate the sun's energy on a ground target.

Space-Based Lasers

Light Amplification by the Stimulated Emission of Radiation (acronym LASER) excite molecules within a chamber, creating an electronic state that releases energy in the form of photons. The photons pass by other molecules, spreading energy, making more photons. To make an actual laser, a beam has to pass through mass quantities of laser medium by bouncing back and forth between mirrors placed at opposing ends. Then the light beam exits through one of the mirrors which is more transparent than the other. Making a functional laser requires the electrons to not only reach their excited state, but is reliant on the time it takes for them to get excited, and also the time for the energy created to reach new electrons. The efficiency of the laser relies on the amount of heat that exits. In terms of lasers, the power of the laser far outweighs the chemical efficiency. Of course the trajectory of the laser matters as well as its ability to hit the target it is aimed at, but when lasers are placed in space, Diffraction can cause interference.

Lethality of Space Lasers
Lasers require mirrors in the system to direct their beams to achieve impact, but if not done correctly, major damage can affect the skin. However, if the laser or lasers does make impact,

"a 10 meter mirror with a HF laser beam would yield a 0.32 micro-radian divergence angle and create a laser spot 1.3 meter in diameter at a range of 4,000 meters. The distribution of the 20MW over the laser spot would create an energy flux of 1.5 kilowatts per square centimeter (kW/cm^2). The laser spot would need to dwell on the target for 6.6 seconds to create the nominal lethal fluence of 10 kilojoules per square centimeter (kJ/cm^2)"

meaning that the laser would essentially blow holes into missiles they are aimed at, as long as the laser mirrors are aimed correctly and the heated molecules exit the beam quickly. Other factors of impact would be the type of laser itself, the amount of exposure, what the laser is attempting to hit (the target), environmental factors, and the ability of the target to either absorb or reflect the laser beam itself. So what happens when a target is hit? Since this is a topic of space-based lasers it's safe to assume that the target is in the atmosphere so,

"a beam with an intensity of around 10 million watts per square centimeter would cause the air immediately in front of the target to ionize, which would create a layer of plasma as the beam hits the surface. The plasma would absorb the energy of the laser beam and grow extremely hot (around 6,000 degrees Celsius). The plasma would distribute this energy in two ways, by emitting ultraviolet radiation and by expanding explosively. These mechanisms could increase the extent of the beam energy attached to the target to approximately 30 percent and reduce the amount of energy the laser would have to produce."

When a laser is placed on the ground there are many more chances for obscurity in terms of a laser beam having to travel through the atmosphere as well as a much farther length of travel for the beam to hit the target. Other issues that can cause the laser beam to not be efficient is a state called Thermal blooming when the laser heats up the air around it which can cause diffusion because of the heat, sparking, and simply decreasing the beam size by increasing the mirror size could fight against thermal blooming. The atmosphere can also cause absorption, scattering, turbulence, and sparking to the beam, even simply bending the beam so the target isn't accurate.

Practical Considerations

Space warfare is likely to be conducted at far greater distances and speeds than terrestrial combat. The vast distances involved pose difficult challenges for targeting and tracking, as even light requires a few seconds to traverse ranges measured in hundreds of thousands of kilometers. For example, if attempting to fire upon a target at the distance of the Moon from the Earth, the image one sees reflects the position of the target slightly more than a second earlier. Thus even a laser would need approximately 1.28 seconds, meaning a laser-based weapon system would need to lead a target's apparent position by $1.28\times2 = 2.56$ seconds. A projectile from a railgun recently tested by the US Navy would take over eighteen hours to cross that distance, assuming that it would travel in a straight line at a constant velocity of 5.8 km/s along its entire trajectory.

Three factors conspire to make engaging targets in space very difficult. First, the vast distances involved mean that an error of even a fraction of a degree in the firing solution could result in a miss by thousands of kilometers. Second, space travel involves tremendous speeds by terrestrial standards—a geostationary satellite moves at a speed of 3.07 km/s whereas objects in low earth orbit can move at up to 8 km/s. Third, though distances are large, targets remain relatively small. The International Space Station, currently the largest artificial object in Earth orbit, measures slightly over 100m at its largest span. Other satellites can be orders of magnitude smaller, e.g. Quickbird measures a mere 3.04m.

External ballistics for stationary terrestrial targets is enormously complicated—some of the earliest analog computers were used to calculate firing solutions for naval artillery, as the problems were already beyond manual solutions in any reasonable time—and the issues in targeting objects in space make a difficult problem even harder. Additionally, though not a problem for orbital kinetic weapons, any directed energy weapon would require large amounts of electricity. So far the most practical batteries are lithium batteries, and the most practical method of generating electricity in space is through photovoltaic modules, which are currently only up to 30% efficient, and fuel cells, which have limited fuel. Current technology might not be practical for powering effective lasers, particle beams, and railguns in space. In the context of the Strategic Defense Initiative, the Lawrence Livermore National Laboratory in the United States worked on a project for expandable space-based x-ray lasers powered by a nuclear explosion, Project Excalibur, a project canceled in 1992 for lack of results.

General William L. Shelton has said that in order to protect against attacks, Space Situational Awareness is much more important than additional hardening or armoring of satellites. The Air Force Space Command has indicated that their defensive focus will be on "Disaggregated Space Architectures".

Space Debris
Anti-satellite attacks, especially ones involving kinetic kill vehicles, can contribute to the formation of space debris which can remain in orbit for many years and could interfere with future space activity or in a worst case trigger a Kessler Syndrome. In January 2007 China demonstrated a satellite knock out whose detonation alone caused more than 40,000 new chunks of debris with a diameter larger than one centimeter and a sudden increase in the total amount of debris in orbit. The PRC is reported to be developing "soft-kill" techniques such as jamming and vision kills that do not generate much debris.

Possible Warfare Over Space
Most of the world's communications systems rely heavily on the presence of satellites in orbit around Earth. Protecting these assets might seriously motivate nations dependent upon them to consider deploying more space-based weaponry, especially in conflicts involving advanced countries with access to space.

Since 2017, the United States Air Force has run an annual military exercise called "Space Flag" at Peterson Air Force Base, which involves a red team simulating attacks on U.S. satellites.

7 Electronic Warfare

Drones

UAVs

Robots (Animaloid)

Robots (Humanoid)

8 Traps & Explosives

IEDs

An improvised explosive device (IED) is a bomb constructed and deployed in ways other than in conventional military action. It may be constructed of conventional military explosives, such as an artillery shell, attached to a detonating mechanism. IEDs are commonly used as roadside bombs. IEDs are generally seen in heavy terrorist actions or in asymmetric unconventional warfare by insurgent guerrillas or commando forces in a theatre of operations. In the second Iraq War, IEDs were used extensively against US-led invasion forces and by the end of 2007 they had become responsible for approximately 63% of coalition deaths in Iraq. They are also used in Afghanistan by insurgent groups, and have caused over 66% of coalition casualties in the 2001–present Afghanistan War. IEDs were also used extensively by cadres of the rebel Tamil Tiger (LTTE) organisation against military targets in Sri Lanka.

Background

An IED is a bomb fabricated in an improvised manner incorporating destructive, lethal, noxious, pyrotechnic, or incendiary chemicals and designed to destroy or incapacitate personnel or vehicles. In some cases, IEDs are used to distract, disrupt, or delay an opposing force, facilitating another type of attack. IEDs may incorporate military or commercially sourced explosives, and often combine both types, or they may otherwise be made with homemade explosives (HME). An HME lab refers to a Homemade Explosive Lab, or the physical location where the devices are crafted. An IED has five components: a switch (activator), an initiator (fuse), container (body), charge (explosive), and a power source (battery). An IED designed for use against armoured targets such as personnel carriers or tanks will be designed for armour penetration, by using a shaped charge that creates an explosively formed penetrator. IEDs are extremely diverse in design and may contain many types of initiators, detonators, penetrators, and explosive loads.

Antipersonnel IEDs typically also contain fragmentation-generating objects such as nails, ball bearings or even small rocks to cause wounds at greater distances than blast pressure alone could. In the conflicts of the 21st century, anti-personnel improvised explosive devices (IED) have partially replaced conventional or military landmines as the source of injury to dismounted (pedestrian) soldiers and civilians. These injuries were recently reported in BMJ Open to be far worse with IEDs than with landmines resulting in multiple limb amputations and lower body mutilation. This combination of injuries has been given the name "Dismounted Complex Blast Injury" and is thought to be the worst survivable injury ever seen in war. IEDs are triggered by various methods, including remote control, infrared or magnetic triggers, pressure-sensitive bars or trip wires (victim-operated). In some cases, multiple IEDs are wired together in a daisy chain to attack a convoy of vehicles spread out along a roadway. IEDs made by inexperienced designers or with substandard materials may fail to detonate, and in some cases, they actually detonate on either the maker or the placer of the device. Some groups, however, have been known to produce sophisticated devices constructed with components scavenged from conventional munitions and standard consumer electronics components, such as mobile phones, consumer-grade two-way radios, washing machine timers, pagers, or garage door openers.

The sophistication of an IED depends on the training of the designer and the tools and materials available. IEDs may use artillery shells or conventional high-explosive charges as their explosive load as well as homemade explosives. However, the threat exists that toxic chemical, biological, or radioactive (dirty bomb) material may be added to a device, thereby creating other life-threatening effects beyond the shrapnel, concussive blasts and fire normally associated with bombs. Chlorine liquid has been added to IEDs in Iraq, producing clouds of chlorine gas. A vehicle-borne IED, or VBIED, is a military term for a car bomb or truck bomb but can be any type of transportation such as a bicycle, motorcycle, donkey (DBIED), etc. They are typically employed by insurgents in particular ISIS, and can carry a relatively large payload. They can also be detonated from a remote location. VBIEDs can create additional shrapnel through the destruction of the vehicle itself and use vehicle fuel as an incendiary weapon. The act of a person's being in this vehicle and detonating it is known as an SVBIED suicide. Of increasing popularity among insurgent forces in Iraq is the house-borne IED, or HBIED from the common military practice of clearing houses; insurgents rig an entire house to detonate and collapse shortly after a clearing squad has entered.

An IED is rarely, if ever, produced by traditional manufacturing processes with a rigid mode of employment. The key to them is their 'improvised' nature – one that will utilize available materials in order to attack an opponent. An explosive charge might be constructed from commonly available chemicals, but can also include conventional munitions (such as artillery shells adapted as roadside bombs). IEDs are certainly not a new phenomenon, with records of IED use over the last 500 years. But they continue to evolve both in their design, which is defined by available materials and by the use to which they are put. Typically, IEDs have four key components: a main charge of explosives, an explosive initiator (a small amount of energetic explosives), a switching mechanism and a container of some sort. Most developments in IED design and construction involve one or more of these.

Recent developments in the design of IEDs have focused on a number of areas, namely:
1. Explosive component design (for instance to provide better target effects and become more lethal). Here, the main charge and the container in which it is contained are changed or developed.
2. Explosive component precursors (for instance the use of commonly available precursors to make explosives). Here the main charge is developed. In some cases alternate explosive initiators have been developed.
3. Design of projected IEDs such as improvised mortars and rockets, to extend range and effect. Here a range of aspects including the container and other components have been developed.
4. Device concealment to better hide the presence of an IED. Here the container is developed to conceal the device better.
5. Command initiation developments, typically to utilise modern radio technology. Here the switching mechanism is developed.
6. Sensor initiation developments, typically to utilise modern sensors to initiate victim operated devices. Again this is a switching mechanism development. Some developments in IEDs however have seen a regressive use of technology – old, well known technology (such as the use of two saw blades set in parallel which form a circuit when they touch due to the pressure of a foot continually recycle over the ages).

Explosive Component Design
Perpetrators of IED attacks are faced with a range of targets and naturally those targets may take measures to improve their protection in the event of an attack. This naturally leads to the perpetrator considering ways in which to amplify the effect of the explosive component in order to overcome those defensive measures. At the simplest level this might simply be the use of larger quantities of explosives. In the 1970s, a car bomb or Vehicle IED (VBIED) might typically contain explosives within a container such as a barrel or a suitcase loaded into the trunk of the vehicle, because targets of VBIEDs were not protected. Today, with a greater awareness and presence of the VBIED threat, defences include protected facilities or greater 'stand-off' achieved by security measures. Over the last few years we have seen larger and larger VBIEDs in a variety of countries around the world as security protocols, using things such as road blocks, keep VBIEDs further from their targets. A second development is the use of a more sophisticated explosive component design. When faced with armoured targets some terrorist groups have used the physics of explosive component design to develop the design of the warhead to create a more penetrative effect, using – for instance – shaped charges. Shaped charges come in a variety of configurations, from high angle cones to dishes, all of which are deformed by the complex transition of the explosive blast wave into a range of penetrative effects. These effects can be further developed by the use of a range of different metals, which deform in different ways.

Explosive Component Precursors
Perpetrators of IED attacks do not necessarily have access to military explosives. In these circumstances, those constructing IEDs must develop their own explosives. Typically, this has been by utilizing a mix of an 'oxidiser' and a 'fuel' in appropriate portions, which one might consider as precursor chemicals. The chemistry of an oxidising reaction is such that in the right proportions and with the right level of mixing, the reaction becomes explosive when properly initiated. Over the past few decades one of the most common explosive mixes has been Fuel Oil (fuel) and Ammonium Nitrate (oxidiser), commonly called ANFO. However, a very wide range of different fuels are possible and they do not need to be carbon based – some recent developments have seen the use of a range of differing fuels and oxidisers, usually driven by the availability of material (e.g. if Ammonium Nitrate is made difficult to obtain by security legislation). Sometimes, albeit rarely, the explosive mix might be chosen to provide a slightly different effect, such as Ammonium Nitrate and Aluminium powder (the fuel in this case), which has a shorter peak pressure than ANFO – more likely to 'crack' concrete than perhaps 'lift and throw' it. But there may be other reasons for this development.

ANFO mixes separate out over time as the liquid fuel oil moves to the bottom of the container, causing less than perfect mixing – but an Aluminium powder and Ammonium Nitrate mix separates much less over time. The range of possible fuels and oxidizers is quite significant, and some developments have seen the use of innovative precursor materials. In other circumstances, rather than create a mix of fuels and oxidisers some IED constructors have developed explosive compounds – a single chemical material that is explosive when it decomposes. Such explosives were effectively first discovered in the 19th century, with the work of Nobel to develop Nitroglycerine and subsequently others to develop TNT. While theoretically today's IED user could produce such material, very often they use easier-to-obtain precursors such as Hydrogen peroxide and acetone to produce TATP, a particularly sensitive explosive. TATP has been used in devices as a main charge, but is also energetic and sensitive enough to be used as an initiator.

Device Concealment
In recent years there have been some significant developments to conceal IEDs so that they can pass a variety of forms of security screenings. Devices have been built in to the body of a vehicle, into shoes so to hide them during pre-flight aviation security, and in one incident built into a complex piece of equipment (a printer) to allow it to be loaded on an aircraft. In truth, concealing devices is not new but IED users are continuing to show innovative developments in this regard.

Sensor Initiation Developments
Makers of IEDs have always used radio initiation systems to remove themselves from the site of a bomb location. Ever since "jammers" were deployed by those defending against such attacks, terrorists have explored ways of getting around such defences, either by moving the frequency of the command system to an area of spectrum outside the jammer's capability or using a combination of switches. Such as a radio control signal to turn on a sensor before a vehicles jammer affects the radio signal, allowing the sensor to trigger the device. Fundamentally, the radio control system is no more than a switch, but a switch that many nations have now spent billions of dollars to defeat. IED designers will use a variety of ingenious mechanisms for victim operated switching. Sometimes these will use the latest technology, such as IR heat sensors, but less sophisticated mechanical booby trap pull-switches or pressure-plates are constantly being used and updates. The ways in which IEDs are employed are as diverse as the methods of construction. While IEDs are certainly used as a tactical weapon to defeat personnel and vehicles, they also play an important role at the strategic level of warfare. As Michael D. Barbero, Lieutenant General, U.S. Army Director JIEDDO, has succinctly said: 'The IED is a weapon used strategically to cause casualties, create the perception of insecurity, and influence national will.' A current example of the use of IEDs as weapons of both tactical and strategic use is their use – both suicide-initiated and otherwise, by the so-called Islamic State (IS).

Offensive Operations
At the tactical level, Iraqi Ba'atthist doctrines of superior firepower at the outset of attacks have been adopted by IS in its more conventional (ground holding) military operations. However, as sufficient resources of armour and artillery are in short supply, they have adapted to using Suicide Vehicle Borne IEDs (SVBIEDs) in place of conventional military equipment to achieve the same aim. In their attack on Ramadi in May 2015, for example, IS used up to 30 car bombs to overwhelm static military defences in advance of an infantry attack. In the same offensive campaign, IS also used roadside IEDs to block roads to cut off the city from reinforcements – again showing their ability to use improvised weapons for conventional fighting. Another important example of the use of IEDs as a tactic in offensive operations was the Abu Ghraib prison break on 21 July 2013, where the use of SVBIEDs led the way for an infantry assault which resulted in the escape of over 500 prisoners, bolstering the numbers of al- Qaeda in Iraq.

Defensive Operations
IEDs also play an important role in the defence of IS held territory at the tactical level. For example, during the YPG's assault on Hassaka neighbourhood of al-Zuhur, IS fighters placed IEDs to slow the Kurdish advance, showing their adaptability in using improvised weapons as a tactic of a conventional fighting force. At a strategic level, while they may be struggling to hold ground in recent months, the extensive placement of IEDs can prevent or delay post-conflict stabilisation of areas IS formerly held, which disguises their numerical inferiority. This 'economy of force' strategy is, according to Michael Knights and Alexandre Mello of the Washington Institute for Near East Policy, an under-acknowledged capability of the Islamic State, and this 'slow burn' strategy is 'where its real strength lies'. This underlines the importance of the use of IEDs to IS's broader strategy.

Types

IED - By Warhead

Explosive	A device placed or fabricated in an improvised manner incorporating destructive, lethal, noxious, pyrotechnic, or incendiary chemicals and designed to destroy, incapacitate, harass, or distract. It may incorporate military stores, but is normally devised from non-military components.
Explosively formed penetrator/projectiles (EFPs)	IEDs have been deployed in the form of explosively formed projectiles (EFP), a special type of shaped charge that is effective at long standoffs from the target (50 meters or more), however they are not accurate at long distances. This is because of how they are produced. The large "slug" projected from the explosion has no stabilization because it has no tail fins and it does not spin like a bullet from a rifle. Without this stabilization the trajectory can not be accurately determined beyond 50 meters. An EFP is essentially a cylindrical shaped charge with a machined concave metal disc (often copper) in front, pointed inward. The force of the shaped charge turns the disc into a high velocity slug, capable of penetrating the armour of most vehicles in Iraq.
Directionally Focused Charges	Directionally focused charges (also known as directionally focused fragmentary charges depending on the construction) are very similar to EFPs, with the main difference being that the top plate is usually flat and not concave. It also is not made with machined copper but much cheaper cast or cut metal. When made for fragmentation, the contents of the charge is usually nuts, bolts, ball bearings and other similar shrapnel products and explosive. If it only consists of the flat metal plate, it is known as a platter charge, serving a similar role as an EFP with reduced effect but easier construction.
Chemical	A device incorporating the toxic attributes of chemical materials designed to result in the dispersal of these toxic chemical materials for the purpose of creating a primary patho-physiological toxic effect (morbidity and mortality), or secondary psychological effect (causing fear and behaviour modification) on a larger population. Such devices may be fabricated in a completely improvised manner or may be an improvised modification to an existing weapon.
Biological	A device incorporating biological materials designed to result in the dispersal of vector borne biological material for the purpose of creating a primary patho-physiological toxic effect (morbidity and mortality), or secondary psychological effect (causing fear and behaviour modification) on a larger population. Such devices are fabricated in a completely improvised manner.
Incendiary	A device making use of exothermic chemical reactions designed to result in the rapid spread of fire for the purpose of creating a primary patho-physiological effect (morbidity and mortality), or secondary psychological effect (causing fear and behaviour modification) on a larger population or it may be used with the intent of gaining a tactical advantage. Such devices may be fabricated in a completely improvised manner or may be an improvised modification to an existing weapon. A common type of this is the Molotov cocktail.
Radiological	A speculative device incorporating radioactive materials designed to result in the dispersal of radioactive material for the purpose of area denial and economic damage, and/or for the purpose of creating a primary patho-physiological toxic effect (morbidity and mortality), or secondary psychological effect (causing fear and behaviour modification) on a larger population. Such devices may be fabricated in a completely improvised manner or may be an improvised modification to an existing nuclear weapon. Also called a Radiological Dispersion Device (RDD) or "dirty bomb".
Nuclear	Improvised nuclear device of most likely gun-type or implosion-type. Nanotechnology can theoretically be used to develop miniaturised laser-triggered pure fusion weapon that will be easier to produce than conventional nuclear weapons and could be used in terrorist attacks.

IED - By Delivery Mechanism

Car	A vehicle may be laden with explosives, set to explode by remote control or by a passenger/driver, commonly known as a car bomb or vehicle-borne IED (VBIED, pronounced vee-bid). On occasion the driver of the car bomb may have been coerced into delivery of the vehicle under duress, a situation known as a proxy bomb. Distinguishing features are low-riding vehicles with excessive weight, vehicles with only one passenger, and ones where the interior of the vehicles look as if they have been stripped down and built back up. Car bombs can carry thousands of pounds of explosives and may be augmented with shrapnel to increase fragmentation. The U.S. State Department has published a guide on car bomb awareness. ISIS has used truck bombs with devastating effects.
Boat	Boats laden with explosives can be used against ships and areas connected to water. An early example of this type was the Japanese Shinyo suicide boats during World War II. The boats were laden with explosives and attempted to ram Allied ships, sometimes successfully, having sunk or severely damaged several American ships by war's end. Suicide bombers used a boat-borne IED to attack the USS Cole, US and UK troops have also been killed by boat-borne IEDs in Iraq.

Animal	Monkeys and war pigs were used as incendiaries around 1000 AD. More famously the "anti-tank dog" and "bat bomb" were developed during World War II. In recent times, a two-year-old child and seven other people were killed by explosives strapped to a horse in the town of Chita in Colombia The carcasses of certain animals were also used to conceal explosive devices by the Iraqi insurgency.
Collar	IEDs strapped to the necks of farmers have been used on at least three occasions by guerrillas in Colombia, as a way of extortion. American pizza delivery man Brian Douglas Wells was killed in 2003 by an explosive fastened to his neck, purportedly under duress from the maker of the bomb. In 2011 a schoolgirl in Sydney, Australia had a suspected collar bomb attached to her by an attacker in her home. The device was removed by police after a ten-hour operation and proved to be a hoax.
Suicide	Suicide bombing usually refers to an individual wearing explosives and detonating them in order to kill others including themselves, a technique pioneered by LTTE (Tamil Tigers). The bomber will conceal explosives on and around their person, commonly using a vest (or possibly a prosthetic) and will use a timer or some other trigger to detonate the explosives. The logic behind such attacks is the belief that an IED delivered by a human has a greater chance of achieving success than any other method of attack. In addition, there is the psychological impact of fighters prepared to deliberately sacrifice themselves for their cause.
Surgically Implanted	In May 2012 American counter-terrorism officials leaked their acquisition of documents describing the preparation and use of surgically implanted improvised explosive devices. The devices were designed to evade detection. The devices were described as containing no metal, so they could not be detected by X-rays. Security officials referred to bombs being surgically implanted into suicide bombers' "love handles". According to the Daily Mirror UK security officials at MI-6 asserted that female bombers could travel undetected carrying the explosive chemicals in otherwise standard breast implants. The bomber would blow up the implanted explosives by injecting a chemical trigger.
Robot	Robots can be used to carry explosives. First such documented case was during the aftermath of 2016 shooting of Dallas police officers when a bomb disposal robot was used to deliver explosives to kill Micah Xavier Johnson, who was hiding in a place unaccesible to police snipers.
Tunnel	ISIS and Al-Nusra have used bombs detonated in tunnels dug under targets.
Improvised Rocket	In 2008, rocket-propelled IEDs, dubbed Improvised Rocket Assisted Munitions, Improvised Rocket Assisted Mortars and (IRAM) by the military, came to be employed in numbers against U.S. forces in Iraq. They have been described as propane tanks packed with explosives and powered by 107 mm rockets. They are similar to some Provisional IRA barrack buster mortars. New types of IRAMs including Volcano IRAM and Elephant Rockets, are used during Syrian Civil War.
Improvised Mortar	Improvised mortar has been used by many insurgent groups including during civil war in Syria and Boko Haram insurgency. IRA used improvised mortars called barrack busters.
Improvised Artillery	Improvised artillery including hell cannons are used by rebel forces during Syrian Civil War.
IED - By Trigger Mechanism	
Wire	Command-wire improvised, explosive devices (CWIED) use an electrical firing cable that affords the user complete control over the device right up until the moment of initiation.
Radio	The trigger for a radio-controlled improvised explosive device (RCIED) is controlled by radio link. The device is constructed so that the receiver is connected to an electrical firing circuit and the transmitter operated by the perpetrator at a distance. A signal from the transmitter causes the receiver to trigger a firing pulse that operates the switch. Usually the switch fires an initiator; however, the output may also be used to remotely arm an explosive circuit. Often the transmitter and receiver operate on a matched coding system that prevents the RCIED from being initiated by spurious radio frequency signals or jamming. An RCIED can be triggered from any number of different mechanisms including car alarms, wireless door bells, cell phones, pagers and encrypted GMRS radios.
Mobile Phone	A radio-controlled IED (RCIED) incorporating a mobile phone that is modified and connected to an electrical firing circuit. Mobile phones operate in the UHF band in line of sight with base transceiver station (BTS) antennae sites. In the common scenario, receipt of a paging signal by phone is sufficient to initiate the IED firing circuit.
Victim-Operated	Victim-operated improvised explosive devices (VOIED), also known as booby traps, are designed to function upon contact with a victim. VOIED switches are often well hidden from the victim or disguised as innocuous everyday objects. They are operated by means of movement. Switching methods include tripwire, pressure mats, spring-loaded release, push, pull or tilt. Common forms of VOIED include the under-vehicle IED (UVIED), improvised landmines, and mail bombs.
Infrared	The British accused Iran and Hezbollah of teaching Iraqi fighters to use infrared light beams to trigger IEDs. As the occupation forces became more sophisticated in interrupting radio signals around their convoys, the insurgents adapted their triggering methods. In some cases, when a more advanced method was disrupted, the insurgents regressed to using uninterruptible means, such as hard wires from the IED to detonator; however, this method is much harder to effectively conceal. It later emerged however, that these "advanced" IEDs were actually old IRA technology. The infrared beam method was perfected by the IRA in the early '90s after it acquired the technology from a botched undercover British Army operation. Many of the IEDs being used against the invading coalition forces in Iraq were originally developed by the British Army who unintentionally passed the information on to the IRA. The IRA taught their techniques to the Palestine Liberation Organisation and the knowledge spread to Iraq.
Timed	The IED is initiated by a timing mechanism, set by the perpetrator, so they can remove themselves from the scene. The timing mechanisms might be a burning fuse, a mechanical timer or an electronic timer.

Counterefforts

Counter-IED efforts are done primarily by military and law enforcement (led by intelligence efforts) with the assistance of the diplomatic and financial communities. It involves a comprehensive approach of countering the threat networks that employ improvised explosive devices (IEDs), defeating the devices themselves, and training others. Counter-IED, or C-IED, is usually part of a broader counter-terrorism, counter-insurgency, or law enforcement effort. Because IEDs are a subset of a number of forms of asymmetric warfare used by insurgents and terrorists, C-IED activities are principally against adversaries and not only against IEDs. C-IED treats the IED as a systemic problem and aims to defeat the IED System. This IED System requires multiple actions and resources in order to stage an IED Event. The IED System may be either hierarchical or non-hierarchical but it will contain nodes such as personnel, resources and other actions that are linked.

The importance of these nodes and the linkages between them will vary and identifying the critical vulnerabilities within the IED System is an important C-IED activity. Some IED Systems may be part of large, international terrorist organizations and some may be state sponsored. Some may work completely independently, while others may extend from theatre down to village level. This span of possibilities increases the complexity of military and law enforcement operations and requires a comprehensive approach to C-IED potentially involving close cooperation and coordination between the diplomatic, military, economic, and informational levers of power. The complexity of the IED System is increased since mobile phones and the internet provide a low-cost and easily accessible medium for information sharing and the swift promulgation of tactical ideas and practices, thereby facilitating the efficient operation of these diverse systems. IED network members also have the ability to operate part-time and can blend back into the civilian population when their actions are completed. Such systems can be extremely resilient, invariably hard to target and are, therefore, survivable.

Also, adversary targets can range from the specific such as host nation security force bases and recruiting events to the indiscriminate such as concentrations of people in public places. However, IEDs are not only found within the land environment; other targets may include maritime choke points and ships alongside, as well as aircraft in flight or on the ground. The first organization to tackle IED's on a large scale was the Joint IED Defeat Organization or JIEDDO of the U.S. Department of Defence on 14 February 2006. NATO later adopted JIEDDO's tactics, techniques and procedures. The C-IED approach used by NATO involves 3 mutually supporting and complementary pillars of activity which are: attack the network, defeat the device, and prepare the force. These are all underpinned by understanding and intelligence. (Counter-IED efforts can also be broken up into 6 key operational activities: predict, prevent, detect, neutralize, mitigate, and exploit.)

Countering Threat Networks (CTN)
A growing danger to the international community consists of highly complex adversary networks with international span that employ criminal financing as well as terror attacks and other destructive capabilities. Effectively countering these dynamic and violent illicit networks requires the creation of an international and multi-functional framework to share information on these networks as well as collaborative multinational countermeasures. Attack the network (AtN) is the principal pillar requiring this joint, inter-agency and multinational approach. Attack the network operations are defined as actions, kinetic or non-kinetic, used to disrupt, destroy, or reduce an enemy's capacity to mount terror operations, specifically groups that use IEDs. It consists of largely offensive and proactive activities, driven by intelligence that may go beyond the theatre of operations, designed to disrupt the networks of the adversary's IED System. Counter-network operations usually focus on leadership targeting of an organization, which follows the logic that by catching the right hornet, the whole colony dies. What is often overlooked in this approach, however, is that if just a worker bee is killed, the nest is aggravated and a much bigger problem is created.

While this concept provides a convenient metaphor to discuss possible targeting methodology, it seldom resembles the facts, because human networks are not directly analogous to a hornet's nest. In other words, not every situation can be resolved by a single kill or capture of the "queen". Activity is focused on the critical vulnerabilities of the IED System, for example, by denying the supply of components, finance, leaders, specialists and recruits and adversary exploitation and isolating the adversary from the local population. AtN/CTN seeks to 1) shape and influence IED networks, 2) disrupt their operations, and 3) undermine their financiers and supply chains. Exploitation is a vital component of the attack the networks activity. Information gained provides a picture of adversary capabilities and intentions, perpetrator relationships and the technical construction of the device. This enables the prediction of forthcoming IED activity, informs the targeting process, and enables follow up activities to further disrupt the IED System. Intelligence gained from exploitation also feeds into the other C-IED pillars.

9 War Targets

This section covers the likely targets that may be attacked during a war to help you avoid them. You may already be living close to one of the following, so consider the risk of staying or moving your house or BOL elsewhere.

Common War Targets

Military Troops	Any large gatherings of troops make good targets for adversaries.
Military Bases	All military bases regardless whether they are for the army, navy or air force are often the highest priority targets.
Power Plants	
Nuclear Plants	
Dams	Dams have been targeted in previous wars to help 'starve out' the opposition.
Airports	Civilian airports can sometimes be targeted, especially when they are being used to transport military troops.
Weapons Depot	Weapons depots are targeted to destroy the enemies weapons before they have a chance to use them.
Communications & Radars	All large scale communications towers and long range radars are often high priority targets.
Rail Networks	Railways are targeted because of their efficiency in transporting military equipment around a country.
Gas Pipelines	
Major Roads	Major roads used to transport supplies such as ammo, food, water and weapons could be targeted by enemies.

Restricted War Targets

These locations are generally not targeted or are outside the scope of 'humane' warfare. There are however those countries or armies who are considered scum and will still attack them out of hatred and spite disregarding the rules of fair warfare.

Hospitals	
Hospital Ships	Sometimes hospital ships have been known to be attacked in wars, particularly by Germany during world war 1.

Article four of the Hague Convention X outlined the restrictions for a hospital ship:
- Ship must be clearly marked and lighted as a hospital ship
- The ship should give medical assistance to wounded personnel of all nationalities
- The ship must not be used for any military purpose
- The ship must not interfere with or hamper enemy combatant vessels
- Belligerents, as designated by the Hague Convention, can search any hospital ship to investigate violations of the above restrictions
- Belligerents will establish the location of a hospital ship

Schools	Both Primary and Secondary.
Places of Worship	Churches and Mosques.

Civilian Dwellings	Suburbs.

Security

Camouflage, infiltration and awareness tips

"I changed my password to 'incorrect' so whenever I forget what it is, the computer will say 'Your password is incorrect'."
Unknown

Introduction

Tactics and Stealth are vital factors when bugging out or even when bugging in as the need to avoid people has never been higher. Today almost everything we do is tracked and monitored which can be extremely dangerous when the government is seeking to kill preppers.

Purpose	The aim of SECURITY is to conceal you from the eye of bystanders, from technology such as thermal and infrared, from animals, and from government agencies. It also has information on 'antisocial' behaviours such as building infiltration, lockpicking, siphoning fuel, hacking and spying. Finally it includes tips on military tactics to help you understand how armies are likely to proceed so you can avoid them, and information on observing and evading authorities such as governments and police using situational awareness.
Lost?	● For life security and staying alive against nature, see the PREPAREDNESS section. ● For information about the military vehicles with infrared and thermal, see the WARFARE section. ● For information on global wars, national hacking operations and terrorism, see the MAN-MADE DISASTERS section. ● For information on national security, see the SAFETY & SECURITY section. ● For the effects of nuclear warfare on our planet, see the MASS DESTRUCTION section. ● For buildings and shelters that can withstand modern missiles and nuclear weapons, see the SHELTER section. ● For personal defence against modern weapons, see the DEFENCE section. ● For the lootability of military bases and military vehicles, see the LOCATIONS section. ● If you wish to communicate stealthily and securely, see the COMMUNICATION > Codes section. ● For the terms used in this section, see the ADDENDUM > Dictionary section.

Contents

1 Personal Security

Safeguarding an individual's well-being, safety, and privacy. Essentially, the art of being your own bodyguard with the mindset of Jason Bourne.

Awareness

Awareness is primarily about being highly attuned to your surroundings, your own state, and how these factors interact to influence your vulnerability to threats. It's the cognitive foundation upon which all other personal security measures are built.

Situational Awareness

Situational awareness (SA) is a critical cognitive skill, particularly in dynamic and high-stakes environments. It's not just about "being aware" but involves a structured process of perceiving, understanding, and projecting. The most widely accepted model of situational awareness, proposed by Dr. Mica Endsley, breaks it down into three hierarchical levels:

Perception of Elements in the Environment

This is the foundational level, involving actively gathering information about the relevant elements in your surroundings. It's about being vigilant and observing cues through your senses. Key aspects include:

Observation: Consciously scanning your environment, noticing people, objects, events, and their current states (locations, conditions, actions). This includes both expected and unexpected elements.
Data Gathering: Collecting sensory input (sight, sound, smell, touch) and also internal information (e.g., equipment readings, system status).
Cue Detection: Identifying critical pieces of information that might signal a change or a potential issue.
Monitoring: Continuously tracking the status and dynamics of these elements over time.

Comprehension of the Current Situation

This level goes beyond simply perceiving individual elements. It's about understanding what those perceived elements mean when integrated together, in relation to your goals and objectives. It involves:

Integration: Connecting disparate pieces of information to form a coherent mental picture of the situation.
Interpretation: Assigning meaning to the perceived information, drawing on your knowledge, experience, and mental models. This helps answer the "so what?" question.
Pattern Recognition: Identifying familiar patterns or anomalies that indicate a particular state or development.
Assessment: Evaluating the significance of the situation in terms of its impact on your goals or potential threats.

Projection of Future Status

This is the highest level of situational awareness and is crucial for effective decision-making and proactive action. It involves anticipating how the current situation will evolve in the near future. Key elements include:

Prediction: Forecasting future events or states based on your comprehension of the current situation and your knowledge of how things typically progress.
Anticipation: Thinking ahead about potential developments, opportunities, or threats.
Mental Simulation: Running "what-if" scenarios in your mind to evaluate possible outcomes.
Goal-Directed Action Planning: Using your projections to determine the most favorable course of action to achieve your objectives or mitigate risks.

Cooper Readiness Code

To help people prepare the mind for danger, Cooper taught what is now known as the Cooper Colour Code. The most important means of surviving a lethal confrontation, according to Cooper, is neither the weapon nor the martial skills. The primary tool is the ‘combat mindset’. As taught by Cooper, it relates to the degree of peril you are willing to do something about — which allows you to move from one level of mindset to another to enable you to properly handle a given situation. The Black code has been added by members of the community to split the decision to fight and the decision to end a threat's life since you want to try every alternative prior to having to shoot.

White Unaware and Unprepared	This is a condition you should try to avoid. You will probably lose a fight here. One of the only times in condition white is when you’re asleep. And even then you wouldn’t consider yourself unprepared; you’re just unaware. If attacked in Condition White, the only thing that may save you is the “inadequacy or ineptitude” of your attacker. When suddenly confronted while in this condition your immediate reaction will probably be “OMG! This can’t be happening to me…”
Yellow Relaxed Alert	Yellow means you are aware of what is happening around you, but you do not perceive a potential threat. Your mindset should be prepared to defend yourself if the need arises. Everywhere you go, you should be in Condition Yellow. You should keep a pretty good watch on the people around you, and continuously rate each person’s danger level in your mind. There is no specific threat situation. Your mindset is that “today could be the day I may have to defend myself”. You are simply aware that the world is a potentially unfriendly place and that you are prepared to defend yourself, if necessary. You use your eyes and ears. You don’t have to be armed in this state, but if you are armed you should be in Condition Yellow. You use your eyes and ears. You don’t have to be armed in this state, but if you are armed you should be in Condition Yellow. You should always be in Yellow whenever you are in unfamiliar surroundings or among people you don’t know. You can remain in Yellow for long periods, as long as you are able to “Watch your six.” (In aviation 12 o’clock refers to the direction in front of the aircraft’s nose. Six o’clock is the blind spot behind the pilot.) In Yellow, you are “taking in” surrounding information in a relaxed but alert manner, like a continuous 360 degree radar sweep. As Cooper put it, “I might have to shoot.”
Orange Specific Alert	It means that there is a potential threat that's gained your attention. This can be almost anything and usually results in nothing, at which time you go back to yellow. An example of Condition Orange could be when you spot a firearm under that bulky coat… Instantly, you determine what you’re going to do if he reaches for that gun. Something is not quite right and has your attention. Your radar has picked up a specific alert. You shift your primary focus to determine if there is a threat (but you do not drop your six). Your mindset shifts to “I may have to shoot that person today”, focusing on the specific target which has caused the escalation in alert status. In Condition Orange, you set a mental trigger: “If that person does “X”, I will need to stop them”. Your pistol usually remains holstered in this state. Staying in Orange can be a bit of a mental strain, but you can stay in it for as long as you need to. If the threat proves to be nothing, you shift back to Condition Yellow.

Red Primed	It means that you are in a lethal mode of mindset and will fight if the circumstances are warranted. In the make-believe scenario, Bulky Coat draws a gun from under his coat and begins yelling at the people around them. At this point, you implement your action plan that was determined during Condition Orange. This doesn't always mean fight. If there are too many innocents around or you don't have the means, your best plan might be to wait and see what happens or even retreat and call the police. Your mental trigger (established back in Condition Orange) has been tripped. "If 'X' happens I will move to Black and shoot that person". In short, the Colour Code helps you "think" in a fight. As the level of danger increases, your willingness to take certain actions increases. If you ever do go to Condition Red, the decision to use lethal force has already been made (your "mental trigger" has been tripped).
Black Fight	This state means that you've made the decision to fight and have committed to eliminate the theat. You have determined that the only way out of this conflict is to subdue the attacker physically. In the scenario, Bulky Coat guy begins firing at people. Your mindset shifts to "I am going to shoot that person in order to save myself and those around me", focusing on the specific target which has caused the escalation in alert status. Remember that shooting does not mean killing. You can shoot to disarm someone, or otherwise render them incapacitated.

Self-Awareness

While often overlooked in security discussions, understanding yourself is crucial. This includes:

Your Habits and Routines: Recognizing if you have predictable patterns that could make you a target (e.g., always leaving home at the same time, taking the same route, posting your location on social media).
Your Physical State: Are you tired, distracted, under the influence of alcohol, or otherwise impaired? These states reduce your ability to perceive and respond to threats.
Your Emotional State: Are you stressed, preoccupied, or overly confident? Emotions can impact your judgment and alertness.
Your Appearance and Demeanour: How do you present yourself? Do you appear confident and aware, or distracted and vulnerable? Attackers often look for easy targets.
Your Instincts: Trusting your gut feeling. If a situation makes you feel uneasy, even if you can't logically explain why, it's a critical piece of personal awareness that should prompt you to take action.

Threat Awareness

This involves recognizing the types of dangers that exist (e.g., crime, natural disasters, cyberattacks, scams, accidents).

Assessing Your Vulnerabilities

Identifying your personal weak points or habits that could make you a target (e.g., predictable routines, displaying valuables, poor home security, sharing too much online).

Recognizing Suspicious Behavior

Learning to identify behaviors that might indicate a potential threat, such as loitering, unusual interest in your routine, or attempts to gain unauthorized access.

Deterrence

Making Yourself Less Appealing as a Target: This involves adopting behaviors and implementing measures that discourage potential attackers.
Physical Deterrents: Good lighting, visible security cameras, strong locks, alarm systems, well-maintained fencing, and a clear distinction between public and private space around your home.
Behavioral Deterrents: Walking confidently, making eye contact, avoiding distractions (like excessive phone use), and not displaying expensive items.
Establishing Boundaries: Clearly communicating "no" or "stop" to unwanted advances.

Prevention

Home Security

Physical Barriers: Deadbolts, window locks, reinforced doors, security screens.
Alarm Systems: Monitored alarms are generally more effective.
Lighting: Exterior and interior lighting (including timers).
Key Management: Keeping keys secure, not labeling them, changing locks if keys are lost.
Neighborhood Watch: Engaging with your community to collectively deter crime.

Personal Safety Out & About

Route Planning: Choosing well-lit, familiar routes.
Travel Companions: Traveling with friends or informing someone of your whereabouts.
Car Safety: Locking doors, parking in well-lit areas, having keys ready before approaching your vehicle, checking the backseat, knowing what to do if followed.
Public Transport: Being aware of your surroundings, avoiding isolated stops.
Valuables: Keeping them out of sight, carrying bags securely.

Digital Security

Strong Passwords & Two-Factor Authentication (2FA): Unique, complex passwords and using 2FA for all accounts.
Software Updates: Keeping operating systems, browsers, and apps updated to patch vulnerabilities.
Wi-Fi Security: Securing your home network, avoiding public Wi-Fi or using a VPN.
Phishing/Scam Awareness: Recognizing and avoiding suspicious links, emails, and texts.
Privacy Management: Being cautious about what personal information you share online.

Response & Self-Defense

Emergency Planning: Having a plan for various emergencies (e.g., fire, medical crisis, assault), including emergency contacts and evacuation routes.
Self-Defense Training: Learning basic self-defense techniques can increase confidence and provide options if a physical confrontation is unavoidable.
Personal Safety Devices: Carrying items like pepper spray (where legal), personal alarms, or whistles.
Reporting Incidents: Reporting all crimes or suspicious activities to the authorities helps build data and can prevent future incidents.
Trusting Instincts: If a situation feels wrong, remove yourself immediately.

Continuous Improvement

Regular Review: Periodically assessing your security measures and habits to ensure they are still effective.
Learning from Experience: Both your own and others' experiences can provide valuable lessons.
Staying Informed: Keeping up-to-date on new threats and security best practices.

2 Physical Security

Physical security normally refers to the security systems used on a property used as a dwelling (commonly including doors, locks, alarm systems, lighting, fencing); and personal security practices (such as ensuring doors are locked, alarms activated, windows closed etc.)

Perimeter Security

This is the first line of defense, establishing a boundary around the protected area.

Physical Barriers
Fences and Walls: Create a clear boundary and deter casual trespassers. Can be enhanced with barbed wire, razor wire, or electric fencing.
Gates and Turnstiles: Control entry and exit points for vehicles and pedestrians.
Bollards and Planters: Prevent unauthorized vehicle access to sensitive areas.
Reinforced Structures: Walls, doors, windows designed to resist forced entry.

Environmental Design
Lighting: Proper illumination deters intruders and enhances visibility for surveillance.
Landscaping: Clear sightlines, avoid dense bushes that can provide hiding spots, use thorny plants as barriers.
Signage: Clearly indicate boundaries, restricted areas, and security measures.

Access Control

These measures restrict who can enter a secured area and when.

Mechanical Locks and Keys: Traditional locks provide basic security but can be compromised by lost or duplicated keys.
Electronic Locks:
- Keypad Entry: Requires a PIN code.
- Card Readers (Keycards, Fobs): Require an authorized credential to open a locked door.
- Biometric Scanners: Use unique physical traits (fingerprints, iris scans, facial recognition) for authentication, offering high security.
- Mobile Access Control: Uses smartphones as credentials.

Security Personnel/Guards: Control entry points, verify identities, and provide a visible deterrent.
Visitor Management Systems: Track visitors, issue temporary credentials, and ensure they are escorted or limited to specific areas.

Surveillance and Monitoring

These systems observe and record activities to detect threats and provide evidence.

Closed-Circuit Television (CCTV) / IP Cameras: Strategically placed cameras provide real-time monitoring and recorded video feeds.
- Video Analytics: Advanced software that can detect unusual activity, motion, loitering, facial recognition, or unauthorized access attempts.

Monitoring Stations: Centralized locations where security personnel watch live feeds and respond to alerts.
Intrusion Detection Systems (IDS):
- Motion Sensors: Detect movement (PIR, microwave, ultrasonic).
- Glass Break Detectors: Sense the sound or vibration of breaking glass.
- Door/Window Sensors: Detect when a door or window is opened.
- Vibration Sensors: Detect attempts to breach walls or ceilings.
- Perimeter Sensors: Infrared beams, seismic sensors, buried cables to detect intrusions across a boundary.

Alarm Systems: Audible and/or visual alarms that trigger upon detection of a breach, alerting personnel or authorities.

Response Measures

These are the procedures and personnel in place to react to a security incident.

Security Personnel: Trained guards who can physically respond to incidents, apprehend intruders, or manage emergencies.
Law Enforcement/Emergency Services Integration: Direct lines of communication and established protocols for involving police, fire, or medical services.
Communication Systems: Radios, intercoms, and other systems to coordinate response efforts.
Emergency Procedures: Lockdowns, evacuation plans, and crisis management protocols.

Specialized Physical Security

Asset Protection: Safes, vaults, secure cabinets for high-value items, documents, or data.
Environmental Controls: Measures to protect against natural disasters (fire suppression systems, flood barriers, reinforced structures for earthquakes or storms) or utility disruptions (backup power, uninterruptible power supplies - UPS).
Cyber-Physical Security Integration: The growing convergence of IT security and physical security, where physical access systems, cameras, and alarms are connected to a network and managed through software, introducing cybersecurity considerations.

3 Cybersecurity

Electronic security, also known as cyber security or IT security, refers to the security of computing devices such as computers and smartphones, as well as computer networks such as private and public networks, and the Internet.

Encryption	
Offline Files	Any files offline are completely secure against being hacked, therefore all your preparedness plans should be in a device with no access to the internet. To be considered completely disconnected from the internet - any transmitting card and antennas should be removed, especially in mobiles.

4 National Security

National security refers to the security of a nation state, including its people, economy, and institutions.

5 Other Security Types

These are other smaller categories of security which don't require as much space or are referred to in other parts of this document.

Food Security

Food security refers to the ready supply of, and access to, safe and nutritious food.

Financial Security

Environmental Security

Environmental security, also known as environmental security, refers to the integrity of ecosystems and the biosphere, particularly in relation to their capacity to sustain a diversity of life-forms (including human life).

6 Surveillance

Surveillance is the monitoring of behaviour, activities, or other changing information for the purpose of influencing, managing, directing, or protecting people. To hide from surveillance methods first you need to understand how they work and the programming behind them.

Computer Surveillance

The vast majority of computer surveillance involves the monitoring of data and traffic on the Internet but can also include local monitoring such as recording keystrokes. In the United States for example, under the Communications Assistance For Law Enforcement Act, all phone calls and broadband Internet traffic (emails, web traffic, instant messaging, etc.) are required to be available for unimpeded real-time monitoring by federal law enforcement agencies. There is far too much data on the Internet for human investigators to manually search through all of it. Therefore, automated Internet surveillance computers sift through the vast amount of intercepted Internet traffic to identify and report to human investigators the traffic that is considered interesting or suspicious. This process is regulated by targeting certain "trigger" words or phrases, visiting certain types of web sites, or communicating via email or online chat with suspicious individuals or groups.

Telephone Surveillance

The official and unofficial tapping of telephone lines is widespread. In the United States for instance, the Communications Assistance For Law Enforcement Act (CALEA) requires that all telephone and VoIP communications be available for real-time wiretapping by Federal law enforcement and intelligence agencies. Two major telecommunications companies in the U.S.—AT&T Inc. and Verizon—have contracts with the FBI, requiring them to keep their phone call records easily searchable and accessible for Federal agencies, in return for $1.8 million per year. Between 2003 and 2005, the FBI sent out more than 140,000 "National Security Letters" ordering phone companies to hand over information about their customers' calling and Internet histories. About half of these letters requested information on U.S. citizens. Human agents are not required to monitor most calls. Speech-to-text software creates machine-readable text from intercepted audio, which is then processed by automated call-analysis programs, such as those developed by agencies such as the Information Awareness Office, or companies such as Verint, and Narus, which search for certain words or phrases, to decide whether to dedicate a human agent to the call.

Law enforcement and intelligence services in the United Kingdom and the United States possess technology to activate the microphones in cell phones remotely, by accessing phones' diagnostic or maintenance features in order to listen to conversations that take place near the person who holds the phone. The StingRay tracker is an example of one of these tools used to monitor cell phone usage in the United States and the United Kingdom. Originally developed for counterterrorism purposes by the military, they work by broadcasting powerful signals that cause nearby cell phones to transmit their IMSI number, just as they would to normal cell phone towers. Once the phone is connected to the device, there is no way for the user to know that they are being tracked. The operator of the stingray is able to extract information such as location, phone calls, and text messages, but it is widely believed that the capabilities of the StingRay extend much further. Mobile phones are also commonly used to collect location data. The geographical location of a mobile phone (and thus the person carrying it) can be determined easily even when the phone is not being used, using a technique known as multilateration to calculate the differences in time for a signal to travel from the cell phone to each of several cell towers near the owner of the phone. The legality of such techniques has been questioned in the United States, in particular whether a court warrant is required. Records for one carrier alone (Sprint), showed that in a given year federal law enforcement agencies requested customer location data 8 million times.

Camera Surveillance

Surveillance cameras are video cameras used for the purpose of observing an area. They are often connected to a recording device or IP network, and may be watched by a security guard or law enforcement officer. Cameras and recording equipment used to be relatively expensive and required human personnel to monitor camera footage, but analysis of footage has been made easier by automated software that organizes digital video footage into a searchable database, and by video analysis software (such as VIRAT and HumanID). The amount of footage is also drastically reduced by motion sensors which only record when motion is detected.

With cheaper production techniques, surveillance cameras are simple and inexpensive enough to be used in home security systems, and for everyday surveillance. There are about 350 million surveillance cameras worldwide as of 2016. About 65% of these cameras are installed in Asia. The growth of CCTV has been slowing in recent years. In 2018, China was reported to have a huge surveillance network of over 170 million CCTV cameras with 400 million new cameras expected to be installed in the next three years, many of which use facial recognition technology.

Box Camera	A Box Style camera is a standalone camera. The name is derived from the shape of the camera.	**Features** ● Functions like any other camera ● Can be used in Outdoor Environmental Housings or for Indoor mountings if aesthetics are not a concern	**Benefits** ● Allows for customization of the lens, camera and housing to fit the needs of the installation ● Offers many lens options, including vari-focal and fixed
Dome Camera	A dome camera is a combination of camera, lens, and ceiling mount packaged in a discreet dome shape.	**Features** ● Functions like any other camera but comes in a dome-shaped housing ● Is well-suited for environments that tend to get dirty, like kitchens and warehouses ● Typically available in indoor or outdoor housings	**Benefits** ● Aesthetically pleasing / compact in appearance ● Available in vandal-resistant housings
PTZ Security Camera	A PTZ camera contains mechanical controls that allow the operator to remotely pan, tilt, and zoom the camera.	**Features** ● Pan, Tilt and Zoom features ● Control movement via joystick or software ● Can automatically run patterns or turn to a preset position	**Benefits** ● Focuses on areas of interest ● Auto Track movement ● Survey a wide area of interest and zoom in to detail
Bullet Security Camera	A bullet camera is a combination of camera, lens, and housing packaged in a bullet-style body.	**Features** ● Commonly includes IR illuminators ● Sealed enclosure decreases need for servicing ● Small footprint	**Benefits** ● Requires no separate housing or lens ● Good for low-light situations
IP Security Camera	An IP camera transmits a digital signal using Internet Protocol over a network.	**Features** ● Increased resolution and scalability ● Many have built-in video analytic software	**Benefits** ● Better system management than analog cameras ● Resolutions from VGA to 29 Megapixel
Day/Night Security Camera	A day/night camera is a camera used indoor and outdoor for environments with low light conditions.	**Features** ● IR filter that is lifted as lighting levels decrease	**Benefits** ● Handles both day and night-time lighting situations

SECURITY Surveillance Camera Surveillance

Thermal Security Camera	A thermal camera uses thermal imaging to produce surveillance footage in dark or harsh environments. It uses heat to differentiate objects.	**Features** ● Uses heat sensing to distinguish objects and people	**Benefits** ● Detect people and objects in smoke, haze, dust, light fog ● Works in complete darkness
Wide Dynamic Security Camera	Wide Dynamic Cameras have the ability to balance light-levels on a pixel-by-pixel basis.	**Features** ● Capable of handling a wide range of lighting levels in the same scene	**Benefits** ● Capture clear face shots when a people are entering with bright light behind them and with dark shadows on their faces ● Used in areas with too much sunshine or where headlights are used, such as parking lots
Wireless IP Camera	Wireless IP security cameras offers ease of installation and eliminates the cost of network cabling when adding this camera to your video surveillance system.	**Features** ● Wi-Fi enabled for easy installation and setup ● Tilting and swivel options to maximize viewing	**Benefits** ● Motion detection for instant alerts of intruders ● Crystal clear images, even in low light conditions

Social Network Analysis

One common form of surveillance is to create maps of social networks based on data from social networking sites such as Facebook, MySpace, Twitter as well as from traffic analysis information from phone call records such as those in the NSA call database, and others. These social network "maps" are then data mined to extract useful information such as personal interests, friendships & affiliations, wants, beliefs, thoughts, and activities. Many U.S. government agencies such as the Defence Advanced Research Projects Agency (DARPA), the National Security Agency (NSA), and the Department of Homeland Security (DHS) are investing heavily in research involving social network analysis. The intelligence community believes that the biggest threat to U.S. power comes from decentralized, leaderless, geographically dispersed groups of terrorists, subversives, extremists, and dissidents. These types of threats are most easily countered by finding important nodes in the network, and removing them. To do this requires a detailed map of the network. AT&T developed a programming language called "Hancock", which is able to sift through enormous databases of phone call and Internet traffic records, such as the NSA call database, and extract "communities of interest"—groups of people who call each other regularly, or groups that regularly visit certain sites on the Internet. AT&T originally built the system to develop "marketing leads", but the FBI has regularly requested such information from phone companies such as AT&T without a warrant, and, after using the data, stores all information received in its own databases, regardless of whether or not the information was ever useful in an investigation.

Biometric

Biometric surveillance is a technology that measures and analyses human physical and/or behavioural characteristics for authentication, identification, or screening purposes. Examples of physical characteristics include fingerprints, DNA, and facial patterns. Examples of mostly behavioural characteristics include gait (a person's manner of walking) or voice. Facial recognition is the use of the unique configuration of a person's facial features to accurately identify them, usually from surveillance video. Both the Department of Homeland Security and DARPA are heavily funding research into facial recognition systems. The Information Processing Technology Office ran a program known as Human Identification at a Distance which developed technologies that are capable of identifying a person at up to 500 ft (150 m) by their facial features.

Another form of behavioural biometrics, based on affective computing, involves computers recognizing a person's emotional state based on an analysis of their facial expressions, how fast they are talking, the tone and pitch of their voice, their posture, and other behavioural traits. This might be used for instance to see if a person's behaviour is suspect (looking around furtively, "tense" or "angry" facial expressions, waving arms, etc.). A more recent development is DNA profiling, which looks at some of the major markers in the body's DNA to produce a match. The FBI is spending $1 billion to build a new biometric database, which will store DNA, facial recognition data, iris/retina (eye) data, fingerprints, palm prints, and other biometric data of people living in the United States. The computers running the database are contained in an underground facility about the size of two American football fields. The Los Angeles Police Department is installing automated facial recognition and license plate recognition devices in its squad cars, and providing handheld face scanners, which officers will use to identify people while on patrol.

Aerial Surveillance

Aerial surveillance is the gathering of surveillance, usually visual imagery or video, from an airborne vehicle—such as an unmanned aerial vehicle, helicopter, or spy plane. Military surveillance aircraft use a range of sensors (e.g. radar) to monitor the battlefield. Digital imaging technology, miniaturized computers, and numerous other technological advances over the past decade have contributed to rapid advances in aerial surveillance hardware such as micro-aerial vehicles, forward-looking infrared, and high-resolution imagery capable of identifying objects at extremely long distances. For instance, the MQ-9 Reaper, a U.S. drone plane used for domestic operations by the Department of Homeland Security, carries cameras that are capable of identifying an object the size of a milk carton from altitudes of 60,000 feet, and has forward-looking infrared devices that can detect the heat from a human body at distances of up to 60 kilometres.

The United States Department of Homeland Security is in the process of testing UAVs to patrol the skies over the United States for the purposes of critical infrastructure protection, border patrol, "transit monitoring", and general surveillance of the U.S. population. Miami-Dade police department ran tests with a vertical take-off and landing UAV from Honeywell, which is planned to be used in SWAT operations. Houston's police department has been testing fixed-wing UAVs for use in "traffic control".

The United Kingdom, as well, is working on plans to build up a fleet of surveillance UAVs ranging from micro-aerial vehicles to full-size drones, to be used by police forces throughout the U.K. In addition to their surveillance capabilities, MAVs are capable of carrying tasers for "crowd control", or weapons for killing enemy combatants.

Data Mining / Profiling

Data mining is the application of statistical techniques and programmatic algorithms to discover previously unnoticed relationships within the data. Data profiling in this context is the process of assembling information about a particular individual or group in order to generate a profile — that is, a picture of their patterns and behaviour. Data profiling can be an extremely powerful tool for psychological and social network analysis. A skilled analyst can discover facts about a person that they might not even be consciously aware of themselves. Economic (such as credit card purchases) and social (such as telephone calls and emails) transactions in modern society create large amounts of stored data and records. In the past, this data was documented in paper records, leaving a "paper trail", or was simply not documented at all.

Correlation of paper-based records was a laborious process—it required human intelligence operators to manually dig through documents, which was time-consuming and incomplete, at best. But today many of these records are electronic, resulting in an "electronic trail". Every use of a bank machine, payment by credit card, use of a phone card, call from home, checked out library book, rented video, or otherwise complete recorded transaction generates an electronic record. Public records—such as birth, court, tax and other records—are increasingly being digitized and made available online. In addition, due to laws like CALEA, web traffic and online purchases are also available for profiling.

Electronic record-keeping makes data easily collectable, storable, and accessible—so that high-volume, efficient aggregation and analysis is possible at significantly lower costs. Information relating to many of these individual transactions is often easily available because it is generally not guarded in isolation, since the information, such as the title of a movie a person has rented, might not seem sensitive. However, when many such transactions are aggregated they can be used to assemble a detailed profile revealing the actions, habits, beliefs, locations frequented, social connections, and preferences of the individual. This profile is then used, by programs such as ADVISE and TALON, to determine whether the person is a military, criminal, or political threat. In addition to its own aggregation and profiling tools, the government is able to access information from third parties — for example, banks, credit companies or employers, etc. — by requesting access informally, by compelling access through the use of subpoenas or other procedures, or by purchasing data from commercial data aggregators or data brokers. The United States has spent $370 million on its 43 planned fusion centres, which are national network of surveillance centres that are located in over 30 states. The centres will collect and analyse vast amounts of data on U.S. citizens. It will get this data by consolidating personal information from sources such as state driver's licensing agencies, hospital records, criminal records, school records, credit bureaus, banks, etc. – and placing this information in a centralized database that can be accessed from all of the centres, as well as other federal law enforcement and intelligence agencies.

Human Operatives

Organizations that have enemies who wish to gather information about the groups' members or activities face the issue of infiltration. In addition to operatives' infiltrating an organization, the surveilling party may exert pressure on certain members of the target organization to act as informants (i.e., to disclose the information they hold on the organization and its members). Fielding operatives is very expensive, and for governments with wide-reaching electronic surveillance tools at their disposal the information recovered from operatives can often be obtained from less problematic forms of surveillance such as those mentioned above. Nevertheless, human infiltrators are still common today. For instance, in 2007 documents surfaced showing that the FBI was planning to field a total of 15,000 undercover agents and informants in response to an anti-terrorism directive sent out by George W. Bush in 2004 that ordered intelligence and law enforcement agencies to increase their HUMINT capabilities.

Identification

One of the simplest forms of identification is the carrying of credentials. Some nations have an identity card system to aid identification, whilst others are considering it but face public opposition. Other documents, such as passports, driver's licenses, library cards, banking or credit cards are also used to verify identity. If the form of the identity card is "machine-readable", usually using an encoded magnetic stripe or identification number (such as a Social Security number), it corroborates the subject's identifying data. In this case it may create an electronic trail when it is checked and scanned, which can be used in profiling, as mentioned above.

RFID & Geolocation

Radio Frequency Identification (RFID) tagging is the use of very small electronic devices (called "RFID tags") which are applied to or incorporated into a product, animal, or person for the purpose of identification and tracking using radio waves. The tags can be read from several meters away. They are extremely inexpensive, costing a few cents per piece, so they can be inserted into many types of everyday products without significantly increasing the price, and can be used to track and identify these objects for a variety of purposes. Some companies appear to be "tagging" their workers by incorporating RFID tags in employee ID badges. Workers in U.K. considered strike action in protest of having themselves tagged; they felt that it was dehumanizing to have all of their movements tracked with RFID chips.

GPS Tracking	In the U.S., police have planted hidden GPS tracking devices in people's vehicles to monitor their movements, without a warrant. In early 2009, they were arguing in court that they have the right to do this. Several cities are running pilot projects to require parolees to wear GPS devices to track their movements when they get out of prison.
Mobile Phones	Mobile phones are also commonly used to collect geolocation data. The geographical location of a mobile phone (and thus the person carrying it) can be determined easily (whether it is being used or not), using a technique known multilateration to calculate the differences in time for a signal to travel from the cell phone to each of several cell towers near the owner of the phone. Dr. Victor Kappeler of Eastern Kentucky University indicates that police surveillance is a strong concern, stating the following statistics from 2013: Of the 321,545 law enforcement requests made to Verizon, 54,200 of these requests were for "content" or "location" information—not just cell phone numbers or IP addresses. Content information included the actual text of messages, emails and the wiretapping of voice or messaging content in real-time. A comparatively new off-the-shelf surveillance device is an IMSI-catcher, a telephone eavesdropping device used to intercept mobile phone traffic and track the movement of mobile phone users. Essentially a "fake" mobile tower acting between the target mobile phone and the service provider's real towers, it is considered a man-in-the-middle (MITM) attack. IMSI-catchers are used in some countries by law enforcement and intelligence agencies, but their use has raised significant civil liberty and privacy concerns and is strictly regulated in some countries.

Microchips

A human microchip implant is an identifying integrated circuit device or RFID transponder encased in silicate glass and implanted in the body of a human being. A subdermal implant typically contains a unique ID number that can be linked to information contained in an external database, such as personal identification, medical history, medications, allergies, and contact information. Several types of microchips have been developed in order to control and monitor certain types of people, such as criminals, political figures and spies, a "killer" tracking chip patent was filed at the German Patent and Trademark Office (DPMA) around May 2009. Verichip is an RFID device produced by a company called Applied Digital Solutions (ADS).

Verichip is slightly larger than a grain of rice, and is injected under the skin. The injection reportedly feels similar to receiving a shot. The chip is encased in glass, and stores a "VeriChip Subscriber Number" which the scanner uses to access their personal information, via the Internet, from Verichip Inc.'s database, the "Global VeriChip Subscriber Registry". Thousands of people have already had them inserted. In Mexico, for example, 160 workers at the Attorney General's office were required to have the chip injected for identity verification and access control purposes.

Devices (Bugs)

Covert listening devices and video devices, or "bugs", are hidden electronic devices which are used to capture, record, and/or transmit data to a receiving party such as a law enforcement agency. The U.S. has run numerous domestic intelligence operations, such as COINTELPRO, which have bugged the homes, offices, and vehicles of thousands of U.S. citizens, usually political activists, subversives, and criminals. Law enforcement and intelligence services in the U.K. and the United States possess technology to remotely activate the microphones in cell phones, by accessing the phone's diagnostic/maintenance features, in order to listen to conversations that take place nearby the person who holds the phone.

Stakeout

A stakeout is the coordinated surveillance of a location or person. Stakeouts are generally performed covertly and for the purpose of gathering evidence related to criminal activity. The term derives from the practice by land surveyors of using survey stakes to measure out an area before the main building project is commenced.

Counter Surveillance

How to stay under the radar and avoid being detected.

7 Counter Surveillance

How to hide from modern technology such as thermal imaging, mobile tracking and night vision technology.

Thermal Concealment

How to conceal yourself from thermal imaging devices.

Thermal Concealment	A warm body can be detected by thermal imaging equipment from its IR (Infrared) heat signature. It's a difficult challenge to avoid detection, be it animal or human. Warm blooded. You may be camouflaged in the best concealment there is, but highly visible to IR thermal imaging on the ground or maybe a drone flying overhead. The same thing applies for any warm or hot equipment that you may wish to conceal.
What is Infrared	It's light that's not visible to the human eye. It's electromagnetic radiation with longer wavelengths than visible light. Infrared extends from the red edge of the visible spectrum at 700 nanometres (frequency 430 THz), to 1 millimetre (300 GHz). Most of the thermal radiation emitted by objects near room temperature is infrared. Humans actually emit (instead of just reflecting) at IR wavelengths. Our normal body temperature radiates chiefly within the thermal infrared region of (8 – 15 μm) or (0.008 – 0.015 millimetres) – a frequency range of 20–37 THz. That's right in the infrared spectrum and is detectable by sophisticated modern instrumentation. Thermal imaging devices can 'see' you. They create images based on differences in surface temperature by detecting infrared radiation (heat) that emanates from objects (e.g. your body or that of an animal) and their surrounding environment.

Concealment

Space Blanket	A simple method to block IR (with caveats) is an ordinary 'space blanket', 'emergency blanket' or 'thermal blanket'. They are made of mylar foil and will block any Infrared (IR) heat signature behind it. However, if you wrap yourself in it, there's a problem. Heat will build up and will eventually heat the mylar itself up to make you visible again. This heat will then be visible to IR thermal imaging devices. Concealment for the most part will be temporary without more elaborate techniques to disperse the heat. So instead of wrapping yourself, spread the blanket out a metre (3ft) or so above you and tie it up. The breeze between you and the UAVs or cameras will then keep the blanket cool and shield you from the thermal cameras.
Glass	One of the most effective methods to block IR is to conceal behind glass. Glass is entirely opaque to thermal imaging. It's not a practical solution though, due to the obvious impracticality of movement or 'on-the-go'. But it's good to know.
Netting Materials	Thick Netting will help. Especially visible detection. The holes throughout the netting / webbing will help disperse heat signature – though not completely. A significant deterrent though from thermal IR heat detection. It will help to disperse the heat or hot spots that may be underneath as the airflow will be somewhat broken up by the webbing. The heat signature will not be as intense, but spread out more. An example may be to cover a vehicle that has been running with netting. Best to leave some air gap between the material and hot surface (prop it up).
Heavy Blanket	For a quick temporary method of IR concealment, throw a blanket over yourself. A thick woollen blanket will help defeat thermal imaging. It works surprisingly well. Covering with a layer of insulation, the heat is blocked (or partially blocked) so that it doesn't radiate. This is only temporary concealment as the heat builds beneath the blanket. It may work long enough to conceal during a quick TI scan or Drone flyover.
Other Heat Sources	Concealment by blending in next to other warm objects, like warm stones or thick walls that may still be holding the heat from the day. The vents in buildings may be out-flowing warm air; a source of heat that can help obscure your own thermal outline. You get the idea… wherever there is existing natural or man-made heat, you can blend in with that to help conceal your presence to an IR or thermal imager.
Ghillie Suit	A Ghillie suit will certainly help disperse your heat signature. It won't block it, but it will help diffuse a heat signature.
Insulated Jacket	Insulated pants and a hat. It won't be 100% but it will help lessen the heat signature. Again, the heat will build and escape through the neck openings and face. You could cover your face with cool mud, which will work temporarily. It's all pretty much common sense; reduce, disperse, or cover the sources of heat.
Objects Between the Sensor	Put trees and/or brush between you and the suspected IR imager. Trees overhead will help break up the infrared signature, especially under a heavy canopy of leaves.
Stationary	A moving heat signature at night is quicker to identify than a stationary one (up to a point). Avoid detection by moving slowly.
Tips	When you are hiding your heat signature (with a Mylar emergency blanket or other means), under some conditions your signature may look 'too cold' to an IR scan of the area (an extra dark outline, or a 'black hole'), which may make you detectable. The problem with most IR cloaking methods, IR clothing or netting designed to block IR, is that it will also block the background IR – creating a black hole of varying degrees. Ideally you would want something that 'cloaks' or blends your IR signature such that the background scatter at your location is what the observer sees. Avoid open spaces and skylines by day or night. Thermal Imaging does not perform well in falling rain.

Hiding from Thermal/Infrared

- Use ground, hills and heavy undergrowth to stop your infrared radiation. Block your body heat. Keep it as close to the background temperature as possible.

SECURITY Technology Stealth Thermal Concealment Hiding from Thermal/Infrared

- Thermal images are composed of heat emissions and the coefficient of emissivity for objects. To hide from thermal you need to reduce your heat output and camouflage the emissivity output.
- Staying near water in warm weather, as the evaporating moisture will hold heat and distort the image.
- Hide in an area with a multi-temperature background.
- In an emergency, setting things on fire will help camouflage you.
- White phosphorous or rubber-impregnated smoke shells to block thermal pictures, because they fill the air with burning particles and create a wall of heat that's opaque to the imager.
- Thermal Crossover: Just after Sunrise and Sunset thermal imagers don't work as effectively and reduce the contrast of the viewer. On a bright sunny day it can be a few seconds but if the weather's overcast it can last several minutes. High humidity will extend the length of crossover, and so will wind.
- Use decoys such as heat packs to confuse the observer.
- During day, white clothes can reflect more heat, keeping you closer to ambient temperature.
- Insulating your heat from the imager, such as a wool blanket. The more effective the insulation, the more time you have bought yourself.
- Spreading your heat over a larger surface area. Your body has a finite surface area, if you can transfer your body heat to a larger object, that object will be cooler. Think of a heat sink.
- You can vent heat to the atmosphere. The thermal imager cannot see the heat travelling through the air, at least not at the temperatures we are talking about. It would have to be directly to the atmosphere because if the heat were to heat up your cover, that would be noticeable.
- You can mechanically trap heat.
- Use infrared LEDs in high numbers to blind the camera or distract them from you.
- Mylar foil appears opaque on infrared imaging - so use for windows to prevent seeing in.
- Companies have begun producing anti-IR garments; metalized fabrics similar to space blankets woven into overcoats, ponchos, hoodie -- even panties.
- Dazzle Camouflage: Designed to break up an object's silhouette against the background.
- Detergents that contain brighteners cause them to light up like a white light under infrared.

Thermal	The most obvious issue in evading thermal imaging is dealing with the heat that a human produces. It is impossible to stop the body from producing heat and it is also impossible to inexpensively contain all of the heat the body produces. Expensive thermal cameras, such as the ones in drones and helicopters, sense the actual photons emitted from an object. Less expensive handhelds use a material that measures the differences in temperature. Either one first needs the heat from your body to reach the sensor. If your heat cannot reach the sensor, you cannot be seen. A physical object between you in the camera, such as the roof of your house, a boulder, or a tree will stop the infrared energy from reaching the sensor.
Emissivity	After the sun sets different objects cool at different rates. If you were successful enough to create a cloak that can achieve near ambient air temperature you may now appear colder than your surroundings. Your best bet is to know what objects offer the closest temperature/emissivity match, tall grasses may cool faster than rocks, pine needles and leaves may be good options.
Shape	Paints and dyes are really effective in visible light, but are almost useless in thermal. Ideally, the layer facing the imager would be constructed of different materials with mis-matched emissivities, sort of like covering yourself with leaves, branches, grasses, etc. This is probably not commercially viable, but if you were to do so by hand it would probably benefit the overall effectiveness of your camouflage. If you've masked your thermal signature but can't quite match the emissivity your best bet is to look like something nearby, a rock, bush, a patch of bare dirt. Unless you can create something with very complex emissivity patterns you have to do the next best thing, not look human.
Stealth	Thermal imagers have a finite resolution. It is pretty easy to understand, standard definition TV (the old stuff) had a digital resolution of 720×480 pixels. High Definition TV has a resolution of 1280×720 (720P) or 1920×1080 (1080P or Blu-Ray). Most of you know from experience that your eyes couldn't resolve a persons face in a crowd at a sporting event on old TV, but you can now. Again, the same is true with thermal. High end military imagers are about the equivalent of 720P television.
Distance	Military imagers can detect a person at a distance of many miles, but to achieve this distance the lensing only affords a very narrow field of view, like looking through a straw. In airborne systems, the thermal imagers will generally have two selectable options, a wide field of view for surveillance, and a narrow field of view for target acquisition. Unless they've already seen you, they will be searching using the wider field of view. If you've reduced your signature by 90%, the imager needs to be 90% closer to detect you.

Night Vision Concealment

SECURITY Technology Stealth Night Vision Concealment

Image Intensification	Image intensification technology maximizes the amount of light received from different natural sources (like starlight or moonlight). This technology doesn't work in complete darkness because there is no light to absorb and magnify. Night vision devices with image intensification technology are best recognized by the green image they create. **Hiding:** To hide from this type of technology scientist have developed various models of military camouflage that's covered with carefully crafted patterns which reflect infrared lights and blend the person wearing it with the environment. Researchers at UC Irvine have created a new camouflage coating inspired by the pencil squid that is invisible to infrared cameras. A film that can easily be applied to all sorts of materials and surfaces which need to be hidden.
Active Illumination	Combines image intensification technology with an active illumination source of the near or shortwave infrared band. These types of cameras provide high-quality imaging at night or low-light conditions. They are widely used in commercial, residential and government security. **Hiding:** Hiding from this types of camera is difficult, but a German company Blucher Systems GmbH developed thermal/IR (Infrared) camouflage fabric technology that makes the person wearing it nearly invisible to infrared cameras. Fabric for this camouflage uses metalized fibres to achieve infrared and thermal signature reduction.

Mobile Concealment

SECURITY Technology Stealth Mobile

Mobile companies can track your phone usage and triangulate your position, sometimes even when your phone is turned off. This section will assist in how you can protect yourself from being tracked via your phone.

Air Concealment

Technology Stealth Air

Concealment from any type of scouting aircraft such as drones, UAVs and scout helicopters.

8 Infiltration

This section is for accessing areas which are normally inaccessible such as locked houses and cars.

Subheadings

1 Combination Locks & PIN Numbers

This section helps give you the best chance to open a combination lock (or guess a PIN) in the fewest number of tries using math and bias. Combination locks are those that have any number of rotatable digit/letter rows which opens when the code is correct and you pull on the lock. You may need to use a bike which has been abandoned but is chained to a pole, there might be a combination lock preventing you from entering a section of a building you're hunkering down in which may have supplies or you might want to access a bank account you forgot the PIN to.

The Odds
1 Tumbler Lock - (10 Digits) - (10 Combinations)
2 Tumbler Locks - (10 Digits) - (100 Combinations)
3 Tumbler Locks - (10 Digits) - (1,000 Combinations)
4 Tumbler Locks - (10 Digits) - (10,000 Combinations)
5 Tumbler Locks - (10 Digits) - (100,000 Combinations)
6 Tumbler Locks - (10 Digits) - (1,000,000 Combinations)
7 Tumbler Locks - (10 Digits) - (10,000,000 Combinations)
8 Tumbler Locks - (10 Digits) - (100,000,000 Combinations)

This is how long it would take to brute force the each lock with 2 seconds for each attempt:
1 Tumbler - (10 Digits) = 20s (0.2m) **(No lock would only have 1 tumbler)**
2 Tumblers - (10 Digits) = 200s (3.3m) **(No lock would only have 2 tumblers)**
3 Tumblers - (10 Digits) = 2,000s (33.3m) **(Very easy to crack even if you have to brute-force it)**
4 Tumblers - (10 Digits) = 20,000s (333.3m / 5.5h) **(Anything bigger than this is not worth trying to crack after the most common numbers)**
5 Tumblers - (10 Digits) = 200,000s (3,333.3m / 55.5h / 2.2d) **(Only try the most common 50 numbers from here on)**
6 Tumblers - (10 Digits) = 2,000,000s (33,333m / 555.5h / 23.1d)
7 Tumblers - (10 Digits) = 20,000,000s (333,333m / 5,555.5h / 231d) **(It would be easier to find lock cutters than crack this)**
8 Tumblers - (10 Digits) = 200,000,000s (3,333,333m / 55,555.5h / 2,314d / 6.5y) **(It would be easier to forge your own lock cutters than crack this)**

Cracking the Code

To greatly reduce the time it would take to brute force the lock there are a number of sequences that people commonly use which will give you a much higher chance to break the code quicker. The below shows you how.

1	Start by attempting the most common numbers: 0000, 1111, 2222, 3333, 4444, 5555, 6666, 7777, 8888, 9999 1234, 1212, 1004, 2000, 6969, 1122, 1313, 4321, 2001, 1010, 0007, 0070, 2580, 2468, 1357, (The current year)
2	Try years from 1960-1999 and then years 2000 to about 10 years in the future from the current year: 1960, 1961, 1962… 1998, 1999… 2000, 2001, 2002… 2020, 2021, 2022, 2023, 2024, 2025… 2033, 2034, 2035.
3	Start on dates or birthdays which people commonly use for combinations. Use the date format most used in your country - so MMDD for the U.S. and DDMM for Australia etc. An example is 0301 (Jan 3rd in Australia) or 0103 (Jan 3rd in the U.S.). (MMDD) 0101, 0102, 0103… 0131, 0201…
4	Then a few of the least likely numbers because people who have read articles online are likely to use them: 8068, 8093, 9629, 6835, 7637, 0738, 8398, 6793, 9480, 8957, 0859, 7394, 6827, 6093, 7063, 8196, 9539, 0439, 8438, 9047, 8557 **(If you're creating your own pin or combination code you should try something similar to those on this list, but not one of them)**
5	If you still haven't cracked the code yet you should start from 0000 and head up to 9999 while skipping the patterns you've already tried.

Tips

- People generally prefer even numbers over odd.
- People often choose important years as codes such as the 19xx range and 20xx range.
- People may often choose the current year, the past few years or upcoming years.
- Dates in the DDMM or MMDD formats are very popular. (01-31 / 31-01)
- Numbers close to each other (67, 32, 98) occur much more frequently than numbers widely spaced (29, 17, 18)
- 1 is by far the most likely first digit in the code, followed by 0 then 2 through 9 in that order.
- Numerical runs are very high choices for codes, such as: 1234, 7890, 5678.
- Repeated pair couplets (XYXY) make up 17.8% of all pins. (3434)

Notes

- Make sure you pull the lock strongly each time you try a code or you may accidentally skip the correct combination.

2 Breaking Glass

You may be in an emergency situation where you have to break glass quickly to escape such as in a sinking car. This section shows the best ways to break different types of glass.

Before you can talk about how to break a window, you need to know what kind of glass you are dealing with. This will help you to safely plan your emergency entry. There are three main types of glass you will encounter: tempered glass, non-tempered glass, and laminated glass. This list is not exhaustive as there are many variations on each type.

Tempered Glass	Tempered glass is heat-treated and is much stronger than non-tempered glass. Tempered glass is used where there is a likelihood of human contact and as such is made to shatter into small ¼" pieces when broken. The small pieces are not very sharp and safer to deal with than non-tempered glass.
Non-Tempered Glass	When broken, non-tempered glass makes large, irregular, jagged pieces that are razor sharp. It is much more dangerous than tempered glass.
Laminated Glass	Laminated glass has plastic layers sandwiched between glass layers. Because of the plastic sheeting, it tends not to break, but be punctured under force. High impact is needed to defeat laminated glass, and fragmentation and spalling can occur which send small flakes and powdered glass inward.

Tools

These are the recommended items for breaking glass.

Purpose-Built Window Punch	Best used for cars windows but they will smash any type of glass quickly and efficiently.
Baton	A baton can be used to break windows and remove the resulting glass shards from the frame.
Spark Plug (Or Broken Ceramic)	Get a spark plug and break the porcelain casing around the spark plug with a hammer. Then take a sharp piece of the ceramic and throw it at the window you want broken. When throwing the ceramic piece aim for the edges as this is where the glass is weakest. This works best against tempered glass.

Window Glass

Buildings can have either tempered or non-tempered glass. Many commercial applications, storefront windows and modern sliding glass doors are made of tempered glass. In fact, there are often building codes or laws that require tempered glass to be installed in residential and commercial windows that are within 48" of doors.

You can sometimes identify tempered glass as it normally has a manufacturer's watermarks at all four corners. However, this is not foolproof as it can be ordered without the watermarks. Non-tempered glass is most often encountered in ordinary residential windows, whether jalousie, casement, Miami-style, single or double-hung. Older sliding glass doors and older storefront windows were also made from non-tempered glass.

Large windows made of non-tempered glass can cause severe lacerations and even kill you when shattered. These break into large, heavy, sharp shards. When these come crashing down a single piece can slice your arm, face or leg open. In the wrong place, you could bleed out before paramedics got to you.

This is another reason why you should carry a tourniquet on your person. Skylights and some commercial storefront doors and windows are constructed with laminated glass. As with car windshields, these are tough to defeat also. Another type of laminated glass is wire glass. This is made for security purposes and is very hard to defeat, as the wire mesh is anchored to the window or door's frame.

Breaking Window Glass
The safest place to strike large glass is near an upper corner, while you are standing as far to the side of the window as you can. Once the glass is broken, use a longer item, like your baton or a long-handled tool, to clear the glass from the opening. Pay particular attention to clearing out the glass above you. Breaking tempered glass in a residence is the same as with a car window. You can use a punch and attack a lower corner. Just make sure you are certain it is tempered glass. If you have to break out a large window in an older structure, don't break it at the bottom. If it is non-tempered glass, it will rain down heavy fragments that will injure you badly.

Breaking Glass Silently

Firstly duct tape the window around the edges with a big X through the centre and another + across the whole window if you want to reduce noise further. Then get a piece of broken ceramic such as one from a spark plug and throw it at one of the corners of the glass without tape. Repeat this multiple times until you can easily pull the tape off and most of the glass shards come with it.

Car Glass

Glass types are selected based on where and for what they will be used. The two primary locations where police officers will need to break glass are automobile windows and building windows. Auto glass is purposefully strong and resists breaking. If non-tempered glass was used in cars, there would be far more injuries and deaths from auto accidents. Car side and rear windows are frequently made of tempered glass. However, there is a push to use laminated glass for all car windows. Right now, tempered glass is the norm. Car windshields are constructed with laminated glass, which is the safest but toughest of the glass types discussed here. The problem is that you have to punch out the entire plastic sheet to clear the window and it can take some time.

Breaking Car Glass
Car windows are made from tempered glass and are designed to resist blunt force. As such, pounding on a window with a blunt object may have no effect. Window punches used for car side glass are usually effective at a lower corner. In general, there is less danger from the tempered safety glass than with non-tempered glass when it comes down. Target around the edges, not the center, as this is where the glass breaks more easily. Also, do not try and break the front windshield or back windows of a car as these are manufactured to break differently than passenger windows and will be nearly impossible to break through.

Climbing Through

This is how you can climb through a shattered window safely.

1	Once you've smashed the glass the first thing you want to do before climbing through is to remove the jagged pieces from the frame. Run a long blunt object such as a mallet or baton along the frame of the window to break off these smaller pieces so there's less of a chance they will catch you on the way through. There shouldn't be any pieces of glass around the frame larger than 1cm, and next to none visible on the bottom.
2	If you have boots on, slide the glass on the floor to either side just in case you fall back through.
3	Find a thick piece of cloth or clothing to wrap around your hands multiple times to help prevent shards impaling you as you hold the frame. The cloth should be 2.5cm (1 in) thick at a minimum on all sides of your hand.

4	Put a few more thick pieces of piece of cloth (such as towels) onto the lower part of the frame to provide a safe area to sit on if you don't think you can jump out the window. Let them drape down both sides of the window a decent amount so they won't easily fall out.
5	If possible, make it easier to climb through the window by pushing a large secure object under the window to stand on.
6	Place your hands on the lower frame of the window to support yourself as you swing your leg onto the frame. From there lift your other leg onto the frame so you're in a squatting position. Alternatively you can sit down at this point if you feel like you covered the bottom frame well enough. From here just jump out of the window if you're squatting (being sure not to contact the top of the window with your head), or swing your legs to the other side of the window and slide out if you're sitting.

3 Lockpicking

How to pick the locks of houses and cars.

Lockpicks

Pick Shapes

Picks come in several shapes and sizes. Figure A.1 shows the most common shapes. The handle and tang of a pick are the same for all picks. The handle must be comfortable and the tang must be thin enough to avoid bumping pins unnecessarily. If the tang is too thin, then it will act like a spring and you will loose the feel of the tip interacting with the pins. The shape of the tip determines how easily the pick passes over the pins and what kind of feedback you get from each pin. The design of a tip is a compromise between ease of insertion, ease of withdrawal and feel of the interaction.

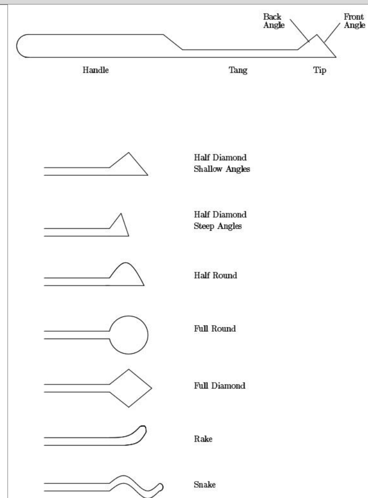

Figure A.1: Selection of pick shapes

The half diamond tip with shallow angles is easy to insert and remove, so you can apply pressure when the pick is moving in either direction. It can quickly pick a lock that has little variation in the lengths of the key pins.

If the lock requires a key that has a deep cut between two shallow cuts, the pick may not be able to push the middle pin down far enough. The half diamond pick with steep angles could deal with such a lock, and in general steep angles give you better feedback about the pins. Unfortunately, the steep angles make it harder to move the pick in the lock. A tip that has a shallow front angle and a steep back angle works well for Yale locks.

The half round tip works well in disk tumbler locks. See section 9.13. The full diamond and full round tips are useful for locks that have pins at the top and bottom of the keyway. The rake tip is designed for picking pins one by one. It can also be used to rake over the pins, but the pressure can only be applied as the pick is withdrawn. The rake tip allows you to carefully feel each pin and apply varying amounts of pressure.

Some rake tips are flat or dented on the top to makes it easier to align the pick on the pin. The primary benefit of picking pins one at a time is that you avoid scratching the pins. Scrubbing scratches the tips of the pins and the keyway, and it spreads metal dust throughout the lock. If you want to avoid leaving traces, you must avoid scrubbing. The snake tip can be used for scrubbing or picking. When scrubbing, the multiple bumps generate more action than a regular pick.

The snake tip is particularly good at opening five pin household locks. When a snake tip is used for picking, it can set two or three pins at once. Basically, the snake pick acts like a segment of a key which can be adjusted by lifting and lowering the tip, by tilting it back and forth, and by using either to top or bottom of the tip. You should use moderate to heavy torque with a snake pick to allow several pins to bind at the same time. This style of picking is faster than using a rake and it leaves as little evidence.

Making Lockpicks

The spring steel bristles used on street cleaners make excellent tools for lock picking. The bristles have the right thickness and width, and they are easy to grind into the desired shape. The resulting tools are springy and strong. The section below describes how to make tools that are less springy out of bicycle spokes. The first step in making tools is to sand off any rust on the bristles. Course grit sand paper works fine as does a steel wool cleaning pad (not copper wool). If the edges or tip of the bristle are worn down, use a file to make them square.

A torque wrench has a head and a handle as shown in figure A.2. The head is usually 1/2 to 3/4 of an inch long and the handle varies from 2 to 4 inches long. The head and the handle are separated by a bend that is about 80 degrees. The head must be long enough to reach over any protrusions (such as a grip-proof collar) and firmly engage the plug. A long handle allows delicate control over the torque, but if it is too long, it will bump against the doorframe. The handle, head and bend angle can be made quite small if you want to make tools that are easy to conceal (e.g., in a pen, flashlight, or belt buckle). Some torque wrenches have a 90 degree twist in the handle.

The twist makes it easy to control the torque by controlling how far the handle has been deflected from its rest position. The handle acts as a spring which sets the torque. The disadvantage of this method of setting the torque is that you get less feedback about the rotation of the plug. To pick difficult locks you will need to learn how to apply a steady torque via a stiff handled torque wrench. The width of the head of a torque wrench determines how well it will fit the keyway. Locks with narrow keyways (e.g., desk locks) need torque wrenches with narrow heads. Before bending the bristle, file the head to the desired width. A general purpose wrench can be made by narrowing the tip (about 1/4 inch) of the head. The tip fits small keyways while the rest of the head is wide enough to grab a normal keyway. The hard part of making a torque wrench is bending the bristle without cracking it. To make the 90 degree handle twist, clamp the head of the bristle (about one inch) in a vise and use pliers to grasp the bristle about 3/8 of an inch above the vise.

You can use another pair of pliers instead of a vise. Apply a 45 degree twist. Try to keep the axis of the twist lined up with the axis of the bristle. Now move the pliers back another 3/8 inch and apply the remaining 45 degrees. You will need to twist the bristle more than 90 degrees in order to set a permanent 90 degree twist.

To make the 80 degree head bend, lift the bristle out of the vise by about 1/4 inch (so 3/4 inch is still in the vise). Place the shank of a screw driver against the bristle and bend the spring steel around it about 90 degrees. This should set a permanent 80 degree bend in the metal. Try to keep the axis of the bend perpendicular to the handle. The screwdriver shank ensures that the radius of curvature will not be too small. Any rounded object will work (e.g., drill bit, needle nose pliers, or a pen cap). If you have trouble with this method, try grasping the bristle with two pliers separated by about 1/2 inch and bend. This method produces a gentle curve that won't break the bristle.

A grinding wheel will greatly speed the job of making a pick. It takes a bit of practice to learn how make smooth cuts with a grinding wheel, but it takes less time to practice and make two or three picks than it does to hand file a single pick. The first step is to cut the front angle of the pick. Use the front of the wheel to do this. Hold the bristle at 45 degrees to the wheel and move the bristle side to side as you grind away the metal. Grind slowly to avoid overheating the metal, which makes it brittle.

If the metal changes color (to dark blue), you have overheated it, and you should grind away the colored portion. Next, cut the back angle of the tip using the corner of the wheel. Usually one corner is sharper than the other, and you should use that one. Hold the pick at the desired angle and slowly push it into the corner of the wheel. The side of the stone should cut the back angle. Be sure that the tip of the pick is supported. If the grinding wheel stage is not close enough to the wheel to support the tip, use needle nose pliers to hold the tip.

The cut should should pass though about 2/3 of the width of the bristle. If the tip came out well, continue. Otherwise break it off and try again. You can break the bristle by clamping it into a vise and bending it sharply. The corner of the wheel is also used to grind the tang of the pick. Put a scratch mark to indicate how far back the tang should go. The tang should be long enough to allow the tip to pass over the back pin of a seven pin lock. Cut the tang by making several smooth passes over the corner. Each pass starts at the tip and moves to the scratch mark. Try to remove less than a 1/16th of an inch of metal with each pass. I use two fingers to hold the bristle on the stage at the proper angle while my other hand pushes the handle of the pick to move the tang along the corner.

Use whatever technique works best for you. Use a hand file to finish the pick. It should feel smooth if you run a finger nail over it. Any roughness will add noise to the feedback you want to get from the lock. The outer sheath of phone cable can be used as a handle for the pick. Remove three or four of the wires from a length of cable and push it over the pick. If the sheath won't stay in place, you can put some epoxy on the handle before pushing the sheath over it.

An alternative to making tools out of street cleaner bristles is to make them out of nails and bicycle spokes. These materials are easily accessible and when they are heat treated, they will be stronger than tools made from bristles. A strong torque wrench can be constructed from an 8-penny nail (about .1 inch diameter). First heat up the point with a propane torch until it glows red, slowly remove it from the flame, and let it air cool; this softens it. The burner of a gas stove can be used instead of a torch.

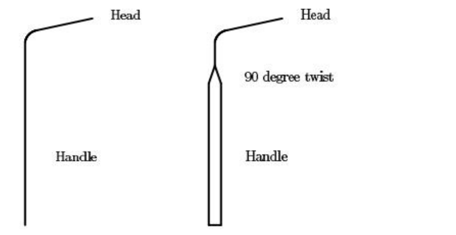

Figure A.2: Torque wrenches

Grind it down into the shape of a skinny screwdriver blade and bend it to about 80 degrees. The bend should be less than a right angle because some lock faces are recessed behind a plate (called an escutcheon) and you want the head of the wrench to be able to reach about half an inch into the plug. Temper (harden) the torque wrench by heating to bright orange and dunking it into ice water. You will wind up with a virtually indestructible bent screwdriver that will last for years under brutal use.

Bicycle spokes make excellent picks. Bend one to the shape you want and file the sides of the business end flat such that it's strong in the vertical and flexy in the horizontal direction. Try a right-angle hunk about an inch long for a handle. For smaller picks, which you need for those really tiny keyways, find any large-diameter spring and unbend it. If you're careful you don't have to play any metallurgical games.

Lockpicking Basics

The following lockpicking guide below was produced by "Ted the Tool" on September 1, 1991.

How a Key Opens a Lock (Chapter 2)

This chapter presents the basic workings of pin tumbler locks, and the vocabulary used in the rest of this booklet. The terms used to describe locks and lock parts vary from manufacture to manufacture and from city to city, so even if you already understand the basic workings of locks, you should look at figure 2.1 for the vocabulary. Knowing how a lock works when it is opened by a key is only part of what you need to know. You also need to know how a lock responds to picking. Chapters 3 and 5 present models which will help you understand a lock's response to picking. Figure 2.1 introduces the vocabulary of real locks.

The key is inserted into the keyway of the plug. The protrusions on the side of the keyway are called wards. Wards restrict the set of keys that can be inserted into the plug. The plug is a cylinder which can rotate when the proper key is fully inserted. The non-rotating part of the lock is called the hull.

The first pin touched by the key is called pin one. The remaining pins are numbered increasingly toward the rear of the lock. The proper key lifts each pin pair until the gap between the key pin and the driver pin reaches the sheer line.

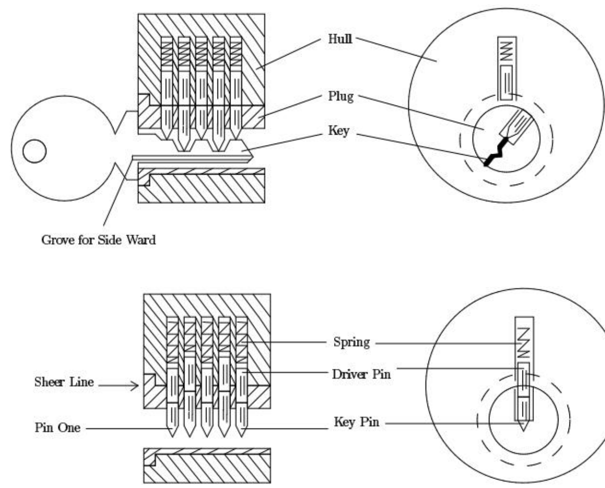

Figure 2.1: Workings of pin tumbler locks

When all the pins are in this position, the plug can rotate and the lock can be opened. An incorrect key will leave some of the pins protruding between the hull and the plug, and these pins will prevent the plug from rotating.

The Flatland Model (Chapter 3)

In order to become good at picking locks, you will need a detailed understanding of how locks works and what happens as it is picked. This document uses two models to help you understand the behavior of locks. This chapter presents a model that highlights interactions between pin positions. Chapter 4 uses this model to explain how picking works.

Chapter 9 (not included in this excerpt) will use this model to explain complicated mechanical defects. The "flatland" model of a lock is shown in Figure 3.1. This is not a cross section of a real lock.

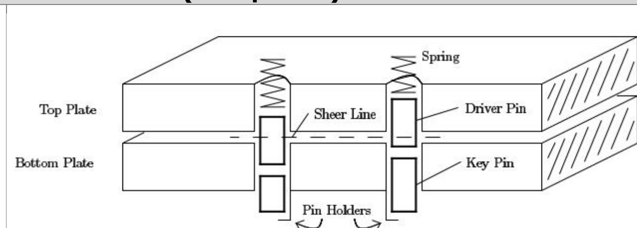

Figure 3.1: Flatland model of a lock

It is a cross section of a very simple kind of lock. The purpose of this lock is to keep two plates of metal from sliding over each other unless the proper key is present. The lock is constructed by placing the two plates over each other and drilling holes which pass through both plates.

The figure shows a two hole lock. Two pins are placed in each hole such that the gap between the pins does not line up with the gap between the plates. The bottom pin is called the key pin because it touches the key. The top pin is called the driver pin. Often the driver and key pins are just called the driver and the pin.

A protrusion on the underside of the bottom plate keeps the pins from falling out, and a spring above the top plate pushes down on the driver pin. If the key is absent, the plates cannot slide over each other because the driver pins pass through both plates.

The correct key lifts the pin pairs to align the gap between the pins with the gap between the plates. See Figure 3.3. That is, the key lifts the key pin until its top reaches the lock's sheer line. In this configuration, the plates can slide past each other.

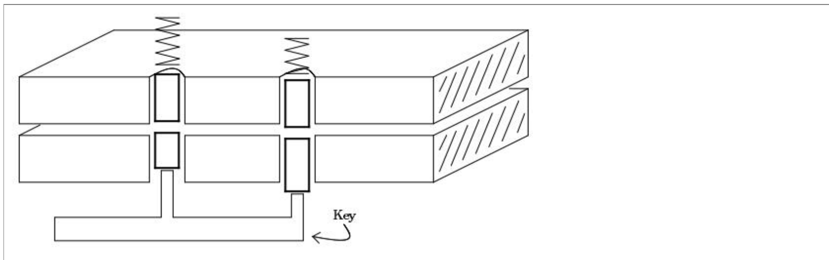

Figure 3.2: (a) Flatland key raises pins

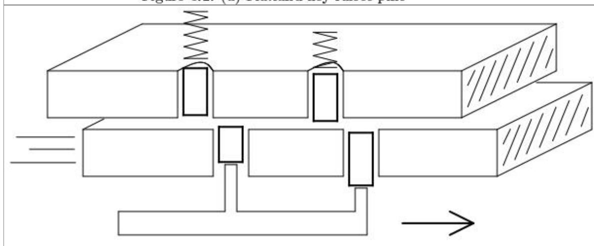

Figure 3.3: (b) Proper key allows plates to slide

Figure 3.3 also illustrates one of the important features of real locks. There is always a sliding allowance. That is, any parts which slide past each other must be separated by a gap. The gap between the top and bottom plates allows a range of keys to open the lock. Notice that the right key pin in Figure 3.3 is not raised as high as the left pin, yet the lock will still open.

Basic Picking & The Binding Defect (Chapter 4)

The flatland model highlights the basic defect that enables lock picking to work. This defect makes it possible to open a lock by lifting the pins one at a time, and thus you don't need a key to lift all the pins at the same time. Figure 4.3 shows how the pins of a lock can be set one at a time. The first step of the procedure is to apply a sheer force to the lock by pushing on the bottom plate.

This force causes one or more of the pins to be scissored between the top and bottom plate. The most common defect in a lock is that only one pin will bind. Figure 4.3a shows the left pin binding.

Even though a pin is binding, it can be pushed up with a picking tool, see Figure 4.3b. When the top of the key pin reaches the sheer line, the bottom plate will slide slightly. If the pick is removed, the driver pin will be held up by the overlapping bottom plate, and the key pin will drop down to its initial position, see Figure 4.3c. The slight movement of the bottom plate causes a new pin to bind. The same procedure can be used to set the new pin.

Thus, the procedure for one pin at a time picking a lock is to apply a sheer force, find the pin which is binding the most, and push it up.

When the top of the key pin reaches the sheer line, the moving portion of the lock will give slightly, and driver pin will be trapped above the sheer line. This is called setting a pin.
Chapter 9 (not included in this excerpt) discusses the different defects that cause pins to bind one at a time.

1. Apply a sheer force.
2. Find the pin that is binding the most.
3. Push that pin up until you feel it set at the sheer line.
4. Go to step 2.

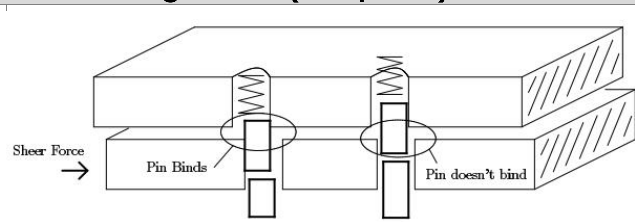

Figure 4.1: (a) Sheer force causes driver to bind

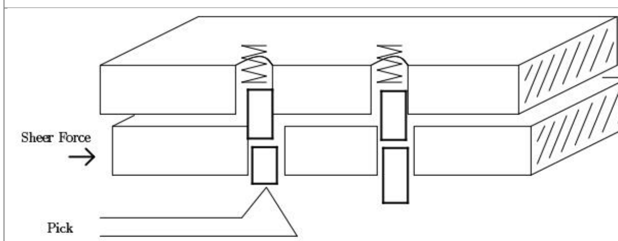

Figure 4.2: (b) Pick lifts the binding pin

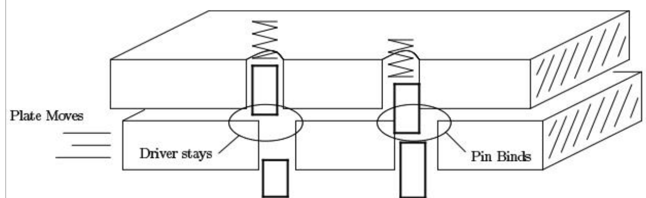

Figure 4.3: (c) Left driver sets and right driver binds

The Pin Column Model (Chapter 5)

The flatland model of locks can explain effects that involve more than one pin, but a different model is needed to explain the detailed behavior of a single pin.

See Figure 5.1.

The pin-column model highlights the relationship between the torque applied and the amount of force needed to lift each pin. It is essential that you understand this relationship. In order to understand the "feel" of lock picking you need to know how the movement of a pin is affected by the torque applied by your torque wrench (tensioner) and the pressure applied by your pick.

A good way to represent this understanding is a graph that shows the minimum pressure needed to move a pin as a function of how far the pin has been displaced from its initial position.

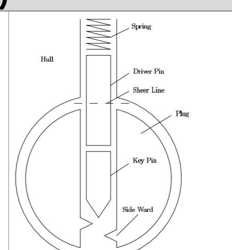

Figure 5.1: The pin-column model

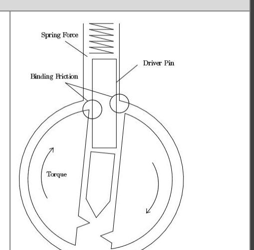

Figure 5.2: Binding in the pin-column model

The remainder of this chapter will derive that force graph from the pin-column model. Figure 5.2 shows a single pin position after torque has been applied to the plug. The forces acting of the driver pin are the friction from the sides, the spring contact force from above, and the contact force from the key pin below. The amount of pressure you apply to the pick determines the contact force from below.

The spring force increases as the pins are pushed into the hull, but the increase is slight, so we will assume that the spring force is constant over the range of displacements we are interested in. The pins will not move unless you apply enough pressure to overcome the spring force. The binding friction is proportional to how hard the driver pin is being scissored between the plug and the hull, which in this case is proportional to the torque.

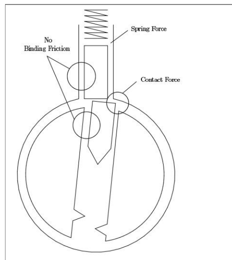

Figure 5.3: Pins at the sheer line

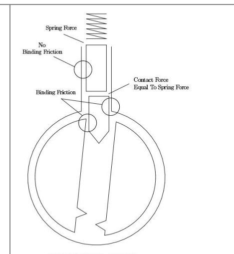

Figure 5.4: Key pin enters hull

The more torque you apply to the plug, the harder it will be to move the pins. To make a pin move, you need to apply a pressure that is greater than the sum of the spring and friction forces. When the bottom of the driver pin reaches the sheer line, the situation suddenly changes. See Figure 5.3. The friction binding force drops to zero and the plug rotates slightly (until some other pin binds). Now the only resistance to motion is the spring force. After the top of the key pin crosses the gap between the plug and the hull, a new contact force arises from the key pin striking the hull. This force can be quite large, and it causes a peak in the amount of pressure needed to move a pin. If the pins are pushed further into the hull, the key pin acquires a binding fiction like the driver pin had in the initial situation.

See Figure 5.4.

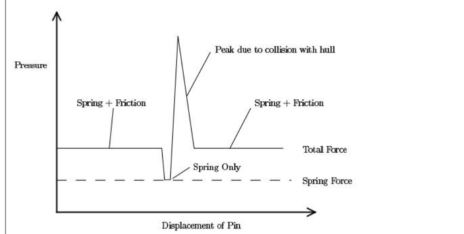

Figure 5.5: Pressure required to move pins

Thus, the amount of pressure needed to move the pins before and after the sheer line is about the same. Increasing the torque increases the required pressure. At the sheer line, the pressure increases dramatically due to the key pin hitting the hull. This analysis is summarized graphically in figure 5.5.

Basic Scrubbing (Chapter 6)

At home you can take your time picking a lock, but in the field, speed is always essential. This chapter presents a lock picking technique called scrubbing that can quickly open most locks. The slow step in basic picking (chapter 4) is locating the pin which is binding the most.

The force diagram (Figure 5.5) developed in chapter 5 suggests a fast way to select the correct pin to lift. Assume that all the pins could be characterized by the same force diagram. That is, assume that they all bind at once and that they all encounter the same friction.

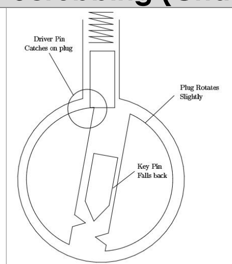

Figure 6.1: Driver pin catches on plug

Now consider the affect of running the pick over all the pins with a pressure that is great enough to overcome the spring and friction forces but not great enough to overcome the collision force of the key pin hitting the hull. Any pressure that is above the at portion of the force graph and below the top of the peak will work.

As the pick passes over a pin, the pin will rise until it hits the hull, but it will not enter the hull. See Figure 5.3. The collision force at the sheer line resists the pressure of the pick, so the pick rides over the pin without pressing it into the hull. If the proper torque is being applied, the plug will rotate slightly. As the pick leaves the pin, the key pin will fall back to its initial position, but the driver pin will catch on the edge of the plug and stay above the sheer line. See figure 6.1. In theory one stroke of the pick over the pins will cause the lock to open.

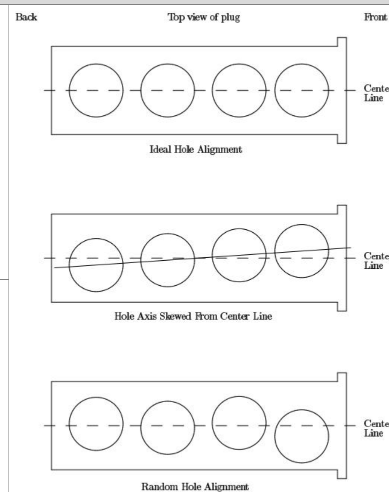

Figure 6.2: Alignment of plug holes

In practice, at most one or two pins will set during a single stroke of the pick, so several strokes are necessary. Basically, you use the pick to scrub back and forth over the pins while you adjust the amount of torque on the plug. The exercises in chapter 8 will teach you how to choose the correct torque and pressure. You will find that the pins of a lock tend to set in a particular order. Many factors affect this order, but the primary cause is a misalignment between the center axis of the plug and the axis on which the holes were drilled. See figure 6.2.

If the axis of the pin holes is skewed from the center line of the plug, then the pins will set from back to front if the plug is turned one way, and from front to back if the plug is turned the other way.

Many locks have this defect. Scrubbing is fast because you don't need to pay attention to individual pins. You only need to find the correct torque and pressure. Figure 6.1 summarizes the steps of picking a lock by scrubbing. The exercises will teach you how to recognize when a pin is set and how to apply the correct forces. If a lock doesn't open quickly, then it probably has one of the characteristics described in chapter 9 and you will have to concentrate on individual pins.

Advanced Lock Picking (Chapter 7)

Simple lock picking is a trade that anyone can learn. However, advanced lock picking is a craft that requires mechanical sensitivity, physical dexterity, visual concentration and analytic thinking. If you strive to excel at lock picking, you will grow in many ways.

Mechanical Skills
Learning how to pull the pick over the pins is surprisingly difficult. The problem is that the mechanical skills you learned early in life involved maintaining a fixed position or fixed path for your hands independent of the amount of force required. In lock picking, you must learn how to apply a fixed force independent of the position of your hand. As you pull the pick out of the lock you want to apply a fixed pressure on the pins. The pick should bounce up and down in the keyway according to the resistance offered by each pin. To pick a lock you need feedback about the effects of your manipulations. To get the feedback, you must train yourself to be sensitive to the sound and feel of the pick passing over the pins. This is a mechanical skill that can only be learned with practice. The exercises will help you recognize the important information coming from your fingers.

Zen and the Art of Lock Picking
In order to excel at lock picking, you must train yourself to have a visually reconstructive imagination. The idea is to use information from all your senses to build a picture of what is happening inside the lock as you pick it. Basically, you want to project your senses into the lock to receive a full picture of how it is responding to your manipulations. Once you have learned how to build this picture, it is easy to choose manipulations that will open the lock. All your senses provide information about the lock. Touch and sound provide the most information, but the other senses can reveal critical information. For example, your nose can tell you whether a lock has been lubricated recently.

As a beginner, you will need to use your eyes for hand-eye coordination, but as you improve you will find it unnecessary to look at the lock. In fact, it is better to ignore your eyes and use your sight to build an image of the lock based on the information you receive from your fingers and ears. The goal of this mental skill is to acquire a relaxed concentration on the lock. Don't force the concentration. Try to ignore the sensations and thoughts that are not related to the lock. Don't try to focus on the lock.

Analytic Thinking
Each lock has its own special characteristics which make picking harder or easier. If you learn to recognize and exploit the "personality traits" of locks, picking will go much faster. Basically, you want to analyze the feedback you get from a lock to diagnose its personality traits and then use your experience to decide on an approach to open the lock. Chapter 9 (not included in this excerpt) discusses a large number of common traits and ways to exploit or overcome them. People underestimate the analytic skills involved in lock picking. They think that the picking tool opens the lock. To them the torque wrench is a passive tool that just puts the lock under the desired stress. Let me propose another way to view the situation.

The pick is just running over the pins to get information about the lock. Based on an analysis that information the torque is adjusted to make the pins set at the sheer line. It's the torque wrench that opens the lock. Varying the torque as the pick moves in and out of the keyway is a general trick that can be used to get around several picking problems. For example, if the middle pins are set, but the end pins are not, you can increase the torque as the pick moves over the middle pins.

This will reduce the chances of disturbing the correctly set pins. If some pin doesn't seem to lift up far enough as the pick passes over it, then try reducing the torque on the next pass. The skill of adjusting the torque while the pick is moving requires careful coordination between your hands, but as you become better at visualizing the process of picking a lock, you will become better at this important skill.

Lock Picking Exercises (Chapter 8)

This chapter presents a series of exercises that will help you learn the basic skill of lock picking. Some exercises teach a single skill, while others stress the coordination of skills. When you do these exercises, focus on the skills, not on opening the lock. If you focus on opening the lock, you will get frustrated and your mind will stop learning.

The goal of each exercise is to learn something about the particular lock you are holding and something about yourself. If a lock happens to open, focus on the memory of what you were doing and what you felt just before it opened. These exercises should be practiced in short sessions. After about thirty minutes you will find that your fingers become sore and your mind looses its ability to achieve relaxed concentration.

Exercise 1: Bouncing the pick
This exercise helps you learn the skill of applying a fixed pressure with the pick independent of how the pick moves up and down in the lock. Basically you want to learn how to let the pick bounce up and down according to the resistance o ered by each pin. How you hold the pick makes a difference on how easy it is to apply a fixed pressure. You want to hold it in such a way that the pressure comes from your fingers or your wrist. Your elbow and shoulder do not have the dexterity required to pick locks. While you are scrubbing a lock notice which of your joints are fixed, and which are allowed to move. The moving joints are providing the pressure. One way to hold a pick is to use two fingers to provide a pivot point while another finger levers the pick to provide the pressure. Which fingers you use is a matter of personal choice.

Another way to hold the pick is like holding a pencil. With this method, your wrist provides the pressure. If your wrist is providing the pressure, your shoulder and elbow should provide the force to move the pick in and out of the lock. Do not use your wrist to both move the pick and apply pressure. A good way to get used to the feel of the pick bouncing up and down in the keyway is to try scrubbing over the pins of an open lock. The pins cannot be pushed down, so the pick must adjust to the heights of the pins.

Try to feel the pins rattle as the pick moves over them. If you move the pick quickly, you can hear the rattle. This same rattling feel will help you recognize when a pin is set correctly. If a pin appears to be set but it doesn't rattle, then it is false set. False set pins can be fixed by pushing them down farther, or by releasing torque and letting them pop back to their initial position. One last word of advice. Focus on the tip of the pick. Don't think about how you are moving the handle; think about how you are moving the tip of the pick.

Exercise 2: Picking pressure
This exercise will teach you the range of pressures you will need to apply with a pick. When you are starting, just apply pressure when you are drawing the pick out of the lock. Once you have mastered that, try applying pressure when the pick is moving inward. With the flat side of your pick, push down on the first pin of a lock. Don't apply any torque to the lock. The amount of pressure you are applying should be just enough to overcome the spring force. This force gives you an idea of minimum pressure you will apply with a pick.

The spring force increases as you push the pin down. See if you can feel this increase. Now see how it feels to push down the other pins as you pull the pick out of the lock. Start out with both the pick and torque wrench in the lock, but don't apply any torque. As you draw the pick out of the lock, apply enough pressure to push each pin all the way down.

The pins should spring back as the pick goes past them. Notice the sound that the pins make as they spring back. Notice the popping feel as a pick goes past each pin. Notice the springy feel as the pick pushes down on each new pin. To help you focus on these sensations, try counting the number of pins in the lock. Door locks at MIT have seven pins, padlocks usually have four. To get an idea of the maximum pressure, use the flat side of your pick to push down all the pins in the lock. Sometimes you will need to apply this much pressure to a single pin. If you encounter a new kind of lock, perform this exercise to determine the stiffness of its springs.

Exercise 3: Picking Torque
This exercise will teach you the range of torque you will need to apply to a lock. It demonstrates the interaction between torque and pressure which was describe in chapter 5. The minimum torque you will use is just enough to overcome the friction of rotating the plug in the hull. Use your torque wrench to rotate the plug until it stops. Notice how much torque is needed to move the plug before the pins bind. This force can be quite high for locks that have been left out in the rain. The minimum torque for padlocks includes the force of a spring that is attached between the plug and the shackle bolt. To get a feel for the maximum value of torque, use the flat side of the pick to push all the pins down, and try applying enough torque to make the pins stay down after the pick is removed. If your torque wrench has a twist in it, you may not be able to hold down more than a few pins.

If you use too much torque and too much pressure you can get into a situation like the one you just created. The key pins are pushed too far into the hull and the torque is sufficient to hold them there. The range of picking torque can be found by gradually increasing the torque while scrubbing the pins with the pick.

Some of the pins will become harder to push down. Gradually increase the torque until some of the pins set. These pins will loose their springiness. Keeping the torque fixed, use the pick to scrub the pins a few times to see if other pins will set. The most common mistake of beginners is to use too much torque. Use this exercise to find the minimum torque required to pick the lock.

Exercise 4: Identifying Set Pins
While you are picking a lock, try to identify which pins are set. You can tell a pin is set because it will have a slight give. That is, the pin can be pushed down a short distance with a light pressure, but it becomes hard to move after that distance (see chapter 6 for an explanation). When you remove the light pressure, the pin springs back up slightly. Set pins also rattle if you flick them with the pick. Try listening for that sound. Run the pick over the pins and try to decide whether the set pins are in the front or back of the lock (or both).

Try identifying exactly which pins are set. Remember that pin one is the frontmost pin (i.e., the pin that a key touches first). The most important skill of lock picking is the ability to recognize correctly set pins. This exercise will teach you that skill. Try repeating this exercise with the plug turning in the other direction. If the front pins set when the plug is turned one way, the back pins will set when the plug is turned the other way. See Figure 6.2 for an explanation.

One way to verify how many pins are set is to release the torque, and count the clicks as the pins snap back to their initial position. Try this. Try to notice the difference in sound between the snap of a single pin and the snap of two pins at once. A pin that has been false set will also make a snapping sound. Try this exercise with different amounts of torque and pressure. You should notice that a larger torque requires a larger pressure to make pins set correctly. If the pressure is too high, the pins will be jammed into the hull and stay there.

Exercise 5: Projection
As you are doing the exercises try building a picture in your mind of what is going on. The picture does not have to be visual, it could be a rough understanding of which pins are set and how much resistance you are encountering from each pin. One way to foster this picture building is to try to remember your sensations and beliefs about a lock just before it opened.

When a lock opens, don't think "that's over", think "what happened". This exercise requires a lock that you find easy to pick. It will help you refine the visual skills you need to master lock picking. Pick the lock, and try to remember how the process felt. Rehearse in your mind how everything feels when the lock is picked properly.

Basically, you want to create a movie that records the process of picking the lock. Visualize the motion of your muscles as they apply the correct pressure and torque, and feel the resistance encountered by the pick. Now pick the lock again trying to match your actions to the movie. By repeating this exercise, you are learning how to formulate detailed commands for your muscles and how to interpret feedback from your senses. The mental rehearsal teaches you how to build a visual understanding of the lock and how to recognize the major steps of picking it.

This concludes the guide on lockpicking. There is more discussed in the full guide by 'Ted the Tool' which you can find online.

Lockpicking Houses

Lockpicking Cars

Lockpicking Padlocks

Padlocks are those rectangular locks with a thick metal "U" bending up and around into the lock. These use relatively small keys to open and are often found on sheds or bike locks.

4 Hotwiring

5 Hacking

Hacking is the gaining of entry into a computer system to read, change, remove or add files. It is often done remotely but can also be done in person.

Hacking Computers

Hacking WiFi

9 Stealth

This section on using stealth and camouflage effectively as well as being a "Grey Man" in suburbia.

Grey Man

The term "Grey Man" (or "Gray Man") in a security context refers to an individual who intentionally cultivates an inconspicuous appearance and demeanor to blend seamlessly into their environment and avoid drawing any unwanted attention. The goal is to become unremarkable, forgettable, and therefore, less of a target. It's a strategy rooted in the principle of avoidance and is highly valued in personal security, intelligence, and survival/prepper communities.

Core Principles
- Inconspicuousness: The primary objective is to not stand out from the crowd. This means avoiding anything that would make you memorable or cause someone to take a second look.
- Blending In: Adapting your appearance, behavior, and even possessions to match the "baseline" of your surroundings. What's normal in one environment (e.g., hiking gear in a national park) would make you stand out in another (e.g., the same gear in a city center).
- Reduced Target Profile: By being unremarkable, you reduce your chances of being singled out by criminals, hostile actors, or even just people seeking assistance (especially in a crisis situation).
- Concealment of Capabilities: A true Grey Man is often well-prepared and capable, but they do not outwardly display these capabilities (e.g., no overt tactical gear, no bragging about survival skills).

Becoming a Grey Man

Here's the steps of becoming a Grey Man.

Appearance

● Neutral Clothing: Wear colors that are common and blend with the environment (greys, blues, browns, blacks, creams). Avoid bright, flashy, or highly patterned clothing.
● No Logos or Branding: Avoid prominent brand names, sports team logos, political statements, or anything that could identify you or attract attention.
● Unremarkable Accessories: Keep jewelry to a minimum or none at all. Use plain, common bags or backpacks rather than tactical ones.
● Appropriate for the Environment: Dress according to the local fashion norms, weather, and activity. Don't wear a suit to a beach or camouflage in a city unless it's genuinely part of the local norm.
● No "Tactical" Look: Avoid clothing or gear that screams "prepper," "military," or "security." This includes cargo pants, tactical vests, obvious knife clips, or tactical boots unless they genuinely blend in.

Behavior & Demeanor

● Neutral Body Language: Walk with purpose but without arrogance or extreme urgency. Avoid fidgeting or looking lost. Maintain a neutral expression.
● Avoid Eye Contact (mostly): While situational awareness requires scanning, prolonged or aggressive eye contact can be perceived as a challenge or invitation to interaction. Learn to observe with your peripheral vision.
● Quiet and Calm: Avoid being loud, boisterous, or drawing attention through your voice or gestures.
● Don't Engage Unnecessarily: Avoid lengthy conversations with strangers or expressing strong opinions. Be polite but brief.
● Mimic the Crowd: Observe how others around you are behaving (their pace, their level of engagement, their typical actions) and subtly adjust your own to match. If people are hurrying, hurry. If they're leisurely, be leisurely.
● Don't Show Off: Don't display wealth (e.g., expensive watches, cash), gadgets, or any signs of preparedness.

Possessions

● Concealed Gear: Any necessary self-defense items, first-aid kits, or survival tools should be carried discreetly and not be visible or obvious.
● Plain Bags: Use common, everyday backpacks or bags that don't look tactical or specialized.
● Digital Discretion: Be mindful of what you share online, especially regarding your location, possessions, or routines, as this can undermine the Grey Man approach.

Camouflage

Hiding yourself within nature.

Identifiers

To detect objects the human visual system looks for object signatures which differentiates it from the background. The term visual saliency is used in cognitive science to describe the features that make objects detectable.

Movement	Shapes moving in a static environment or not moving in a dynamic environment will draw attention.
Shine & Glint	Metal, glass, plastic, sweaty skin, etc.
Shape	Humanoid shapes draw attention. i.e. Faces in rock formation, man shaped trees stumps.
Silhouette	A contrasting blob against the background.
Colour & Texture	Blue in a green jungle doesn't work, neither does low texture in a high texture environment.
Shadow	The mind can calculate probable shapes from the shadows cast, especially human shapes.
Spacing & Patterns	Regular spaced objects form a pattern that will draw attention.
Smell	Animals can pick up your scent from a great distance, especially dogs.
Sound	Unusual sounds can cause you to stand out, or the absence of sound if birds know you are nearby. Know what sounds animals make when they know someone is nearby.

Camouflage Families

These are the different camouflage families which have been utilized by military's worldwide over the years.

Camouflage Name	Description	Camouflage Types	Pattern
Woodland	It is a four colour, high contrast disruptive pattern with irregular markings in sand, brown, green and black. **Use:** Woods	● Australian Multicam (2014) ● A-TACS (2010) ● Desert Camouflage Pattern (1991) ● Disruptive Pattern Camouflage (2017) ● HyperStealth Afghan Forest (2009) ● Multicam (2002) ● Operational Camouflage Pattern (2015) ● U.S. Woodland (1981)	
Digital	Multi-scale camouflage is a type of military camouflage combining patterns at two or more scales, often (though not necessarily) with a digital camouflage pattern created with computer assistance. **Use:** American Armed Forces	● AOR-1 (NWU Type II) (2010) ● AOR-2 (NWU Type III) (2010) ● Canadian Disruptive Pattern (2002) ● M05 (2007) ● Marine Pattern (MARPAT) (2002) ● NWU Type I (2018) ● Type 07 (China) (2007) ● Universal Camouflage Pattern (2018)	Flecktarn	Flecktarn "mottled camouflage" is a family of 3-, 4-, 5- or 6-color disruptive camouflage patterns, the most common consisting of dark green, light green, black, red brown and green brown or tan depending on the manufacturer. **Use:** European Temperate Woodland Terrain.	● Bundeswehr Tropentarn (1993) ● Flächentarnmuster (1967) ● Flecktarn (1990) ● M84 (1984) ● Multitarn (2016) ● Platanenmuster (1937)	

DPM (Disruptive Pattern Material)	The main variants of DPM are a four-colour woodland pattern, and desert patterns in two, three or four colours. **Use:** British Armed Forces	● Disruptive Pattern Material (1968) ● Multi-Terrain Pattern (2010)	Frog Skin	Frog Skin is a battledress camouflage pattern with mottle and disruptive coloration to blend into the environment similar to a frog's crypsis skin.	● Frog Skin/Spot (1942)	
Lizard	The lizard pattern is a family of many related designs of military camouflage pattern, first used by the French Army on uniforms from 1947 to the late 1980s.	● Lizard (1947)	
Splinter	Splinter pattern camouflage is a military camouflage pattern consisting of polygons.	● M90 (1989)	

Somebody Else's Problem (SEP)

Somebody Else's Problem (SEP) is a psychological effect where people choose to dissociate themselves from an issue that may be in critical need of recognition. An SEP is something we can't see, or don't see, or our brain doesn't let us see, because we think that it's somebody else's problem. The brain just edits it out, it's like a blind spot. The Somebody Else's Problem field... relies on people's natural predisposition not to see anything they don't want to, weren't expecting, or can't explain. An example would be a bunch of people dressed up as clowns going about their days work. People will look for a while, while trying to grasp their purpose but then leave it for someone else to fix.

Urban Camouflage

The gray man is an individual who moves around the periphery of our awareness without creating any stimulus. This makes that person invisible for all practical purposes.

Size	Height is an element of being a gray man that we have little control over. The best gray man is ordinary in every respect. He's of average height and weight. He has no obvious physical features that draw attention, ie, big nose, bald head, facial hair, etc.
Dress	Dress is an element within our control. For the most part, natural and neutral colours work best; Browns and greys. Nothing to create a memory like a T-shirt with a saying or photos. Style of clothing tends to be very conservative. Nothing showing skin, nothing too fashionable, nothing to out of fashion. Ordinary is the key word here.
Mannerisms	Since the gray man attracts no attention, his mannerisms must be small and discreet. No sweeping gestures. Energetically, the gray man is withdrawn. He does not project confidence. He does not look around much, he avoids eye contact.
Movement	One of the key elements of camouflage is learning to match your movement to the baseline. If you spend any time in a city, you will notice that every neighbourhood has a unique flavour. We call that the baseline. It refers to the sound, motion, activity level of the neighbourhood in a normal situation. The speed at which people move, the way they gesture, the volume and speed with which they speak. All these elements and many more make up the baseline. You can learn the baseline for a given neighbourhood by sitting somewhere and watching.
Route	A key element in avoiding trouble is not to go where trouble tends to be. This means you must know the terrain like a native. You must know what neighbourhoods are safe (relatively) and which ones to avoid. You must know roads and routes, locations of police stations, gas stations, convenience stores and emergency clinics. You should know what areas have street lights at night and which are dark. Know where the choke points are and where LE is likely to set up blockades. Being a gray man means avoiding trouble by not going where trouble is, unless necessary.
Observation	Sit back and watch the crowd. Notice the stimulus that drew your eye. The purpose is to pound into your consciousness the stimulus – what you notice about each person. "That guy has a huge nose." Then after a few minutes, someone will walk by and you will not find anything. Pay attention to that person. Observe them carefully. See how they move, what kind of energy they project. See how they interact with others, what they pay attention to (or not). If possible follow them for a bit. Observe them move.

House Camouflage

During times of crisis your house should be camouflaged to fit in with those around you. This can be done by looking at the state of nearby houses and matching what they look like. If they appear to be trashed with junk all over the lawn, overgrown and with broken windows, you should blend it in by doing the same and lessening the chance someone will target you. If all the other houses in the street don't have power, don't go lighting up every room and showing that you have power. Instead tape up any windows that you will have light in and ensure there's no gaps. This also applies to sound, food scent and even smoke coming from your chimney.

Stealth Camping

Stealth camping is camping overnight (generally illegally) and leaving without being detected. By setting up camp at dusk and packing up at dawn, the camper spends the least number of hours with the shelter set up to avoid detection. The following section details tips on being as stealthy as possible.

SECURITY Stealth Stealth Camping

- Don't wear a full set of camo in public areas or people may ask questions. Instead, switch into camo clothes when you are at your campsite.
- Choose hiking, backpacking, and camping gear and clothing that are natural earth tone colours like green, brown, tan, or black.
- Shelters should ideally be below 80cm (31.5in) high to remain hidden easier. Under 60cm (23.6in) is preferred. Their width and length doesn't matter too much.
- Bring a camo net to camouflage your shelter with the background and ensure it's a suitable colour for the environment.
- Pad metallic items in your bag so they don't make noise when hiking and never put pots and pans outside your pack.
- Ensure you don't have any reflective/glowing or luminous surfaces on your gear which could give away your position.
- Try not to carry too much gear in an oversized backpack or people may start to ask questions. Have answers ready if someone does ask you such as you're training for the army.
- Ensure your tent has no reflective markers on it which could bounce torchlight back.
- Use a brown or green toned or camo tent with a low maximum height.
- Mobiles keep your location data on hand so be sure to disable any connections before setting out. They can even store data while offline and upload it after you reconnect.
- Ensure mobiles are set to silent as a ringtone or even a vibration is a sure way of being found.

Giveaways

Try to reduce the amount of gear which can give away your position in various ways, such as:

Reflective Surfaces	Any items with reflective surfaces such as watches, glasses or mirrors.
Clanging/Bumping	Any items in your pack that bump together and produce sound.
Bright Colours	Any items that have colours contrasting to the natural surroundings.
Tall Objects	Objects such as tents which stand up taller than 80cms.
Electronic Sound	Any items that can produce sound electronically such as mobiles and watches.
Artificial Sound	Any items that can produce artificial sounds such as gas stoves, tent zippers and velcro.
Luminous Objects	Items that glow in the dark or are designed to reflect light.
Scent	The smell of cooking food or body odour can easily give away your position.

Moving

- Avoid situations where your moving silhouette is visible, especially at dusk and dawn.
- Cover your tracks if your footprints are visible and you believe it will help your situation. Use a stick of leaves to scrub the tracks clean as you walk.
- Only let people see you when you want to be seen such as before you've set up your camp and when you're returning from camp.

Hiking

- Stay on the trail if it is muddy or wet. Hike through it. If you walk around the mud the trail will widen and become even muddier in the future. Mud is part of the backcountry challenge. Wear waterproof boots and gaiters to protect your feet from mud and water. Stay on the trail!
- Stay on designated trails while hiking or backpacking. Walk single file in the centre of the path. Leave only the lightest of footprints.
- Use existing trails. Don't shortcut switchbacks.
- To minimize trail damage, wear as light a boot as possible for the conditions. Heavy boots with deep treads compact the soil more and tend to tear up the trail. Wear camp shoes (sandals, sneakers, moccasins, etc.) to minimize impact while in camp.
- If travelling cross-country hike on durable surfaces (rock, sand, gravel, snow, pine needles, or dry grasses) to prevent vegetation damage and erosion. Have your group spread out while hiking off-trail so that new trails aren't created.
- Camp and travel in small groups. They are quieter and do less damage.
- Cover up any footprints or vehicle tracks you make which could lead people to you.
- Stay on tracks that are already defined such as an established hiking trail. Walk through muddy sections of track to conceal your tracks more as most people will go around.
- Move slowly as it's harder to detect.
- To be stealthy when walking through mud, slide your boots into the water without breaking the surface and then take them off the bottom just enough to take another step without taking them out of the water.
- Walk on the most durable ground you can find to reduce your impact on that location and conceal your footprints. Rocks instead of dirt and dead leaves instead of live flora.
- If you always pretend that people are following you and you want to lose them, you will quickly learn how to evade detection.

Regulations

- Know the regulations and concerns for the area you'll be hiking, backpacking, or camping in. Restrictions are based on any past abuse and the special conditions of an area.
- Some areas don't allow fires or only allow fires in designated areas. Know the regulations for the area you will be visiting.
- The laws change wildly from country to country and knowing what your rights are can help persuade people who find you that you're in the right, or didn't know the law.

Car Parking

- Leaving a note on your car saying it's broken down and detailing a fictional friend "Dave" who will come and pick it up could deter carjackers and thieves. Just make sure it looks like that problem has occurred.
- Blend your car in by leaving typical gear in it that people nearby use such a fishing rod and bucket.
- Take an essential part of your car with you rending it inoperable until you return and replace it such as a spark plug.
- Remove or hide any items that are in the car to deter thieves from breaking into it.

Scouting

- Google Earth locations prior to setting out so you have a few options to check out and pick the best from.
- You could set up a game camera in an area you wish to camp in prior to heading there to see what sort of activity there is from humans and animals.
- Read over maps of the destination prior to going so you understand the terrain and have a few ideal spots in mind.
- Know what the weather will be for your trip as this will have a large impact on your campsite location.

Location Tips

SECURITY Stealth Stealth Camping Location Tips

- Try to position your camp so that you have thick vegetation on most sides.
- If you're on a hiking trip never camp in the same place multiple times in a row, find a new one every night to make it harder to be detected.
- Don't let anyone see you entering or leaving a campsite, if you're spotted make it look like you're just hiking through.
- If it's not a SHTF situation, ensure that someone knows where you are in case an emergency arises.
- Use shadows to your advantage. Hide in dark spaces near fallen trees where you won't be spotted.
- People tend to look down more then up and some won't bother climbing hills so try to camp high.
- Good campsites are found, not made so try not to alter the terrain to suit.
- Be sure to camp on durable surfaces. Avoid fragile areas that will impact easily and take a long time to heal after you leave. Try to concentrate use into campsites that are already established. Give places just beginning to show impact a chance to heal themselves.
- Look for large natural fallen logs to set up near as they will provide a wind break, additional camouflage and protection from falling branches and sticks.
- Know the location, your way out and keep track of where you've been.

- Nobody will know where you are so you are your only source of help unless you have an emergency beacon or let someone know exactly where you will be.
- Beware of floor based dangers such as traps, pitfalls, landmines or quicksand.
- Have an escape plan in mind in case you have to get out of the area swiftly without being detected, such as nearby humans who haven't seen you yet.
- Getting more practice can help the experience become easier as you know what to look for in a campsite and what to avoid.
- The harder it is to get to your campsite, the less likely you will be found.
- Pitching amongst bushes or long grass will help cut your silhouette out and completely hide you however there may be unwanted critters in there you wake up to such as snakes or ticks.

Hazards

- Check your potential camping area for hazards like dead branches, tall trees, game trails, deadly creatures, sharp objects etc.
- Ensure your chosen camp isn't a safety hazard such as prone to floods, wildfires or dangerous animals.

Avoid

Popular Areas	Avoid popular areas during heavy use times such as parks, fishing hotspots and patrolled areas.
Cut Grass	Watch out for cut grass, it could be a sign this area is a commonly occupied space such as a park or grazing area.
Private Property	Don't camp in areas where there are Private Property or No Trespassing signs, you don't have an excuse of not knowing and it generally means they keep an eye for campers or it's happened in the past.
Camp Away From Water	Don't camp near water. Camp at least 61m (200ft) away from water sources. Animals come to water to drink and may be scared off. Areas near water are also more fragile and camping too close can lead to erosion.
Avoid Cattle	Avoid areas with large amounts of cattle, this is easy to detect as the landscape will be spotted with faeces and animals can detect you easier then humans.
Purple Paint	Purple paint on fences or trees denote they are privately owned.
Geocachers	Avoid areas frequented by geocachers, they are likely to find you if you are near a cache. Create a geocacher account just to look up where caches are so you can avoid those areas.

Setup

- Pile sticks and other natural elements around your tent so it blends in more and breaks up any sharp lines.
- Pitch the tent at dusk and pack it up at dawn. You need to use the night as cover.
- Stay away from frequently travelled paths or where domestic pets can pick up your scent.
- Keep your fire profile low and below ground level to avoid the bright flames being seen - if you need a fire at all.
- If you are discovered before setting up your camp while hiking around, ensure to move at least 1km away and out of that person's land.
- Avoid pitching your tent in the dark, find a suitable location for camping prior to setting up and go for a local hike to scout the location out and return when it's almost dark.
- Set up hammocks low to the ground or barely touching it to maintain a low profile.
- Try to keep tents as taut as possible to avoid them flapping about in wind.
- Don't let people see you setting up your camp or leaving the trail as this will arouse suspicion.

Speed

- Know how to set up and dismantle your camp easily, keep as much done as possible so you can pack up within 2 minutes if you need to get out fast.
- Time yourself at home and try to get the tent set up and dismantled within 2 minutes.
- Learn to dismantle your entire camp with no trace within a few minutes.
- If your shelter takes over 5 minutes to set up it's recommended to either practice until you can set it up under 2 minutes or buy another, simpler one.
- Setup Speed (Fastest to Slowest) - Bivy, Bedroll, Swag, Hammock, Tent

Cover

- Place a few natural materials on and around your shelter to blend it in more naturally than camo nets because its colours may be slightly off.
- When placing sticks and branches around your site be careful they don't puncture your shelter.
- Handfuls of leaves on top of a camo net shelter is a perfect final step for blending it in to the environment.

Overnight

- Keep as quiet as possible and avoid using light sources over 10 lumens for long. Or just use the sun as your light and sleep at night.
- Know what's in your pack and where you keep it for easy access if you're in a hurry.
- Keep the items you aren't using in your pack so you can make a quick getaway if you need to.

Inside the Shelter

- While inside the shelter keep unnatural sounds to a minimum such as bag zips, inflatable mattress sounds, clanging and velcro tearing.
- Minimise bodily noises like sneezing, coughing and yes, farting.
- If you snore, try to sleep in a position that minimises your noise or purchase a device that prevents snoring as you're at your most vulnerable when asleep.

Entering & Exiting

SECURITY Stealth Stealth Camping

- Avoid getting in and out of your shelter as much as possible as the sound of zippers and velcro can easily give you away. If you must, unzip it slowly.
- Before moving out of your shelter, take a few moments to look and listen around you for people, animals or other threats.
- Keep lighting to a minimum when moving around your campsite and only use red or green lights.

Awareness

- Know what's going on around you and always pay attention to the sounds outside your shelter.
- Try to identify any foreign sounds if you're uncomfortable with them.
- Try not to shut out the world when you're in your shelter by listening to music, try to keep at least one earbud off to listen out.

Fire

- Keep your fire small. Use small (wrist size or smaller) dead wood that was already on the ground. Break wood into smaller pieces as needed. Using small wood will ensure that it burns more completely.
- Building a pit fire is the best option to hide the flames at night which can be visible from many miles away.
- Using gas or liquid fuels like butane and denatured alcohol instead of wood is stealthier and are less visible if you wish to cook.
- Smoke from a fire gives away your position easily, not only by sight by from small also so try to make them at night when it's harder to see and there's less people around.
- Keep in mind that cooked food can be smelt from ages away and will draw predators and possibly humans to the source.

Animals

- If a bear beats your bear bag system and steals your food bag during the night, try and find the remains and properly dispose of them before you leave. The bear will be done eating in the morning and most likely had his feast a little ways from your campsite. You are responsible for everything you bring into the backcountry.
- Do not feed the animals! You will create a nuisance because the animal will develop a taste for human food, associate humans with food, and then raid our campsites to steal our food. Cook and eat away from your campsite so you don't attract bears.
- Learn how to properly store your food to protect it from bears and other animals.
- Treat the animals you encounter with respect. Remember that you are a visitor and are travelling and camping in their backyard.
- Observe wildlife from a distance so you don't interfere with their natural decisions.
- If you are on a horse you are responsible for its waste also. Would you do to the toilet in the middle of a hiking trail? Move your horse's waste off the trail. Do not let your horse do it's thing by any water sources or campsites.
- Learn how to properly store your food to protect it from bears and other animals.

Hygiene

- Wash yourself and dishes 200 feet from any water sources and away from campsites.
- Food scraps will attract insects and animals. Filter your dishwater and carry out your food scraps with the rest of your trash.
- Don't use soap or shampoo. Keep chemicals out of the backcountry! So-called biodegradable soap still has an impact on the environment. If you absolutely must use soap use it 200 feet from any water sources and only use a little bit.
- Bury human waste in cat holes about 6-8" deep 200 feet from any water sources, campsites, or trails. It is good to carry out used toilet paper since animals often dig it up and spread it all over. Carry out all plastic or cotton feminine hygiene products. Do not bury them.

Getting Caught

- Public/Private Land (No Trespassing Sign) Generally they ask you to leave.
- Public/Private Land (With Trespassing Signs) 50/50 chance of prosecution in America.
- Real Estate Land - Prosecution, Fine and Jail.
- If you get caught you may be searched, harassed and questioned.
- It's best to be truthful in these situations and they might go easier on you.
- Don't Have: Firearms, Drugs, Illegal Knives.
- If you're found, act lost, like you didn't know the rules, say you'll leave or that it's completely fine to camp there if they aren't a ranger or the land owner.
- If you're found, even by someone who appears not to care, move your campsite.
- During dry periods it can be dangerous or against regulations to build a fire. Make sure your fire is completely out before leaving an area.

Speed

- Know Your Tent - Know how to dismantle your camp quickly and keep as much done as possible so you can pack up within 2 minutes if you need to get out fast.
- Time Challenge - Time yourself at home and try to get the tent set up and dismantled within 2 minutes.
- Dismantle Speed - Learn to dismantle your entire camp with no trace within a few minutes.

Leave No Trace

Leave No Trace	Make it look like you were never there when you leave.
Trash Bag	Make sure you have a way to properly dispose of your trash. (Use your Ziploc bags or bring an extra garbage bag)
Environmental Impact	Get back to the basics. Select your gear and plan your trip by thinking about how it will impact the environment and also how it may affect others as well.
Camp Lighting	Use a candle lantern for light instead of building a fire. If you use regular candles don't leave your wax drippings all over the place. It is not "natural".
Unburnable Waste	Contrary to popular belief tin foil and plastic bottles do not completely burn.
Negative Trace	Practice "Negative Trace". Pick up trash that others may have missed or that were dropped by accident. Pick up trash you find along the trail.
Never Bury Trash	Do not bury your trash. Animals will dig it up or it will become exposed later on for someone else to find.
Remove Evidence	Make your site or travel route look like nobody was ever there. Leave no signs of human influence. Remove all evidence of your stay. Inspect your campsite for trash or misplaced gear before you leave.
Carry Out Trash	If it wasn't there when you came then don't leave it there when you leave! You are responsible for anything you bring into the backcountry. Carry out all your trash.
Rules	Take only pictures, leave only the lightest of footprints, and bring home only memories.
Don't Steal Nature	Resist the temptation to take home souvenirs. Leave stones, feathers, artefacts, shells, petrified wood, etc. so that others may enjoy them.
Keep Nature Pristine	Leave the place you're visiting in a natural condition. Do not alter a site in any way. Good campsites are found, not made. Don't pound nails into trees or damage live vegetation or trees.

Reduce Trash	Reduce the amount of trash you bring into the woods by eliminating all unnecessary packaging like cardboard boxes, etc.
Unburned Trash	Remove all unburned trash from your fire ring. Contrary to popular belief aluminium foil and plastic bottles do not completely burn in fires. Scatter your leftover cold ashes over a large area away from campsites.
Use Dead Wood	Don't break or saw off branches from dead trees, live trees, or fallen trees. Use only wood that's on the ground. Don't burn green wood. Don't peel the bark off trees for use as fuel. It takes many years to heal and remains an eyesore in the meantime.
Reusable Containers	Repackage your food into re-usable containers like Ziploc bags. Avoid tin or aluminium cans and glass.
Use Tree Straps	If using a hammock use tree straps to reduce the impact and damage to the trees.
Footprints	Leaving nothing but your footprints.
Blackened Rocks	Don't make a fire ring with rocks. Blackened rocks are very unsightly and stay that way for many years.

Stealth Vehicle Camping

Grid Up

This section is about sleeping in a vehicle stealthily overnight without being detected. It is assumed that the grid is up and society is functional.

Vehicle Tips

Choose a van with no obvious features, typically white without decals, paint jobs etc. A sprinter van can be fitted out to look like a small apartment.	**Possible Vehicles** ● Mercedes-Benz Sprinter ● Nissan NV2500 ● Ford Transit ● Dodge RAM ProMaster

Parking Tips

● The most obvious place to park is the best, it looks natural outside homes but try to find a spot between houses so it looks to each one like you're visiting the other's house.
● Don't stay in the same place more than 2-3 nights in a row to avoid suspicion.
● Try to avoid revealing the interior of the van and showing there's a bed inside, so be quick when entering and leaving the vehicle.
● Look for a shaded area if it becomes hot during the day.

Examples

Sprinter Van	A wonderfully compact and modern looking sprinter van to house conversion. URL: stealthsprinter.com/
Van Build	URL: sean.cm/i/van-build/

Grid Down

This section is about sleeping in a vehicle stealthily overnight without being detected. It is assumed that the grid is down and a SHTF situation is ensuing.

Vehicle Tips

● If you're using a brightly coloured car change the colour to a white, black or gray colour if possible.
● Use a camo net to cover the car if you're parking in the bush.
● Keep out of sight from any roads and preferably behind thick foliage.
● Cars have a lot of shiny reflective surfaces which can be seen from miles away so try to reduce these surfaces as much as possible.

Weapon Concealment

How to conceal weapons effectively on your body and in your home.

10 Tactics

Military Routine

While away from the secure base it is normal to develop a routine linked to the change from day to night, as this is the time when the effect of the environment changes. A defensive posture is adopted, and a set of routine actions are conducted around daybreak and another around sunset. These are called morning and evening routines and are described as follows:

Morning Routine

Reveille	Everybody is woken, shelters are struck if applicable, all equipment is packed and weapons are manned at all times.
Stand-to	The duration of any stand-to varies according to the season and the country but is always for a specific time (not necessarily first and last light). Each member puts on their fighting equipment, occupies fire positions and remains alert. Clearing patrols may be sent out in this period and stand-down ordered only when all tasks are completed and sentries posted.

SECURITY
Tactics
Military Routine
Morning Routine

Communications	All forms of communications are checked and tested.
Security	All sensor devices are checked, tested and repositioned as required. Observation posts (OP) are also checked and repositioned for day routines as ordered.
Weapons and Ammunition	Avoid cleaning all weapons simultaneously. Individuals in pits should remain alert while the buddy checks and cleans theirs. The cleaning and inspection of light support weapons must be coordinated, so that not all are out of action together. Soldiers are responsible for reporting any defects or requirements for deeper maintenance.
Administration	Troops conduct ablutions, an free from infestation/infection inspection is undertaken and water bottles are filled and sterilised. Breakfast may be cooked or eaten in pairs under section arrangements. Any anti-malarial or other drugs are taken. The section area is cleaned, equipment laid out for specific use and camouflage refurbished. Clothing and equipment is checked and repaired as required.
Briefings	The section or team is briefed on the day's activities, patrol requirements, duties, rest requirements and any special tasks.
Tasks	Operational tasks are prepared and undertaken, such as reconnaissance, area improvements, camouflage and wiring.

Evening Routine

SECURITY
Tactics
Military Routine
Evening Routine

Weapons / Ammo / Equip	Re-clean and check all weapons, ammunition natures and equipment.
Personal Hygiene	Re-check personal hygiene, reapplying medications as required for foot and crotch care and conduct a further free from infestation/infection inspection.
Prepare and Conduct Night Routine	The evening meal is eaten and orders for the night are issued. These include preparations for the evening such as sentry rosters, OP/listening posts, checking night vision equipment, clearing patrols and preparations for night activities. Personal equipment is prepared and laid out for the evening as required. Rest is taken and security is maintained throughout the evening hours.
Tasks	The force is then prepared for night patrols and so on.

Rest Periods

SECURITY
Tactics
Military Routine
Rest

Rest Periods	Rest periods are a requirement and, if not placed in the soldier's routine, can lead to sleep loss, fatigue and stress.
Rest Programs	Commanders must take every opportunity to program rest periods which include a periodic release from duty, sleep periods for those on 24-hour duties.
Sleep	As a rule, every soldier should attempt to get 4 to 5 hours of unbroken sleep daily.

Military Food Acquisition

SECURITY
Tactics
Military Routine
Military Food Acquisition

Fresh Rations	These are fresh foodstuffs made available through the catering and supply system for consumption in established kitchens, or field kitchens, in a camp or secure defended area. They are prepared by catering personnel allotted to the unit.
Individual Meal Combat Ration	The individual meal combat ration provides sufficient rations for one soldier for one meal and is prepared by the soldier.
Combat Rations One Man	The combat rations one man is designed to last 24 hours and offers five different menus. It is designed to ensure that a soldier receives the energy and vitamins required each day for demanding operations. The combat rations one man is prepared by the soldier and it is recommended that all the food in the pack be consumed.
Patrol Ration One Man	The patrol ration one man consists of two dehydrated main meals and a number of sundry items. This ration is designed to ensure that a soldier receives sufficient energy and vitamins for 24 hours.
Combat Ration Five Man	The combat ration five man consists of three main meals and a number of sundry items, capable of feeding five soldiers for one day. Most items consist of portion-controlled packs for individual meals and are prepared collectively by the soldiers.
Emergency Rations	Emergency rations consist of high energy chocolate bars designed to provide sufficient energy for a short period, until other food is available.
Locally Acquired Food Sources	On some types of operations, there may be a requirement to purchase food stuffs from local sources. Caution should be exercised in relation to hygiene standards. Unit SOP may dictate the extent of local acquisition or ban it entirely.

General Combat Tactics

SECURITY
Tactics
General Combat Tactics

Exploiting Prevailing Weather	The tactical use of weather as a force multiplier has influenced many important battles throughout history, such as the Battle of Waterloo.
Fire Attacks	Reconnaissance by fire is used by apprehensive soldiers when they suspect the enemy is nearby.
Force Concentration	The practice of concentrating a military force against a portion of an enemy force.
Night Combat	Combat that takes place at night. It often requires more preparation than combat during daylight and can provide significant tactical advantages and disadvantages to both the attacker and defender.
Reconnaissance	A mission to obtain information by visual observation or other detection methods, about the activities and resources of the enemy or potential enemy, or about the meteorologic, hydrographic, or geographic characteristics of a particular area.
Smoke Screening	The practice of creating clouds of smoke positioned to provide concealment, allowing military forces to advance or retreat across open terrain without coming under direct fire from the enemy.

Tactics
cs

Small Unit Tactics

Individual Movement Techniques
Individual movement techniques or IMTs (also known as infantry minor tactics in Australia) are the most basic tactics that are employed at the fire team, squad, section or platoon level. They are similar in most modern armies. In most situations except static defence, IMTs are based on the principle of fire and movement. That is, firing and moving as fire teams, with one team suppressing (supporting) the enemy whilst the other moves either toward the enemy or to a more favourable position. The movement is often only 5–10 metres per move. When closing on the enemy position, the team breaks down into pairs for better angles of suppression, and this technique is referred to as "pepper-potting" (British/Commonwealth).

The United States Army focuses on the three individual movement techniques of high crawl, low crawl, and 3-5 second rush. Individual movement techniques are typically taught to all arms and services both in basic training and often also whilst undergoing non-infantry specialty training. In some military forces, such as the Australian Army, the entire British Armed Forces and the United States Military, all units in the field force regardless of corps, regiment, trade or specialty are supposed to undergo annual refresher training in IMTs, on the basis that all soldiers can be expected to at least provide local security for their unit.

Most IMTs are taught in the form of a battle drill, a series of choreographed steps that occur automatically in reaction to certain stimuli, such as sighting an enemy to the front, or being fired upon by an enemy from the flank. The initial stages of the drill are always the same and therefore action does not require full appraisal of the situation. Such stimulus-response training allows coordinated responses without the need for direct orders. In combat, this allows the first few moments of the engagement to occur almost automatically and gives the soldiers a way to respond appropriately and predictably while the unit commander evaluates the situation prior to issuing orders.

Fire and Movement	Working in 'fire teams', one team attempts to suppress the enemy while the other moves either toward the enemy or to a more favourable position.
Basic Drill	A standard drill that all individual soldiers are supposed to perform if they come under fire.

Topography Restrictions

Topography refers to the shape of the land surface. It includes the degree of slope and the surface material such as bare rock, fertile soil or loose sand. The surface can be covered or saturated with water, or dry. Each of these has a particular effect on military manoeuvre. The following are some effects of topography on military actions:

Topography

● Steeper slopes limit or deny access to vehicles and so access may be limited to dismounted soldiers or air insertion. For the dismounted soldier, movement is strenuous and the need to man-pack loads adds to the level of exertion required.
● At high elevations, the oxygen content of the air is less, making breathing difficult.
● On mountains, observation of close areas can be restricted, although elevated positions offer good observation of large parts of the surrounding area.
● Manoeuvre is restricted in mountain areas. Access is often only possible through naturally formed or artificially made tracks, passes and roads of various standards.
● Mountains can be lightly wooded on the lower slopes, becoming bare as the gradient increases. The bare areas provide little cover or concealment by vegetation but may contain caves and crevices that can be used as fire positions.
● Flat and undulating land offers good going for both foot and mounted forces, allowing large areas to be dominated but at the same time allowing rapid changes in the tactical situation as forces manoeuvre.
● Low land, particularly plains near rivers, is subject to flooding or at least water logging during heavy rain and with a reduction in accessibility.

● Soil conditions in desert areas vary from bare rock to gibber to loose sand. Equipment and tactics need to be modified and adapted to account for dusty and rugged landscapes that can damage suspensions or bog vehicles.
● All equipment is subject to abrasion from sand, and specific lubricants are used to avoid build-up of sand on weapons and so on. With the arrival of sandstorms, the levels of visibility can drop from 50 km to a few metres.
● The soil type affects the way in which soldiers 'dig in' in defensive positions, with special requirements for revetting in sandy soils to prevent collapse and a change to above-ground 'sangars' in rocky ground that cannot be excavated.
● In most parts of the world, the areas with better quality soil are cleared for cultivation. Cultivated areas include open farmland for crops and grazing, rice paddies, market gardens and plantations, or anywhere food or cash crops are grown.
● Some cultivated areas may not contain any crops but have been prepared for planting. Some of these areas have a water supply and are subject to inundation. Cultivated areas, whether cropped or recently ploughed, should be regarded as obstacles, as they provide little concealment, and signs of passage often remain obvious.

● For humanitarian reasons, these areas should be avoided (unless the mission requires their clearance), as local populations depend on these areas for their only source of food and sustainment. There may also be high levels of organic matter such as animal and human faeces leading to increased skin and generalised infection risk.
● Grazing areas generally have most of the larger vegetation removed to encourage the growth of natural grasses and cultivated improved pastures. Herds of domestic animals, like crops, should be avoided for humanitarian reasons and soldiers need to be aware of their position being given away by animal actions such as freezing and looking or stampeding.
● Beach landings across sandy beaches can present 'desert' conditions, at least for the first few metres, while in other areas the foreshore may be swampy and covered with mangroves and create the same challenges as a forest environment, or the terrain may be rugged.
● Operations on islands present particular challenges to the soldier. It is necessary to travel between islands in exposed boats and to disembark onto the shore. This is often difficult to do without detection and the transition from one form of transport to another is an ideal time for engagement. Sound landing drills and discipline are required to achieve success for the landing force.

● Wetlands are created by the rise of the water table beneath the soil, or by water from creeks and rivers flowing into a low-lying area. They also exist along the coast between the high and low tide levels. Wetlands include swamps and bogs, usually covered by specialised flora. In many cases there is little or no canopy or overhead cover but mangrove swamps are an exception to this. Wetlands provide very difficult going for both mounted and dismounted forces, and restrict manoeuvre.
● Forces will need to move from one terrain type to another during operations. For example, close country may be interspersed with cultivated areas, steep slopes, rivers and waterways, and patches of close country may occur in generally open country. The perimeters of urban terrain will interface with other terrain types. The change from one type of terrain to another necessitates changes in formation, mounting or dismounting and thus the threat level is heightened.

Vegetation

The types of plants existing in the natural environment are closely tied to the climate of the region. The following considerations apply to vegetation:

● The vegetation provides much of the concealment that soldiers need to maintain security, and its density and type varies. Camouflage must take account of the background.
● Close country is an area with dense vegetation, as found in temperate and tropical forests, and in jungle. Often the ground is relatively clear of undergrowth in forests but there is usually good overhead cover or canopy.
● Jungle refers to those areas in tropical rainforests adjacent to clearings or streams where the sunlight penetrates, causing the growth of a mass of vines and undergrowth. Indigenous populations in forest areas clear patches of forest for cultivation and this area reverts to jungle when abandoned.
● In both forest and jungle, there is limited observation and restricted fields of fire for most weapon systems. Close country inhibits mounted movement and requires separation of mounted and dismounted FE. Close country affords opportunities for deliberate or immediate ambush by either combatant.
● Open country is characterised by terrain that can be devoid of vegetation, through to savannah and grassland, with copses of lightly forested areas. A key feature of open country for the soldier is the lack of any significant overhead cover or canopy. Open country generally offers good observation in most directions and wide fields of fire for any weapon system.
● Some plants can be dangerous. Examples include gympie bush, a rainforest plant that has stinging barbs on its leaves and the branches of some eucalypts which can fall without warning, causing impact injuries.
● Some particular plants inhibit movement. Examples include 'wait-a-while' vines whose barbs catch on skin and clothing, the above-ground root systems of mangroves and moss that can make rocky surfaces very slippery.
● Water and food can be safely obtained from some plants such as palms and bamboo. This can be useful in survival situations if the soldier is well-trained in what is safe.

Animals

Generally, most animals will have little effect on military operations with the following being some significant exceptions:

● Animals startled by soldiers' actions can alert the enemy to their presence. Good knowledge of the behaviours of local animal populations can turn this to an advantage for either side.
● Poisonous animals exist on land and in the water. Bites from these can have effects ranging from discomfort to death. Also, the bites of many non-venomous animals can create infected wounds.
● Animals such as crocodiles, tigers and sharks can attack and kill humans.
● Some diseases are carried by animals and transmitted to humans through close contact or bites. Some examples of animals transmitting disease include paralysis tick, mosquito, dogs with rabies, rodents and any bird populations that are infected with avian influenza.
● Some diseases such as amoebic dysentery are caused directly by organisms (amoeba) ingested in impure drinking water.
● Diseases such as cholera and influenza are caused by bacteria and viruses respectively. These diseases can be contracted from airborne particles or direct contact with infected animals or persons.
● In a survival situation, many animals provide a source of food but care must be taken to cook the meat as un-domesticated animals are likely to contain parasites which can affect the consumer.

Deception

Sun Tzu said that all war is based on deception back in the 4th century BC; a wise commander takes measures to let his opponent only react to the wrong circumstances. Diversionary attacks, feints, decoys; there are thousands of tricks that have been successfully used, and still have a role in the future.

Perfidy	Combatants tend to have assumptions and ideas of rules and fair practices in combat, but the ones who raise surrender flags to lure their attackers in the open, or who act as stretcher bearers to deceive their targets, tend to be especially disliked.
False Flag	An ancient ruse de guerre – in the days of sail, it was permissible for a warship to fly the flag of an enemy power, so long as it properly hoisted its true colours before attacking. Wearing enemy uniforms and using enemy equipment to infiltrate or achieve surprise is also permissible though they can be punished as spies if caught behind enemy lines.
Demoralization	A process in psychological warfare that can encourage them to retreat, surrender, or defect rather than defeating them in combat.

Disinformation

Military Camouflage

Stealth Technology

Feint & Diversionary Attacks

Electronic Warfare

Electronic Countermeasures

Electronic Counter-Countermeasures	
Radio Silence	While travelling, a fleet will refrain from communicating by radio to avoid detection by enemy forces.

Force Multiplication

Use of Surprise

Parthian Shot	
Hit-and-Run Tactics	
Irregular Warfare	

Tactical Formation

The following are infantry tactical formations. The arrows indicate which the direction of travel is, or which way the individual faces if more than one arrow.

Column		Line		
Square		Wedge		Inverted Wedge		Echelon		Wedge		Vee		Staggered Column		Herringbone		
Military Movement

Route Selection
When patrolling, soldiers should be prepared for enemy contact by selecting a route that allows them to rapidly adopt a fire position that provides cover. When in contact prior to leaving a place of cover, the next position and the best route to it must be selected. The next position must be one from which the soldier can observe and engage the enemy while being covered from enemy fire (fire position). The route should, as much as possible, be clear of obstructions and be short enough to allow the soldier to complete it in less time than the enemy can be expected to take to acquire a sight picture. It must conform to the axis of advance. The method of movement (run, walk, crawl etc.) must be determined to match the tactical situation and the amount of cover available. To provide the section with all-round observation and protection, each soldier has an arc of responsibility. This arc is observed and covered with the weapon, while moving and when in a fire position. When not being engaged, the soldier will not actually adopt a fire position, but must be selecting positions so as to be prepared to do so if the enemy engages. Each soldier must choose the best route according to the threat and environment, using speed, deception and cover to continue advancing from fire position to fire position, planning each movement in advance.

Once engaged, the soldier applies the following basic drill: 1. run, 2. down, 3. crawl, 4. observe, 5. aim, 6. fire, and 7. move again.	Identification of Potential Enemy Positions. Identifying potential enemy positions assists in finding and planning the safest route and the locations that should be checked include: (1) positions of elevation such as dominating buildings and rooftops, high ground, towers, trees; (2) windows or other openings facing down the street; and (3) foliage, rubble, vehicles and industrial material that provide cover or concealment.
Blind Spaces	Each soldier must be aware that there are areas of the battlespace that are not visible to that soldier. However, with a dispersed fire team, other members of the team may be able to observe some or all of these areas. Figure 3–16 shows blind spaces associated with a single building. In urban terrain, there will be far more extensive areas of blind space. In thick vegetation, much of the area will be blind space.

Movement Methods

Movement Methods	Each soldier should know how to combine techniques of concealment and cover with movement in all environments. Different methods of movement are required for different heights of cover. The following are important considerations for any soldier planning to change position: ● a. Movement of foliage or stirred up dust can attract the enemy's attention. ● b. The reaction of local populations, animals or birds can attract attention. ● c. All movement should be covered by observation and the ability to apply fire from within the section. ● d. Movement during any distraction, such as loud noises or low flying aircraft can assist in covering movement. ● e. Fog, smoke, or haze can assist in concealment.
Patrolling	On a dismounted patrol, the method of movement is the walk. This is not just a stroll but involves deliberate movement between potential fire positions while maintaining observation and weapon orientation. It is important that the body is kept balanced in preparation for rapid deployment.
The Monkey Run	The monkey run is useful when moving behind low cover or through dead ground. The monkey run involves the following: ● a. holding the weapon in the master hand; ● b. using the non-master hand and feet (or knees) as a balanced three-point support to 'run' while keeping a low profile; and ● c. ensuring that observation is maintained.
The Leopard Crawl	The leopard crawl involves crawling on the elbows and the inside of the knees. It is useful when moving behind very low cover, when moving to a fire position and during the break-in and fight-through of an assault. It involves the following: ● a. holding the weapon with the master hand on the pistol grip with the butt over the forearm and the weapon balanced in the crook of the elbow of the non-master arm; and ● b. moving alternate elbows and knees, the weight of the body is carried on the forearm and the inner calves. The body is rolled slightly as each knee is bent. With the leopard crawl, the weapon is not immediately ready for use but the body is as low as possible. If it is necessary to have the weapon more readily available it can be held horizontal in front of your face. This will have the effect of raising the body somewhat and is more physically demanding. In either method, observation must be maintained.
The Stomach Crawl	The stomach crawl is a very quiet means of closing with the enemy used mainly at night. It is slow and tiring. Lie on the stomach and search the ground ahead for twigs, dry leaves and trip wires with the non-master hand. Lift the body on the forearms and toes, press the body forward, and lower it to the ground. The weapon should be moved with the master hand. As a result, this method should only be used when extreme caution is required or when crossing open ground with sparse cover. When using this method the head is pressed as close to the ground as is possible, and as a result frequent stops must be made in order to observe and listen.
The Roll	The roll is a very quick method of moving away from a position when already in the prone position. The arms and the weapon remain close to the body so that the body will roll quickly.
Rushing	The rush is the fastest means of moving from one position to another and is usually used when crossing ground that provides no cover while under enemy fire. It involves bursting quickly from cover as soon as covering fire is effective and moving as fast as possible by the shortest route to the new position, then applying the basic drill. When facing frontal fire, the soldier should zigzag to make it more difficult for the enemy to effectively aim their weapons. If enfilade fire is expected, a direct route will minimise the time of exposure.

Movement at Night

When using NFE, the vision through the NVG is tunnelled and thus the ground immediately in the soldier's path is not seen without moving the head. The monocular does not provide depth perception. Additional care must be taken to identify and avoid any hazards.

11 Strategy

Offensive

Air Superiority	Essential to a successful air campaign. It is achieved by 1) mastery of the air, 2) attacking the means of production, 3) maintain battle ourselves, 4) prevent the enemy from battle
Attrition Warfare	A strategy of wearing down the enemy to the point of collapse through continuous loss of personnel and material. Used to defeat enemies with low resources and high morale.
Bait and Bleed	To induce rival states to engage in a protracted war of attrition against each other "so that they bleed each other white", similar to the concept of divide and conquer.
Battle of Annihilation	The goal of destroying the enemy military in a single planned pivotal battle.
Bellum se ipsum alet	A strategy of feeding and supporting an army with the potentials of occupied territories.
Blitzkrieg	An attack that uses concentrated force and rapid speed to break through enemy lines, named after the German World War II strategy meaning Lightning War.
Blockade / Siege	An attempt to cut off food, supplies, war material or communications from a particular area by force, usually taking place by sea.
Clear and Hold	A counter-insurgency strategy.
Coercion	Compelling the enemy to involuntarily behave in a certain way by targeting the leadership, national communications, or political-economic centres.
Command of the Sea	The naval equivalent of air superiority.
Counter-Offensive	A strategic offensive taking place after the enemy's front line troops and reserves have been exhausted, and before the enemy has had the opportunity to assume new defensive positions. Tactic is usually implemented through surging at the enemy after their attack..

SECURITY	Strategy	Offensive		**Counterforce**	A strategy used in nuclear warfare of targeting military infrastructure (as opposed to civilian targets)
				Countervalue	The opposite of counterforce; targeting of enemy cities and civilian populations. Used to distract the enemy.
				Decapitation	Achieving strategic paralysis by targeting political leadership, command and control, strategic weapons, and critical economic nodes.
				Divide and Conquer	Bringing a large portion of one's own force to bear on small enemy units in sequence, rather than engaging the bulk of the enemy force all at once.
				Deception	A strategy that seeks to deceive, trick, or fool the enemy and create a false perception in a way that can be leveraged for a military advantage.
				Denial	A strategy that seeks to destroy the enemy's ability to wage war.
				Distraction	An attack by some of the force on one or two flanks, drawing up to a strong frontal attack by the rest of the force.
				Encirclement	Both a strategy and tactic designed to isolate and surround enemy forces.
				Ends, Ways, Means, Risk	Strategy is much like a three legged stool of ends, ways, means balanced on a plane of varying degree of risk
				Exhaustion	A strategy that seeks to erode the will or resources of a country.
				Feint	To draw attention to another point of the battle where little or nothing is going on.
				Flanking Manoeuvre	Involves attacking the opponent from the side, or rear.
				Guerrilla Tactics	Involves ambushes on enemy troops. Usually used by insurgency.
				Heavy Force	A counterinsurgency strategy that seeks to destroy an insurgency with overwhelming force while it is still in a manageable state.
				Human Wave Attack	An unprotected frontal attack where the attacker tries to move as many combatants as possible into engaging close range combat with the defender.
				Incentive	A strategy that uses incentives to gain cooperation.
				Indirect Approach	Dislocation is the aim of strategy. Direct attacks almost never work, one must first upset the enemy's equilibrium, fix weakness and attack strength, Eight rules of strategy: 1) adjust your ends to your means, 2) keep your object always in mind, 3) choose the line of the least expectation, 4) exploit the line of least resistance, 5) take the line of operations which offers the most alternatives, 6) ensure both plans and dispositions are flexible, 7) do not throw your weight into an opponent while he is on guard, 8) do not renew an attack along the same lines if an attack has failed.
				Interior Lines	Placing one's forces in between the enemy forces and attacking each in turn in order to allow one's forces to have better communications and allows one to mass all of one's forces against a part of the enemies.
				Limited War	A war in which the survival of a nation is not at stake.
				Penetration	A direct attack through enemy lines, then an attack on the rear once through.
				Periclean Strategy	The two basic principles of the "Periclean Grand Strategy" were the rejection of appeasement (in accordance with which he urged the Athenians not to revoke the Megarian Decree) and the avoidance of overextension.
				Persisting Strategy	A strategy that seeks to destroy the means by which the enemy sustains itself.
				Pincer Ambush	A "U"-shaped attack with the sides concealed and the middle held back until the enemy advances, at which point the concealed sides ambush them.
				Pincer Manoeuvre	Allowing the enemy to attack the centre, sometimes in a charge, then attacking the flanks of the charge.
				Punishment	A strategy that seeks to push a society beyond its economic and physiological breaking point.
				Rapid Decisive Operations	Compelling the adversary to undertake certain actions or denying the adversary the ability to coerce or attack others..
				Raiding	Attacking with the purpose of removing the enemy's supply or provisions.
				Refusing the Flank	lding back one side of the battle line to keep the enemy from engaging with that flank. The refused flank is held by smallest force necessary to hold out against the enemy's attack while concentrating the main battle force against the enemy's centre or other flank.
				Separation of Insurgents	A counterinsurgency strategy should first seek to separate the enemy from the population, then deny the enemy re-entry, and finally execute long enough to deny the insurgent access.
				Scorpion Attack	A pincer attack that is supplemented by an air strike.
				Shape, Clear, Hold, Build	The counterinsurgency theory that states the process of winning an insurgency is shape, clear, hold, build.
				Siege	Continuous attack by bombardment on a fortified position, usually by artillery.
				Shock and Awe	A military doctrine using overwhelming power to try to achieve rapid dominance over the enemy.
				Swarming	Military swarming involves the use of a decentralized force against an opponent, in a manner that emphasizes mobility, communication, unit autonomy and coordination/synchronization.
				Theatre Strategy	Concepts and courses of action directed toward securing the objectives of national and multinational policies and strategies through the synchronized and integrated employment of military forces and other instruments of national power.
				Total War	War in which a nation's survival is at stake.
				Troop Surge	Deploying a large number of troops into theatre in order to overcome resistance.
				Turning Manoeuvre	An attack that penetrates the enemy's flank, then curls into its rear to cut it off from home.

SECURITY Strategy Defensive

Win Without Fighting	Sun Tzu argued that a brilliant general was one that could win without killing anybody.

Defensive

Boxing Manoeuvre	Boxing manoeuvre – A strategy used to "box in" and force an attack on all sides at once.
Choke Point	A use of strategic geography, usually in a narrow area, intended to concentrate the enemy into a confined area where the defender can maximize his forces.
Defence in Depth	A strategy to delay rather than prevent the advance of the attackers by buying time and causing additional casualties by yielding space so that the momentum of the attack is lost and the attacking force can be attacked on its flanks.
Elastic Defence	A strategy to flexibly absorb then repel the advance of attackers through carefully planned integrated fighting positions, perfected by the German Army in WWI.
Fortification	A semi-permanent or permanent defensive structure that gives physical protection to a military unit.
Fabian Strategy	Wearing down the enemy by using attrition warfare and indirection, while avoiding pitched battles or frontal assaults. Named after Quintus Fabius Maximus Verrucosus in his defence against Carthage. See Pyrrhic warfare.
Military District	An area controlled by a military force, for administrative purposes rather than combat. Also known as Wehrkreis in German.
Scorched Earth	Destroying anything that might be of use to the enemy while retreating, or advancing.
Turtling	Continuous reinforcement of the military front until it has reached its full strength, then an attack with the now-superior force.
Withdrawal	A retreat of forces while maintaining contact with the enemy.

Concepts

Centre of Gravity	The hub of all power and movement on which everything depends, the point at which all energies should be directed.
Decisive Point	A geographic place, specific key event, critical system, or function that allows commanders to gain a marked advantage over an enemy and greatly influence the outcome of an attack.
DIME(FIL)	The elements of national power diplomacy, information, military, and economics, often included are financial, intelligence, and law enforcement see MIDLIFE.
Expediency	War is a matter of expedients – von Moltke.
Fog, Friction, Chance	War is characterized by fog, friction, and chance.
Golden Bridge	To leave an opponent an opportunity to withdraw in order to not force them to act out of desperation – Sun Tzu.
Iron Calculus of War	Resistance = Means x Will – Clausewitz.
MIDLIFE	The elements of national power diplomacy, information, military, and economics, often included are financial, intelligence, and law enforcement, see DIME(FIL).
Moral Ascendancy	Moral force is the trump card for any military event because as events change the human elements of war remain unchanged – Du Piq.
OODA Loop	Decision-making occurs in a recurring cycle of observe-orient-decide-act. An entity (whether an individual or an organization) that can process this cycle quickly, observing and reacting to unfolding events more rapidly than an opponent, can thereby "get inside" the opponent's decision cycle and gain the advantage – Boyd.
Paradoxical Nature	The nature of strategy is a paradoxical and does not follow a linear pattern – Luttwak.
Positive Ends	The possibility of taking advantage of a new security environment to create conditions for long-term peace – Wass de Czege
Primary Trinity	(1) primordial violence, hatred, and enmity; (2) the play of chance and probability; and (3) war's element of subordination to rational policy – Clausewitz.
Secondary Trinity	People, Army, and Government – Clausewitz.
Systems Approach	Nation-states operate like biological organisms composed of discrete systems. These systems included: leadership, organic essentials, infrastructure, population, and the military – Warden
Tipping Point	The point at which "the momentum for change becomes unstoppable." – Gladwell.
VUCA	Volatility, uncertainty, complexity and ambiguity characterize the strategic environment – U.S. Army War College.

Principles of War

Objective	Direct every military operation towards a clearly defined, decisive, and attainable objective.
Offensive	Seize, retain, and exploit the initiative.
Mass	Concentrate combat power at the decisive place and time.
Economy of Force	Allocate minimum essential combat power to secondary efforts.
Manoeuvre	Place the enemy in a disadvantageous position through the flexible application of combat power.
Unity of Command	For every Objective, ensure Unity of effort under one responsible commander.
Security	Never permit the enemy to acquire an unexpected advantage.

Surprise	Strike the enemy at a time, at a place, or in a manner for which he is unprepared.
Simplicity	Prepare clear, uncomplicated plans and clear, concise orders to ensure thorough understanding

Weinberger-Powell Doctrine

A list of questions have to be answered affirmatively before military action is taken by the United States.

- Is a vital national security interest threatened?
- Do we have a clear attainable objective?
- Have the risks and costs been fully and frankly analysed?
- Have all other non-violent policy means been fully exhausted?
- Is there a plausible exit strategy to avoid endless entanglement?
- Have the consequences of our action been fully considered?
- Is the action supported by the people?
- Do we have genuine broad international support?

Economic Concepts

- Always pay your troops on time.
- Ensure the cost of enemy losses (or objectives) is at least an order of magnitude higher than the costs of attacking.
- Ensure there is sufficient funds and revenue streams to finish the war.

12 Evasion

How to escape and keep evading people, search dogs, gangs or even the government.

Escaping

How to escape from a location if you're being held against your will, such as a prison or concentration camp.

Evading

How to evade authorities, governments or search parties who are actively looking for you.

Changing Identity

How to change your identity to help prevent detection and keep you ahead of any pursuers.

Removing Your Digital Presence

The first step in changing your identity is to eliminate all personal electronic devices which can give away your future identity. Governments can easily track the location of your phone - even when it's off, they can take pictures with your phone and can listen in to calls and can listen in even if you're not on a call. If you're dedicated to changing your identity you may have to give up on a phone and comunication technology altogether. If you know you're being tracked you may want to leave your phone with a friend to make it look like you're just going about your daily life as normal to give you more time to complete the identity change.

Items that can track you today:
- Mobile Phone - Can track you via GPS, WiFi, Bluetooth, Cameras and the Microphone.
- Smart Watches and Health Devices - Can link to mobile phones and track you in all the same ways and more, including heart rate.
- Bank Cards - Once a transaction is made they can positively identify you are in that area.
- Cars - Some cars have tracking software, but particularly hired cars.
- Computers - Computers and laptops can be used to identify your position via IP addresses and WiFi as well as any attached cameras.
- Swipe Cards - Such as those used for entering buildings such as Gyms and office buildings will give away your position.

Changing Your Appearance

Changing your appearance is the next step in changing your identity. Robin Williams was lucky enough to have his own make-up artists and mask builders in 'Mrs Doubtfire', but you probably won't have any contacts like that who will keep your new identity a secret. Therefore you will likely have to make all these changes yourself. The main goal of this step is to make you look 'generic' and boring with no easily identifiable features.

Here's a list of recommended changes you can make to help you look like a new person:
- Full Face Mask - If you want to go all the way you could use a full-face mask like the ones used in Mission Impossible or Mrs Doubtfire.
- Hair Length - It's easier to go shorter than longer, however wigs are an option.
- Hair Colour - Change the colour of your hair, or wear a coloured wig as mentioned above.
- Haircut Style - Change the style of your haircut to something radically different.
- Glasses - If you wear glasses, try to move to contacts, or if you don't try wearing glasses that just look prescription, sunglasses are another good option.
- Eye Colour - This can be done with contact lenses.
- Makeup - Wear some makeup and eyeliner if you don't usually and go without if you normally do.
- Facial Hair - Try growing it out or shortening it if you're able.
- Bling - Change around the items you wear on your body like necklaces, watches, rings and bangles.
- Piercings - If you have some piercings remove them, and if you don't try adding clip-on ones.
- Tattoos - Removing tattoos is difficult but can be done to some extent. If you don't have any, you could buy some temporary tattoos.
- Body Mass - You could add some stuffing for a little extra body mass if you're a thin or average build.
- Clothing - Change your clothing style entirely, something generic and plain with no words, brands, symbols or band names etc.

There are quite a few additional things you can change about yourself to make you harder to detect such as:
- Always wear sunglasses in public - This will greatly reduce your chance of getting a visual match on your face, particularly if they are large aviators.
- Always wear a hat in public - This can eliminate the chance that cameras high up will match your face.
- Wearing a particle mask such as most of the population in China could reduce your chances of a camera identifying you.

Changing Your Locality

There's no point in changing your identity if you hang out in all the old places you usually do. The next step is to 'secretly' move house without letting others know. This is the point where being a minimalist would come in extremely handy, when you can pack everything you own into a single car or backpack. You may have to pre-arrange to live with a (distant) friend or family member both in terms of your relationship with them and their distance away from your current place. The most ideal location would be somewhere in the bush in a small town where there's little digital surveillance.

Changing Your Accent

Changing an accent is quite difficult to do, but can be done with enough practise and repetition. Try watching YouTube videos on the desired accent you want to achieve, however as per the first step above, it's recommended you download these videos before starting your identity change or they may be able to trace you. Better yet, if you can speak a second language, you could only speak that and pretend you don't speak your original one. Alternatively you could learn a new language from scratch and exclusively speak that.

Changing Your Personality

Changing your personality is another difficult one to accomplish since it's hardwired into you from birth. Over time though you can slowly forge a new personality. There is a list of personalities in the POPULATION > Personalities section which you can go through to choose one you feel you can emulate.

Changing Your Mannerisms

There are cameras in China that can identify you by the way you walk. To fully hide from this kind of technology within a city you will need to change every aspect about the way your move, including your unconscious mannerisms. This is probably the hardest part of the journey as you often don't realize you do them such as writing left or right handed.

Speech Mannerisms	● Uses a falling inflection ● Ends sentences with question marks ● Speaks in a whisper ● Always talks over others ● Tendency to mumble ● Slurs words, even when sober ● Has a sing-song speech pattern	● Shortness of breath from talking too fast ● Unnecessary or exaggerated throat clearing ● Deep breaths between every sentence ● Constantly swallowing when nervous ● Heavy reliance on buffer words: “Like,” “Um,” “Uh,” “Totally,” “Basically,” “You know”	
Noise Mannerisms	● Whistling ● Humming ● Sighing ● Stuttering ● Coughing ● Scoffing	● Laughter to fill in uncomfortable silences ● Muttering to oneself ● Noisy breathing ● “Sorry” ● “Tsk” ● “God”	
Head Mannerisms	● Tilting head in thought ● Hair tossing ● Hair playing or twirling when flirting ● Head bobbing while listening to music ● Grinding teeth ● Scratching the head ● Flaring nostrils	● Rubbing the neck when embarrassed ● Raised eyebrows ● Head on the chin in resting position ● Jaw clenching in moments of tension ● Sweating excessively ● Jutted chin ● Nose twitching or wrinkling	
Mouth Mannerisms	● Smacking lips in satisfaction ● Mouthing the lyrics of a song ● Licking the lips when nervous ● Sticking out the tongue while thinking ● Counting teeth with the tongue when distracted	● Biting the bottom lip ● Pulling at the bottom lip ● Biting the inside of the cheek ● Movement of the mouth: quivering, curling, pursed, twitching, tensed	
Eye Mannerisms	● Sideways glance ● Likes to wink ● Fluttering eyelids ● Tendency to look down one’s nose ● Eyes that dart everywhere ● Tendency to avoid eye contact ● Always breaking eye contact ● Prolonged eye contact in conversation	● Looking down at feet while walking ● Rapid blinking when lying ● Frequently gazes off into space ● Has a thousand-yard stare ● Movement of the eyes: rolling, squinting, twitching ● Description of the eyes: wide, glassy, crossed, dilated, narrowed	
Hand Mannerisms	● Movement of the index finger: pointing, jabbing downwards, stabbing the air ● Arms crossed over chest ● Pinching the bridge of the nose ● Rubbing the temple ● Stroking chin in thought ● Tracing scars without thinking ● Standing with hands clasped behind back ● Doodling absently ● Wiping clammy hands ● Tightly clenched hands ● Running a hand through the hair	● Standing with hands in pocket ● Picking or pinching at the flesh ● Covering mouth with a hand when smiling ● Rubbing the tips of fingers together ● Hooking a thumb in pockets while standing ● Braiding hair automatically ● Covering mouth while chewing or laughing ● Passing a hand over the face when tired ● Flexing fingers and cracking knuckles ● Drumming fingers on a surface or twiddling thumbs ● Swinging arms back and forth when walking	● Steepled hands ● Snapping fingers ● Rubbing the eyes ● Touching the nose ● Tugging at ear ● Wild gesturing while talking ● Biting fingernails
Upper Body Mannerisms	● Shrugging shoulders ● Dropping shoulders ● Swaying while standing	● Slouching, slumping posture ● Tight, drawn-in shoulders when sitting ● Broad stance when standing	

Leg Mannerisms	● Crossing legs when sitting ● Foot drags while walking ● Foot stamping ● Foot tapping ● Legs will uncontrollably shake ● Strides quickly when walking ● Stands too close to others when talking	● Knees knocking against each other ● Rocking back and forth on heels ● Shifting weight from one foot to the other ● Pacing back and forth in a room ● Sitting, legs apart ● Bouncing leg up and down in a chair	
Interactive Mannerisms	● Adjusting or pushing up glasses ● Putting earpiece of glasses in mouth ● Has a cigarette always dangling out of mouth ● Always buttoning and unbuttoning coat ● Always sitting on the very edge of chair ● Hands habitually on coat lapels ● Chewing the tip of a pen or pencil ● Jingling money in pockets ● Playing with the marker ● Tugging at pants before sitting ● Tearing at a napkin at the table ● Checking watch repeatedly	● Using a toothpick at all times ● Touching up makeup constantly ● Repeatedly checking cell phone ● Twirling a pencil at a desk ● Clicking a ballpoint pen open and close ● Playing with a Rubix Cube when bored ● Shredding paper without thinking ● Peeling labels from bottles ● Bending paperclips in half ● Twisting the rings on fingers ● Leaning against the wall while talking ● Tugging at collar of shirt when nervous	● Peering over glasses ● Tipping chair back ● Cleaning their glasses ● Fiddling with earrings ● Smacking gum

Changing Your Identification

If you still use your old documentation such as a birth certificate and drivers licence you will need to secure new (faked) forms of identification. This would be amazingly simple if you have an identical twin, but unfortunately most people don't.

Changing Your DNA

Unfortunately changing your DNA isn't possible. The alternative is to try to make as little contact as possible with the surfaces you interact with. In the 1997 movie Gattaca, DNA and any evidence of Vincent's existence was methodically cleaned, vacuumed and wiped after doing anything. It may be extreme, but if you need to do this, it's certainly an option.

Shadowing

Shadowing is covertly following a person without being detected in one instance or over multiple instances usually to obtain information or to find an opportunity to confront them. It's generally used to gather intelligence on the 'mark'.

Being Stalked

Being stalked is a pattern of unwanted behaviour where an individual (who often knows the person) is tracking someone's movements over a period. The perpetrator's intent is to harass, intimidate, control, threaten, or cause fear or distress to the victim.

Behaviors (can include, but are not limited to):
● Repeatedly following or loitering near someone (at home, work, places they frequent).
● Unwanted contact through any means: repeated calls, texts, emails, social media messages, letters, unwanted gifts.
● Surveillance: Watching, monitoring, or tracking a person's movements, activities, or communications (including using technology like GPS trackers, spyware, or constantly checking social media).
● Interfering with property: Vandalism, leaving unwanted items.
● Making threats: Direct or indirect threats of harm to the person, their loved ones, or pets.
● Spreading rumors or publishing private information.
● Using third parties to contact or gather information about the victim.

If you suspect you are being stalked, it's crucial to document all incidents (dates, times, locations, descriptions of behavior, screenshots of messages) and seek assistance from law enforcement or support organizations.

Being Followed

Being followed is generally worse than being stalked and implies that the follower doesn't want to be noticed and that they want to do something to cause harm in the opportune moment. They almost always have a line of sight or multiple people to tag in and out with. They may be watching you over the period of a few minutes or keeping tabs on you for over a year. The intent may be innocent, such as wanting to return an item you dropped, or they recognised you from years ago, but oftentimes they want to physically harm the individual - or see them as a target.

Threats can follow you many different ways, these are some of the different combinations.
● You're on foot - the suspect is on foot
● You're on foot - the suspect is in a car
● You're in a car - the suspect is on foot
● You're in a car - the suspect is in a car
● You're stationery (at home) - the suspect is watching from a car
● You're stationery (at home) - the suspect is watching from a nearby building

Terms

Some of the terms used when being followed.

Rough Shadowed	A private investigations industry term that means following someone at close range with the intent of being noticed.
Piggybacking	Two people or cars take turns following you to avoid suspicion.
Caltrops (In a Vehicle)	Always have one side facing up which will puncture tires if driven over. Keep a box in your car for emergencies.

Followed Confirmation

SECURITY Evasion Being Followed

Followed Confirmation

How to tell if you're being followed.

Spotting Someone Multiple Times	If you notice someone three times during your outing, chances are that it might be more than just coincidence. It may that someone is following you and time to change your situational awareness level from condition Yellow to condition Orange.
Someone Matches Your Speed	If someone behind you is continually matching your pace, the alarm bells should ring. The situation will become more revealing if you change your pace several times and the follower continues to match. Chances are that someone is following you.
Excessive Eye Contact	You can't help but make eye contact with others while out in public. There's a normality about making eye contact with a stranger. But when eye contact is "too long" and especially when there are multiple occurrences, you know you're being focused upon. Exception: Some of you gals may simply appear "hot", and I'm sure you're used to being stared at occasionally. You might look at it as a blessing rather than a curse. However don't dismiss it quickly, raise your alert to condition Orange as well.

Action Plan

Immediately upon recognizing that you're being followed, change your posture to one of confidence. Some people tend to slouch and appear weak. If that's you, walk tall. Shoulders back and head up. Criminals look for weak prey, not strong prey.

● Move to a location with more people around, this will help unsettle the pursuer with more witnesses if something happens.
● Slow down, stop, and turn around or sideways. Appear as though you are looking for someone else. Then look right at the person who you suspect is following you. This sudden turn of events may likely thwart the follower who will move on.
● You might turn and confront the follower using your choice of WTF verbiage. Again, most non-professional criminals are looking for an easy target. When you confront them, you are no longer an easy target.
● If you're walking alone and see people nearby walk up them if they look friendly and start chatting to one of them making it seem like you know them.
● Stay in well lit areas, or at night head towards a populated or well secured building such as a bars, banks, police stations, casinos or hospitals which often have security guards nearby.
● Check reflective surfaces instead of looking behind you to gauge if you're being followed.
● Caution: Some people are just plain crazy and arguably shouldn't be out in public. Often it's easy to tell if someone fits in this category. Best not to confront them. Use your best judgement. Not everyone can present a firm, confident, or even threatening posture under the circumstances of confrontation.

Losing a Tail

Use mass transit to your advantage by slipping amongst the people and abruptly changing directions every so often until you lose them. Cause distractions to put the pursuer off their game and become the centre of attention. Change the pursuers mental image of you by removing your jacket or putting on a hat when they've lost sight of you for a second.

Being Tracked

Being tracked is slightly different to being followed. Tracked means that your pursuer has no line of sight to you or which direction you may have gone in. Tracking can even occur days after you've been through that area. Trackers commonly use sniffer dogs to find a scent and follow it.

Search Dogs	While search and rescue dogs are capable, in principle, of being trained as both air scent and trailing dogs, most dog handlers train their dogs to perform only one of these disciplines. Therefore, the most valuable dog team, in terms of obtaining a high probability of detection, is one with a dog that can switch back and forth between air scenting and trailing as conditions dictate. All humans, alive or dead, constantly emit microscopic particles bearing human scent. Millions of these are airborne and are carried by the wind for considerable distances.
Air Scent Dogs	The air scent dog is the type most frequently encountered. This dog finds lost people by picking up traces of human scent that are drifting in the air, and looks for the "cone" of scent where it is most concentrated. This dog will not normally discriminate scents, so there is the possibility of a "false alarm" if other people (searchers, citizens) are nearby. Airscent dogs work best in situations such as large parks or private lands that are closed at the time, since the dog will home in on any human scent. The success of an air scent dog will be affected by a number of factors, including wind conditions, air temperature, time of day, terrain, and presence or absence of contamination (auto exhaust, smoke, etc.). The best conditions for air scent dogs to work are early mornings or late afternoons on cool, cloudy days when there is a light wind.
Trailing Dogs	The trailing dog is often referred to as a "tracking" dog, although "tracking" and "trailing" are not the same to the purist. The trailing dog is directed to find a specific person by following minute particles of human tissue or skin cells cast off by the person as he or she travels. These heavier-than-air particles, which contain this person's scent, will normally be close to the ground or on nearby foliage, so the trailing dog will frequently have its "nose the ground," unlike the air scent dog. A Bloodhound is typically trained for scent discrimination. Each dog is usually worked in a harness, on a leash, and given an uncontaminated scent article (such as a piece of clothing) belonging to the missing person. The dog follows that scent and no other. At times, the dog may track, following the person's footsteps, or air scent, and home in on the subject's scent. Field contamination (scent of others) should not affect his work. He should be able to trail scents on pavements, streets, grass, water, etc. If there is a good scent article and a point where the person was last seen, a trailing dog can be the fastest way to find the victim. Without the scent article and a point where the person was last seen, these dogs cannot work effectively. While those are the two standard types of search and rescue dogs, there are also other dogs trained to find lost people.
Tracker Dog	A tracking dog is trained to follow the path of a certain person. It physically tracks the path of the person, without relying on air scenting. This dog is usually worked in a harness and on leash. This type of dog is effective when pursuing an escaped criminal if no scent article is available. These dogs are also used successfully in search and rescue operations.
Disaster Dog	A disaster dog is trained to find human scent in very unnatural environments, including collapsed structures and areas effected by tornadoes, earthquakes and other disasters. This dog is trained to work on unstable surfaces, in small, confined spaces and other settings not usually found in the wilderness.
Cadaver Dog	A cadaver dog reacts to the scent of a dead human. The dog can be trained for above ground and buried cadaver searches. Although many dogs have the potential to detect human scent, whether dead or alive, the cadaver dog is trained to locate only human remains. The training process includes detection of very minute pieces of cadaver or even blood drops in a specified area.
Water Search Dog	A water search dog is trained to detect human scent that is in or under the water, focusing on the scent of the bodily gases that rise up. As a team, the handler and dog usually work in a boat or along the shoreline. Because of currents and general changes in the water, it can be hard to pinpoint the location of a body. To enhance the chance of location, a diver should be ready to search as soon as the dog indicates. Additional teams, unaware of the previous teams' findings, work independently to indicate a location. This allows team members to determine the most likely location of the body.
Avalanche Dog	An avalanche search dog is trained to detect human scent that is in or under snow, subsequent to an avalanche. These dogs are trained to detect the scent under many feet of snow, sometimes, 15 feet or more!

Materials

Uses and types of materials such as wood, metal and plastic

"Make the workmanship surpass the materials."
Ovid

Introduction

There are virtually an infinite number of materials in the world which can be used, reused and recycled for different purposes. The below items are highly useful for survival situations and have multiple uses. These items could be seen as a list of items to look out for when looting a building depending on your current needs.

Purpose	The aim of MATERIALS is to provide you with a foundational knowledge of the basic elements and materials on earth and the composite materials created from them. It also goes into depth about alternative preparedness uses for items you may have at home which may save your life in a survival situation.
Lost?	● If you wish to craft items from materials, see the CRAFTING section. ● For a list of modern manufactured items and their uses, see the GEAR section. ● For the recommended gear and materials you should grab when scavenging, see the LOCATIONS section. ● For information on materials found in the whild which can be used for crafting, see the SURVIVAL section. ● For information on foraging plants and materials, see the PLANTS > Foraging section. ● For a list of electrical componentry and their uses, see the ELECTRICITY section. ● For more information on wood, see the FUEL and CRAFTING > Woodworking sections.

2 Chemistry

How to create chemical compounds.

Chemical Equivalency

A list of alternative chemicals that are required in some nefarious projects such as creating explosives. Some of the chemicals can be found around the house and are easily accessible.

Acacia Gum Arabic	**Acetic Acid** Vinegar	**Aluminium Oxide** Alumina	**Aluminium Potassium Sulphate** Alum	**Aluminium Sulphate** Alum	**Ammonium Carbonate** Hartshorn	**Ammonium Hydroxide** Ammonia	**Ammonium Nitrate** Salt Peter	**Ammonium Oleate** Ammonia Soap	**Amylacetate** Banana Oil	**Barium Sulphide** Black Ash	**Carbon Carbinate** Chalk
Carbontetrachloride Cleaning Fluid	**Calcium Hypochloride** Bleaching Powder	**Calcium Oxide** Lime	**Calcium Sulphate** Plaster of Paris	**Carbonic Acid** Seltzer	**Cetyltrimethylammoniumbromide** Ammonium Salt	**Ethylinedichloride** Dutch Fluid	**Ferric Oxide** Iron Rust	**Furfuraldehyde** Bran Oil	**Glucose** Corn Syrup	**Graphite** Pencil Lead	**Hydrochloric Acid** Muriatic Acid
Hydrogen Peroxide Peroxide	**Lead Acetate** Sugar of Lead	**Lead Tero-Oxide** Red Lead	**Magnesium Silicate** Talc	**Magnesium Sulphate** Epsom Salt	**Methylsalicylate** Winter Green Oil	**Naphthalene** Mothballs	**Phenol** Carbolic Acid	**Potassium Bicarbonate** Cream of Tarter	**Potassium Chromium Sulphate** Chromealum	**Potassium Nitrate** Salt Peter	**Sodium Oxide** Sand
Sodium Bicarbonate Baking Soda	**Sodium Borate** Borax	**Sodium Carbonate** Washing Soda	**Sodium Chloride** Salt	**Sodium Hydroxide** Lye	**Sodium Silicate** Glass	**Sodium Sulphate** Glauber's Salt	**Sodium Thiosulfate** Photographer's Hypo	**Sulphuric Acid** Battery Acid	**Sucrose** Cane Sugar	**Zinc Chloride** Tinner's Fluid	**Zinc Sulphate** White Vitriol

3 Alternative Uses

This is a list of alternative survival or prepping uses for common items.

Ingredients

Salt

Detaching Leeches	Leeches literally fall from your body within seconds when salt is poured onto them.
Supplemental Use	
Water Purification	Salt can be used with water and electricity to generate chlorine. See the Water Section.
Preserving Food	Salt is a natural preserver and salting meats will help them last longer.
Boiling Water	
Cleaning	• Antibacterial Agent
Medicinal Uses	• Soothes Sore Throats • Topical Treatment • Diuretic
Melting Ice / Snow	
Killing Bacteria	
Removing Rust	
Preventing Cheese Mould	
Prevent Iodine Problems	
Test Egg Freshness	
Cleaning Metals	
Scaling Fish	
Cooking With	

Sugar

Fermentation	Allows the brewing of beers and other alcoholic drinks.
Energy	Sugar gives you short bursts of energy.
Medicinal Uses	• Helps Hydration • Skin Healing • Helps Diabetics
Fuel	Sugar can be fermented into alcohol to create fuels.

Honey

Energy	Honey gives you short bursts of energy.
Medicinal Use	• Wound Healing • Wound Protection • Soothes Throat • Burn Care
Maintaining Blood Sugar	
Healing Properties	

Vinegar

Lemons

Alcohol

Drinking	Drowns your sorrows.
Killing Germs	Kills basically all germs on contact within 10 seconds.
Firelighting	Can be lit with a flame, spark or an electric arc.
Self Defence	Can be turned into a molotov cocktail, lit and thrown at an enemy.

Cooking Oil

Corn Starch

Baking Soda

Cayenne Pepper

Stops Bleeding	
Helps Digestion	One of the major cayenne pepper benefits is the positive effect it has on the digestive system.
Migraine Relief	Researchers suggest that cayenne pepper, due to its spice, is able to stimulate a pain response in a different part of the body.
Prevents Blood Clots	Blood clots are blockages in your arteries and blood vessels that limit blood flow through your circulatory system.
Prevents Allergies	Because cayenne is an anti-inflammatory agent, it has the power to prevent allergies and the symptoms related to allergies.

Kitchen Materials

Hydrogen Peroxide

Water Purification	It can be used to purify water by killing pathogens.
Cleaning Wounds	It can be used to clean wounds and kill most pathogens.

Iodine

Water Purification	Iodine can be used to purify water by killing pathogens.

Tinfoil

Light Reflector / Signaller	The reflective properties of tinfoil can be used as a signalling device.
Water Container	It can be used to hold water temporarily.
SODIS Reflector	Place behind a clear bottle to reflect the suns rays back through the bottle to improve SODIS effectiveness.
Heat Reflector	Can be used to reflect heat towards or away from something.
Pot Lid	Used as a lid to keep the heat in thus boiling water faster.

Garbage Bag

Rain Poncho	Can be used for rain protection if nothing else is available.
Water Collector	Can be used to collect rainwater.
Water Container	Store water in the bag for later.
Roof Material	Useful to prevent rain entering your shelter.
Solar Still	Used to obtain water from the ground via a solar still.

Chopsticks

Eating	Used for eating with instead of other utensils.
Tent Pegs	Makeshift tent pegs which will secure your tent better than nothing.
Snares	Can be used to make snares and traps.
Hunting	
Medicinal Uses	• Splint • Tongue Depressor
Kindling	Can be used for kindling in an emergency. (Unless metal)

Aspirin

Pain Treatment	Reduces the amount of pain of an injury or headache.

Tin Cans

Water Storage	Water can be stored and boiled in cans then saved for later use.

Ziplock Bags

Water Storage	These can hold water and can also be used for SODIS.
Kit Bags	They are great at holding smaller loose items and weigh nothing.

Plastic Bottles

Storing Water	Perfect for storing water.
SODIS	Plastic bottles (if clear) can be used for purifying water via SODIS.

Coffee Filters

Filtering Water	You can filter water through a coffee filter to remover larger particulate.

Filtering Coffee	Its default purpose.
Particle Mask	If taped to your face it can be used to remove larger particulate from the air such as dust and dirt.

Drinking Straws

Drinking Hot Water	If recently boiled water isn't cool yet, you might be able to drink it early if sipped through a straw.
Fire Bellows	Can be used to stoke a fire by blowing through the straw at the base of a fire.

Wax

Candle Making	As always it can be used for making candles.
Soap Making	

Bathroom Materials

Safety Pins

Fish Hooks	Can be used for catching fish if bent into shape.
Medicinal Uses	• A Needle • Closing Wounds
Securing	Securing clothes together or other items.
Repairing Clothes	Pins can be used to temporarily repair clothes or to prevent them tearing more.
Starting a Fire w/Battery	When placed between the contacts of a battery it will heat up greatly and can be used to start a fire.
Toothpick	You can use it to remove food from your teeth.

Bobby Pins

Unlubricated Condoms

Water Bag	They can hold about 1L of water when extended, but ensure they are unlubricated.
Sex	They can be used for their original purpose, as people will still be doing it.

Tampons

Wound Control	Tampons can be placed in gunshot wounds to prevent excessive bleeding.
Water Filter	You can use a tampon as a water filter if the water flows through it. It won't remove viruses or most bacteria however.
Tinder	Once fluffed up it makes great tinder.
Candle Wick	Use the string from the tampon in animal fat to create a candle.
Female Requirements	

Zote Soap

Dental Floss

String	Could be used to tie things together.
Flossing	As always it can be used to clean your teeth.
Fishing	Can be used as a replacement fishing line.

Mouthwash

Killing Germs	

Isopropyl Alcohol

Killing Germs	Alcohol as always will kill bacteria on any surfaces it comes in contact with.
Cleaning Surfaces	Cleans marks off most surfaces.
Firelighting	Lights extremely easily with any spark.
Sterilization	It can be used to sterilize medical equipment.

Epsom Salt (Magnesium Sulphate)

Foot Soak	
Medicinal Uses	• A Laxative • Topical Agent • Remove Splinters
Gardening	• Fertilizer

Zote Soap

Activated Charcoal

Poison Extractor	Consume with water to absorb toxins in the body.
Water Purifier	Removes bad odour and taste from water.

Hand Sanitiser

Killing Bacteria	
Firelighting	

Dental Floss

Laundry Materials

Borax

Petroleum Jelly (Vaseline)

Firestarter	When combined with a fibrous material it's great for light with a spark.
Lip Balm	Can be used on chapped lips to prevent further damage.
Rash Treatment	
Seam Sealant	Useful to seal small tears and rips to prevent the ingress of water.

Silica Gel

Bleach

Cleaning	Great for cleaning surfaces and sterilizing items.
Killing Bacteria	Kills pathogens on any surface it touches within 10 seconds.
Purifying Water	Adding 1 drop of unscented bleach per litre can kill pathogens.

Bandana

Water Filter	You can fold it over multiple times and use it to filter particulate out of water.
Air Filter	Filters the air of larger particles such as dust or dirt.

Bucket

Transporting	Buckets are great at transporting water, gear, sand, rocks or anything you need to move.
Storage Container	It can be used to store items for a later date, including water if it's sealed properly.

Chalk

Quick Lime

Garage Materials

Duct Tape

Sealing Holes	Great for sealing holes in tents, tarps etc.
Water Container	Can be used to make water containers or collection bowls.
Medical Tape	You can tape up wounds and broken bones to prevent them from moving if you don't have anything else.
Repairing Objects	Can repair objects like shoes when you can't find more suitable materials.
Securing	It can secure items to other items.
Signalling	You can form words on a beach if you need rescuing.

Paracord

Attaching	Attach items together to hold them.
Shelter Building	Use paracord to lash together some sticks for a shelter.
Tinder	Split the strands to create a flammable tinder.

Steel Wool

Cleaning	Steel wool can make a great scrubbing utensil.
Firelighting	Generates heat and flames when a battery connects strands of fine steel wool.

Superglue

Closing Wounds	You can glue open wounds together.
Bonding Items	Glues items together.

WD-40

Lubricating	Lubricate mechanical items so they function properly.
Self Defence	Spraying a stream into fire will create a flamethrower.
Firelighting	Spraying some onto wood will make it easy to light.

Zip Ties

Securing	Used to secure items to other items.
Handcuffs	Can be used to restrain people provided they are long enough.

Nails / Screws

Hanging Items	Can be used to hang items from walls or trees.
Securing Items	Secures items to something else such as planks against a door.

PVC Pipe

Plumbing	Used as its primary purpose to direct liquids.
Creating Caches	When cut and capped it can be used to store gear watertight underground.

Tarpaulin

Shelter Building	Used as a shelter building material in the wild.
Shelter Roofing	Used to keep the rain off you or to repair a hole in the roof.
Water Collection	It can be placed on the ground to collect or divert water.
Solar Still	When placed over groundwater in the sun, it can heat it up and allow collection of it.

Plastic Sheeting

Water Collection	
Blackout Sheeting	
Solar Still	
Virus Barrier	

Latex Tubing

Slingshot	When combined with a Y stick it can make a slingshot.
Straw	A long rubbery straw, but still a straw.
Binding Items	It can be used to firmly attach two items together.
Belt	Can be used to hold your pants up if required.
Tourniquet	If tightened enough it could stop blood flow.

Pry Bar

Breaking Things	Perfect for smashing and breaking down objects.
Prying	You can separate two objects if they don't want to come apart or haven't been opened in a long time.
Weapon	Make a formidable weapon.

Kerosene

Fuel	Works well with a wick to produce light.

External Materials

Hose

Liquid Transfer	Great for transferring liquids between locations.

Wooden Fence

Firewood	Wooden fences can be used as firewood if you're desperate.
Door Braces	You can hammer the planks to your door to prevent people gaining entry.

Natural Materials

Bamboo

Structural Beam	Bamboo is great for construction beams.
Spear	It can be sharpened to a spear for a formidable weapon.
Water Container	It can be used to store water in its sections if cleaned out.
Piping	It can direct the flow of liquids if split in half and overlapped.

4 Types of Materials

Knowledge of materials allows for comparison of everyday materials, e.g. different kinds of wood, rock, metal, paper, plastic, on the basis of their properties, including hardness, strength, flexibility and magnetic behaviour, and to relate these properties to everyday uses of the materials. The following sections will detail the types of materials and any subcategories.

Wood	Wood is a composite material made from lignin and cellulose. Wood makes use of a lignin matrix and cellulose fibres to form a polymer composite. The lignin holds the cellulose compressively in place so that the cellulose fibres can carry tensile loads. Wood has excellent structural properties, in light of its low weight and high strength.
Metal	Metals are comparatively malleable, optically reflective, and electrically conductive. Most metals and alloys are easily shaped by forming. Their disassociate electron bonding makes them excellent conductors of electricity and heat. Almost all metals have an orderly arrangement of atoms, resulting in a crystalline structure that may have multiple crystal phases bordering each other.
Polymer & Plastic	Plastics/polymers are made up of millions of repeated links to make long molecules or networks that are tangled or cross linked together. Almost all polymers use carbon atoms in very long chains. The carbon atoms may be attached to other carbon, oxygen, nitrogen, and hydrogen atoms. Polymers may or may not have an orderly arrangement of atoms.
Ceramic	A ceramic is a non-metallic material composed of inorganic molecules, normally prepared by heating a powder or slurry. Many common ceramics are made up of oxides or nitride compounds and are highly crystalline with long-range molecular order. Some ceramics are partially or fully amorphous, with no long-range molecular order; these are typically classified as glassy materials.
Glass	Glassy materials are hard, brittle, and noncrystalline. The lack of crystalline grains often results in optical transparency. The glass we are used to is a ceramic usually consisting of a mixture of silicates or sometimes borates or phosphates formed by fusion of silica or of oxides of boron or phosphorus with a flux and a stabilizer into a mass that cools to a rigid condition without crystallization.
Concrete	Concrete is a ceramic composite made up of water, sand, gravel, crushed stone, and cement. The ingredients are mixed together thoroughly, and are poured into a form. After the concrete is completely dry, it has excellent compressive strength.

Composites	Composites are mixtures of two or more bonded materials. Composites are the mixture of multiple materials, which in combination offer superior properties to the materials alone. Structural composites usually refer to the use of fibres which are embedded in a plastic. These composites offer high strength with very little weight.
Biomaterials	A biomaterial is any substance that has been engineered to interact with biological systems for a medical purpose - either a therapeutic (treat, augment, repair or replace a tissue function of the body) or a diagnostic one. The study of biomaterials is called biomaterials science or biomaterials engineering. Biomaterials science encompasses elements of medicine, biology, chemistry, tissue engineering and materials science.
Electronic & Optical	Electronic/optical materials are tailored to conduct electricity or light. These materials may be metals, ceramics or polymers. These materials are carefully formulated to control the intensity, scattering, and bending of electrons or photons which pass through them.
Metamaterials	A metamaterial is an engineered material specifically designed to exhibit a behaviour that can only occur at specific organizations and sizes of materials. Metamaterials often seem to break the rules of physical behaviour. Though many metamaterials phenomenon have not yet been usefully produced at scale, they include materials with negative Poisson's ratios (they expand when stretched instead of getting thinner), unusual interactions with light and other forms of electromagnetic radiation (cloaking and other phenomena), and nanomaterial effects like iridescence and molecular filtering of light and sound.
NanoMaterials	Nanomaterial is a "material with any external dimension in the nanoscale or having internal structure or surface structure in the nanoscale", with nanoscale defined as the "length range approximately from 1 nm to 100 nm". This includes both nano-objects, which are discrete pieces of material, and nanostructured materials, which have internal or surface structure on the nanoscale; a nanomaterial may be a member of both these categories.

5 Wood

Softwoods (Coniferous)

Araucaria	Hoop Pine	Monkey Puzzle Tree	Paraná Pine								
Cedar											
Celery-Top Pine											
Cypress	Arizona Cypress	Bald Cypress	Alerce	Hinoki Cypress	Lawson's Cypress	Mediterranean Cypress					
Douglas-Fir	Coast Douglas-Fir	Rocky Mountain Douglas-Fir									
European Yew											
Fir	Balsam Fir	Silver Fir	Noble Fir	Pacific Silver Fir							
Hemlock	Eastern Hemlock	Mountain Hemlock	Western Hemlock								
Huon Pine / Macquarie Pine											
Kauri											
Queensland Kauri											
Japanese Nutmeg-Yew, Kaya											
Larch	European Larch	Japanese Larch	Tamarack	Western Larch							
Pine	European Black Pine	Jack Pine	Lodgepole Pine	Monterey Pine	Ponderosa Pine	Red Pine	Scots Pine / Red Pine	**White Pine** • Eastern White Pine • Western White Pine • Sugar Pine	**Southern Yellow Pine** • Loblolly Pine • Longleaf Pine • Pitch Pine • Shortleaf Pine		
Red Cedar	Eastern Red Cedar	Western Red Cedar									
Coast Redwood											
Rimu											
Spruce	Norway Spruce	Black Spruce	Red Spruce	Sitka Spruce	White Spruce						
Sugi											
White Cedar	Northern White Cedar	Atlantic White Cedar									
Nootka Cypress											

Hardwoods

Hardwoods (Angiosperms)											
Abachi											
Acacia											
African Padauk											
Afzelia / Doussi											
Agba / Tola											
Alder	Black Alder	Red Alder									
American Chestnut											
Ash	Black Ash	Blue Ash	Common Ash	Green Ash	Oregon Ash	Pumpkin Ash	White Ash				
Aspen	Bigtooth Aspen	European Aspen	Quaking Aspen								
Australian Red Cedar											
Balsa											
Basswood / Linden	American Basswood	White Basswood	American Beech								
Birch	**American Birches** • Gray Birch • Black Birch • Paper Birch • Sweet Birch • Yellow Birch	**European Birches** • Silver Birch • Downy Birch									
Blackbean											
Black Tupelo											
Blackwood	Australian Blackwood	African Blackwood / Mpingo									
Bloodwood											
Boxelder											
Boxwood / Common box											
Brazilian Walnut											
Brazilwood											
Gumbo Limbo											
Buckeye	Horse-Chestnut	Ohio Buckeye	Yellow Buckeye								
Butternut											
California Bay Laurel											
Camphor Tree											
Cape Chestnut											
Catalpa / Catawba											
Ceylon Satinwood											
Cherry	Black Cherry	Red Cherry	Wild Cherry								
Coachwood											
Cocobolo											
Corkwood											
Cottonwood	Balsam Poplar	Eastern Cottonwood	Swamp Cottonwood								
Cucumbertree											
Dogwood	Flowering Dogwood	Pacific Dogwood									
Ebony	Andaman Marblewood	African Ebony	Ceylon Ebony								
Elm	American Elm	English Elm	Rock Elm	Slippery Elm / Red Elm	Wych Elm						
Eucalyptus	Lyptus: Flooded Gum	White Mahogany	Brown Mallet	Banglay / Southern Mahogany	River Red Gum	Karri	Blue Gum	Flooded Gum / Rose Gum	York Gum	Jarrah	Tallowwood
Eucalyptus	Grey Ironbark	Blackbutt	Mountain Ash	Australian Oak	Alpine Ash	Red Mahogany	Swamp Mahogany, Swamp Messmate	Sydney Blue Gum	Mugga / Red Ironbark	Redwood	Wandoo
European Crabapple											
European Pear											
Gonçalo Alves											
Greenheart											
Grenadilla / Mpingo											
Guanandi											
Gum											
Hackberry											
Hickory	Pecan	Pignut Hickory	Shagbark Hickory	Shellbark Hickory							
Hornbeam											
American Hophornbeam											
Iroko / African Teak											
Ironwood	Balau	American Hornbeam	Sheoak / Polynesian Ironwood	Giant Ironwood	Diesel Tree	Borneo Ironwood	**Lignum Vitae** • Guaiacwood • Holywood	Takian	Ipê	Black Ironwood	Lebombo Ironwood
Ironwood	Catalina Ironwood	Ceylon Ironwood	Olive	Desert Ironwood	Persian Ironwood	Brazilian Ironwood / Pau Ferro	Yellow lapacho				

Jacarandá-Boca-De-Sapo											
Jacarandá De Brasil											
Jatobá											
Kingwood											
Lacewood	Northern Silky Oak	American Sycamore	London Plane								
Limba											
Locust	Black Locust	Honey Locust									
Mahogany	**Genuine Mahogany** ● West Indies Mahogany ● Bigleaf Mahogany ● Pacific Coast Mahogany										
Other Mahogany	African Mahogany	Chinese Mahogany	Australian Red Cedar / Indian Mahogany	Philippine Mahogany / Calantis / Kalantis	Indonesian Mahogany / Suren	Sapele	Mountain Mahogany / Bottle Tree	Indian Mahogany / Chickrassy / Chittagong wood	Spanish Cedar / Cedro / Brazilian Mahogany	Light Bosse / Pink Mahogany	Dark Bosse / Pink Mahogany
Other Mahogany	American Muskwood	Carapa / Royal Mahogany / Demerara Mahogany / Bastard Mahogany / Andiroba / Crabwood	Bead-Tree / White Cedar / Persian Lilac								
Maple	**Hard Maple** ● Sugar Maple ● Black Maple	**Soft Maple** ● Boxelder ● Red Maple ● Silver Maple	**European Maple** ● Sycamore Maple								
Marri / Red Gum											
Meranti											
Merbau / Ipil											
Oak	**White Oak** ● White Oak ● Bur Oak ● Post Oak ● Swamp White Oak ● Southern Live Oak ● Swamp Chestnut Oak ● Chestnut Oak ● Chinkapin Oak ● Canyon Live Oak	English Oak	**Red Oak** ● Northern Red Oak ● Eastern Black Oak ● Laurel Oak ● Southern Red Oak ● Water Oak ● Willow Oak ● Nuttall's Oak								
Okoumé											
Olive											
Pink Ivory											
Poplar	Balsam Poplar	Black Poplar	Hybrid Black Poplar	Tulip Tree							
Purpleheart											
Queensland Maple											
Ramin											
Śāl											
Sweetgum											
Sandalwood	Indian Sandalwood										
Sassafras	Southern Sassafras										
Silky Oak											
Silver Wattle											
Sourwood											
Spanish-Cedar											
Spanish Elm											
Tamboti											
Teak											
Thailand Rosewood											
Tupelo											
Turpentine											
Walnut	Eastern Black Walnut	Common Walnut									
Wenge	Panga-Panga										
Willow	Black Willow	Cricket-Bat Willow	White Willow	Weeping Willow							
Zingana / African Zebrawood											
Hardwoods (Monocotyledons)											
Bamboo											
Palm Tree	Coconut Timber	Toddy Palm Timber									

Manufactured Woods

Engineered wood, also called composite wood, man-made wood, or manufactured board, includes a range of derivative wood products which are manufactured by binding or fixing the strands, particles, fibres, or veneers or boards of wood, together with adhesives, or other methods of fixation to form composite materials. These products are engineered to precise design specifications which are tested to meet national or international standards. Engineered wood products are used in a variety of applications, from home construction to commercial buildings to industrial products. The products can be used for joists and beams that replace steel in many building projects.

Typically, engineered wood products are made from the same hardwoods and softwoods used to manufacture lumber. Sawmill scraps and other wood waste can be used for engineered wood composed of wood particles or fibres, but whole logs are usually used for veneers, such as plywood, MDF or particle board. Some engineered wood products, like oriented strand board (OSB), can use trees from the poplar family, a common but non-structural species. Alternatively, it is also possible to manufacture similar engineered bamboo from bamboo; and similar engineered cellulosic products from other lignin-containing materials such as rye straw, wheat straw, rice straw, hemp stalks, kenaf stalks, or sugar cane residue, in which case they contain no actual wood but rather vegetable fibres.

Advantages

● Because engineered wood is man-made, it can be designed to meet application-specific performance requirements. Required shapes and dimension do not drive source tree requirements (length or width of the tree)
● Engineered wood products are versatile and available in a wide variety of thicknesses, sizes, grades, and exposure durability classifications, making the products ideal for use in unlimited construction, industrial and home project application.
● Engineered wood products are designed and manufactured to maximize the natural strength and stiffness characteristics of wood. The products are very stable and some offer greater structural strength than typical wood building materials.
● Glued laminated timber (glulam) has greater strength and stiffness than comparable dimensional lumber and is stronger than steel.
● Some engineered wood products offer more design options without sacrificing structural requirements.
● Engineered wood panels are easy to work with using ordinary tools and basic skills. They can be cut, drilled, routed, jointed, glued, and fastened. Plywood can be bent to form curved surfaces without loss of strength. Large panel size speeds construction.

● Engineered wood products make more efficient use of wood. They can be made from small pieces of wood or wood with defects.
● Wood trusses are competitive in many housing applications, and their high strength-to-weight ratios permit long spans.
● Engineered wood is felt to offer structural advantages for home construction.
● Sustainable design advocates recommend using engineered wood, which can be produced from relatively small trees, rather than large pieces of solid dimensional lumber, which requires cutting a large tree.

Disadvantages

● They require more primary energy for their manufacture than solid lumber.
● The adhesives used in some products may be toxic. A concern with some resins is the release of formaldehyde in the finished product, often seen with urea-formaldehyde bonded products.
● Cutting and otherwise working with some products can expose workers to toxic compounds.
● Some engineered wood products, such as those specified for interior use, may be weaker and more prone to humidity-induced warping than equivalent solid woods. Most particle and fibre-based boards are not appropriate for outdoor use because they readily soak up water.

Plywood

Plywood, a wood structural panel, is sometimes called the original engineered wood product. Plywood is manufactured from sheets of cross-laminated veneer and bonded under heat and pressure with durable, moisture-resistant adhesives. By alternating the grain direction of the veneers from layer to layer, or "cross-orienting", panel strength and stiffness in both directions are maximized. Other structural wood panels include oriented strand board and structural composite panels. It is popular in the furniture and flooring industries due to its inherent strength and resistance to warping due to the bonded cross-ply construction.

Densified Wood	Densified wood is made by using a mechanical hot press to compress wood fibres and increase the density by a factor of three. This increase in density is expected to enhance the strength and stiffness of the wood by a proportional amount. Early studies confirmed this result with a reported increase in mechanical strength by a factor of three.
MDF (Medium Density Fibreboard)	Medium-density fibreboard, is made by breaking down hardwood or softwood residuals into wood fibres, combining it with wax and a resin binder, and forming panels by applying high temperature and pressure. MDF is very strong and is considerably more popular than people think. In-fact many will be surprised as to how much MDF furniture is around them. With its strong/dense structure, your furniture is likely to last a lot longer than you expect, however it's no solid wood, but it's a fraction of the price of solid wood. MDF is extremely popular with IKEA, another leading furniture retailer. In the majority of cases, furniture built with MDF will have a wooden veneer bonded to it to give it an expensive looking finishing touch.
Particle Board (Chipboard)	Particle board is manufactured from wood chips, sawmill shavings, or even sawdust, and a synthetic resin or other suitable binder, which is pressed and extruded. Oriented strand board, also known as flakeboard, waferboard, or chipboard, is similar but uses machined wood flakes offering more strength. Particle board is cheaper, denser and more uniform than conventional wood and plywood and is substituted for them when cost is more important than strength and appearance. A major disadvantage of particleboard is that it is very prone to expansion and discoloration due to moisture, particularly when it is not covered with paint or another sealer. Chipboard is extremely popular when making furniture, especially IKEA furniture. It is a dense wood and is commonly used with a veneered surface which is used for flat-packed furniture and work surfaces.
Oriented Strand Board	Oriented strand board (OSB) is a wood structural panel manufactured from rectangular-shaped strands of wood that are oriented lengthwise and then arranged in layers, laid up into mats, and bonded together with moisture-resistant, heat-cured adhesives. The individual layers can be cross-oriented to provide strength and stiffness to the panel. However, most OSB boards are delivered with more strength in one direction. The wood strands in the outmost layer on each side of the board are normally aligned into the strongest direction of the board. Arrows on the product will often identify the strongest direction of the board (When bought in most cases the height (The longest dimension) of the board). Produced in huge, continuous mats, OSB is a solid panel product of consistent quality with no laps, gaps or voids. OSB is delivered in various dimensions, strengths and levels of water resistance.
Laminated Timber	Glued laminated timber (glulam) is composed of several layers of dimensional timber glued together with moisture-resistant adhesives, creating a large, strong, structural member that can be used as vertical columns or horizontal beams. Glulam can also be produced in curved shapes, offering extensive design flexibility.
Laminated Veneer	Laminated veneer lumber (LVL) is produced by bonding thin wood veneers together in a large billet. The grain of all veneers in the LVL billet is parallel to the long direction. The resulting product features enhanced mechanical properties and dimensional stability that offer a broader range in product width, depth and length than conventional lumber. LVL is a member of the structural composite lumber (SCL) family of engineered wood products that are commonly used in the same structural applications as conventional sawn lumber and timber, including rafters, headers, beams, joists, rim boards, studs and columns. A veneer refers to a thin layer of wood which is cut from the circumference of a tree. It is then bonded onto a dense piece of wood, which is typically MDF, chipboard or plywood. Veneers are available in many sizes, ranging from 3 to 6mm thick. Many people mistakenly assume that veneered furniture is cheaper than solid wood; however, veneers quite often are used in high end furniture pieces and it can be more costly than solid wood. The way to find out if your piece of furniture is veneered is by looking at the edges, and checking if the grain lines run off the top and over the edges of the wood. As a veneer is real wood, it will accept stains and finishes much like solid wood.
Cross Laminated	Cross-Laminated Timber (CLT) is a versatile multi-layered panel made of lumber. Each layer of boards is placed cross-wise to adjacent layers for increased rigidity and strength. CLT can be used for long spans and all assemblies, e.g. floors, walls or roofs. CLT has the advantage of faster construction times as the panels are manufactured and finished off site and supplied ready to fit and screw together as a flat pack assembly project.
Parallel Strand	Parallel strand lumber (PSL) consists of long veneer strands laid in parallel formation and bonded together with an adhesive to form the finished structural section. A strong, consistent material, it has a high load carrying ability and is resistant to seasoning stresses so it is well suited for use as beams and columns for post and beam construction, and for beams, headers, and lintels for light framing construction. PSL is a member of the structural composite lumber (SCL) family of engineered wood products.
Laminated Strand	Laminated strand lumber (LSL) and oriented strand lumber (OSL) are manufactured from flaked wood strands that have a high length-to-thickness ratio. Combined with an adhesive, the strands are oriented and formed into a large mat or billet and pressed. LSL and OSL offer good fastener-holding strength and mechanical connector performance and are commonly used in a variety of applications, such as beams, headers, studs, rim boards, and millwork components. These products are members of the structural composite lumber (SCL) family of engineered wood products. LSL is manufactured from relatively short strands—typically about 1 foot long—compared to the 2 foot to 8 foot long strands used in PSL.
Finger Joint	The finger joint is made up of short pieces of wood combined to form longer lengths and is used in doorjambs, mouldings and studs. It is also produced in long lengths and wide dimensions for floors.

6 Metal

A metal is a material that, when freshly prepared, polished, or fractured, shows a lustrous appearance, and conducts electricity and heat relatively well. Metals are typically malleable (they can be hammered into thin sheets) or ductile (can be drawn into wires). A metal may be a chemical element such as iron; an alloy such as stainless steel; or a molecular compound such as polymeric sulfur nitride.

In physics, a metal is generally regarded as any substance capable of conducting electricity at a temperature of absolute zero. Many elements and compounds that are not normally classified as metals become metallic under high pressures. For example, the nonmetal iodine gradually becomes a metal at a pressure of between 40 and 170 thousand times atmospheric pressure. Equally, some materials regarded as metals can become nonmetals. Sodium, for example, becomes a nonmetal at pressure of just under two million times atmospheric pressure.

Rust Triangle
Require all three sides of the triangle to cause rust on a ferrous metal.

- Iron
- Oxygen
- Moisture

Metal Properties

Metals[n]	**Weight** The weight of the metal per cubic centimetre.	**Strength** The tensile strength of the metal in megapascals.	**Rusts** If this metal rusts or not.	**Corrodes** Whether the metal corrodes or not.	**Melting Point** The temperature the metal begins to melt at and deform at.	**Conductivity** How conductive the metal is in Siemens per Metre.	**Thermal Conductivity** How well the metal conducts heat. Higher is better for cooking on	**Magnetic** Whether this metal is attracted to a magnet.	**Water Sterilization** Whether this metal slowly purifies water by killing bacteria and viruses	**Price[n]** How costly the metal is per kilogram in AUD. Steel

Steel is an alloy of iron and carbon, and sometimes other elements like chromium. Because of its high tensile strength and low cost, it is a major component used in buildings, infrastructure, tools, ships, trains, automobiles, machines, appliances, and weapons.

Iron is the base metal of steel. Iron is able to take on two crystalline forms (allotropic forms), body centred cubic and face-centred cubic, depending on its temperature. In the body-centred cubic arrangement, there is an iron atom in the centre and eight atoms at the vertices of each cubic unit cell; in the face-centred cubic, there is one atom at the centre of each of the six faces of the cubic unit cell and eight atoms at its vertices. It is the interaction of the allotropes of iron with the alloying elements, primarily carbon, that gives steel and cast iron their range of unique properties.

Components of Steel

These are different ingredients of steel which can affect its overall strength and durability. This can be used as a guide if blacksmithing.

Carbon	This ingredient is essential to steel's creation; all steel will have some amount of carbon. It is the most important hardening element, but as it is added it can reduce the toughness of the material. Carbon reduces the amount that the knife will wear over time. So, the amount of carbon in the blade tells you a lot about the quality of the steel. Low carbon means there is (.3% or less), medium has between (.4-.7%), and high is (.8% and above).
Chromium	Combats corrosion. Stainless steel knives will have chromium as a major ingredient, typically at a minimum of 12%. Chromium will also increase the strength of a knife, but adding chromium in large amounts decreases toughness.
Cobalt	Strengthens the blade.
Copper	Combats corrosion.
Manganese	Hardens the blade. If added in high quantities it can increase brittleness.
Molybdenum	Maintains the steel's strength at high temperatures.
Nickel	Adds toughness.
Nitrogen	This element is sometimes used as a replacement for carbon in steel.
Phosphorus	Improves strength.
Silicon	Increases strength. Also, removes oxygen from the metal while it is being formed.
Sulphur	Increases machinability but decreases toughness.
Tungsten	Increases wear resistance.
Vandium	Increases wear resistance and makes the blade harder.

Groups of Steel

The SAE steel grades system is a standard alloy numbering system (SAE J1086 - Numbering Metals and Alloys) for steel grades maintained by SAE International.

In the 1930s and 1940s, the American Iron and Steel Institute (AISI) and SAE were both involved in efforts to standardize such a numbering system for steels. These efforts were similar and overlapped significantly. For several decades the systems were united into a joint system designated the AISI/SAE steel grades. In 1995 the AISI turned over future maintenance of the system to SAE because the AISI never wrote any of the specifications.

Today steel quotes and certifications commonly make reference to both SAE and AISI, not always with precise differentiation. For example, in the alloy/grade field, a cert might say "4140", "AISI 4140", or "SAE 4140", and in most light-industrial applications any of the above is accepted as adequate, and considered equivalent, for the job at hand, as long as the specific specification called out by the designer (for example, "4140 bar per ASTM-A108" or "4140 bar per AMS 6349") is certified to on the certificate. The alloy number is simply a general classifier, whereas it is the specification itself that narrows down the steel to a very specific standard.

Major Classifications of Steel

Carbon steels and alloy steels are designated a four digit number, whereby the first digit indicates the main alloying element(s), the second digit indicates tg (top grade) element(s), and the last two digits indicate the amount of carbon, in hundredths of a percent (basis points) by weight. For example, a 1060 steel is a plain-carbon steel containing 0.60 wt% C.

An "H" suffix can be added to any designation to denote hardenability is a major requirement. The chemical requirements are loosened but hardness values defined for various distances on a Jominy test.

Major Classifications of Steel
1xxx - Carbon Steels
2xxx - Nickel Steels
3xxx - Nickel-chromium steels
4xxx - Molybdenum steels
5xxx - Chromium steels
6xxx - Chromium-vanadium steels
7xxx - Tungsten steels
8xxx - Nickel-chromium-molybdenum steels
9xxx - Silicon-manganese steels

1xxx Carbon Steels	**Carbon Steels** 10xx - Plain carbon (Mn 1.00% max.) 11xx - Resulfurized 12xx - Resulfurized and rephosphorized 15xx - Plain Carbon (Mn 1.00–1.65% max.)	**Manganese Steels** 13xx - Mn 1.75%	

2xxx Nickel Steels	**Nickel Steels** 23xx - Ni 3.50% 25xx - Ni 5.00%		
3xxx Nickel-chromium steels	**Nickel-chromium Steels** 31xx - Ni 1.25%; Cr 0.65%, or 0.80% 32xx - Ni 1.75%; Cr 1.07% 33xx - Ni 3.50%; Cr 1.50%, or 1.57% 34xx - Ni 3.00%; Cr 0.77%	The Klean Kanteen 18/8 stainless steel is from the 3xxx range featuring 18% chromium and 8% nickel. It corrodes faster in the presence of salt.	
4xxx Molybdenum steels	**Molybdenum Steels** 40xx - Mo 0.20%, 0.25%, or Mo 0.25% and S 0.042% 44xx - Mo 0.40%, or 0.52% **Chromium-molybdenum (chromoly) Steels** 41xx - Cr 0.50%, 0.80%, or 0.95%; Mo 0.12%, 0.20%, 0.25%, or 0.30%	**Nickel-molybdenum Steels** 46xx - Ni 0.85%, or 1.82%; Mo 0.20%, or 0.25% 48xx - Ni 3.50%; Mo 0.25%	**Nickel-chromium-molybdenum Steels** 43xx - Ni 1.82%; Cr 0.50–0.80%; Mo 0.25% 43BVxx - Ni 1.82%; Cr 0.50%; Mo 0.12%, or 0.35%; V 0.03% min 47xx - Ni 1.05%; Cr 0.45%; Mo 0.20%, or 0.35%

Stainless Steel

100 Series
Type 102—austenitic general purpose stainless steel

200 Series—austenitic chromium-nickel-manganese alloys
Type 201—austenitic that is hardenable through cold working
Type 202—austenitic general purpose stainless steel

300 Series—austenitic chromium-nickel alloys
Type 301—highly ductile, for formed products. Also hardens rapidly during mechanical working. Good weldability. Better wear resistance and fatigue strength than 304.
Type 302—same corrosion resistance as 304, with slightly higher strength due to additional carbon.
Type 303—free machining version of 304 via addition of sulfur and phosphorus. Also referred to as "A1" in accordance with ISO 3506.
Type 304—the most common grade; the classic 18/8 (18% chromium, 8% nickel) stainless steel. Outside of the US it is commonly known as "A2 stainless steel", in accordance with ISO 3506 (not to be confused with A2 tool steel). The Japanese equivalent grade of this material is SUS304.
Type 304L—same as the 304 grade but lower carbon content to increase weldability. Is slightly weaker than 304.
Type 304LN—same as 304L, but also nitrogen is added to obtain a much higher yield and tensile strength than 304L.
Type 305—same as 304, but with more nickel to decrease work hardening.
Type 308—used as the filler metal when welding 304.
Type 309—better temperature resistance than 304, also sometimes used as filler metal when welding dissimilar steels, along with inconel.

Type 310 310S— is a highly alloyed austenitic stainless steel used for high temperature application. The high chromium and nickel content give the steel excellent oxidation resistance as well as high strength at high temperature. This grade is also very ductile, and has good weldability enabling its widespread usage in many applications.
Type 316—the second most common grade (after 304); for food and surgical stainless steel uses; alloy addition of molybdenum prevents specific forms of corrosion. It is also known as marine grade stainless steel due to its increased resistance to chloride corrosion compared to type 304. 316 is often used for building nuclear reprocessing plants.
Type 316L—is an extra low carbon grade of 316, generally used in stainless steel watches and marine applications, as well exclusively in the fabrication of reactor pressure vessels for boiling water reactors, due to its high resistance to corrosion. Also referred to as "A4" in accordance with ISO 3506.
Type 316Ti—variant of type 316 that includes titanium for heat resistance. It is used in flexible chimney liners.
Type 321—similar to 304 but lower risk of weld decay due to addition of titanium. See also 347 with addition of niobium for desensitization during welding.

400 Series—ferritic and martensitic chromium alloys
Type 405—ferritic for welding applications
Type 408—heat-resistant; poor corrosion resistance; 11% chromium, 8% nickel.
Type 409—cheapest type; used for automobile exhausts; ferritic (iron/chromium only).
Type 410—martensitic (high-strength iron/chromium). Wear-resistant, but less corrosion-resistant.
Type 416—easy to machine due to additional sulfur
Type 420—Cutlery Grade martensitic; similar to the Brearley's original rustless steel. Excellent polishability.
Type 430—decorative, e.g., for automotive trim; ferritic. Good formability, but with reduced temperature and corrosion resistance.
Type 439—ferritic grade, a higher grade version of 409 used for catalytic converter exhaust sections. Increased chromium for improved high temperature corrosion/oxidation resistance.

Type 440—a higher grade of cutlery steel, with more carbon, allowing for much better edge retention when properly heat-treated. It can be hardened to approximately Rockwell 58 hardness, making it one of the hardest stainless steels. Due to its toughness and relatively low cost, most display-only and replica swords or knives are made of 440 stainless. Available in four grades:
Type 440A—has the least amount of carbon making this the most stain-resistant.
Type 440B—slightly more carbon than 440A.
Type 440C—has the greatest amount of carbon of the Type 440 variants. Strongest and considered more desirable in knifemaking than the Type 440A variant, except for diving or other salt-water applications. This variant is also more readily available than other variants of Type 440.
Type 440F—a free-machining variant. Contains the same high carbon content as Type 440C.
Type 446—For elevated temperature service

500 Series—heat-resisting chromium alloys
The 500 series was rumored to be the first choice for the Starship rocket, currently under development by Elon Musk's SpaceX.

600 Series—originally created for proprietary alloys (which are no longer given SAE grade numbers)
601 through 604: Martensitic low-alloy steels.
610 through 613: Martensitic secondary hardening steels.
614 through 619: Martensitic chromium steels.
630 through 635: Semiaustenitic and martensitic precipitation hardening stainless steels.
Type 630 is most common PH stainless, better known as 17-4; 17% chromium, 4% nickel.
650 through 653: Austenitic steels strengthened by hot/cold work.
660 through 665: Austenitic superalloys; all grades except alloy 661 are strengthened by second-phase precipitation.

900 series—austentic chromium-molybdenum alloys
Type 904—similar to 316 but with higher chromium and molybdenum content for more corrosion resistance

Plain Carbon Steels

Plain carbon steels are steels that contain iron, carbon, and a small amount of manganese. In contrast, alloy steels have a specified composition and contain certain percentages of vanadium or molybdenum, and they also typically have a larger amount of manganese. Tool steel contains tungsten, molybdenum, and other alloying elements.

The 10XX Steels
1095 is the most common 10XX steel used for knife blades. Steel in the range 1045-1095 are used for knife blades, although 1050 is more commonly seen in swords. 1045 steel has less carbon (.45%), where 1095 has more (.95%), inversely 1095 has less manganese and 1045 has more. So in essence, 1095 steel would have more wear resistance, but would also be less tough.

1045	Carbon: 0.43-0.50 Manganese: 0.60-0.90 1045 holds an okay edge in comparison to the great edge of 1095.
1050	Carbon: 0.47-0.55 Manganese: 0.60-0.90
1055	Carbon: 0.52-0.60 Manganese: 0.60-0.90
1060	Carbon: 0.55-0.65 Manganese: 0.60-0.90
1065	Carbon: 0.60-0.70 Manganese: 0.60-0.90
1070	Carbon: 0.65-0.75 Manganese: 0.60-0.90
1075	Carbon: 0.70-0.80 Manganese: 0.40-0.70
1080	Carbon: 0.75-0.88 Manganese: 0.60-0.90
1085	Carbon: 0.80-0.93 Manganese: 0.70-1.00
1095	Carbon: 0.90-1.03 Manganese: 0.30-0.50 1095 steel holds an edge great, and is easy to sharpen. The major drawback to this type of steel is that it rusts easily. Because of this issue, you will often see 1095 blades with some type of coating to combat rust. If you buy a knife with this type of blade, be sure to store it well and you should have no problem.

Alloy Steels

This is plain carbon steel (1060) that has been mixed with a little bit of chromium. There is not enough chromium to make it a stainless steel, but the chromium has been added to strengthen the material. This type of steel is known for its outstanding toughness. This type of steel typically has .56-.64% carbon.

8637	Alloy Steel 8637 is medium carbon steel that includes chromium, manganese, and molybdenum. Thanks to its strength and wear resistance, Alloy Steel 8637 is popular in the aerospace, defence, oil and gas, and automotive industries.
41L49	Also sold under the brand name DYNA-LOY 41L49, this cold-drawn alloy steel offers users excellent machinability. Known for its good surface, Alloy Steel 41L49 alloy offers users outstanding finish, tensile strength, elasticity, and a hardness range of Rockwell C43 to C56.
9260	Alloy Steel 9260, also sold AISI 9260, is a high-silicon, spring alloy steel. It offers users outstanding corrosion resistance, hardness, toughness, and strength. Alloy Steel 9260 is machinable in the annealed condition, and is weldable by most common methods except oxyacetylene welding. You will find Alloy Steel 9260 in a wide variety of applications, most of which demand resistance to bending and failures.
8750	Alloy Steel 8750 is a low carbon steel with a medium manganese content. Known for its good hardening properties, Alloy Steel 8750 also offers users fair machinability as well as excellent cold bending and forming operations. It has a decent level of weldability and is perfect for shafting and for applications that do not require the high levels of strength found in higher carbon and alloy steels.
8640	Alloy Steel 8640 is a special-alloy steel that includes chromium, manganese, and molybdenum. Due to its lower carbon levels, Alloy Steel 8640 takes mechanical and heat treatments better than most alloys. Alloy Steel 8640 is popular in the aerospace, defence, oil and gas, and automotive industries.

4150	Alloy Steel 4150, also sold under the name AISI/SAE 4150, is a high-carbon alloy that includes chromium, manganese, and molybdenum. This tough steel alloy offers uniform strength, wear resistance, and great hardness. It is important to note that Alloy Steel 4150 must be heat-treated to be suitable for machining. The weldability of Alloy Steel 4150 is high and can be achieved through most commercial methods.
8630	Alloy Steel 8630, also known as AISI 8630, is a low alloy that is unique due to its levels of chromium, molybdenum, and chromium. Alloy Steel 8630 offers users good mechanical properties, as well as weldability by most common methods. This popular alloy works well with hot forging and rolling, in addition to annealing.
4120	Alloy Steel 4120, also sold as SAE/AISI 4120, is a chromium-molybdenum structural alloy steel. This case-hardened alloy offers users good strength, toughness, and wear-resistance. Leaders in a wide variety of industries, including aerospace, oil and gas, automotive, agricultural and defence.
8620	Alloy Steel 8620, also sold as AISI 8620, is a hardenable, carburizing, low alloy steel. This alloy offers users outstanding flexibility, wear resistance, as well as ease of weldability through conventional methods.
4140	Alloy Steel 4140, also sold under the name AISI/SAE 4140, is a low alloy steel that contains chromium, molybdenum, and manganese. Known for its impact and abrasion resistance, Alloy Steel 4140 also offers users outstanding fatigue and torsional strength. Welding is possible through most popular techniques, and it has a high level of ductility. Machinability is possible in the annealed condition, while Alloy Steel 4140 takes cold working, heating, and quenching well.
5160 Steel	This is plain carbon steel (1060) that has been mixed with a little bit of chromium. There is not enough chromium to make it a stainless steel, but the chromium has been added to strengthen the material. This type of steel is known for its outstanding toughness. This type of steel typically has .56-.64% carbon.
Tool Steels	
This is high carbon tool steel. It typically has .98-1.10% carbon. This steel is harder than many others, and consequently it holds an edge well. This is one of the best steels to use if you are worried about it holding an edge. This material is used often for hunting knives. The major drawback to this steel is that it has less chromium than other steel and consequently can rust.	
52100 Steel	This is high carbon tool steel. It typically has .98-1.10% carbon. This steel is harder than many others, and consequently it holds an edge well. This is one of the best steels to use if you are worried about it holding an edge. This material is used often for hunting knives. The major drawback to this steel is that it has less chromium than other steel and consequently can rust.
A2 Steel	This is very tough steel. However, it has less wear resistance than other tool steels. This steel is often used for custom made combat knives because of its toughness. It has a carbon content range of 0.95-1.05%. This steel does not contain lots of chromium (typically around 5%) and needs to be maintained carefully to avoid rust. It will often be coated on a knife blade to avoid this issue.
CPM 10V Steel	CPM stands for Crucible Particle Metallurgy, which is a brand name. This is one of the most wear resistant tool steels. It also has decent toughness for a tool steel. This is a great choice if you are looking for something with lots of wear resistance, but is not a really tough material.
CPM 3V Steel	This steel was designed to be tough while also being a high wear resistance steel.
CPM M4 Steel	This steel has excellent wear resistance and toughness. Has about 1.42% carbon.
D2 Steel	This steel has high chromium content, just less than what might classify it as stainless steel. Because of this it has good rust resistance. It is much tougher than most stainless steels, but not as tough as most of the other tool steel. This steel does have excellent wear resistance. It has great edge retention but can be very difficult to sharpen. This is also a tough material to mirror polish, so it you will almost never see it that way. Its carbon content is 1.50-1.60%.
L6 Steel	This steel is tough and holds an edge well. However, like other non-stainless steel it rusts easily. Some consider this to be one of the best steels available for cutlery. It is also used frequently in saw blades, but any knife made from this material needs consistent maintenance.
M2 Steel	This steel is extremely heat resistant. It has about .85% carbon. It holds an edge really, really well, but it can be brittle on large knives.
O1 Steel	This material has good edge retention, because it is hard material. Its major problem is that it rusts rather quickly if it isn't maintained. It has a carbon content range of .85-1.00%.
O6 Steel	This is a much tougher metal than 0-1. This is one of the absolute best edge retention steels.
W2 Steel	This steel is basically plain carbon steel with extra carbon. It is very hard and holds an edge well.
Stainless Steels	
Stainless steel knives will have chromium as a main ingredient, typically at a minimum of 12%. Has about .38% carbon. The low carbon content means that this steel is very soft, and doesn't hold an edge well. It is low quality, low cost material. Many cheap knives tend to be made of this material because of its cost. Blades made from this material need to be sharpened frequently, and often chip. Stainless steel knives will have chromium as a main ingredient, typically at a minimum of 12%.	
420 Steel	Has about .38% carbon. The low carbon content means that this steel is very soft, and doesn't hold an edge well. It is low quality, low cost material. Many cheap knives tend to be made of this material because of its cost. Blades made from this material need to be sharpened frequently, and often chip. On the bright side, all 420 stainless steel is extremely rust resistant. This means that one of the best uses for this material is to make diving knives because of their constant contact with saltwater. Sometimes, you will also see 420J. 420J is the lowest quality 420 steel, but is also the most rust resistant.
440 Steel	There are three different types of 440 steel, the hardest part of telling them apart is that often steel makers mark 440 on the tang of the blade and not the letter grade. This is especially true when it is one of the lower grades. This has led certain knife manufacturers to rename 440C as other things in order to differentiate the quality of the product.
440A Steel	Has a carbon content range of .65-.75%. This is a low cost stainless steel. It is the most rust resistant of 440 steel, and 440C is the least rust resistant of the three. However, the 400 series are some of the most rust resistant knives out there.
440B Steel	Very similar to 440A but has a higher carbon content range (.75-.95%).
440C Steel	This has a carbon content range between .95-1.20%. This is considered a higher end stainless steel. This alloy is one of the most common in knives. It is wear resistant, and it is a hard steel.
425M Steel	This is a material similar to the 400 series that has .5% carbon and is used by Buck knives.
154 CM Steel	This is high quality steel. It has a carbon content of 1.05%. It holds an edge well and is hard steel. It actually has pretty good toughness for how hard the steel is as well. It is tougher than 440 C. Some go as far as to call this super steel. This steel often gets compared to ATS 34 because the two are so similar. Some people prefer this steel to ATS 34 because this one is made by Crucible, an American company.

MATERIALS Metal Steel Groups of Steel

8Cr14MoV Steel	This steel is very similar to AUS-8. It is manufactured in China and has about .75% carbon content.
9Cr13CoMoV Steel	This is 440 steel with extra cobalt mixed in to strengthen the blade. Has about .85% carbon.
AEBL Steel	This steel is similar to 440 B.
ATS 34 Steel	This steel is very similar to 154 CM. It has 1.05% carbon. It is also one of those classified in the super category. There are lots of high-end custom knives that use this steel.
ATS 55 Steel	This steel does not have the vanadium that is present in both ATS-34 and 154-CM. This means that it does hold an edge as well, and has also been reported to be less rust resistant than ATS-34. It has a carbon content of 1.00%.
AUS-6 Steel	Has .65% carbon. This is a low quality steel, comparable to 420.
AUS-8 Steel	Has .75% carbon. Cold Steel has made popular use of this steel. This is tough steel, and holds an edge well.
AUS-10 Steel	Has 1.1% carbon. This steel is comparable to 440C. It has more vanadium and less chromium than 440C so it is slightly tougher, but also a little less rust resistant.
BG 42 Steel	This is a relatively new stainless steel that has excellent rust resistance. It is gaining popularity as custom knife makers begin using this steel.
Bohler M390 Steel	Has 1.9% carbon. This material is very stain resistant and has excellent wear resistance. It has vanadium as an additive, consequently it is a popular hard steel. This is also the type of steel used most often for surgical applications.
Bohler N680 Steel	Has .54% carbon. This is another very hard steel that is highly stain resistant, and so is good for salt water applications.
N690 Steel	Has 1.07% carbon. This steel is made in Austria and is very similar to 440C.
Gingami 1 Steel (GIN 1)	This is a wonderful stainless steel. It has .80-.90% carbon. It has good edge retention.

The series below is becoming quite popular because of its strength, ability to resist rust, and how well it holds an edge. These are difficult steels to sharpen though, if you do need to give them an edge. All of these knives are very wear resistant. This type of steel is also very difficult to mirror polish, so you will almost never see it. The 30, 60, and 90 in this series stand for 3%, 6%, and 9% vanadium in the alloy respectively.

S30V Steel	This steel was designed to be used for knives. This steel is very tough, and yet still has great wear resistance. For how tough the steel is, it actually has very good hardness also, which is why many consider it to be one of the best choices for knife making. It has a carbon content of 1.45%.
S60V(CPM T440V) Steel	This stainless steel has high wear resistance. It has lots of vanadium, and also has a carbon content of 2.15%. It is just a step above S30V. Currently, this steel is not commonly used.
S90V(CPM T420V) Steel	This steel has superior edge retention. However, it can be almost impossible to sharpen. Right now custom makers are the only ones using this type of steel. Its carbon content is around 2.30%.
VG 10 Steel	This is another type of steel that gets referred to as super steel. It is a very high end stainless steel. It has vanadium which gives it extra toughness. This steel holds an edge really well. It is also very rust resistant. It has a carbon content of 0.95-1.05%.
X15 Steel	Has .40% carbon. This is a French steel that was developed for the airplane industry. It was developed to resist corrosion in the worst possible conditions. It is the most stain resistant steel on the market, and is a hard material. It is not very tough, but is especially good material for diving knives.
Z60CDV14 Steel	This steel is similar to 440A. It is supposed to hold an edge slightly better than the 440 steels. It has about .40% carbon.

Damascus Steel

Today, pattern welded steel is made to reproduce the look of ancient Damascus steel. This type of steel is made by taking two (or more) layers of different types of steel and folding them together over and over again. After the two different steels are folded together, the steel is acid etched. The colour contrast and patterns on the blade comes from the fact that the two types of steel etch differently. Damascus steel is considered a precious metal, because it is difficult to make, and can result in very beautiful knife blades. This means that knife blades made with Damascus tend to be expensive and only used for custom blades.

Ceramic Blades

Ceramic blades do not rust, so they are popular for use in scuba knives. This material is really, really hard so it almost never needs to be sharpened. It can be almost impossible to sharpen them, but as a trade off ceramic blades are often very brittle.

Titanium Blades

Titanium is popular because it is lightweight and very tough. It does not hold an edge very well so it doesn't usually make a really good blade, but it has been used in diving knives and some custom knives.

Stellite 6-K

Stellite is a special material that has no iron in it. This is a very tough material.

7 Polymers (Plastics)

A polymer is a large molecule, or macromolecule, composed of many repeated subunits. Due to their broad range of properties, both synthetic and natural polymers play essential and ubiquitous roles in everyday life. Polymers range from familiar synthetic plastics such as polystyrene to natural biopolymers such as DNA and proteins that are fundamental to biological structure and function. Polymers, both natural and synthetic, are created via polymerization of many small molecules, known as monomers. Their consequently large molecular mass relative to small molecule compounds produces unique physical properties, including toughness, viscoelasticity, and a tendency to form glasses and semicrystalline structures rather than crystals.

Polymers are of two types: naturally occurring and synthetic or man made. Natural polymeric materials such as shellac, amber, wool, silk and natural rubber have been used for centuries. A variety of other natural polymers exist, such as cellulose, which is the main constituent of wood and paper. The list of synthetic polymers, roughly in order of worldwide demand, includes polyethylene, polypropylene, polystyrene, polyvinyl chloride, synthetic rubber, phenol formaldehyde resin (or Bakelite), neoprene, nylon, polyacrylonitrile, PVB, silicone, and many more. More than 330 million tons of these polymers are made every year (2015). The eight most common types of synthetic organic polymers, commonly found in households are below.

Types

Low-Density Polyethylene (LDPE)

Low-density polyethylene (LDPE) is a thermoplastic made from the monomer ethylene. It was the first grade of polyethylene, produced in 1933 by Imperial Chemical Industries (ICI) using a high pressure process via free radical polymerization. Its manufacture employs the same method today. The EPA estimates 5.7% of LDPE (recycling number 4) is recycled. Despite competition from more modern polymers, LDPE continues to be an important plastic grade. In 2013 the worldwide LDPE market reached a volume of about US$33 billion. LDPE is defined by a density range of 0.917–0.930 g/cm3.

It is not reactive at room temperatures, except by strong oxidizing agents, and some solvents cause swelling. It can withstand temperatures of 80 °C continuously and 90 °C (194 °F) for a short time. Made in translucent or opaque variations, it is quite flexible and tough. LDPE has more branching (on about 2% of the carbon atoms) than HDPE, so its intermolecular forces (instantaneous-dipole induced-dipole attraction) are weaker, its tensile strength is lower, and its resilience is higher. Also, because its molecules are less tightly packed and less crystalline due to the side branches, its density is lower.

Chemical Resistance
- Excellent resistance (no attack / no chemical reaction) to dilute and concentrated acids, alcohols, bases and esters
- Good resistance (minor attack / very low chemical reactivity) to aldehydes, ketones and vegetable oils
- Limited resistance (moderate attack / significant chemical reaction, suitable for short-term use only) to aliphatic and aromatic hydrocarbons, mineral oils and oxidizing agents
- Poor resistance, and not recommended for use with halogenated hydrocarbons.

High-Density Polyethylene (HDPE)

High-density polyethylene (HDPE) or polyethylene high-density (PEHD) is a polyethylene thermoplastic made from petroleum. It is sometimes called "alkathene" or "polythene" when used for pipes. With a high strength-to-density ratio, HDPE is used in the production of plastic bottles, corrosion-resistant piping, geomembranes, and plastic lumber. HDPE is commonly recycled, and has the number "2" as its resin identification code. HDPE is known for its large strength to density ratio. The density of HDPE can range from 930 to 970 kg/m3.

Although the density of HDPE is only marginally higher than that of low-density polyethylene, HDPE has little branching, giving it stronger intermolecular forces and tensile strength than LDPE. The difference in strength exceeds the difference in density, giving HDPE a higher specific strength. It is also harder and more opaque and can withstand somewhat higher temperatures (120 °C/ 248 °F for short periods).

High-density polyethylene, unlike polypropylene, cannot withstand normally required autoclaving conditions. The lack of branching is ensured by an appropriate choice of catalyst (e.g., Ziegler-Natta catalysts) and reaction conditions. HDPE is also used for cell liners in subtitle D sanitary landfills, wherein large sheets of HDPE are either extrusion welded or wedge welded to form a homogeneous chemical-resistant barrier, with the intention of preventing the pollution of soil and groundwater by the liquid constituents of solid waste.

HDPE is preferred by the pyrotechnics trade for mortars over steel or PVC tubes, being more durable and safer. HDPE tends to rip or tear in a malfunction instead of shattering and becoming shrapnel like the other materials. Milk bottles, jugs, and other hollow goods manufactured through blow moulding are the most important application area for HDPE, accounting for one-third of worldwide production, or more than 8 million tonnes.

Applications	• Swimming pool installation • 3-D printer filament • Arena Board (puck board) • Backpacking frames • Ballistic plates • Banners • Bottle caps • Boats • Chemical-resistant piping	• Food storage containers • Fuel tanks for vehicles • Corrosion protection for steel pipelines • Electrical and plumbing boxes • Far-IR lenses • Folding chairs and tables • Storage sheds • Coax cable inner insulator	• Geothermal heat transfer piping systems • Heat-resistant firework mortars • Microwave telescope windows • Natural gas distribution pipe systems • Potable Water Mains • Sewage Mains • Plastic bags • Fireworks	• Plastic lumber • Plastic surgery (skeletal and facial reconstruction) • Root barrier • Snowboard rails and boxes • Stone paper • Telecom ducts • Housewrap (Tyvek) • Wood plastic composites	• Geomembrane for hydraulic applications (such as canals and bank reinforcements) and chemical containment • Water pipes for domestic water supply and agricultural processes • Plastic bottles suitable both for recycling (such as milk jugs) or re-use

Polypropylene (PP)

Polypropylene (PP), also known as polypropene, is a thermoplastic polymer used in a wide variety of applications. It is produced via chain-growth polymerization from the monomer propylene. Polypropylene belongs to the group of polyolefins and is partially crystalline and non-polar. Its properties are similar to polyethylene, but it is slightly harder and more heat resistant. It is a white, mechanically rugged material and has a high chemical resistance. Polypropylene is the second-most widely produced commodity plastic (after polyethylene) and it is often used in packaging and labelling. In 2013, the global market for polypropylene was about 55 million tonnes. Polypropylene is in many aspects similar to polyethylene, especially in solution behaviour and electrical properties.

The methyl group improves mechanical properties and thermal resistance, although the chemical resistance decreases. The density of (PP) is between 0.895 and 0.92 g/cm³. Therefore, PP is the commodity plastic with the lowest density. With lower density, mouldings parts with lower weight and more parts of a certain mass of plastic can be produced. Unlike polyethylene, crystalline and amorphous regions differ only slightly in their density. Polypropylene is normally tough and flexible, especially when copolymerized with ethylene. This allows polypropylene to be used as an engineering plastic, competing with materials such as acrylonitrile butadiene styrene (ABS). Polypropylene is reasonably economical.

The melting point of polypropylene occurs in a range, so the melting point is determined by finding the highest temperature of a differential scanning calorimetry chart. Perfectly isotactic PP has a melting point of 171 °C (340 °F). Commercial isotactic PP has a melting point that ranges from 160 to 166 °C (320 to 331 °F), depending on atactic material and crystallinity. Syndiotactic PP with a crystallinity of 30% has a melting point of 130 °C (266 °F). Below 0 °C, PP becomes brittle. The thermal expansion of polypropylene is very large, but somewhat less than that of polyethylene. Polypropylene at room temperature is resistant to fats and almost all organic solvents, apart from strong oxidants. Non-oxidizing acids and bases can be stored in containers made of PP. At elevated temperature, PP can be dissolved in nonpolar solvents such as xylene, tetralin and decalin.

Due to the tertiary carbon atom PP is chemically less resistant than PE. Most commercial polypropylene is isotactic and has an intermediate level of crystallinity between that of low-density polyethylene (LDPE) and high-density polyethylene (HDPE). Isotactic & atactic polypropylene is soluble in P-xylene at 140 °C. Isotactic precipitates when the solution is cooled to 25 °C and atactic portion remains soluble in P-xylene. Polypropylene is liable to chain degradation from exposure to temperatures above 100 °C. Oxidation usually occurs at the tertiary carbon centres leading to chain breaking via reaction with oxygen. In external applications, degradation is evidenced by cracks and crazing.

Polyvinyl Chloride (PVC)

MATERIALS | Polymers (Plastics) | Types | Polyvinyl Chloride (PVC)

Polyvinyl chloride is the world's third-most widely produced synthetic plastic polymer, after polyethylene and polypropylene. About 40 million tonnes are produced per year. PVC comes in two basic forms: rigid (sometimes abbreviated as RPVC) and flexible. The rigid form of PVC is used in construction for pipe and in profile applications such as doors and windows. It is also used in making bottles, non-food packaging, and cards (such as bank or membership cards). It can be made softer and more flexible by the addition of plasticizers, the most widely used being phthalates. In this form, it is also used in plumbing, electrical cable insulation, imitation leather, flooring, signage, phonograph records, inflatable products, and many applications where it replaces rubber.

With cotton or linen, it is used to make canvas. Pure polyvinyl chloride is a white, brittle solid. It is insoluble in alcohol but slightly soluble in tetrahydrofuran. PVC has high hardness and mechanical properties. The mechanical properties enhance with the molecular weight increasing but decrease with the temperature increasing. The mechanical properties of rigid PVC (uPVC) are very good; the elastic modulus can reach 1500-3,000 MPa. The soft PVC (flexible PVC) elastic limit is 1.5–15 MPa. The heat stability of raw PVC is very poor, so the addition of a heat stabilizer during the process is necessary in order to ensure the product's properties. Traditional product PVC has a maximum operating temperature around 140°F (60°C) when heat distortion begins to occur.

Melting temperatures range from 212°F to 500°F (100°C to 260°C) depending upon manufacture additives to the PVC. The linear expansion coefficient of rigid PVC is small and has good flame retardancy, the limiting oxygen index (LOI) being up to 45 or more. PVC is chemically resistant to acids, salts, bases, fats, and alcohols, making it resistant to the corrosive effects of sewage, which is why it is so extensively utilized in sewer piping systems. It is also resistant to some solvents, this, however, is reserved mainly for uPVC (unplasticized PVC). PVC is commonly used as the insulation on electrical cables such as teck; PVC used for this purpose needs to be plasticized. Flexible PVC coated wire and cable for electrical use has traditionally been stabilised with lead, but these are being replaced with calcium-based systems.

In a fire, PVC-coated wires can form hydrogen chloride fumes; the chlorine serves to scavenge free radicals and is the source of the material's fire retardance. While hydrogen chloride fumes can also pose a health hazard in their own right, it dissolves in moisture and breaks down onto surfaces, particularly in areas where the air is cool enough to breathe, and is not available for inhalation. PVC is a common, strong but lightweight plastic used in construction. It is made softer and more flexible by the addition of plasticizers. If no plasticizers are added, it is known as uPVC (unplasticized polyvinyl chloride) or rigid PVC.

Polystyrene (PS)

MATERIALS | Polymers (Plastics) | Types | Polystyrene (PS)

Polystyrene (PS) is a synthetic aromatic hydrocarbon polymer made from the monomer styrene. Polystyrene can be solid or foamed. General-purpose polystyrene is clear, hard, and rather brittle. It is an inexpensive resin per unit weight. It is a rather poor barrier to oxygen and water vapour and has a relatively low melting point. Polystyrene is one of the most widely used plastics, the scale of its production being several million tonnes per year. Polystyrene can be naturally transparent, but can be coloured with colourants. Uses include protective packaging (such as packing peanuts and CD and DVD cases), containers (such as "clamshells"), lids, bottles, trays, tumblers, disposable cutlery and in the making of models. As a thermoplastic polymer, polystyrene is in a solid (glassy) state at room temperature but flows if heated above about 100 °C, its glass transition temperature.

It becomes rigid again when cooled. This temperature behaviour is exploited for extrusion (as in Styrofoam) and also for moulding and vacuum forming, since it can be cast into moulds with fine detail. Polystyrene is slow to biodegrade and is therefore a focus of controversy among environmentalists. It is increasingly abundant as a form of litter in the outdoor environment, particularly along shores and waterways, especially in its foam form, and also in increasing quantities in the Pacific Ocean. Polystyrene is flammable, and releases lots of black smoke upon burning. Like all organic compounds, polystyrene burns to give carbon dioxide and water vapour.

MATERIALS | Polymers (Plastics) | Types | Polystyrene (PS)

Polystyrene is chemically very inert, being resistant to acids and bases but is easily dissolved by many chlorinated solvents, and many aromatic hydrocarbon solvents. Because of its resilience and inertness, it is used for fabricating many objects of commerce. It is attacked by many organic solvents, which dissolve the polymer. Foamed polystyrene is used for packaging chemicals. Polystyrene is commonly injection moulded, vacuum formed, or extruded, while expanded polystyrene is either extruded or moulded in a special process.

Polystyrene copolymers are also produced; these contain one or more other monomers in addition to styrene. In recent years the expanded polystyrene composites with cellulose and starch have also been produced. Polystyrene (PS) is used for producing disposable plastic cutlery and dinnerware, CD "jewel" cases, smoke detector housings, license plate frames, plastic model assembly kits, and many other objects where a rigid, economical plastic is desired. Polystyrene foams are 95-98% air.

Polystyrene foams are good thermal insulators and are therefore often used as building insulation materials, such as in insulating concrete forms and structural insulated panel building systems. Grey polystyrene foam, incorporating graphite has superior insulation properties. PS foams also exhibit good damping properties, therefore it is used widely in packaging. Discarded polystyrene does not biodegrade for hundreds of years and is resistant to photo-oxidation. Animals do not recognize polystyrene foam as an artificial material and may even mistake it for food. Polystyrene foam blows in the wind and floats on water, due to its low specific gravity. It can have serious effects on the health of birds or marine animals that swallow significant quantities.

Nylon

MATERIALS | Polymers (Plastics) | Types | Nylon

Nylon is a generic designation for a family of synthetic polymers, based on aliphatic or semi-aromatic polyamides. Nylon is a thermoplastic silky material that can be melt-processed into fibres, films or shapes. Nylon was the first commercially successful synthetic thermoplastic polymer. Nylon was first used commercially in a nylon-bristled toothbrush in 1938, followed more famously in women's stockings or "nylons" which were shown at the 1939 New York World's Fair and first sold commercially in 1940. During World War II, almost all nylon production was diverted to the military for use in parachutes and parachute cord. Wartime uses of nylon and other plastics greatly increased the market for the new materials. Nylon clothing tends to be less flammable than cotton and rayon, but nylon fibres may melt and stick to skin. Above their melting temperatures, Tm, thermoplastics like nylon are amorphous solids or viscous fluids in which the chains approximate random coils. Below Tm, amorphous regions alternate with regions which are lamellar crystals. The amorphous regions contribute elasticity and the crystalline regions contribute strength and rigidity.

MATERIALS | Polymers (Plastics) | Types | Nylon

Nylon 6,6 Characteristics	● Pleats and creases can be heat-set at higher temperatures ● More compact molecular structure ● Better weathering properties; better sunlight resistance ● Softer "Hand" ● High melting point (256 °C/492.8 °F) ● Superior colourfastness ● Excellent abrasion resistance
Nylon 6 Characteristics	● Variation of lustre: nylon has the ability to be very lustrous, semilustrous or dull. ● Durability: its high tenacity fibres are used for seatbelts, ballistic cloth etc. ● High elongation ● Excellent abrasion resistance ● Highly resilient (nylon fabrics are heat-set) ● High resistance to insects, fungi, animals, as well as moulds, mildew, rot and many chemicals ● Used in carpets and nylon stockings ● Melts instead of burning ● Good specific strength ● Transparent to infrared light (−12 dB)
Food Packaging	Nylon resins are used as a component of food packaging films where an oxygen barrier is needed. Some of the terpolymers based upon nylon are used every day in packaging. Nylon has been used for meat wrappings and sausage sheaths. The high temperature resistance of nylon makes it useful for oven bags.
Filaments	Nylon filaments are primarily used in brushes especially toothbrushes and string trimmers. They are also used as monofilaments in fishing line. Nylon 610 and 612 are the most used polymers for filaments. Its various properties also make it very useful as a material in additive manufacturing; specifically as a filament in consumer and professional grade fused deposition modelling 3D printers.

Teflon (Polytetrafluoroethylene)

Polytetrafluoroethylene (PTFE) is a synthetic fluoropolymer of tetrafluoroethylene that has numerous applications. The best known brand name of PTFE-based formulas is Teflon by Chemours. PTFE is a fluorocarbon solid, as it is a high-molecular-weight compound consisting wholly of carbon and fluorine. PTFE is hydrophobic: neither water nor water-containing substances wet PTFE, as fluorocarbons demonstrate mitigated London dispersion forces due to the high electronegativity of fluorine. PTFE has one of the lowest coefficients of friction of any solid. PTFE is used as a non-stick coating for pans and other cookware. It is nonreactive, partly because of the strength of carbon–fluorine bonds, and so it is often used in containers and pipework for reactive and corrosive chemicals. Where used as a lubricant, PTFE reduces friction, wear, and energy consumption of machinery. It is commonly used as a graft material in surgical interventions.

Also, it is frequently employed as coating on catheters; this interferes with the ability of bacteria and other infectious agents to adhere to catheters and cause hospital-acquired infections. PTFE is a thermoplastic polymer, which is a white solid at room temperature, with a density of about 2200 kg/m3. According to Chemours, its melting point is 600 K (327 °C; 620 °F).

It maintains high strength, toughness and self-lubrication at low temperatures down to 5 K (−268.15 °C; −450.67 °F), and good flexibility at temperatures above 194 K (−79 °C; −110 °F). PTFE gains its properties from the aggregate effect of carbon-fluorine bonds, as do all fluorocarbons. The only chemicals known to affect these carbon-fluorine bonds are highly reactive metals like the alkali metals, and at higher temperatures also such metals as aluminium and magnesium, and fluorinating agents such as xenon difluoride and cobalt(III) fluoride.

The coefficient of friction of plastics is usually measured against polished steel. PTFE's coefficient of friction is 0.05 to 0.10, which is the third-lowest of any known solid material (BAM being the first, with a coefficient of friction of 0.02; diamond-like carbon being second-lowest at 0.05). PTFE's resistance to van der Waals forces means that it is the only known surface to which a gecko cannot stick. In fact, PTFE can be used to prevent insects climbing up surfaces painted with the material.

PTFE is so slippery that insects cannot get a grip and tend to fall off. For example, PTFE is used to prevent ants climbing out of formicaria. Processing PTFE can be difficult and expensive, because the high melting temperature, 327 °C (621 °F), is above the initial decomposition temperature, 200 °C (392 °F). Even when melted, PTFE does not flow, but instead behaves as a gel due to the absence of crystalline phase and high melt viscosity. The major application of PTFE, consuming about 50% of production, is for wiring in aerospace and computer applications (e.g. hookup wire, coaxial cables).

This application exploits the fact that PTFE has excellent dielectric properties, especially at high radio frequencies, making it suitable for use as an excellent insulator in connector assemblies and cables, and in printed circuit boards used at microwave frequencies. Gore-Tex is a brand of expanded PTFE (ePTFE), a material incorporating a fluoropolymer membrane with micropores. The roof of the Hubert H. Humphrey Metrodome in Minneapolis, US, was one of the largest applications of PTFE coatings.

Thermoplastic Polyurethanes (TPU)

Thermoplastic polyurethane (TPU) is any of a class of polyurethane plastics with many properties, including elasticity, transparency, and resistance to oil, grease and abrasion. Technically, they are thermoplastic elastomers consisting of linear segmented block copolymers composed of hard and soft segments. TPU has many applications including automotive instrument panels, caster wheels, power tools, sporting goods, medical devices, drive belts, footwear, inflatable rafts, and a variety of extruded film, sheet and profile applications. TPU is also a popular material found in outer cases of mobile electronic devices, such as mobile phones. It is also used to make keyboard protectors for laptops. TPU is well known for its applications in performance films, wire and cable jacketing, hose and tube, in adhesive and textile coating applications and as an impact modifier of other polymers. TPU pellets are used as Adidas' most recent cushioning technology, known as Boost. Several thousands of TPU pellets are bound together to create a comfortable sole for the shoe.

Properties
- High abrasion resistance
- Low-temperature performance
- High shear strength
- High elasticity
- Transparency
- Oil and grease resistance

TPUs can be divided mainly in two groups:
- Polyester-based TPUs (mainly derived from adipic acid esters)
- Polyether-based TPUs (mainly based on tetrahydrofuran (THF) ethers).

Trade Names
Epamould, Epaline, Epacol, Pakoflex, Elastollan, Pearlthane, Desmopan, Estane, Pellethane, Irogran, Exelast EC, Laripur, Avalon, Isothane, Zythane, TPU 95A.

8 Ceramics

A ceramic is any of the various hard, brittle, heat-resistant and corrosion-resistant materials made by shaping and then firing a nonmetallic mineral, such as clay, at a high temperature. Common examples are earthenware, porcelain, and brick.

Clay Products

Kaolinite	Kaolinite is a clay mineral, part of the group of industrial minerals, with the chemical composition $Al_2Si_2O_5(OH)_4$. It is a layered silicate mineral, with one tetrahedral sheet of silica (SiO_4) linked through oxygen atoms to one octahedral sheet of alumina (AlO_6) octahedra. Rocks that are rich in kaolinite are known as kaolin or china clay. In many parts of the world it is coloured pink-orange-red by iron oxide, giving it a distinct rust hue. Lighter concentrations yield white, yellow, or light orange colours. Alternating layers are sometimes found, as at Providence Canyon State Park in Georgia, United States. Commercial grades of kaolin are supplied and transported as dry powder, semi-dry noodle or as liquid slurry.
Montmorillonite-Smectite	Montmorillonite is a very soft phyllosilicate group of minerals that form when they precipitate from water solution as microscopic crystals, known as clay. It is named after Montmorillon in France. Montmorillonite, a member of the smectite group, is a 2:1 clay, meaning that it has two tetrahedral sheets of silica sandwiching a central octahedral sheet of alumina. The particles are plate-shaped with an average diameter around 1 μm and a thickness of 0.96 nm; magnification of about 25,000 times, using an electron microscope, is required to "see" individual clay particles. Members of this group include saponite.
Illite	Illite is a group of closely related non-expanding clay minerals. Illite is a secondary mineral precipitate, and an example of a phyllosilicate, or layered alumino-silicate. Its structure is a 2:1 sandwich of silica tetrahedron (T) – alumina octahedron (O) – silica tetrahedron (T) layers. The space between this T-O-T sequence of layers is occupied by poorly hydrated potassium cations which are responsible for the absence of swelling. Structurally, illite is quite similar to muscovite with slightly more silicon, magnesium, iron, and water and slightly less tetrahedral aluminium and interlayer potassium.
Chlorite	The chlorites are a group of phyllosilicate minerals. Chlorites can be described by the following four endmembers based on their chemistry via substitution of the following four elements in the silicate lattice; Mg, Fe, Ni, and Mn. In addition, zinc, lithium, and calcium species are known. The great range in composition results in considerable variation in physical, optical, and X-ray properties. Similarly, the range of chemical composition allows chlorite group minerals to exist over a wide range of temperature and pressure conditions. For this reason chlorite minerals are ubiquitous minerals within low and medium temperature metamorphic rocks, some igneous rocks, hydrothermal rocks and deeply buried sediments.

MATERIALS Ceramics

Traditional Ceramics

Whitewares	Whitewares are not necessarily white. They consist typically of clays, feldspar, potter's flint, and whiting. The modern oxide ceramics would also be in this group. For technical use, these whitewares are usually vitrified (nonporous) or very nearly so. Most commonly the pieces are glazed. To produce white-bodied ceramics, the raw materials must be of superior quality and selection. The range of materials available is comparatively limited. Although clays are widely distributed over the Earth, large, uniform deposits of white burning clays are not common. Most whiteware clays are basically kaolins and chemically are hydrous aluminium silicates. Ball clays are less pure than kaolins and contain free silica and small amounts of other contaminants. Kaolins are generally not highly plastic, whereas ball clays are very plastic. The plasticity derives from the physical form of the minute particles, which are colloidal in size. Ball clays are not as white-burning as kaolins and impart colour to the fired body. Porcelains, china, and stoneware are composed of clays, silica, and feldspar. Steatites are composed of talc (magnesium silicate) and clay. Minor variations are made to enhance special properties.	**Includes** ● Porcelain ● China ● Pottery ● Earthenware ● Stoneware ● Steatites ● Vitreous Tile
Structural Clay Products	Structural clay products, ceramic products intended for use in building construction. Typical structural clay products are building brick, paving brick, terra-cotta facing tile, roofing tile, and drainage pipe. These objects are made from commonly occurring natural materials, which are mixed with water, formed into the desired shape, and fired in a kiln in order to give the clay mixture a permanent bond. Finished structural clay products display such essential properties as load-bearing strength, resistance to wear, resistance to chemical attack, attractive appearance, and an ability to take a decorative finish. Structural clay products are made from 35 to 55 percent clays or argillaceous (clayey) shales, 25 to 45 percent quartz, and 25 to 55 percent feldspar. As with all traditional ceramic products, the clay portion acts as a former, providing shaping ability; the quartz (silica) serves as a filler, providing strength to the formed object; and the feldspar serves as a fluxing agent, lowering the melting temperatures of the clay and quartz during firing. The proportions cited above are often found directly in shale deposits, so that blending is often not necessary. In addition, little or no beneficiation, or crushing and grinding of the mined material, is employed. Local clays or shales of highly variable composition are used in order to keep transportation costs as low as possible. The colour of the finished product derives from impurities, most notably iron oxides, present in the raw materials.	
Bricks	A brick is building material used to make walls, pavements and other elements in masonry construction. Traditionally, the term brick referred to a unit composed of clay, but it is now used to denote any rectangular units laid in mortar. A brick can be composed of clay-bearing soil, sand, and lime, or concrete materials. Bricks are produced in numerous classes, types, materials, and sizes which vary with region and time period, and are produced in bulk quantities. Two basic categories of bricks are fired and non-fired bricks. Block is a similar term referring to a rectangular building unit composed of similar materials, but is usually larger than a brick. Lightweight bricks (also called lightweight blocks) are made from expanded clay aggregate. Fired bricks are one of the longest-lasting and strongest building materials, sometimes referred to as artificial stone, and have been used since circa 4000 BC. Air-dried bricks, also known as mudbricks, have a history older than fired bricks, and have an additional ingredient of a mechanical binder such as straw. Bricks are laid in courses and numerous patterns known as bonds, collectively known as brickwork, and may be laid in various kinds of mortar to hold the bricks together to make a durable structure.	
Tiles	A tile is a thin object usually square or rectangular in shape. Tile is a manufactured piece of hard-wearing material such as ceramic, stone, metal, baked clay, or even glass, generally used for covering roofs, floors, walls, or other objects such as tabletops. Alternatively, tile can sometimes refer to similar units made from lightweight materials such as perlite, wood, and mineral wool, typically used for wall and ceiling applications. In another sense, a tile is a construction tile or similar object, such as rectangular counters used in playing games (see tile-based game). The word is derived from the French word tuile, which is, in turn, from the Latin word tegula, meaning a roof tile composed of fired clay. Tiles are often used to form wall and floor coverings, and can range from simple square tiles to complex or mosaics. Tiles are most often made of ceramic, typically glazed for internal uses and unglazed for roofing, but other materials are also commonly used, such as glass, cork, concrete and other composite materials, and stone. Tiling stone is typically marble, onyx, granite or slate. Thinner tiles can be used on walls than on floors, which require more durable surfaces that will resist impacts.	
Abrasives	Abrasive ceramics are used to grind or cut away other softer material. Primarily, when considering the design of a abrasive material it is hardness and wear resistance that are of the most importance. Toughness is also considered as a necessary requirement so that the abrasive material does not shatter during grinding. Abrasives can be either natural or synthetic. Common examples include diamond, silicon carbide SiC, tungsten carbide WC, or normal silica sand. Abrasives may generally be either bonded to grinding wheels, coated on paper, or exist as loose grains.	
Refractories	Because of their high heat resistance, ceramic materials are used as refractories. Refractory ceramics are insulating materials and are designed to withstand high stresses and temperatures and must also resist the effects of molten metals, abrasive particles and hot gases. Ceramics made of pure oxides are quite often the best refractories, however, these are expensive and therefore mixtures of ceramic compounds are often used.	

Electroceramics

Electronic Substrate Package Ceramics	Electronic substrate and package ceramics, advanced industrial materials that, owing to their insulating qualities, are useful in the production of electronic components. Modern electronics are based on the integrated circuit, an assembly of millions of interconnected components such as transistors and resistors that are built up on a tiny chip of silicon. In order to maintain their reliability, these circuits depend on insulating materials that can serve as substrates (that is, the bases on which the microscopic electronic components and their connections are built) and packages (that is, the structures that seal a circuit from the environment and make it a single, compact unit). The insulating properties of ceramics are well known, and these properties have found application in advanced ceramic materials for substrates and packages. The materials and products are described in this article.
Capacitor Dielectric, Piezoelectric Ceramics	Capacitor dielectric and piezoelectric ceramics, advanced industrial materials that, by virtue of their poor electrical conductivity, are useful in the production of electrical storage or generating devices. Capacitors are devices that store electric energy in the form of an electric field generated in the space between two separated, oppositely charged electrodes. Their capacity to store energy makes them essential components in many electric circuits, and that capacity can be greatly increased by inserting a solid dielectric material into the space separating the electrodes. Dielectrics are materials that are poor conductors of electricity. The nonconducting properties of ceramics are well known, and some ceramics are made into extremely effective dielectrics. Indeed, more than 90 percent of all capacitors are produced with ceramic materials serving as the dielectric. Piezoelectrics are materials that generate a voltage when they are subjected to mechanical pressure; conversely, when subjected to an electromagnetic field, they exhibit a change in dimension. Many piezoelectric devices are made of the same ceramic materials as capacitor dielectrics.
Magnetic Ceramics	Magnetic ceramics, oxide materials that exhibit a certain type of permanent magnetization called ferrimagnetism. Commercially prepared magnetic ceramics are used in a variety of permanent magnet, transformer, telecommunications, and information recording applications.

Optical Ceramics	Optical ceramics, advanced industrial materials developed for use in optical applications. Optical materials derive their utility from their response to infrared, optical, and ultraviolet light. The most obvious optical materials are glasses, which are described in the article industrial glass, but ceramics also have been developed for a number of optical applications. This article surveys several of these applications, both passive (e.g., windows, radomes, lamp envelopes, pigments) and active (e.g., phosphors, lasers, electro-optical components).
Conductive Ceramics	Conductive ceramics, advanced industrial materials that, owing to modifications in their structure, serve as electrical conductors. In addition to the well-known physical properties of ceramic materials—hardness, compressive strength, brittleness—there is the property of electric resistivity. Most ceramics resist the flow of electric current, and for this reason ceramic materials such as porcelain have traditionally been made into electric insulators. Some ceramics, however, are excellent conductors of electricity. Most of these conductors are advanced ceramics, modern materials whose properties are modified through precise control over their fabrication from powders into products.

Advanced Structural Ceramics

Nuclear Ceramics
Nuclear ceramics, ceramic materials employed in the generation of nuclear power and in the disposal of radioactive nuclear wastes. In their nuclear-related functions, ceramics are of major importance. Since the beginning of nuclear power generation, oxide ceramics, based on the fissionable metals uranium and plutonium, have been made into highly reliable fuel pellets for both water-cooled and liquid-metal-cooled reactors. Ceramics also can be employed to immobilize and store nuclear wastes. Although vitrification (glass formation) is a favoured approach for waste disposal, wastes can be processed with other ceramics into a synthetic rock, or synroc, or they can be mixed with cement powder to make hardened cements. All these nuclear applications are extremely demanding. In addition to severe thermal and chemical driving forces, nuclear ceramics are continuously subjected to high radiation doses.

Bioceramics
Bioceramics and bioglasses are ceramic materials that are biocompatible. Bioceramics are an important subset of biomaterials. Bioceramics range in biocompatibility from the ceramic oxides, which are inert in the body, to the other extreme of resorbable materials, which are eventually replaced by the body after they have assisted repair. Bioceramics are used in many types of medical procedures. Bioceramics are typically used as rigid materials in surgical implants, though some bioceramics are flexible. The ceramic materials used are not the same as porcelain type ceramic materials. Rather, bioceramics are closely related to either the body's own materials or are extremely durable metal oxides.

Tribological Ceramics
Tribological ceramics, also called wear-resistant ceramics, ceramic materials that are resistant to friction and wear. They are employed in a variety of industrial and domestic applications, including mineral processing and metallurgy. There are two basic mechanisms of tribological wear—impingement wear and rubbing wear. In impingement wear, particles impact and erode the surface. This is the major wear mechanism encountered in mineral handling, for example. Rubbing wear, on the other hand, occurs when two materials under load slide against each other. This wear occurs in such devices as rotating shafts, valve seats, and metal extrusion and drawing dies. Ceramics are well suited to resisting these mechanisms because, owing to the strong chemical bonds that hold them together, they tend to be extremely hard and strong. These properties are essential to tribological applications, but tribological ceramics display other important properties as well—most notably, elasticity, toughness, thermal expansion, and thermal conductivity.

Automotive Ceramics
Automotive ceramics, advanced ceramic materials that are made into components for automobiles. Examples include spark plug insulators, catalysts and catalyst supports for emission control devices, and sensors of various kinds. Catalytic converters are used to reduce the amounts of nitrogen oxides, carbon monoxide, and unreacted hydrocarbons in automotive emissions. Catalytic conversion requires a precisely balanced air-to-fuel ratio, hence the need for oxygen sensors such as those described in conductive ceramics: Oxygen sensors to aid in feedback control of fuel injection. In dual-bed converter systems the exhaust gases are first reduced in order to eliminate the oxides of nitrogen; then they are oxidized with added air in order to eliminate carbon monoxide and unburned hydrocarbons. In more advanced three-way converters individual catalysts accomplish reduction of each species simultaneously. Catalysts are either platinum-group metals or base metals such as chromium, nickel, and copper. In base-metal catalysts the active surfaces are actually ceramic oxides of the metals. Because platinum metals are extremely expensive, they are deposited on ceramic catalyst supports as salts and then reduced to finely divided metal particles. For efficiency of conversion, extremely large surface areas are required.

9 Glass

Glass is a non-crystalline amorphous solid that is often transparent and has widespread practical, technological, and decorative usage in, for example, window panes, tableware, and optoelectronics. The most familiar, and historically the oldest, types of glass are "silicate glasses" based on the chemical compound silica (silicon dioxide, or quartz), the primary constituent of sand. The term glass, in popular usage, is often used to refer only to this type of material, which is familiar from use as window glass and in glass bottles.

Of the many silica-based glasses that exist, ordinary glazing and container glass is formed from a specific type called soda-lime glass, composed of approximately 75% silicon dioxide (SiO_2), sodium oxide (Na_2O) from sodium carbonate (Na_2CO_3), calcium oxide (CaO), also called lime, and several minor additives. Many applications of silicate glasses derive from their optical transparency, giving rise to their primary use as window panes. Glass will transmit, reflect and refract light; these qualities can be enhanced by cutting and polishing to make optical lenses, prisms, fine glassware, and optical fibres for high speed data transmission by light.

Glass can be coloured by adding metallic salts, and can also be painted and printed with vitreous enamels. These qualities have led to the extensive use of glass in the manufacture of art objects and in particular, stained glass windows. Although brittle, silicate glass is extremely durable, and many examples of glass fragments exist from early glass-making cultures. Because glass can be formed or moulded into any shape, it has been traditionally used for vessels: bowls, vases, bottles, jars and drinking glasses.

In its most solid forms it has also been used for paperweights, marbles, and beads. When extruded as glass fibre and matted as glass wool in a way to trap air, it becomes a thermal insulating material, and when these glass fibres are embedded into an organic polymer plastic, they are a key structural reinforcement part of the composite material fibreglass.

Optical Properties	Glass is in widespread use largely due to the production of glass compositions that are transparent to visible light. In contrast, polycrystalline materials do not generally transmit visible light. The individual crystallites may be transparent, but their facets (grain boundaries) reflect or scatter light resulting in diffuse reflection. Glass does not contain the internal subdivisions associated with grain boundaries in polycrystals and hence does not scatter light in the same manner as a polycrystalline material. The surface of a glass is often smooth since during glass formation the molecules of the supercooled liquid are not forced to dispose in rigid crystal geometries and can follow surface tension, which imposes a microscopically smooth surface. These properties, which give glass its clearness, can be retained even if glass is partially light-absorbing—i.e., coloured. Glass has the ability to refract, reflect, and transmit light following geometrical optics, without scattering it (due to the absence of grain boundaries). It is used in the manufacture of lenses and windows.

Common glass has a refraction index around 1.5. This may be modified by adding low-density materials such as boron, which lowers the index of refraction or increased (to as much as 1.8) with high-density materials such as lead oxide, or in modern uses, less toxic oxides of zirconium, titanium, or barium. These high-index glasses (inaccurately known as "crystal" when used in glass vessels) cause more chromatic dispersion of light, and are prized for their diamond-like optical properties. According to Fresnel equations, the reflectivity of a sheet of glass is about 4% per surface (at normal incidence in air), and the transmissivity of one element (two surfaces) is about 90%. Glass with high germanium oxide content also finds application in optoelectronics—e.g., for light-transmitting optical fibres.

Other Properties	In the process of manufacture, silicate glass can be poured, formed, extruded and moulded into forms ranging from flat sheets to highly intricate shapes. The finished product is brittle and will fracture, unless laminated or specially treated, but is extremely durable under most conditions. It erodes very slowly and can mostly withstand the action of water. It is mostly resistant to chemical attack, does not react with foods, and is an ideal material for the manufacture of containers for foodstuffs and most chemicals. Glass is also a fairly inert substance.
Corrosion	Although glass is generally corrosion-resistant and more corrosion resistant than other materials, it still can be corroded. The materials that make up a particular glass composition have an effect on how quickly the glass corrodes. A glass containing a high proportion of alkalis or alkali earths is less corrosion-resistant than other kinds of glasses. Glass flakes have applications as anti-corrosive coating.
Strength	Glass typically has a tensile strength of 7 megapascals (1,000 psi), however theoretically it can have a strength of 17 gigapascals (2,500,000 psi) due to glass's strong chemical bonds. Several factors such as imperfections like scratches and bubbles and the glass's chemical composition impact the tensile strength of glass. Several processes such as toughening can increase the strength of glass.
Colour	Colour in glass may be obtained by addition of electrically charged ions (or colour centres) that are homogeneously distributed, and by precipitation of finely dispersed particles (such as in photochromic glasses). Ordinary soda-lime glass appears colourless to the naked eye when it is thin, although iron(II) oxide (FeO) impurities of up to 0.1 wt% produce a green tint, which can be viewed in thick pieces or with the aid of scientific instruments. Further FeO and chromium(III) oxide (Cr_2O_3) additions may be used for the production of green bottles. Sulphur, together with carbon and iron salts, is used to form iron polysulfides and produce amber glass ranging from yellowish to almost black. A glass melt can also acquire an amber colour from a reducing combustion atmosphere. Manganese dioxide can be added in small amounts to remove the green tint given by iron(II) oxide. Art glass and studio glass pieces are coloured using closely guarded recipes that involve specific combinations of metal oxides, melting temperatures and "cook" times. Most coloured glass used in the art market is manufactured in volume by vendors who serve this market, although there are some glassmakers with the ability to make their own colour from raw materials.

Silicate Glass

Silica (SiO_2) is a common fundamental constituent of glass. In nature, vitrification of quartz occurs when lightning strikes sand, forming hollow, branching root-like structures called fulgurites. Fused quartz is a glass made from chemically-pure silica. It has excellent resistance to thermal shock, being able to survive immersion in water while red hot. However, its high melting temperature (1723 °C) and viscosity make it difficult to work with. Normally, other substances are added to simplify processing.

One is sodium carbonate (Na_2CO_3, "soda"), which lowers the glass-transition temperature. The soda makes the glass water-soluble, which is usually undesirable, so lime (CaO, calcium oxide, generally obtained from limestone), some magnesium oxide (MgO) and aluminium oxide (Al_2O_3) are added to provide for a better chemical durability. The resulting glass contains about 70 to 74% silica by weight and is called a soda-lime glass.

Soda-lime glasses account for about 90% of manufactured glass. Most common glass contains other ingredients to change its properties. Lead glass or flint glass is more "brilliant" because the increased refractive index causes noticeably more specular reflection and increased optical dispersion. Adding barium also increases the refractive index. Thorium oxide gives glass a high refractive index and low dispersion and was formerly used in producing high-quality lenses, but due to its radioactivity has been replaced by lanthanum oxide in modern eyeglasses.

Iron can be incorporated into glass to absorb infrared radiation, for example in heat-absorbing filters for movie projectors, while cerium(IV) oxide can be used for glass that absorbs ultraviolet wavelengths. The following is a list of the more common types of silicate glasses and their ingredients, properties, and applications:

Fused quartz / Fused-Silica Glass / Vitreous-Silica Glass	Silica (SiO_2) in vitreous, or glass, form (i.e., its molecules are disordered and random, without crystalline structure). It has very low thermal expansion, is very hard, and resists high temperatures (1000–1500 °C). It is also the most resistant against weathering (caused in other glasses by alkali ions leaching out of the glass, while staining it). Fused quartz is used for high-temperature applications such as furnace tubes, lighting tubes, melting crucibles, etc.
Soda-Lime-Silica glass / Window Glass	Silica + sodium oxide (Na_2O) + lime (CaO) + magnesia (MgO) + alumina (Al_2O_3). Is transparent, easily formed and most suitable for window glass (see flat glass). It has a high thermal expansion and poor resistance to heat (500–600 °C). It is used for windows, some low-temperature incandescent light bulbs, and tableware. Container glass is a soda-lime glass that is a slight variation on flat glass, which uses more alumina and calcium, and less sodium and magnesium, which are more water-soluble. This makes it less susceptible to water erosion.
Sodium Borosilicate Glass / Pyrex	Silica + boron trioxide (B_2O_3) + soda (Na_2O) + alumina (Al_2O_3). Stands heat expansion much better than window glass. Used for chemical glassware, cooking glass, car head lamps, etc. Borosilicate glasses (e.g. Pyrex, Duran) have as main constituents silica and boron trioxide. They have fairly low coefficients of thermal expansion (7740 Pyrex CTE is 3.25×10^{-6}/°C as compared to about 9×10^{-6}/°C for a typical soda-lime glass), making them more dimensionally stable. The lower coefficient of thermal expansion (CTE) also makes them less subject to stress caused by thermal expansion, thus less vulnerable to cracking from thermal shock. They are commonly used for reagent bottles, optical components and household cookware.
Lead-Oxide Glass / Crystal Glass / Lead Glass	Silica + lead oxide (PbO) + potassium oxide (K_2O) + soda (Na_2O) + zinc oxide (ZnO) + alumina. Because of its high density (resulting in a high electron density), it has a high refractive index, making the look of glassware more brilliant (called "crystal", though of course it is a glass and not a crystal). It also has a high elasticity, making glassware "ring". It is also more workable in the factory, but cannot stand heating very well. This kind of glass is also more fragile than other glasses and is easier to cut.
Aluminosilicate Glass	Silica + alumina + lime + magnesia + barium oxide (BaO) + boric oxide (B_2O_3). Extensively used for fibreglass, used for making glass-reinforced plastics (boats, fishing rods, etc.) and for halogen bulb glass. Aluminosilicate glasses are also resistant to weathering and water erosion.
Germanium-Oxide Glass	Alumina + germanium dioxide (GeO_2). Extremely clear glass, used for fibre-optic waveguides in communication networks. Light loses only 5% of its intensity through 1 km of glass fibre.
Crushed Alkali Glass	Another common glass ingredient is crushed alkali glass or 'cullet' ready for recycled glass. The recycled glass saves on raw materials and energy. Impurities in the cullet can lead to product and equipment failure. Fining agents such as sodium sulphate, sodium chloride, or antimony oxide may be added to reduce the number of air bubbles in the glass mixture. Glass batch calculation is the method by which the correct raw material mixture is determined to achieve the desired glass composition.

Fibreglass

MATERIALS Glass Fiberglass

Fibreglass (also called glass-reinforced-plastic) is a composite material made up of glass fibres (also called fibreglass or glass friller) embedded in a plastic resin. It is made by melting glass and stretching the glass into fibres. These fibres are woven together into a cloth and left to set in a plastic resin. Fibreglass filaments are made through a pultrusion process in which the raw materials (sand, limestone, kaolin clay, fluorspar, colemanite, dolomite and other minerals) are melted in a large furnace into a liquid which is extruded through very small orifices (5–25 micrometres in diameter if the glass is E-glass and 9 micrometers if the glass is S-glass). Fibreglass has the properties of being lightweight and corrosion resistant. Fibreglass is also a good insulator, allowing it to be used to insulate buildings. Most fibreglasses are not alkali resistant. Fibreglass also has the property of becoming stronger as the glass ages.

Electrolytes

Electrolytes or molten salts are mixtures of different ions. In a mixture of three or more ionic species of dissimilar size and shape, crystallization can be so difficult that the liquid can easily be supercooled into a glass. The best-studied example is Ca0.4K0.6(NO3). Glass electrolytes in the form of Ba-doped Li-glass and Ba-doped Na-glass have been proposed as solutions to problems identified with organic liquid electrolytes used in modern lithium-ion battery cells.

Glass Properties

Glass is a unique and extremely versatile material that can be engineered to exhibit specific optical, thermal, chemical, and mechanical properties. As a result of its exceptional engineering properties – transparency, strength, workability, transmittance and u value, glass has been heavily used in the construction industry. We will briefly feature some of the most common commercial glass types and typical applications.

Annealed Glass (Float Glass)	Annealed glass is the basic flat glass product that is the first result of the float process. It is the common glass that tends to break into large, jagged shards. It is used in some end products -- often in double-glazed windows, for example. It is also the starting material that is turned into more advanced products through further processing such as laminating, toughening, coating, etc. The float glass process is renowned for flatness and optical clarity. It is available in clear, toned, high performance toned, ultra clear low iron glass and Low E pyrolitic coated.
Insulated Glass (Double Glazing)	Two or more panels of glass are bonded to a perimeter spacer, either a metal or thermoplastic spacer, (TPS). Either air or argon gas fills the space between the glass panes. Their primary benefit is insulation and solar control. Most types of glass can be incorporated into an insulating glass unit.
Toughened Glass	Toughened glass is treated to be far more resistant to breakage than simple annealed glass, and to break in a more predictable way when it does break, thus providing a major safety advantage in almost all of its applications. Toughened glass is made from annealed glass treated with a thermal tempering process. A sheet of annealed glass is heated to above its "annealing point" of 600 °C; its surfaces are then rapidly cooled while the inner portion of the glass remains hotter. The different cooling rates between the surface and the inside of the glass produces different physical properties, resulting in compressive stresses in the surface balanced by tensile stresses in the body of the glass. These counteracting stresses give toughened glass its increased mechanical resistance to breakage, and are also, when it does break, what cause it to produce regular, small, typically square fragments rather than long, dangerous shards that are far more likely to lead to injuries. Toughened glass also has an increased resistance to breakage as a result of stresses caused by different temperatures within a pane. Toughened glass has extremely broad application. Glass portions of building façades, glass sliding doors and partitions in houses and offices, and many other products typically use toughened glass. Products made from toughened glass often also incorporate other technologies.
Heat Strengthen Glass	With heat-strengthened glass, the cooling process is slower, which results in lower compression strength. Heat-strengthened glass is approximately twice as strong as annealed, or untreated, glass.
Fully Tempered Glass	Before the glass can be used as a building material it is often heat-treated for durability and safety. There are two different types of heat-treated glasses, heat-strengthened and tempered. While the production process is similar, heating the glass to approximately 1,200°F and then force-cooling, the cooling process in tempered glass is accelerated to create a higher surface and/or edge compression in the glass. This process makes the glass four to five times stronger and safer than annealed or untreated glass. Fully-tempered safety glass is often used for other applications where safety is desirable, because of its break pattern or when significant additional strength is needed to resist wind pressure, thermal stress or both.
Laminated Glass	Laminated glass is made of two or more layers of glass with one or more "interlayers" of polymeric material bonded between the glass layers. Laminated glass offers many advantages. Safety and security are the best-known of these -- rather than shattering on impact, laminated glass is held together by the interlayer, reducing the safety hazard associated with shattered glass fragments, as well as, to some degree, the security risks associated with easy penetration. But the interlayer also provides a way to apply several other technologies and benefits, such as colouring, sound dampening, resistance to fire, ultraviolet filtering, and other technologies that can be embedded in or with the interlayer. Laminated glass is used extensively in building and housing products and in the automotive and transport industries. Most building façades and most car windscreens, for example, are made with laminated glass, usually with other technologies also incorporated.

Laminated glass is produced using one of two methods:
● Poly Vinyl Butyral (PVB) laminated glass is produced using heat and pressure to sandwich a thin layer of PVB between layers of glass. On occasion, other polymers such as Ethyl Vinyl Acetate (EVA) or Polyurethane (PU) are used. This is the most common method.
● For special applications, Cast in Place (CIP) laminated glass is made by pouring a resin into the space between two sheets of glass that are held parallel and very close to each other.

Coated	Surface coatings can be applied to glass to modify its appearance and give it many of the advanced characteristics and functions available in today's flat glass products, such as low maintenance, special reflection/transmission/absorption properties, scratch resistance, corrosion resistance, etc. Coatings are usually applied by controlled exposure of the glass surface to vapours, which bind to the glass forming a permanent coating. The coating process can be applied while the glass is still in the float line with the glass still warm, producing what is known as "hard-coated" glass. Alternatively, in the "off-line" or "vacuum" coating process, the vapour is applied to the cold glass surface in a vacuum vessel. Coated glasses can be toughened, laminated or incorporated into an insulating glass unit.
Security Glass	Glass that is designed to resist physical attack, ballistic and bomb blasts. These products are specialist laminates that use multiple layers of glass and rigid interlayers depending on the resistance required.

Poly Vinyl Butyral (PVB)	Poly Vinyl Butyral or PVB laminated glass is produced using heat and pressure to sandwich a thin layer of PVB between layers of glass. SGP stands for SentryGuard Plus Interlayer manufactured by Dupont. Thanks to its high-security performance, the SGP can withstand severe weather conditions such as storms, hurricane, and cyclones. The SGP also demonstrates higher post breakage strength, as the interlayer offers five times the tear strength and 100 times the rigidity of the more conventional PVB interlayer. Another common polymer known as Ethyl Vinyl Acetate (EVA) is frequently combined with other materials to achieve striking decorative effects. An alternative laminating technique to standard interlayer lamination using PVB or Sentry interlayers is Resin Lamination or Cast in Place (CIP). Resin lamination involves mechanically holding two panels of glass together and pouring liquid resin into the small gap in-between. Once the small cavity between the glass panels has been filled, the resin is then cured, either using a chemical process or under the effect of ultraviolet radiation on UV beds.

Resin lamination is especially suited to glass panels with an uneven surface such as kiln formed or cast glass. Laminated glass is used extensively in building and housing products and in the automotive and transport industries vastly on account of its advanced safety features. Laminated glass displays high-performance impact and bullet resistance capabilities as well as fragment retention performance. So, instead of shattering on impact, it is held together by the interlayer which reduces the safety hazard from the shattered glass fragments. But the interlayer also provides a way to apply several other technologies and benefits, such as colouring, sound dampening, resistance to fire, ultraviolet filtering and other technologies that can be embedded in or with the interlayer.

Screen Printed Glass	Uses ceramic paint that is screen printed and permanently fused to the toughened glass surface.
Mirrored Glass	To produce mirrored glass, a metal coating is applied to one side of the glass. The coating is generally made of silver, aluminium, gold or chrome. For simple mirrored glass, a fully reflective metal coating is applied and then sealed with a protective layer. It can also include a vinyl backing for safety. To produce "one-way" mirrors, a much thinner metal coating is used, with no additional sealing or otherwise opaque layer. Mirrored glass is gaining a more prominent place in architecture, for important functional reasons as well as for the aesthetic effect.
Patterned Glass	Patterned glass is flat glass whose surfaces display a regular pattern. The most common method for producing patterned glass is to pass heated glass (usually just after it exits the furnace where it is made) between rollers whose surfaces contain the negative relief of the desired pattern(s). Patterned glass is mostly used in internal decoration and internal architecture. Today, it is typically used for functional reasons, where light but not transparency is desired, and the patterns are accordingly subtle. However, it has also at times been fashionable as a design feature in itself, in such cases often displaying more prominent patterns.
Self Cleaning Glass	Used for exteriors. The glass incorporates a pyrolitic coating that dissolves dirt (photo activ) and sheds water (hydrophilic) using natural UV light and rain.
Low-Iron/ Extra Clear Glass	Extra clear glass is created by reducing the amount of iron within its content which removes the green tint inherent in standard glass. Extra clear glass's almost completely transparent appearance means it has limited sun reflection properties. It is particularly useful in solar energy applications where it is important that the glass cover lets light through to reach the thermal tubes or photovoltaic cells. Anti-reflective properties can be further increased by applying a special coating on the low-iron glass. It's widely used in windows or facades as it offers brilliant clarity, which allows occupants to appreciate true colours and to enjoy true-to-life views.
Decorative Glass	Today, there are various decorative glass types offer a variety of design options for residential or commercial solutions. Acid etched is called the glass that has been chemically treated with an acidic material, such as hydrofluoric acid, to produce a surface finish that will diffuse transmitted light, reduce glare and has a "frosted" appearance. The treatment on the glass is used to diffuse light, reduce glare and obtain a translucent appearance. The treatment on a mirror is used to obtain a soft matted reflection. The treatment can be applied to provide different levels of translucence, either uniformly over the entire surface or in selected areas creating decorative patterns. While a Ceramic Frit or Silk Screen is a pigmented glass enamel fired onto the glass at temperatures in excess of 1,200°F and permanently fused to the glass surface. Ceramic frit can be applied using a full coverage coating process, a silk screen process or a pre-printed ceramic decal. This type of decorative glass is available in many colours, patterns, and translucencies and is used for both exterior and interior applications.

10 Composites

The below composite materials are common in the camping and ultralight hiking circles. They are harder to get substances and often pricier but offer great statistics for what they do.

Tritan

Tritan is the plastic-like compound which Nalgene uses to produce their unbreakable bottles. It's a very hard wearing and heavy duty substance and they claim to be unbreakable.

Cuben Fibre (Dyneema)

Dyneema Composite Fabrics are high-performance, non-woven, rip-stop, composite laminates. Dyneema fibre is laid out in opposing grid orientations, sandwiched between thin outer layers of polyester film, and melded together in a high-pressure autoclave. Dyneema Composite Fabrics are highly durable but light enough to float on water. The material's unique properties allow for continual flex at stress points without compromising strength or structural integrity. Lighter than Silnylon but stronger than Kevlar, Dyneema Composite Fabrics are 100% waterproof prior to stitching with high chemical and UV resistance. Originally designed for use in high tech sails for America's Cup racing boats, and marketed as Cuben Fibre, Dyneema Composite Fabrics are regarded as the premium material of choice for modern ultralight tents, backpacking tarps, and stuff sacks.

DCF8 **0.8 oz/yd2 // 26 g/m2**	Used in: Ultamid 2, Ultamid 4, Echo II Shelter System, Flat Tarps, Drawstring Stuff Sacks, + Stuff Sack Pillows.
DCF11 **1.3 oz/yd2 // 43 g/m2**	Used in: Pods, Drawstring Stuff Sacks, Roll-Top Stuff Sacks, Stuff Pack, and all Shelter Inserts.
DCF-WPB **1.2 oz/yd2 // 40 g/m2**	Used in: The Shell (Jacket)
DCH50 **3.5 oz/yd2 // 120 g/m2**	50-Denier White: 2400 + 3400 Pack Bodies, Metro + Summit Pack
DCH150 **5.0 oz/yd2 // 170 g/m2**	150-Denier Black: 2400 + 3400 Pack Bodies, Daybreak, Metro + Summit Pack 150-Denier White: 4400 Packs.
DCHW **5.0 oz/yd2 // 170 g/m2**	375-Denier White: The Dyneema Series

Cuben fibre is not as durable as some other materials used in the construction of backpacking gear. In backpacking lighter often means less durable which is generally true for cuben fibre as well. Cuben fibre resists puncture and tearing relatively well. Not so much with abrasion and folding. Cuben fibre is less durable than sil-nylon. It also depends on the application (tent, stuff sack, pack, etc). Once damaged, it is easy to apply duct tape to it for field repair. You can also use cuben fibre patches. Cuben Fibre is often used as a tear resistant groundsheet for camping.

Thickness

The thickness of cuben fibre is measured in oz/sq inch. The following cells describe common thicknesses and how they feel.

0.5 oz/sq inch	Extremely thin and feels like plastic.
0.75 oz/sq inch	
1 oz/sq inch	
2 oz/sq inch	
3 oz/sq inch	
5 oz/sq inch	

Silnylon

Tyvek

Tyvek (House Wrap) is a brand of flashspun high-density polyethylene fibres, a synthetic material. Tyvek is often used as housewrap, a synthetic material used to protect buildings during construction. It can be used as a strong tear resistant groundsheet for camping. Sound very similar to a chip packet as described by many, so this material may not be the best for stealth camping. The material is difficult to tear but can easily be cut with scissors or a knife. Water vapour can pass through Tyvek, but liquid water cannot.

Properties
- Light weight
- Class 1 flammability rating
- Chemical resistant
- Dimensional stabilized
- Opaque
- Neutral pH
- Tear resistant

11 Dangerous Goods

There are 9 dangerous goods classes. Substances, and articles are assigned to one of the following 9 classes according to the most predominant hazards they pose in transport. Some of the classes can be further divided down.

Class 1

Class 1 - Explosives	**Class 1 dangerous goods are explosive substances and articles.**	Commonly transported Class 1 Dangerous Goods include ammunitions, fireworks, air bag inflactors and fuse, etc.			
Divisions	**Division 1.1:** Mass explosion hazard **Division 1.2:** Projection hazard but not a mass explosion hazard **Division 1.3:** Fire hazard and a minor blast hazard, a minor projection hazard or both	**Division 1.4** Present no significant hazard; only a small hazard in the event of ignition or initiation	**Division 1.5** Very insensitive substances which have a mass explosion hazard	**Division 1.6** Extremely insensitive articles which do not have a mass explosion hazard	
Symbols	 **Class 1** Division 1.1, 1.2, 1.3	 **Class 1** Division Type 1.4	 **Class 1** Division Type 1.5	 **Class 1** Division Type 1.6	
Examples	• Ammunition/cartridges • Fireworks/pyrotechnics • Flares • Blasting caps / detonators • Fuse	• Primers • Explosive charges (blasting, demolition etc) • Detonating cord • Air bag inflators	• Igniters • Rockets • TNT / TNT compositions • RDX / RDX compositions • PETN / PETN compositions		

Class 2

Class 2 - Gases	**Class 2 dangerous goods are gases. It covers compressed gases, liquefied gases, dissolved gases, refrigerated liquefied gases, mixtures of gases and aerosol dispensers/articles containing gas.**	Commonly transported class 2 dangerous goods include oxygen, natural gas, carbon dioxide, lighters, and aerosols.				
Divisions	**Division 2.1** Flammable gases		**Division 2.2** Non-flammable, non-toxic gases		**Division 2.3** Toxic gases	
Symbols	 **Class 2** **Division 2.1** Flammable Gases	 **Class 2** **Division 2.1** Flammable Gases	 **Division Type 2.2** Non-flammable, non-toxic Gases	 **Division Type 2.2** Non-flammable, non-toxic Gases	 **Class 2** **Division Type 2.3** Toxic Gases	
Examples	• Aerosols • Compressed air • Hydrocarbon gas-powered devices • Fire extinguishers • Gas cartridges • Natural gas • Oil gas • Petroleum gases	• Ethylene • Fertilizer ammoniating solution • Insecticide gases • Refrigerant gases • Lighters • Acetylene / Oxyacetylene • Butane • Propane • Ethane	• Methane • Carbon dioxide • Helium / helium compounds • Hydrogen / hydrogen compounds • Oxygen / oxygen compounds • Nitrogen / nitrogen compounds • Methane • Dimethyl ether • Propene / propylene			

Class 3

Class 3 - Flammable Liquids	**Class 3 dangerous goods are flammable liquids with flash points no more than 60°C.**	It covers liquid substances, molten solid substances with a flash point above 60°C and liquid desensitized explosives. Commonly transported class 3 dangerous goods include acetone, adhesives, paints, gasoline, perfume, ethanol, methanol and some pesticides with flammable solvents.				
Symbols	 **Class 3**	 **Class 3**				
Examples	• Acetone / acetone oils • Adhesives • Paints / lacquers / varnishes • Alcohols • Perfumery products • Kerosene • Resins • Tars • Turpentine • Carbamate insecticides • Organochlorine pesticides • Ethers	• Gasoline / Petrol • Diesel fuel • Aviation fuel • Liquid bio-fuels • Coal tar / coal tar distillates • Ethanol • Benzene • Butanols • Dichloropropenes • Diethyl ether • Organophosphorus pesticides	• Petroleum crude oil • Petroleum distillates • Gas oil • Shale oil • Heating oil • Isobutanols • Isopropyls • Methanol • Octanes • Copper based pesticides • Esters			

Class 4

Class 4 - Flammable Solids	**Class 4 dangerous goods include flammable solids, substances liable to spontaneous combustion and substances which, in contact with water, emit flammable gases.**	Commonly transported class 4 dangerous goods include sulphur, matches, activated carbon, alkali metals and some metal powders.				
Divisions	**Division 4.1** Flammable solids	**Division 4.2** Substances liable to spontaneous combustion	**Division 4.3** Substances which, in contact with water, emit flammable gases			
Symbols	 **Class 4** **Division 4.1** Flammable Solids	 **Class 4** **Division 4.2** Possible Spontaneous Combustion	 **Class 4** **Division 4.3** Emits flammable gas on water contact	 **Class 4** **Division 4.3** Emits flammable gas on water contact		

Examples	• Alkali metals • Metal powders • Aluminium phosphide • Sodium batteries • Sodium cells • Firelighters • Matches • Calcium carbide • Camphor • Carbon	• Activated carbon • Celluloid • Cerium • Copra • Seed cake • Oily cotton waste • Desensitized explosives • Oily fabrics • Oily fibres • Ferrocerium	• Iron oxide (spent • Iron sponge/direct-reduced iron (spent) • Metaldehyde • Naphthalene • Nitrocellulose • Phosphorus • Sulphur	

Class 5

Class 5 - Oxidizing Substances	**Class 5 dangerous goods are oxidizing substances and organic peroxides.**	Commonly transported class 5 dangerous goods include hydrogen peroxide, potassium permanganate, sodium nitrite, ammonium nitrate fertilizers and oxygen generators.				
Divisions	**Division 5.1** Oxidizing substances	**Division 5.2** Organic peroxides				
Symbols	 **Class 5** **Division 5.1** Oxidizing Substances	 **Class 5** **Division 5.2** Organic Peroxides	 **Class 5** **Division 5.2** Organic Peroxides			
Examples	• Chemical oxygen generators • Ammonium nitrate fertilizers • Chlorates • Nitrates • Nitrites • Perchlorates • Permanganates • Persulphates • Aluminium nitrate	• Ammonium dichromate • Hydrogen peroxide • Magnesium peroxide • Lead nitrate • Lithium hypochlorite • Potassium chlorate • Ammonium nitrate • Ammonium persulphate • Calcium hypochlorite	• Calcium nitrate • Calcium peroxide • Potassium nitrate • Potassium chlorate • Potassium perchlorate • Potassium permanganate • Sodium nitrate • Sodium persulphate			

Class 6

Class 6 - Toxic and Infectious Substances	**Class 6 dangerous goods are toxic substances and infectious substances.**	Usually chemicals which are classified as acute toxicity category 1, 2 and 3 under GHS belong to class 6.1 dangerous goods. Commonly transported class 6 dangerous goods include cyanides, lead compounds, phenol, cresols, some pesticides, biological samples and clinical wastes.				
Divisions	**Division 6.1** Toxic substances	**Division 6.2** Infectious substances				
Symbols	 **Class 6** **Division 6.1** Toxic Substances	 **Class 6** **Division 6.2** Infectious Substances				
Examples	• Medical/Biomedical waste • Clinical waste • Biological cultures / samples / specimens • Medical cultures / samples / specimens • Tear gas substances • Motor fuel anti-knock mixture • Dyes • Carbamate pesticides • Alkaloids	• Acids • Arsenates • Arsenites • Cyanides • Thiols/mercaptans • Cresols • Barium compounds • Arsenics / arsenic compounds • Beryllium/ beryllium compounds • Lead compounds • Resorcinol	• Mercury compounds • Nicotine / nicotine compounds • Selenium compounds • Antimony • Ammonium metavanadate • Adiponitrile • Chloroform • Dichloromethane • Hexachlorophene • Phenol • Allyls			

Class 7

Class 7 - Radioactive Materials	**Class 7 dangerous goods are radioactive materials. There is no sub-division.**	However, there are different labels for radioactive materials which depend on the content and activity of such materials. Commonly transported class 7 dangerous goods include enriched uranium, radioactive ores, isotopes and some medical equipments or parts.				
Symbols	 **Class 7** **Division 7A** Radioactive	 **Class 7** **Division 7B** Radioactive	 **Class 7** **Division 7C** Radioactive	 **Class 7** **Division 7E** Fissile Material		

MATERIALS | Dangerous Goods | Class

Examples	• Radioactive ores • Medical isotopes • Yellowcake • Density gauges • Mixed fission products • Enriched Uranium	• Surface contaminated objects • Caesium radionuclides / isotopes • Iridium radionuclides / isotopes • Americium radionuclides / isotopes • Plutonium radionuclides / isotopes • Radium radionuclides / isotopes	• Thorium radionuclides / isotopes • Uranium radionuclides / isotopes • Depleted uranium / depleted uranium products • Uranium hexafluoride	

MATERIALS | Dangerous Goods | Class 8 -

Class 8

MATERIALS | Dangerous Goods | Class 8 - Corrosive Substances

Class 8 - Corrosive Substances	**Class 8 dangerous goods are corrosive substances. There is no sub-division.**	Corrosive substances may cause severe damage when in contact with living tissue such as skin or damage or destroy surrounding materials in case of leakage. Commonly transported class 8 dangerous goods include acids such as sulphuric acid, strong bases such as sodium hydroxide, batteries and its fluids.				
Divisions	Skin irritation/corrosion category 1 (1A/1B/1C) - GHS. Class 8 corrosive substances, Packing group I, II, III - TDG					
Symbols	 Class 8					
Examples	• Acids/acid solutions • Batteries • Battery fluid • Fuel cell cartridges • Dyes • Fire extinguisher charges • Formaldehyde • Flux • Paints	• Alkylphenols • Amines • Polyamines • Sulphides • Polysulphides • Chlorides • Chlorosilanes • Bromine • Cyclohexylamine	• Phenol / carbolic acid • Hydrofluoric acid • Hydrochloric acid • Sulphuric acid • Nitric acid • Sludge acid • Hydrogen fluoride • Iodine • Morpholine			

MATERIALS | Dangerous Goods

Class 9

MATERIALS | Dangerous Goods | Class 9 - Miscellaneous Substances

Class 9 - Miscellaneous Dangerous Substances	**Class 9 Miscellaneous Dangerous Goods are substances and articles which during transport present a danger or hazard not covered by other 8 classes.**	This class encompasses, but is not limited to, environmentally hazardous substances, substances that are transported at elevated temperatures, miscellaneous articles and substances, genetically modified organisms and micro-organisms and magnetized materials and aviation regulated substances. Commonly transported class 9 dangerous goods include marine pollutants such as zinc oxide, lithium ion batteries, genetically modified organisms, air bag modules and motor engines.				
Symbols	 Class 9					
Examples	• Dry ice / cardice / solid carbon dioxide • Expandable polymeric beads / polystyrene beads • Ammonium nitrate fertilizers • Blue asbestos / crocidolite • Lithium ion batteries • Lithium metal batteries • Battery powered equipment • Battery powered vehicles	• Internal combustion engines • Vehicles • Magnetized material • Dangerous goods in apparatus • Dangerous goods in machinery • Genetically modified organisms • Genetically modified micro-organisms • Chemical kits • First aid kits	• Life saving appliances • Air bag modules • Seatbelt pretensioners • Plastics moulding compound • Castor bean plant products • Polychlorinated biphenyls • Polychlorinated terphenyls • Dibromodifluoromethane • Benzaldehyde • Fuel cell engines			

Communication

Any form of contact from radio to smoke signals and chalk markings

"The single biggest problem in communication
is the illusion that it has taken place."
George Bernard Shaw

Introduction

There are a huge array of communication forms from visual, digital, verbal and physical. Knowing which to use and how to communicate a message is vital.

The main steps inherent to all communication are:
1. The formation of communicative motivation or reason.
2. Message composition (further internal or technical elaboration on what exactly to express).
3. Message encoding (for example, into digital data, written text, speech, pictures, gestures and so on).
4. Transmission of the encoded message as a sequence of signals using a specific channel or medium.
5. Noise sources such as natural forces and in some cases human activity (both intentional and accidental) begin influencing the quality of signals propagating from the sender to one or more receivers.
6. Reception of signals and reassembling of the encoded message from a sequence of received signals.
7. Decoding of the reassembled encoded message.
8. Interpretation and making sense of the presumed original message.

Purpose	The aim of COMMUNICATION is to educate the reader on a multitude of different ways they can communicate a message to another person. It includes information on speaking, gestures, digital communication, radio communication, codes, ciphers, markings and more.
Lost?	● If you want to communicate with someone who speaks another language, see the LANGUAGE section. ● If you are looking for effective communication techniques for a leader, see the LEADERSHIP section. ● If you want to work out how far a broadcast will travel, see the GEOGRAPHY > World Map section. ● For information on setting up a communications hub in your home, see the HOMESTEADING section. ● If you want to communicate for leisure, see the ENTERTAINMENT section. ● If you want to understand the meaning of unknown words, see the ADDENDUM > Dictionary section.

Contents

1 Unpowered Communication

This section covers any unpowered forms of communication and how to use them.

Subheadings

1. Signalling for Help	**2. Body Gestures**	**3. Flag Semaphore**	**4. Audible Communication**

1 Signalling for Help

This section helps you to be found by bystanders if you're lost or trapped.

SOS is the International Morse code distress signal. It is used as a start-of-message mark for transmissions requesting help when loss of life or catastrophic loss of property is imminent. In popular usage, SOS became associated with such phrases as "Save our Souls" and "Save our Ship". The radio frequency of 500 kilohertz (500 kHz) has been an international calling and distress frequency for Morse code maritime communication since early in the 20th century. The radio frequency 2182 kHz is one of the international calling and distress frequencies for maritime radio communication in a frequency band allocated to the mobile service on primary basis, exclusively for distress and calling operations.	SOS • • • — — — • • •

Mirror Signalling

Light the signal fire to produce thick black smoke. Use a mirror or reflective surface to bounce it off the plane. Have an SOS or HELP sign to convey you need assistance.

Fire Signalling

Light the signal fire in a large open area so the light is visible from a great distance.

Flare Gun

Use a flare or flare gun to attract attention.

Light Sources

Use any lighting sources such as mobiles to wave around to attract attention.

Smoke Signals

Smoke

Smoke signals are a form of visual communication used over long distances. In general smoke signals are used to transmit news, signal danger, or gather people to a common area. To kick up your smokiness, gather a bundle of green sticks and grass. Dump them on your fire. Douse your bedroll with water – and toss it over your fire until no more smoke is rising from the flames. Once the smoke has stopped rising, quickly pull the blanket off the fire. A white cloud of smoke should rise from the flames, just in time for you to throw the blanket back over the fire. The cloud will rise as a single puff, your first signal. Once you can send smoke signals, encoding your long-distance messages isn't hard. Although there is no universal smoke-signal language, American campers have a pretty clear system of signalling. A single puff simply lets observers know where you are. A series of two signals is generally accepted as a code that all's well, while three puffs in quick succession alert viewers to an emergency.

2 Body Gestures

One Handed Gestures

These are common one handed gestures which are used to communiate a particular message.

A-ok or Okay	Made by connecting the thumb and forefinger in a circle and holding the other fingers straight, may signal the word okay.
Beckoning sign	In North America or Northern Europe a beckoning sign is made with the index finger sticking out of the clenched fist, palm facing the gesturer. The finger moves repeatedly towards the gesturer (in a hook) as to draw something nearer. It has the general meaning of "come here"
Hand of benediction and blessing	The benediction gesture (or benediction Latina gesture) is a raised right hand with the ring finger and little finger touching the palm, while the middle and index fingers remain raised.
Blah-blah	Blah-blah. The fingers are kept straight and together, held horizontal or upwards, while the thumb points downwards. The fingers and thumb then snap together repeatedly to suggest a mouth talking. The gesture can be used to indicate that someone talks too much, gossips, is saying nothing of any consequence, or is boring.
Check, please	This gesture, used to mean that a dinner patron wishes to pay the bill and depart, is executed by touching the index finger and thumb together and "writing" a checkmark, circle, or wavy line (as if signing one's name) in the air.
Clenched Fist	Used as a gesture of defiance or solidarity. Facing the signer, it threatens physical violence (i.e., "a thumping").
Crossed Fingers	Used to superstitiously wish for good luck or to nullify a promise.
Cuckoo Sign	Touched or screw loose. In North America, making a circling motion of the index finger at the ear or temple signifies that the person "has a screw loose", i.e. is speaking nonsense or is crazy.
Cuckold's Horns	Traditionally placed behind an unwitting man (the cuckold) to insult him and represent that his wife is unfaithful. The "symbolism has been forgotten but the insult remains" in modern culture as bunny ears.
Fig Sign	A gesture made with the hand and fingers curled and the thumb thrust between the middle and index fingers, or, rarely, the middle and ring fingers, forming the fist so that the thumb partly pokes out. In some areas of the world, the gesture is considered a good luck charm; in others (including Indonesia, Japan, Korea, Russia, Serbia and Turkey among others), it is considered an obscene gesture.
The Finger	An extended middle finger with the back of the hand towards the recipient, is an obscene hand gesture used in much of Western culture.
Finger Gun	A hand gesture in which the subject uses their hand to mimic a handgun. If pointed to oneself (with or without the "hammer falling" of the thumb indicating firing), it may indicate boredom or awkwardness in the sense of wanting to commit (social) suicide; when pointed to another, it is interpreted as a threat of violence, either genuine or in jest.

Fist Bump	Is similar to a handshake or high five which may be used as a symbol of respect.
Fist Pump	A celebratory gesture in which a closed fist is raised before the torso and subsequently drawn down in a vigorous, swift motion.
Hand Plateau	The extending of an open hand with an upturned palm to indicate an item or person. When swept horizontally it can signify an entire area. It is considered more polite than a pointed finger.
Handshake	A greeting ritual in which two people grasp each other's hands and may move their grasped hands up and down.
High Five	A celebratory ritual in which two people simultaneously raise one hand and then slap these hands together.
Hitchhiking Gesture	Sticking one thumb upward, especially in North America, or pointing an index finger toward the road elsewhere to request a ride in an automobile.
Horn Sign	A hand gesture made by extending the index and little finger straight upward. It has a vulgar meaning in some Mediterranean Basin countries like Italy and is used in rock and roll, especially in heavy metal music.
ILY sign	Extend the thumb, index finger, and little finger while the middle and ring finger touch the palm. It is an informal expression of love.
Knocking on Wood	a superstitious gesture used to ensure that a good thing will continue to occur after it has been acknowledged. However, it is sometimes used after speaking of a plausible unfortunate event, so that it does not actually occur.
Loser	Made by extending the thumb and forefinger to resemble the shape of an L on the forehead is an insulting gesture.
Money Sign	The thumb rubs repeatedly over the tip of the index finger and middle finger. This gesture resembles the act of rubbing coins or bills together and is generally used when speaking about money.
Nazi Salute	Was used in Germany and Italy during World War II to indicate loyalty to Adolf Hitler or Benito Mussolini and their respective parties. The right arm is raised in a straight diagonal position forward with the palm open facing downward.
Outstretched hand	(with palm up) is a near-universal gesture for begging or requesting, extending beyond human cultures and into other primate species. This gesture can also be done with both hands to form a bowl.
Pointing	With index finger may be used to indicate an item or person.
Raised Fist	A salute and logo most often used by leftist activists.
Respect	A gesture made by extending the index, middle, and ring fingers of one hand at another person with the middle finger raised slightly higher than the index and ring fingers. It is used in restricted circle as a sign of respect and approval.
Scout Handshake	A left-handed handshake used as a greeting among members of various Scouting organizations.
Shocker	A hand gesture with a sexual connotation. The ring finger and thumb are curled or bent down while the other fingers are extended. It suggests simultaneous vaginal and (unexpected) anal penetration.
So-so Gesture	Expresses neutral ("so-so") sentiment or mild dissatisfaction ("meh"), or can describe an uncertain situation ("maybe"). The hand is held parallel to the ground (face down) and rocked slightly.
Talk to the Hand	An English language slang expression of contempt popular during the 1990s. The associated hand gesture consists of extending a palm toward the person insulted.
Telephone	Thumb and little outstretched, other fingers tight against palm. Thumb to ear and little finger to mouth as though they were a telephone receiver. Used to say, "I'll call you", or may be used to request a future telephone conversation or to tell someone of a call.
Thumbs Up / Thumbs Down	Common gestures of approval or disapproval made by extending the thumb upward or downward.
V Sign / Victory	Made by raising the index and middle fingers and separating them to form a V, usually with the palm facing outwards. This sign began to be used during World War II to indicate "V for Victory".
Vulcan salute	Used in the television program Star Trek. It consists of all fingers raised and parted between the ring and middle fingers with the thumb sticking out to the side. It was devised and popularized by Leonard Nimoy, who portrayed the half-Vulcan character Mr. Spock.
Wanker	Made by curling the fingers into a loose fist and moving the hand up and down as though masturbating. The gesture has the same meaning as the British slang insult, "wanker", or might indicate a failure or waste in other countries.
Wave	A gesture in which the hand is raised and moved left and right, as a greeting or sign of departure.

Two Handed Gestures

These are common two handed gestures which are used to communiate a particular message.

Air Quotes	Made by raising both hands to eye level and flexing the index and middle fingers of both hands while speaking. Their meaning is similar to that of scare quotes in writing.
Añjali Mudrā (namaste)	A sign of respect in India and among yoga practitioners. It is made by pressing the palms together.
Applause	An expression of approval made by clapping the hands together to create repetitive staccato noise. Applause is most appropriate within a group setting, to collectively show approval by the volume, duration, and clamor of the noise.
Awkward Turtle	A two handed gesture used to mark a moment as awkward. One hand is placed flat atop the other with both palms facing down, fingers extended outward from the hand and thumbs stuck out to the sides. The thumbs are rotated to symbolize flippers
Batsu	In Japanese culture, the batsu (literally: ×-mark) is a gesture made by crossing one's arms in the shape of an "X" in front of them in order to indicate that something is "wrong" or "no good".
Bras d'honneur	An obscene gesture made by flexing one elbow while gripping the inside of the bent arm with the opposite hand

Golf Clap	Unlike applause, is a timid and practically silent clapping of the palms together, to silently approve of something. It may be performed when loud applause is inappropriate; however, it may instead be done in mockery or to display faux approval.
Hand-rubbing	Rubbing both hands palms together along the fingers' direction may mean that one is expecting or anticipating something or that one feels cold.
Hands Up	A gesture expressing military surrender by lifting both hands. This may have originated with that you would show that you had no weapons, making you not a threat.
Hand Heart	A recent pop culture symbol meaning love. The hands form the shape of a heart.
Jazz Hands	Used in dance or other performances by displaying the palms of both hands with fingers splayed.
Mani Giunte	An Italian gesture used when expressing exasperation or disbelief by putting both palms together in prayer and moving them down and back up towards your chest repeatedly.
Mano a Borsa	An Italian gesture, used when something is unclear. It is created by extending all the digits on the hand bringing them together with palms facing up and moving the hand up and down by the action of the wrist and/or elbow. It implies a question, such as "what do you want?", "what are you saying?" or "what is your point?", and it generally requires a response. This gesture can be done with either hand or both hands.
Maru	In Japanese culture is a gesture made by holding both arms curved over the head with the hands joined, thus forming a circular shape, to express that something is "correct" or "good". This is the counterpart of "batsu", above, though its daily use is not quite as widespread.
Merkel-Raute	Described as "probably one of the most recognizable hand gestures in the world", the signature gesture of Angela Merkel has become a political symbol used by both her supporters and opponents. a hand gesture made by resting one's hands in front of the stomach so that the fingertips meet, with the thumbs and index fingers forming a rough quadrangular shape.
Open Palms	A gesture seen in humans and other animals as a psychological and subconscious behaviour in body language to convey trust, openness and compliance.
Praying Hands	A reverent clasping of the hands together, is an expression used in most major religions during prayer. The palms of the hands are held together with the fingers extended and touching or the fingers folded upon the opposite hand. This gesture is often made with the two hands held at chest or head level, the elbows against the side, and the head bowed towards the hands.
Suck It	Used to express superiority over another by forming an X with hands over the groin area.
Victory Clasp	Used to exclaim victory by clasping one's own hands together and shaking them to one's side to another at, or above, one's head.
Whatever	Made with the thumb and forefinger of both hands to form the letter "W", the gesture is used to signal that something is not worth the time and energy.

Other Body Gestures

These are common body gestures which are used to communiate a particular message.

Air Kiss	Conveys meanings similar to kissing, but is performed without making bodily contact
Blowing a Raspberry	AKA Bronx cheer, signifies derision by sticking out the tongue and blowing (Lingualabial trill) to create a sound similar to flatulence.
Bowing	Lowering the torso or head; a show of respect in many cultures.
Cheek Kissing	Pressing one's lips to another person's cheek, may show friendship or greeting.
Curtsey	A greeting typically made by women, performed by bending the knees while bowing the head.
Dabbing or Dab	Is a simple dance move in which a person drops the head into the bent crook of their slanted arms.
Davai vyp'yem (Russian drinking sign)	The index finger is flicked against the side of the neck, just below the jaw.
Duck Face	A popular gesture among teenagers which involves puckering lips. The gesture is often used as a "funny face" when taking pictures.
Eskimo Kissing	A gesture in Western cultures loosely based on an Inuit greeting, performed by two people touching noses.
Eyebrow Raising	Briefly raising the eyebrows is used to acknowledge the presence of another person or to signal assent.
Eye-rolling	Performed by rotating the eyes upward and back down; can indicate incredulity, contempt, boredom, frustration, or exasperation; can be performed unconsciously or consciously; occurs in many countries of the world, and is especially common among adolescents.
Facepalm	An expression of frustration or embarrassment made by raising the palm of the hand to the face.
Genuflection	A show of respect by bending at least one knee to the ground.
Hand-kissing	A greeting made by kissing the hand of a person worthy of respect.
Hat Tip	A salutation or show of respect made by two people removing their hats.
Head Shake	Indicates a negative reaction to a query or a rejection in English-speaking cultures; also used occasionally in disbelief.
Headbanging	A deep and abrupt shaking of the head, sometimes to whip long hair back and forth. Done in time with music, headbanging is used as a sign of excitement and appreciation of a performance.
Hongi	A traditional Māori greeting in New Zealand, performed by pressing one's nose and forehead (at the same time) to another person.

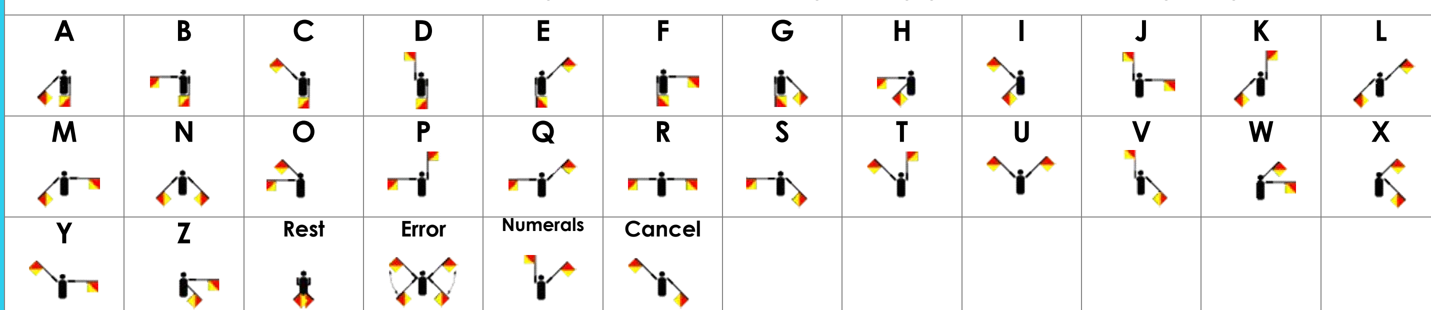
Kowtow	Shows respect by bowing deeply and touching one's head to the ground.
Mooning	A show of disrespect by displaying one's bare buttocks.
Namaste	Is a praying hands gesture usually coupled with a greeting and a head bow.
Nod	Tilting the head up and down that usually indicates assent. When shaken once firmly, it is an expression of strong agreement such as "Indeed" or "Yes sir." When shaken quickly the person is indicating a desire to move along with the topic.
Puppy Face	Tilting the head down with eyes looking up, like a puppy; has a number of uses.
Shrug	Lifting both shoulders indicates lack of knowledge or concern. Sometimes the gesture is a palms upwards from bent elbows motion with possible raised eyebrows.
Shush	the index finger of one hand is extended and placed vertically in front of the lips, with the remaining fingers curled toward the palm with the thumb forming a fist; used to demand or request silence from those to whom it is directed. Can be silent or accompanied by an audible "Sssh!" sound which alone has the same meaning.
Sign of the Cross	Used in many Christianity rituals, consists of drawing the shape of a cross over one's body or in the air.
Throat slash	Made by moving one's index finger, thumb or entire hand, held straight and with palm down, horizontally across one's throat; the gesture imitates cutting a person's throat with a blade, indicating strong disapproval, extreme anger, or displeasure with others or with oneself; alternatively, it can be a signal to stop broadcasting.
Thumbing the Nose	A sign of derision in Britain made by putting the thumb on the nose, holding the palm open and perpendicular to the face, and wiggling the remaining fingers, often combined with sticking out the tongue.
Touching Heads	Is a gesture to express positive emotions between friends, relatives, lovers etc.
Twisting the Cheek	Thumb and forefinger are placed against the cheek, and a screwing motion, as if making a dimple, is made by twisting the wrist; in Italian culture, this can mean that something is delicious; in Germany, the gesture can be used to suggest that someone is crazy.
Woe is Me	A melodramatic gesture of distress made by lifting the arm and placing the back of the hand on the forehead.
Exaggerated Yawning	Generally with one hand held to the mouth, is used to express boredom.

Unintentional Body Language

Sign Language

3 Flag Semaphore

Flag semaphore is the telegraphy system conveying information at a distance by means of visual signals with hand-held flags, rods, disks, paddles, or occasionally bare or gloved hands. Information is encoded by the position of the flags; it is read when the flag is in a fixed position. Semaphores were adopted and widely used (with hand-held flags replacing the mechanical arms of shutter semaphores) in the maritime world in the 19th century. It is still used during underway replenishment at sea and is acceptable for emergency communication in daylight or using lighted wands instead of flags, at night.



4 Audible Communication

Communication is the act of conveying meanings from one entity or group to another through the use of mutually understood signs, symbols, and semiotic rules.

Talking

Speech is human vocal communication using language. Each language uses phonetic combinations of vowel and consonant sounds that form the sound of its words (that is, all English words sound different from all French words, even if they are the same word, e.g., "role" or "hotel"), and using those words in their semantic character as words in the lexicon of a language according to the syntactic constraints that govern lexical words' function in a sentence. In speaking, speakers perform many different intentional speech acts, e.g., informing, declaring, asking, persuading, directing, and can use enunciation, intonation, degrees of loudness, tempo, and other non-representational or paralinguistic aspects of vocalization to convey meaning. In their speech speakers also unintentionally communicate many aspects of their social position such as sex, age, place of origin (through accent), physical states (alertness and sleepiness, vigor or weakness, health or illness), psychic states (emotions or moods), physico-psychic states (sobriety or drunkenness, normal consciousness and trance states), education or experience, and the like.

Although people ordinarily use speech in dealing with other persons (or animals), when people swear they do not always mean to communicate anything to anyone, and sometimes in expressing urgent emotions or desires they use speech as a quasi-magical cause, as when they encourage a player in a game to do or warn them not to do something. There are also many situations in which people engage in solitary speech. People talk to themselves sometimes in acts that are a development of what some psychologists (e.g., Lev Vygotsky) have maintained is the use in thinking of silent speech in an interior monologue to vivify and organize cognition, sometimes in the momentary adoption of a dual persona as self addressing self as though addressing another person. Solo speech can be used to memorize or to test one's memorization of things, and in prayer or in meditation (e.g., the use of a mantra).

NATO Phonetic Alphabet

The NATO phonetic alphabet is the most widely used radiotelephone spelling alphabet. It is officially the International Radiotelephony Spelling Alphabet, and also commonly known as the ICAO phonetic alphabet.

The International Civil Aviation Organization (ICAO) assigned codewords acrophonically to the letters of the English alphabet, so that critical combinations of letters and numbers are most likely to be pronounced and understood by those who exchange voice messages by radio or telephone, regardless of language differences or the quality of the communication channel. Such spelling alphabets are often called "phonetic alphabets", but they are unrelated to phonetic transcription systems such as the International Phonetic Alphabet.

A = Alfa	J = Juliett	S = Sierra
B = Bravo	K = Kilo	T = Tango
C = Charlie	L = Lima	U = Uniform
D = Delta	M = Mike	V = Victor
E = Echo	N = November	W = Whiskey
F = Foxtrot	O = Oscar	X = X-ray
G = Golf	P = Papa	Y = Yankee
H = Hotel	Q = Quebec	Z = Zulu
I = India	R = Romeo	

Whistling

Whistling can be either a sound produced by your mouth or a physical whistle.

Mouth Whistling

How to whistle using your lips and mouth.

1	Wet your lips and pucker them.
2	Blow air through your lips, softly at first. You should hear a tone.
3	Blow harder, keeping your tongue relaxed.
4	Adjust your lips, jaw, and tongue to create different tones.

Finger Whistling

Knowing how to whistle with your fingers can come in handy when you need to hail a cab or get someone's attention. Whistling with your fingers can be tricky, but with a little practice, you'll be whistling loudly in no time!

1	Press the end of your index finger and thumb together. It doesn't matter which hand you use, but you should only be using one hand. It may be easier to use your dominant hand. Your index finger and thumb should be making a ring shape.
2	Open your mouth and stretch your lips over your teeth. You want your teeth to be completely covered. Your lips should be curled into your mouth.
3	Move your tongue back in your mouth. Curl your tongue up so the end is pointing toward the roof of your mouth. Then, move it back in your mouth so the space in the front of your mouth is open. There should be about .5 inches (1.3 cm) between your tongue and your front teeth.
4	Put your index finger and thumb in your mouth. Push your fingers into your mouth until they touch your tongue. The ring shape between your fingers should be horizontal now.
5	Take a deep breath and close your mouth around your fingers. Keep your lips stretched over your teeth. The only gap between your lips should be the space between your fingers. That's where the air will come out when you whistle.
6	Blow air through your fingers and out of your mouth. Blow out forcefully, but not so much that it hurts. Don't worry if you don't make a whistling sound at first. It may take some practice before you're able to whistle with your fingers. If you don't make a whistling sound, take in another deep breath and try again. Eventually you'll get it!

Physical Whistle

A whistle can come in handy in circumstances you want to find someone or be found without expending much energy.

1	Simply blow into the end of the whistle. The power of your breath usually dictates the volume and pitch of the sound.

5 Ground Signals

The following symbols can be used to assist others in finding your location. Be sure to create them in a location they will be seen and won't be blown away or trampled over.

Grass Signals

Long grass such as a tuft can be visual cues to assist direction to others.	**Tied Tuft - Vertical:** Means straight ahead **Tied Tuft - Leaning Left:** Turn Left **Tied Tuft - Leaning Right:** Turn Right

Stick Signals

Signals left in the form of sticks to convey a message.

	**Direction**	A basic directional arrow – it can be made from sticks, stones or even twisted grass.

	**Not This Way**	Use this symbol when you do not want those following to take a particular route.
	**Turn Left or Right**	A variation on the basic directional arrow.
	**Over Obstacle**	Use this symbol when a trail crosses over an obstacle like a fence or a stream.
	**Water in this Direction**	This sign shows followers the direction of a water source.
	**Message this Way**	This symbol indicates that a message or note has been left nearby – usually somewhere high up and visible such as the branches of a tree or on a rock.
	**Party Split Up**	This symbol shows that the main party has split up and is now following two separate paths.
	**Gone Home**	This symbol means it is the end of the trail and everybody has gone home or back to base.

Pebble Signals

Many small pebbles can be used as a direction guide. A arrow signifies which direction should be taken.	**Horizontal Row:** Don't go this way

Rock Signals

Fewer larger rocks can also be direction guides.	**Two Rocks Stacked:** Straight Ahead **Two Rocks Stacked with one Right:** Turn Right **Two Rocks Stacked with one Left:** Turn Left **Row of Rocks:** Don't go this way

6 Ground to Air Signals

These are ground to air signals that can be created on the ground with sticks, rocks or anything else handy. Lay signals in the open, easily viewed from all angles on an open field with little else nearby. Each symbol should be around 3m (9.8ft) high based on available space. Trampled snow stands out if done deep enough.

I	II	F	N	Y	LL	X	↑	K	JL	□	△
Require Doctor / Medical Evacuation	Need Medical Supplies	Need Food and Water	Negative (No)	Affirmative (Yes)	All is Well	Unable to Move On	Am Moving on this Way	Indicate Direction to Proceed	Do Not Understand	Need Compass and Map	Think Safe to Land Here
¦	L7		L	V	NN	<u>LL</u>		++	XX		
Need Radio / Signal Lamp / Battery	Aircraft Badly Damaged	Require Fuel and Oil	Require Fuel and Oil	Require Assistance	Nothing Found, Will Continue to Search	Found All Missing Persons	Have divided into two groups, proceeding in directions shown	We Have Found Only Some Missing Personnel	We are not able to continue. Returning to base.		

Aircraft Acknowledgements
Message Understood: An aircraft will indicate that ground signals have been understood by rocking from side to side or by making green flashes with a signal lamp.
Message Not Understood: An aircraft will indicate that ground signals are not understood by making a complete right-hand circuit or by making red flashes with a signal lamp.
Yes / Affirmative: An aircraft will indicate yes or affirmative by tilting the nose up and down.
No / Negative: An aircraft will indicate no or negative by shaking the nose left and right.

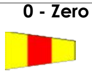
7 International Code of Signals (ICS)

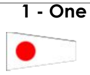
The International Code of Signals (ICS) is an international system of signals and codes for use by vessels to communicate important messages regarding safety of navigation and related matters. Signals can be sent by flaghoist, signal lamp ("blinker"), flag semaphore, radiotelegraphy, and radiotelephony. The International Code is the most recent evolution of a wide variety of maritime flag signalling systems.

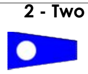
	**A - Alfa**	"I have a diver down; keep well clear at slow speed."
	**B - Bravo**	"I am taking in or discharging or carrying dangerous goods."
	**C - Charlie**	"Affirmative."
	**D - Delta**	"Keep clear of me; I am manoeuvring with difficulty."
	**E - Echo**	"I am altering my course to starboard."
	**F - Foxtrot**	"I am disabled; communicate with me."
	**G - Golf**	"I require a pilot."
	**H - Hotel**	"I have a pilot on board."
	**I - India**	"I am altering my course to port."
	**J - Juliet**	"I am on fire and have dangerous cargo on board: keep well clear of me." or "I am leaking dangerous cargo."
	**K - Kilo**	"I wish to communicate with you."
	**L - Lima**	In harbour: "The ship is quarantined." At sea: "You should stop your vessel instantly."
	**M - Mike**	"My vessel is stopped and making no way through the water."
	**N - November**	"Negative."
	**O - Oscar**	"Man overboard." (Often attached to the man overboard pole on boats).

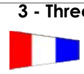
	**P - Papa**	In harbour: All persons should report on board as the vessel is about to proceed to sea. At sea: It may be used by fishing vessels to mean: "My nets have come fast upon an obstruction."
	Q - Quebec	"My vessel is 'healthy' and I request free pratique."
	**R - Romeo**	(No ICS meaning as a single flag)
	**S - Sierra**	"I am operating astern propulsion."
	**T - Tango**	"Keep clear of me; I am engaged in pair trawling."
	**U - Uniform**	"You are running into danger."
	**V - Victor**	"I require assistance."
	**W - Whiskee**	"I require medical assistance."
	**X - Xray**	"Stop carrying out your intentions and watch for my signals."
	**Y - Yankee**	"I am dragging my anchor."
	**Z - Zulu**	"I require a tug." By fishing vessels near fishing grounds: "I am shooting nets."
The substitutes below allow any four letter or number combination to be sent using only one set of flags.		
	**1st Substitute**	Used to repeat the first flag of a hoist later within the same hoist.
	**2nd Substitute**	Used to repeat the second flag of a hoist later within the same hoist.
	**3rd Substitute**	Used to repeat the third flag of a hoist later within the same hoist.
	**Code/Answer Pennant**	At the dip (about half-way up the halyard): Ready to receive message **Close up:** Message has been received and understood (the flag is then hauled back at the dip to receive the next hoist) **Hauled down:** Signals end of message. **With numerals:** Decimal point **By a warship:** When flown over a hoist, indicates the message is to be read according to the ICS.

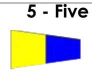
International Code of Signals (ICS)	**0 - Zero**	**1 - One**	**2 - Two**	**3 - Three**	**4 - Four**	**5 - Five**	**6 - Six**	**7 - Seven**	**8 - Eight**	**9 - Nine**
										

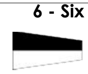












International Code of Signals (ICS) Multi-Flag Signal Examples	**Code - 'AC':** I am abandoning my vessel. **Code - 'AD':** I am abandoning my vessel which has suffered a nuclear accident and is a possible source of radiation danger. **Code - 'AN':** I need a doctor. **Code - 'AN1':** I need a doctor; I have severe burns. **Code - 'AN2':** I need a doctor; I have radiation casualties. **Code - 'EL':** Repeat the distress position. **Code - 'EL1':** What is the position of vessel in distress? **Code - 'GM':** I cannot save my vessel. **Code - 'GN':** You should take off persons. **Code - 'GN1':** I wish some persons taken off. Skeleton crew will remain on board. **Code - 'GN2':** I will take off persons.
International Code of Signals (ICS) Multi-Flag Signal Examples	**Code - 'GN3':** Can you take off persons? **Code - 'IT':** I am on fire. **Code - MAA':** I request urgent medical advice. **Code - MAB':** I request you to make rendezvous in position indicated. **Code - MAC':** I request you to arrange hospital admission. **Code - MAD':** I am . . . (indicate number) hours from the nearest port. **Code - MS1':** My vessel is a dangerous source of radiation; you may approach from my starboard side. **Code - VG':** The coverage of low clouds is… (number of octants or eighths of sky covered). **Code - US4':** Nothing can be done until weather moderates. **Code - NC':** I am in distress and require immediate assistance (Distress signal).

2 Radio

Radio is the technology of signaling and communicating using radio waves. Radio waves are electromagnetic waves of frequency between 30 hertz (Hz) and 300 gigahertz (GHz). They are generated by an electronic device called a transmitter connected to an antenna which radiates the waves, and received by a radio receiver connected to another antenna. Radio is very widely used in modern technology, in radio communication, radar, radio navigation, remote control, remote sensing and other applications. Radio waves travel much further at night.

ITU Radio Bands

A radio band is a small contiguous section of the radio spectrum frequencies, in which channels are usually used or set aside for the same purpose. To prevent interference and allow for efficient use of the radio spectrum, similar services are allocated in bands. For example, broadcasting, mobile radio, or navigation devices, will be allocated in non-overlapping ranges of frequencies. Each of these bands has a basic bandplan which dictates how it is to be used and shared, to avoid interference and to set protocol for the compatibility of transmitters and receivers.

As a matter of convention, the ITU divides the radio spectrum into 12 bands, each beginning at a wavelength which is a power of ten (10n) metres, with corresponding frequency of 3×108−n hertz, and each covering a decade of frequency or wavelength. Each of these bands has a traditional name. For example, the term high frequency (HF) designates the wavelength range from 100 to 10 metres, corresponding to a frequency range of 3 MHz to 30 MHz. This is just a naming convention and is not related to allocation; the ITU further divides each band into subbands allocated to different uses.

Above 300 GHz, the absorption of electromagnetic radiation by Earth's atmosphere is so great that the atmosphere is effectively opaque, until it becomes transparent again in the near-infrared and optical window frequency ranges. These ITU radio bands are defined in the ITU Radio Regulations. Article 2, provision No. 2.1 states that "the radio spectrum shall be subdivided into nine frequency bands, which shall be designated by progressive whole numbers in accordance with the following table".

The idea to give each band a number, in which the number is the logarithm of the approximate geometric mean of the upper and lower band limits in Hz, originated with B.C. Fleming-Williams, who suggested it in a letter to the editor of Wireless Engineer in 1942. (For example, the approximate geometric mean of Band 7 is 10 MHz, or 107 Hz.)

Band Name	Abbreviation	ITU band number	Frequency and Wavelength	Example Uses	Band Name	Abbreviation	ITU band number	Frequency and Wavelength	Example Uses
Extremely Low Frequency	ELF	1	3–30 Hz 100,000–10,000 km	Communication with submarines	**High Frequency**	HF	7	3–30 MHz 100–10 m	Shortwave broadcasts, citizens band radio, amateur radio and over-the-horizon aviation communications, RFID, over-the-horizon radar, automatic link establishment (ALE) / near-vertical incidence skywave (NVIS) radio communications, marine and mobile radio telephony
Super Low Frequency	SLF	2	30–300 Hz 10,000–1,000 km	Communication with submarines	**Very High Frequency**	VHF	8	30–300 MHz 10–1 m	FM, television broadcasts, line-of-sight ground-to-aircraft and aircraft-to-aircraft communications, land mobile and maritime mobile communications, amateur radio, weather radio
Ultra Low Frequency	ULF	3	300–3,000 Hz 1,000–100 km	Submarine communication, communication within mines	**Ultra High Frequency**	UHF	9	300–3,000 MHz 1–0.1 m	Television broadcasts, microwave oven, microwave devices/communications, radio astronomy, mobile phones, wireless LAN, Bluetooth, ZigBee, GPS and two-way radios such as land mobile, FRS and GMRS radios, amateur radio, satellite radio, Remote control Systems, ADSB
Very Low Frequency	VLF	4	3–30 kHz 100–10 km	Navigation, time signals, submarine communication, wireless heart rate monitors, geophysics	**Super High Frequency**	SHF	10	3–30 GHz 100–10 mm	Radio astronomy, microwave devices/communications, wireless LAN, DSRC, most modern radars, communications satellites, cable and satellite television broadcasting, DBS, amateur radio, satellite radio
Low Frequency	LF	5	30–300 kHz 10–1 km	Navigation, time signals, AM longwave broadcasting (Europe and parts of Asia), RFID, amateur radio	**Extremely High Frequency**	EHF	11	30–300 GHz 10–1 mm	Radio astronomy, high-frequency microwave radio relay, microwave remote sensing, amateur radio, directed-energy weapon, millimetre wave scanner, wireless LAN (802.11ad)
Medium Frequency	MF	6	300–3,000 kHz 1,000–100 m	AM (medium-wave) broadcasts, amateur radio, avalanche beacons	**Tremendously High Frequency (Terahertz)**	THF / THz	12	300–3,000 GHz 1–0.1 mm	Experimental medical imaging to replace X-rays, ultrafast molecular dynamics, condensed-matter physics, terahertz time-domain spectroscopy, terahertz computing/communications, remote sensing, amateur radio

IEEE Radar Bands

Frequency bands in the microwave range are designated by letters. This convention began around World War 2 with military designations for frequencies used in radar, which was the first application of microwaves. Unfortunately there are several incompatible naming systems for microwave bands, and even within a given system the exact frequency range designated by a letter varies somewhat between different application areas. One widely used standard is the IEEE radar bands established by the US Institute of Electrical and Electronic Engineers.

Band Designation	Frequency Range	Explanation of Meaning
HF	0.003 to 0.03 GHz	High Frequency
VHF	0.03 to 0.3 GHz	Very High Frequency
UHF	0.3 to 1 GHz	Ultra High Frequency
L	1 to 2 GHz	Long wave
S	2 to 4 GHz	Short wave
C	4 to 8 GHz	Compromise between S and X
X	8 to 12 GHz	Used in WW II for fire control, X for cross (as in crosshair). Exotic.
Ku	12 to 18 GHz	Kurz-under
Ku	18 to 27 GHz	Kurz (German for "short")
Ka	27 to 40 GHz	Kurz-above
V	40 to 75 GHz	
W	75 to 110 GHz	W follows V in the alphabet
mm or G	110 to 300 GHz	Millimetre

EU, NATO, US ECM Frequency Designations

The radio spectrum is the part of the electromagnetic spectrum with frequencies from 30 Hz to 300 GHz. Electromagnetic waves in this frequency range, called radio waves, are widely used in modern technology, particularly in telecommunication. To prevent interference between different users, the generation and transmission of radio waves is strictly regulated by national laws, coordinated by an international body, the International Telecommunication Union (ITU).

Different parts of the radio spectrum are allocated by the ITU for different radio transmission technologies and applications; some 40 radiocommunication services are defined in the ITU's Radio Regulations (RR). In some cases, parts of the radio spectrum are sold or licensed to operators of private radio transmission services (for example, cellular telephone operators or broadcast television stations). Ranges of allocated frequencies are often referred to by their provisioned use (for example, cellular spectrum or television spectrum). Because it is a fixed resource which is in demand by an increasing number of users, the radio spectrum has become increasingly congested in recent decades, and the need to utilize it more effectively is driving modern telecommunications innovations such as trunked radio systems, spread spectrum, ultra-wideband, frequency reuse, dynamic spectrum management, frequency pooling, and cognitive radio.

NATO Letter Band Designation

New Nomenclature		Old Nomenclature		Broadcasting Band Designation
Band	**Frequency (MHz)**	**Band**	**Frequency (MHz)**

Radio Propagation

	Band	Frequency	Wavelength	Propagation Via
ELF	Extremely Low Frequency	3–30 Hz	100,000–10,000 km	Guided between the Earth and the D layer of the ionosphere.
SLF	Super Low Frequency	30–300 Hz	10,000–1,000 km	Guided between the Earth and the ionosphere.
ULF	Ultra Low Frequency	0.3–3 kHz (300–3,000 Hz)	1,000–100 km	Guided between the Earth and the ionosphere.
VLF	Very Low Frequency	3–30 kHz (3,000–30,000 Hz)	100–10 km	Guided between the Earth and the ionosphere.
LF	Low Frequency	30–300 kHz (30,000–300,000 Hz)	10–1 km	Guided between the Earth and the ionosphere. Ground waves.
MF	Medium Frequency	300–3000 kHz (300,000–3,000,000 Hz)	1000–100 m	Ground waves. E, F layer ionospheric refraction at night, when D layer absorption weakens.
HF	High Frequency (Short Wave)	3–30 MHz (3,000,000–30,000,000 Hz)	100–10 m	E layer ionospheric refraction. F1, F2 layer ionospheric refraction.
VHF	Very High Frequency	30–300 MHz (30,000,000–300,000,000 Hz)	10–1 m	Line-of-sight propagation. Infrequent E ionospheric (Es) refraction. Uncommonly F2 layer ionospheric refraction during high sunspot activity up to 50 MHz and rarely to 80 MHz. Sometimes tropospheric ducting or meteor scatter
UHF	Ultra High Frequency	300–3000 MHz (300,000,000–3,000,000,000 Hz)	100–10 cm	Line-of-sight propagation. Sometimes tropospheric ducting.
SHF	Super High Frequency	3–30 GHz (3,000,000,000–30,000,000,000 Hz)	10–1 cm	Line-of-sight propagation. Sometimes rain scatter.
EHF	Extremely High Frequency	30–300 GHz (30,000,000,000–300,000,000,000 Hz)	10–1 mm	Line-of-sight propagation, limited by atmospheric absorption to a few kilometres
THF	Tremendously High Frequency	0.3–3 THz (300,000,000,000–3,000,000,000,000 Hz)	1–0.1 mm	Line-of-sight propagation.

Modes

Direct Modes (Line-of-Sight)
Line-of-sight refers to radio waves which travel directly in a line from the transmitting antenna to the receiving antenna. It does not necessarily require a cleared sight path; at lower frequencies radio waves can pass through buildings, foliage and other obstructions. This is the most common propagation mode at VHF and above, and the only possible mode at microwave frequencies and above. On the surface of the Earth, line of sight propagation is limited by the visual horizon to about 40 miles (64 km). This is the method used by cell phones, cordless phones, walkie-talkies, wireless networks, point-to-point microwave radio relay links, FM and television broadcasting and radar. Satellite communication uses longer line-of-sight paths; for example home satellite dishes receive signals from communication satellites 22,000 miles (35,000 km) above the Earth, and ground stations can communicate with spacecraft billions of miles from Earth. Ground plane reflection effects are an important factor in VHF line of sight propagation. The interference between the direct beam line-of-sight and the ground reflected beam often leads to an effective inverse-fourth-power (1/distance4) law for ground-plane limited radiation.

Surface Modes (Groundwave)
Lower frequency (between 30 and 3,000 kHz) vertically polarized radio waves can travel as surface waves following the contour of the Earth; this is called groundwave propagation. In this mode the radio wave propagates by interacting with the conductive surface of the Earth. The wave "clings" to the surface and thus follows the curvature of the Earth, so groundwaves can travel over mountains and beyond the horizon. Ground waves propagate in vertical polarization so vertical antennas (monopoles) are required. Since the ground is not a perfect electrical conductor, ground waves are attenuated as they follow the Earth's surface.

Attenuation is proportional to frequency, so ground waves are the main mode of propagation at lower frequencies, in the MF, LF and VLF bands. Ground waves are used by radio broadcasting stations in the MF and LF bands, and for time signals and radio navigation systems. At even lower frequencies, in the VLF to ELF bands, an Earth-ionosphere waveguide mechanism allows even longer range transmission. These frequencies are used for secure military communications. They can also penetrate to a significant depth into seawater, and so are used for one-way military communication to submerged submarines.

Early long distance radio communication (wireless telegraphy) before the mid-1920s used low frequencies in the longwave bands and relied exclusively on ground-wave propagation. Frequencies above 3 MHz were regarded as useless and were given to hobbyists (radio amateurs). The discovery around 1920 of the ionospheric reflection or skywave mechanism made the medium wave and short wave frequencies useful for long distance communication and they were allocated to commercial and military users.

Ionospheric Modes (Skywave)
Skywave propagation, also referred to as skip, is any of the modes that rely on reflection (actually refraction) of radio waves from the ionosphere. The ionosphere is a region of the atmosphere from about 60 to 500 km (37 to 311 mi) that contains layers of charged particles (ions) which can refract a radio wave back toward the Earth. A radio wave directed at an angle into the sky can be reflected back to Earth beyond the horizon by these layers, allowing long distance radio transmission. The F2 layer is the most important ionospheric layer for long-distance, multiple-hop HF propagation, though F1, E, and D-layers also play significant roles. The D-layer, when present during sunlight periods, causes significant amount of signal loss, as does the E-layer whose maximum usable frequency can rise to 4 MHz and above and thus block higher frequency signals from reaching the F2-layer.

The layers, or more appropriately "regions", are directly affected by the sun on a daily diurnal cycle, a seasonal cycle and the 11-year sunspot cycle and determine the utility of these modes. During solar maxima, or sunspot highs and peaks, the whole HF range up to 30 MHz can be used usually around the clock and F2 propagation up to 50 MHz is observed frequently depending upon daily solar flux 10.7cm radiation values.

During solar minima, or minimum sunspot counts down to zero, propagation of frequencies above 15 MHz is generally unavailable. Although the claim is commonly made that two-way HF propagation along a given path is reciprocal, that is, if the signal from location A reaches location B at a good strength, the signal from location B will be similar at station A because the same path is traversed in both directions. However, the ionosphere is far too complex and constantly changing to support the reciprocity theorem. The path is never exactly the same in both directions.

Ionospheric Modes (Meteor Scattering)
Meteor scattering relies on reflecting radio waves off the intensely ionized columns of air generated by meteors. While this mode is very short duration, often only from a fraction of second to couple of seconds per event, digital Meteor burst communications allows remote stations to communicate to a station that may be hundreds of miles up to over 1,000 miles (1,600 km) away, without the expense required for a satellite link. This mode is most generally useful on VHF frequencies between 30 and 250 MHz.

COMMUNICATION Radio Radio Propagation Modes

Ionospheric Modes (Auroral Backscatter)
Intense columns of Auroral ionization at 100 km altitudes within the auroral oval backscatter radio waves, including those on HF and VHF. Backscatter is angle-sensitive—incident ray vs. magnetic field line of the column must be very close to right-angle. Random motions of electrons spiralling around the field lines create a Doppler-spread that broadens the spectra of the emission to more or less noise-like—depending on how high radio frequency is used. The radio-auroras are observed mostly at high latitudes and rarely extend down to middle latitudes. The occurrence of radio-auroras depends on solar activity (flares, coronal holes, CMEs) and annually the events are more numerous during solar cycle maxima. Radio aurora includes the so-called afternoon radio aurora which produces stronger but more distorted signals and after the Harang-minima, the late-night radio aurora (sub-storming phase) returns with variable signal strength and lesser doppler spread. The propagation range for this predominantly back-scatter mode extends up to about 2000 km in east-west plane, but strongest signals are observed most frequently from the north at nearby sites on same latitudes. Rarely, a strong radio-aurora is followed by Auroral-E, which resembles both propagation types in some ways.

Ionospheric Modes (Sporadic-E Propagation)
Sporadic E (Es) propagation can be observed on HF and VHF bands. It must not be confused with ordinary HF E-layer propagation. Sporadic-E at mid-latitudes occurs mostly during summer season, from May to August in the northern hemisphere and from November to February in the southern hemisphere. There is no single cause for this mysterious propagation mode. The reflection takes place in a thin sheet of ionisation around 90 km height. The ionisation patches drift westwards at speeds of few hundred km per hour. There is a weak periodicity noted during the season and typically Es is observed on 1 to 3 successive days and remains absent for a few days to reoccur again. Es do not occur during small hours; the events usually begin at dawn, and there is a peak in the afternoon and a second peak in the evening. Es propagation is usually gone by local midnight. Observation of radio propagation beacons operating around 28.2 MHz, 50 MHz and 70 MHz, indicates that maximum observed frequency (MOF) for Es is found to be lurking around 30 MHz on most days during the summer season, but sometimes MOF may shoot up to 100 MHz or even more in ten minutes to decline slowly during the next few hours. The peak-phase includes oscillation of MOF with periodicity of approximately 5...10 minutes. The propagation range for Es single-hop is typically 1000 to 2000 km, but with multi-hop, double range is observed. The signals are very strong but also with slow deep fading.

Tropospheric Modes
Radio waves in the VHF and UHF bands can travel somewhat beyond the visual horizon due to refraction in the troposphere, the bottom layer of the atmosphere below 20 km. This is due to changes in the refractive index of air with temperature and pressure. Tropospheric delay is a source of error in radio ranging techniques, such as the Global Positioning System (GPS). In addition, unusual conditions can sometimes allow propagation at greater distances.

Tropospheric Modes (Tropospheric Ducting)
Sudden changes in the atmosphere's vertical moisture content and temperature profiles can on random occasions make UHF, VHF and microwave signals propagate hundreds of kilometres up to about 2,000 kilometres (1,200 miles)—and for ducting mode even farther—beyond the normal radio-horizon. The inversion layer is mostly observed over high pressure regions, but there are several tropospheric weather conditions which create these randomly occurring propagation modes. Inversion layer's altitude for non-ducting is typically found between 100 and 1,000 meters (330 and 3,280 feet) and for ducting about 500 to 3,000 meters (1,600 to 9,800 feet), and the duration of the events are typically from several hours up to several days. Higher frequencies experience the most dramatic increase of signal strengths, while on low-VHF and HF the effect is negligible. Propagation path attenuation may be below free-space loss. Some of the lesser inversion types related to warm ground and cooler air moisture content occur regularly at certain times of the year and time of day. A typical example could be the late summer, early morning tropospheric enhancements that bring in signals from distances up to few hundred kilometres for a couple of hours, until undone by the Sun's warming effect.

Tropospheric Modes (Tropospheric Scattering (Troposcatter))
At VHF and higher frequencies, small variations (turbulence) in the density of the atmosphere at a height of around 6 miles (9.7 km) can scatter some of the normally line-of-sight beam of radio frequency energy back toward the ground. In tropospheric scatter (troposcatter) communication systems a powerful beam of microwaves is aimed above the horizon, and a high gain antenna over the horizon aimed at the section of the troposphere though which the beam passes receives the tiny scattered signal. Troposcatter systems can achieve over-the-horizon communication between stations 500 miles (800 km) apart, and the military developed networks such as the White Alice Communications System covering all of Alaska before the 1960s, when communication satellites largely replaced them.

Tropospheric Modes (Rain Scattering)
Rain scattering is purely a microwave propagation mode and is best observed around 10 GHz, but extends down to a few gigahertz—the limit being the size of the scattering particle size vs. wavelength. This mode scatters signals mostly forwards and backwards when using horizontal polarization and side-scattering with vertical polarization. Forward-scattering typically yields propagation ranges of 800 km. Scattering from snowflakes and ice pellets also occurs, but scattering from ice without watery surface is less effective. The most common application for this phenomenon is microwave rain radar, but rain scatter propagation can be a nuisance causing unwanted signals to intermittently propagate where they are not anticipated or desired. Similar reflections may also occur from insects though at lower altitudes and shorter range. Rain also causes attenuation of point-to-point and satellite microwave links. Attenuation values up to 30 dB have been observed on 30 GHz during heavy tropical rain.

Tropospheric Modes (Airplane Scattering)
Airplane scattering (or most often reflection) is observed on VHF through microwaves and, besides back-scattering, yields momentary propagation up to 500 km even in mountainous terrain. The most common back-scatter applications are air-traffic radar, bistatic forward-scatter guided-missile and airplane-detecting trip-wire radar, and the US space radar.

Tropospheric Modes (Lightning Scattering)
Lightning scattering has sometimes been observed on VHF and UHF over distances of about 500 km. The hot lightning channel scatters radio-waves for a fraction of a second. The RF noise burst from the lightning makes the initial part of the open channel unusable and the ionization disappears quickly because of recombination at low altitude and high atmospheric pressure. Although the hot lightning channel is briefly observable with microwave radar, no practical use for this mode has been found in communications.

Other Effects (Diffraction)
Knife-edge diffraction is the propagation mode where radio waves are bent around sharp edges. For example, this mode is used to send radio signals over a mountain range when a line-of-sight path is not available. However, the angle cannot be too sharp or the signal will not diffract. The diffraction mode requires increased signal strength, so higher power or better antennas will be needed than for an equivalent line-of-sight path. Diffraction depends on the relationship between the wavelength and the size of the obstacle. In other words, the size of the obstacle in wavelengths. Lower frequencies diffract around large smooth obstacles such as hills more easily. For example, in many cases where VHF (or higher frequency) communication is not possible due to shadowing by a hill, it is still possible to communicate using the upper part of the HF band where the surface wave is of little use. Diffraction phenomena by small obstacles are also important at high frequencies. Signals for urban cellular telephony tend to be dominated by ground-plane effects as they travel over the rooftops of the urban environment. They then diffract over roof edges into the street, where multipath propagation, absorption and diffraction phenomena dominate.

Other Effects (Absorption)
Low-frequency radio waves travel easily through brick and stone and VLF even penetrates sea-water. As the frequency rises, absorption effects become more important. At microwave or higher frequencies, absorption by molecular resonances in the atmosphere (mostly from water, H_2O and oxygen, O_2) is a major factor in radio propagation. For example, in the 58–60 GHz band, there is a major absorption peak which makes this band useless for long-distance use. This phenomenon was first discovered during radar research in World War II. Above about 400 GHz, the Earth's atmosphere blocks most of the spectrum while still passing some - up to UV light, which is blocked by ozone - but visible light and some of the near-infrared is transmitted. Heavy rain and falling snow also affect microwave absorption.

Practical Effects

The average person can notice the effects of changes in radio propagation in several ways. In AM broadcasting, the dramatic ionospheric changes that occur overnight in the mediumwave band drive a unique broadcast license scheme, with entirely different transmitter power output levels and directional antenna patterns to cope with skywave propagation at night. Very few stations are allowed to run without modifications during dark hours, typically only those on clear channels in North America. Many stations have no authorization to run at all outside of daylight hours. Otherwise, there would be nothing but interference on the entire broadcast band from dusk until dawn without these modifications.

For FM broadcasting (and the few remaining low-band TV stations), weather is the primary cause for changes in VHF propagation, along with some diurnal changes when the sky is mostly without cloud cover. These changes are most obvious during temperature inversions, such as in the late-night and early-morning hours when it is clear, allowing the ground and the air near it to cool more rapidly. This not only causes dew, frost, or fog, but also causes a slight "drag" on the bottom of the radio waves, bending the signals down such that they can follow the Earth's curvature over the normal radio horizon.

The result is typically several stations being heard from another media market — usually a neighbouring one, but sometimes ones from a few hundred kilometres away. Ice storms are also the result of inversions, but these normally cause more scattered omnidirection propagation, resulting mainly in interference, often among weather radio stations. In late spring and early summer, a combination of other atmospheric factors can occasionally cause skips that duct high-power signals to places well over 1000 km away.

Non-broadcast signals are also affected. Mobile phone signals are in the UHF band, ranging from 700 to over 2600 Megahertz, a range which makes them even more prone to weather-induced propagation changes. In urban (and to some extent suburban) areas with a high population density, this is partly offset by the use of smaller cells, which use lower effective radiated power and beam tilt to reduce interference, and therefore increase frequency reuse and user capacity. However, since this would not be very cost-effective in more rural areas, these cells are larger and so more likely to cause interference over longer distances when propagation conditions allow.

While this is generally transparent to the user thanks to the way that cellular networks handle cell-to-cell handoffs, when cross-border signals are involved, unexpected charges for international roaming may occur despite not having left the country at all.

This often occurs between southern San Diego and northern Tijuana at the western end of the U.S./Mexico border, and between eastern Detroit and western Windsor along the U.S./Canada border. Since signals can travel unobstructed over a body of water far larger than the Detroit River, and cool water temperatures also cause inversions in surface air, this "fringe roaming" sometimes occurs across the Great Lakes, and between islands in the Caribbean. Signals can skip from the Dominican Republic to a mountainside in Puerto Rico and vice versa, or between the U.S. and British Virgin Islands, among others. While unintended cross-border roaming is often automatically removed by mobile phone company billing systems, inter-island roaming is typically not.

Modulation Types

AM	Amplitude modulation is the simplest type and the most commonly used for shortwave broadcasting. The instantaneous amplitude of the carrier is controlled by the amplitude of the signal (speech, or music, for example). At the receiver, a simple detector recovers the desired modulation signal from the carrier.
SSB	Single sideband transmission is a form of amplitude modulation but in effect filters the result of modulation. An amplitude-modulated signal has frequency components both above and below the carrier frequency. If one set of these components is eliminated as well as the residual carrier, only the remaining set is transmitted. This reduces power in the transmission, as roughly 2⁄3 of the energy sent by an AM signal is in the “carrier”, which is not needed to recover the information contained in the signal. It also reduces signal bandwidth, enabling less than one-half the AM signal bandwidth to be used. The drawback is the receiver is more complicated, since it must re-create the carrier to recover the signal. Small errors in the detection process greatly affect the pitch of the received signal. As a result, single sideband is not used for music or general broadcast. Single sideband is used for long-range voice communications by ships and aircraft, Citizen's Band, and amateur radio operators. Lower sideband (LSB) is customarily used below 9 MHz and USB (upper sideband) above 9 MHz.
VSB	Vestigal sideband transmits the carrier and one complete sideband, but filters out the other sideband. It is a compromise between AM and SSB, enabling simple receivers to be used, but requires almost as much transmitter power as AM. One advantage is only half the bandwidth of an AM signal is used. It can be heard in the transmission of certain radio time signal stations. Vestigial sideband is used for over the air Television Broadcasts both analog and digital.
NFM	Narrow-band frequency modulation (NBFM or NFM) is used typically above 20 MHz. Because of the larger bandwidth required, NBFM is commonly used for VHF communication. Regulations limit the bandwidth of a signal transmitted in the HF bands, and the advantages of frequency modulation are greatest if the FM signal has a wide bandwidth. NBFM is limited to short-range transmissions due to the multiphasic distortions created by the ionosphere.
DRM	Digital Radio Mondiale (DRM) is a digital modulation for use on bands below 30 MHz. It is a digital signal, like the data modes, below, but is for transmitting audio, like the analog modes above.

Station Types

International Broadcasting	International broadcasting primarily by government-sponsored propaganda, international news (for example, the BBC World Service) or cultural stations to foreign audiences: the most common use of all.
Domestic Broadcasting	Domestic broadcasting: to widely dispersed populations with few longwave, mediumwave and FM stations serving them; or for specialty political, religious and alternative media networks; or of individual commercial and non-commercial paid broadcasts.
Oceanic Air Traffic Control	Oceanic air traffic control uses the HF/shortwave band for long distance communication to aircraft over the oceans and poles, which are far beyond the range of traditional VHF frequencies. Modern systems also include satellite communications, such as ADS-C/CPDLC.
"Utility" Stations	"Utility" stations transmitting messages not intended for the general public, such as merchant shipping, marine weather, and ship-to-shore stations; for aviation weather and air-to-ground communications; for military communications; for long-distance governmental purposes, and for other non-broadcast communications.
Amateur Radio	Amateur radio operators at the 80/75, 60, 40, 30, 20, 17, 15, 12, and 10-meter bands. Licenses are granted by authorized government agencies.
Time Signal and Radio Clock Stations	Time signal and radio clock stations: In North America, WWV radio and WWVH radio transmit at these frequencies: 2.5 MHz, 5 MHz, 10 MHz, and 15 MHz; and WWV also transmits on 20 MHz. The CHU radio station in Canada transmits on the following frequencies: 3.33 MHz, 7.85 MHz, and 14.67 MHz. Other similar radio clock stations transmit on various shortwave and longwave frequencies around the world. The shortwave transmissions are primarily intended for human reception, while the longwave stations are generally used for automatic synchronization of watches and clocks.
Clandestine Stations	These are stations that broadcast on behalf of various political movements such as rebel or insurrectionist forces. They may advocate civil war, insurrection, rebellion against the government-in-charge of the country to which they are directed. Clandestine broadcasts may emanate from transmitters located in rebel-controlled territory or from outside the country entirely, using another country's transmission facilities.

Numbers Stations	These stations regularly appear and disappear all over the shortwave radio band but are unlicensed and untraceable. It is believed that Numbers Stations are operated by government agencies and are used to communicate with clandestine operatives working within foreign countries. However, no definitive proof of such use has emerged. Because the vast majority of these broadcasts contain nothing but the recitation of blocks of numbers, in various languages, with occasional bursts of music, they have become known colloquially as "Number Stations". Perhaps the most noted Number Station is the "Lincolnshire Poacher", named after the 18th century English folk song, which is transmitted just before the sequences of numbers.
Unlicensed Two Way Radio	Unlicensed two way radio activity by individuals such as taxi drivers, bus drivers and fishermen in various countries can be heard on various shortwave frequencies. Such unlicensed transmissions by "pirate" or "bootleg" two way radio operators can often cause signal interference to licensed stations.
Pirate Radio	Pirate radio broadcasters who feature programming such as music, talk and other entertainment, can be heard sporadically and in various modes on the shortwave bands.
Over-The-Horizon Radar	Over-the-horizon radar: From 1976 to 1989, the Soviet Union's Russian Woodpecker over-the-horizon radar system blotted out numerous shortwave broadcasts daily.
Ionospheric Heaters	Ionospheric heaters used for scientific experimentation such as the High Frequency Active Auroral Research Program in Alaska, and the Sura ionospheric heating facility in Russia.

Broadcasting Frequencies

Shortwave AM Radio	**Mediumwave AM Radio**	**Longwave AM Radio**			
1.7 MHz – 30 MHz (HF)	525 kHz – 1710 kHz (MF)	148.5 kHz – 283.5 kHz (LF)			

Shortwave Radio

Shortwave radio is radio transmission using shortwave radio frequencies. There is no official definition of the band, but the range always includes all of the high frequency band (HF), and generally extends from 1.7–30 MHz (176.3–10.0 m); from the high end of the medium frequency band (MF) just above the mediumwave AM broadcast band, to the end of the HF band. Radio waves in the shortwave band can be reflected or refracted from a layer of electrically charged atoms in the atmosphere called the ionosphere.

Therefore, short waves directed at an angle into the sky can be reflected back to Earth at great distances, beyond the horizon. This is called skywave or "skip" propagation. Thus shortwave radio can be used for very long distance communication, in contrast to radio waves of higher frequency which travel in straight lines (line-of-sight propagation) and are limited by the visual horizon, about 40 miles (64 km).

Shortwave radio is used for broadcasting of voice and music to shortwave listeners over very large areas; sometimes entire continents or beyond. It is also used for military over-the-horizon radar, diplomatic communication, and two-way international communication by amateur radio enthusiasts for hobby, educational and emergency purposes, as well as for long distance aviation and marine communications. Shortwave radio frequency energy is capable of reaching any location on the Earth as it is influenced by ionospheric reflection back to the earth by the ionosphere, (a phenomenon known as "skywave propagation").

A typical phenomenon of shortwave propagation is the occurrence of a skip zone where reception fails. With a fixed working frequency, large changes in ionospheric conditions may create skip zones at night. As a result of the multi-layer structure of the ionosphere, propagation often simultaneously occurs on different paths, scattered by the E or F region and with different numbers of hops, a phenomenon that may be disturbed for certain techniques.

Particularly for lower frequencies of the shortwave band, absorption of radio frequency energy in the lowest ionospheric layer, the D layer, may impose a serious limit. This is due to collisions of electrons with neutral molecules, absorbing some of a radio frequency's energy and converting it to heat. Predictions of skywave propagation depend on:

- The distance from the transmitter to the target receiver.
- Time of day. During the day, frequencies higher than approximately 12 MHz can travel longer distances than lower ones. At night, this property is reversed.
- With lower frequencies the dependence on the time of the day is mainly due to the lowest ionospheric layer, the D Layer, forming only during the day when photons from the sun break up atoms into ions and free electrons.
- Season. During the winter months of the Northern or Southern hemispheres, the AM/MW broadcast band tends to be more favourable because of longer hours of darkness.
- Solar flares produce a large increase in D region ionization so high, sometimes for periods of several minutes, all skywave propagation is non-existent.

Air Band

Band 118 to 137 MHz	Airband refers to VHF frequencies 118 to 137 MHz, used for navigation and voice communication with aircraft. Trans-oceanic aircraft also carry HF radio and satellite transceivers.

Marine Band

The greatest incentive for development of radio was the need to communicate with ships out of visual range of shore. From the very early days of radio, large oceangoing vessels carried powerful long-wave and medium-wave transmitters. High-frequency allocations are still designated for ships, although satellite systems have taken over some of the safety applications previously served by 500 kHz and other frequencies. 2182 kHz is a medium-wave frequency still used for marine emergency communication. Marine VHF radio is used in coastal waters and relatively short-range communication between vessels and to shore stations. Radios are channelized, with different channels used for different purposes; marine Channel 16 is used for calling and emergencies.

HAM Radio

Get your HAM radio licence and know how to operate the radio. Pal up with other radio enthusiasts prior to SHTF and keep in contact even if nothing happens. Understand the procedures and broadcasting restrictions as well as the frequencies you can use. Amateur radio frequency allocations vary around the world. Several bands are common for amateurs worldwide, usually in the HF part of the spectrum. Other bands are national or regional allocations only due to differing allocations for other services, especially in the VHF and UHF parts of the radio spectrum.

Citizen Band

Citizens' band radio is allocated in many countries, using channelized radios in the upper HF part of the spectrum (around 27 MHz). It is used for personal, small business and hobby purposes. Other frequency allocations are used for similar services in different jurisdictions, for example UHF CB is allocated in Australia. A wide range of personal radio services exist around the world, usually emphasizing short-range communication between individuals or for small businesses, simplified or no license requirements, and usually FM transceivers using around 1 watt or less.

Land Mobile Band

Bands of frequencies, especially in the VHF and UHF parts of the spectrum, are allocated for communication between fixed base stations and land mobile vehicle-mounted or portable transceivers. In the United States these services are informally known as business band radio. Police radio and other public safety services such as fire departments and ambulances are generally found in the VHF and UHF parts of the spectrum. Trunking systems are often used to make most efficient use of the limited number of frequencies available.

Radio Control

Reliable radio control uses bands dedicated to the purpose. Radio-controlled toys may use portions of unlicensed spectrum in the 27 MHz or 49 MHz bands, but more costly aircraft, boat, or land vehicle models use dedicated radio control frequencies near 72 MHz to avoid interference by unlicensed uses. The 21st century has seen a move to 2.4 gigahertz spread spectrum RC control systems. Licensed amateur radio operators use portions of the 6-meter band in North America. Industrial remote control of cranes or railway locomotives use assigned frequencies that vary by area.

Radar

Radar applications use relatively high power pulse transmitters and sensitive receivers, so radar is operated on bands not used for other purposes. Most radar bands are in the microwave part of the spectrum, although certain important applications for meteorology make use of powerful transmitters in the UHF band. Radio waves are a type of electromagnetic radiation with wavelengths in the electromagnetic spectrum longer than infrared light. Radio waves have frequencies as high as 300 GHz to as low as 3 kHz, though some definitions describe waves above 1 or 3 GHz as microwaves, or include waves of any lower frequency.

At 300 GHz, the corresponding wavelength is 1 mm (0.039 in), and at 3 kHz is 100 km (62 mi). Like all other electromagnetic waves, they travel at the speed of light. Naturally occurring radio waves are generated by lightning, or by astronomical objects. Artificially generated radio waves are used for fixed and mobile radio communication, broadcasting, radar and other navigation systems, communications satellites, computer networks and innumerable other applications. Radio waves are generated by radio transmitters and received by radio receivers.

Different frequencies of radio waves have different propagation characteristics in the Earth's atmosphere; long waves can diffract around obstacles like mountains and follow the contour of the earth (ground waves), shorter waves can reflect off the ionosphere and return to earth beyond the horizon (skywaves), while much shorter wavelengths bend or diffract very little and travel on a line of sight, so their propagation distances are limited to the visual horizon.

To prevent interference between different users, the artificial generation and use of radio waves is strictly regulated by law, coordinated by an international body called the International Telecommunications Union (ITU), which defines radio waves as "electromagnetic waves of frequencies arbitrarily lower than 3 000 GHz, propagated in space without artificial guide". The radio spectrum is divided into a number of radio bands on the basis of frequency, allocated to different uses.

Signal Jammer

Blocks GPS, GLONASS, Compass, Galileo, QZSS, SBAS, GSM, 3G, radio, Tv, bluetooth and wifi signals. Banned in a lot of countries so getting one will be the hardest problem. Extremely useful device, can prevent calls in and out, drops drones from the sky, blocks radio and Tv frequencies. GSM bands might be used in technologies like Cell ID to triangulate the location of cell phone user between three closest cell phone towers. Such technologies are used by corporations to find out where you are. In addition GSM signals might be intercepted and used for eavesdropping of your conversations in real time.

Listening

This section contains a list of the English Short Wave radio stations around the world, ordered by country. **LSB** = lower sideband, **USB** = upper sideband, **v** = frequency varies or is not exact. Many of these stations are easily heard; some are difficult and rarely audible.

Shortwave Listening Tips
- USA: Listen to Asia and Australia in the morning and listen to Europe at night.
- No SW frequency operates 24 hours. You may not hear anything unless you are listening at the right time, or you may hear another language, or you may hear some other country sharing the frequency.
- Many countries are better heard in non-English broadcasts.
- Some stations only air a few minutes of English; or only in ID announcements (Mexico); or only language lessons (Ecuador).
- Country of origin is shown. Many of the frequencies are relayed from elsewhere. In the case of China, all of them shown below are relays. Don't assume any particular frequency is actually coming directly from the originating country.
- Some major countries no longer broadcast to North America intentionally, such as Australia, Germany, South Africa or the UK. Longer frequency lists for these give you more chances to hear something directed elsewhere.
- More than one station may be involved under some countries, or even outside broadcasts to that country (Liberia, Nigeria, Sudan).
- Many of the strongest signals from strictly religious broadcasters in the US and elsewhere are not shown.

Full sized rows under a country are additional stations you may want to listen to. The table headings are as follows:
Country - Station - UTC Time - Notes - Frequencies

Licences

Class Licences
A class licence lets you use common radio equipment on shared frequencies. There are 15 class licences. Each licence has rules about the type of equipment you can use, and how you can use it. These rules aim to prevent interference to you and other users. You do not need to apply for a class licence and there are no licence fees.

Spectrum Licences
A spectrum licence lets you use a range of radio devices in a specific: Geographic area or Frequency band.
Spectrum licences may be valid for up to 15 years. We usually auction spectrum licences. Organisations consider them assets. If you hold a spectrum licence, you can also trade it (or parts of it) with others.

There are 15 class licences (shown below). You must follow the rules of the class licence to use the equipment.

- **27 MHz handphone stations** - Use a 27 MHz handphone station.
- **Aircraft and aeronautical mobile stations** - Use mobile radio equipment on or near an aircraft.
- **Body scanners** - For trained people who use body scanners at Australian airports.
- **Cellular mobile telecom devices** - Use devices that communicate with a licensed PTS base station.
- **Citizen band radio stations** - Use CB radio to communicate over short distances.
- **Communication with a space object** - Operate earth stations that communicate with a licensed space station.
- **Cordless communications devices** - Use certain cordless devices.
- **Emergency locating devices** - To help search and rescue groups find survivors.
- **Intelligent transport systems** - Wireless technology for vehicles and traffic systems.
- **Low interference potential devices (LIPD)** - Use a range of low power radiocommunications devices.
- **Maritime ship station – 27 MHz and VHF** - Lets qualified people use marine radio equipment on certain frequencies.
- **Overseas amateur visiting Australia** - Lets visitors to Australia use the amateur frequencies for a short time.
- **Public safety and emergency response** - Only for public safety agencies.
- **Radio-controlled models** - Use a device that controls a model plane, train, car or boat.
- **Radio navigation satellite service** - Use GPS (Global Positioning System) receivers.

Citizen Band Radio Stations Class Licence
This class licence lets you use citizen band (CB) radios to communicate over short distances.
● You can use CB radio to communicate over short distances via the Citizen Band Radio Service (CBRS).

You can use the CBRS for any voice communications, telemetry and telecommand. All users operate on shared frequencies. You don't need to apply for a class licence or pay any fees. Your equipment cannot exceed the maximum power stated in the class licence. We do not allow packet radio and other types of data operation on CB bands.

You can only use CB radios on designated channels in these frequencies:
● HF – 26.965 MHz to 27.405 MHz (inclusive)
● UHF – 476.4125 to 477.4125 MHz (inclusive)

Call signs are a unique series of letters and numbers. They make it easy to identify a station. You do note need to use a call sign for class licences. But we recommend that you identify yourself when you communicate by CB radio.

There are 2 channels you can use to contact other CB users for the first time. These are:
● Channel 11 (AM) (27.085 MHz) and Channel 16 (SSB) (27.155 MHz) in the HF band
● Channel 11 (476.675 MHz) in the UHF band
After you've made contact you should move to another channel. This leaves the channel available for other users to contact each other.

We set aside 2 channels that are only for emergency messages:
● Channel 9 (27.065 MHz) in the HF band
● Channels 5/35 (476.525/477.275 MHz) in the UHF band

Australian Channels	**Australian Citizen Band Frequencies** HF 26.965-27.405 MHz UHF 476.4125-477.4125 MHz	**Australian Citizen Band Frequencies** 148-174 MHz 403-420 MHz 450-520 MHz	**Contacting Travellers** Channel 11 AM 27.085 MHz Channel 16 SSB 27.155 MHz Channel 11 UHF 476.675 MHz	**Data Transmitting** UHF 22 476.950 UHF 23 476.975	**Emergency Channels** Channel 9 27.065 MHz Channel 5 476.525 Channel 35 UHF 477.275 MHz

Radio Triangulation

These are the various ways you can find the position of a radio broadcaster. This is part of the Search & Rescue manual in the SURVIVAL section.

Maximum Radio Signal Range Calculations
By using the following formula:
Maximum Range (in Nautical Miles) = 1.2 x √h (Square Root x height)
(Where: h = height/altitude of the receiving antenna in feet)

The theoretical maximum range of the transmitter may be calculated, or for search purposes, the theoretical maximum distance at which a beacon signal may be received given the receiving antenna's height above ground level. Note: The transmitting antenna is assumed to be at ground level. The area in which the transmitter is located may be determined by plotting a circle, with radius equal to the calculated range, from the position at which the beacon was heard. The intersection of circles plotted from two or more hearing positions will result in a fix of the probable position of the transmitter.

Locating a Signal from the Ground

Ground parties may be able to locate the source of a signal using a portable Aviation Band Multichannel AM VHF Radio. If the radio is tuned to 121.55 or 121.45 MHz and a signal is heard, it is likely that the source of the signal is within 100 metres. Progressive detuning whilst retaining the signal will locate the source of the signal. If a beacon signal can only be heard on 121.5 MHz, the beacon is some distance away.

Using a building or obstruction as a shield, if the signal is lost the building or obstruction is between the receiver and the beacon. It is also possible to use the body as a shield by holding the receiver to the chest. The signal should be weakest with the back to the signal. To check individual craft as the source of a signal, a domestic FM or AM radio is likely to receive the signal if placed within a few metres of the source. Also the aerial may be removed from an Aviation VHF radio if the signal is still received the source is very close.

Detecting a beacon by hand can be done with one or more hand-held 121.5MHz DF sets. A single device is used in a gentle sweeping action from side to side, attempting to maintain the strongest signal in the centre of the arc of swing. Slowly walking towards the strongest signal while continually sweeping from side to side will eventually arrive at the beacon.

With two or more DF sets each can be set some distance apart and the apparent direction of the strongest signal plotted onto a map, the 'cocked hat' where the bearings intersect should be the most probable location of the beacon. The DF sets may have to be moved several times to take into account obstructions caused by the environment.

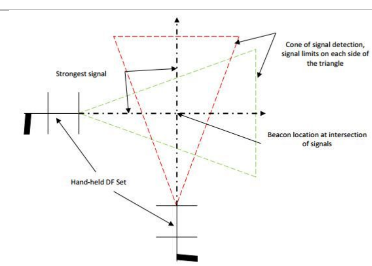

Figure 4-17 Hand-held DF Set usage

3 Antennas

In radio, an antenna is the interface between radio waves propagating through space and electric currents moving in metal conductors, used with a transmitter or receiver. In transmission, a radio transmitter supplies an electric current to the antenna's terminals, and the antenna radiates the energy from the current as electromagnetic waves (radio waves). In reception, an antenna intercepts some of the power of a radio wave in order to produce an electric current at its terminals, that is applied to a receiver to be amplified.

Antennas are essential components of all radio equipment, and are used in radio broadcasting, broadcast television, two-way radio, communications receivers, radar, cell phones, satellite communications and other devices. An antenna is an array of conductors (elements), electrically connected to the receiver or transmitter. During transmission, the oscillating current applied to the antenna by a transmitter creates an oscillating electric field and magnetic field around the antenna elements. These time-varying fields radiate energy away from the antenna into space as a moving transverse electromagnetic field wave, a radio wave.

Conversely, during reception, the oscillating electric and magnetic fields of an incoming radio wave exert force on the electrons in the antenna elements, causing them to move back and forth, creating oscillating currents in the antenna. Antennas can be designed to transmit and receive radio waves in all horizontal directions equally (omnidirectional antennas), or preferentially in a particular direction (directional or high gain antennas). An antenna may include parasitic elements, parabolic reflectors or horns, which serve to direct the radio waves into a beam or other desired radiation pattern.

Antennas are required by any radio receiver or transmitter to couple its electrical connection to the electromagnetic field. Radio waves are electromagnetic waves which carry signals through the air (or through space) at the speed of light with almost no transmission loss. Radio transmitters and receivers are used to convey signals in broadcast (audio) radio, television, mobile telephones, Wi-Fi (WLAN) data networks, and remote control devices among many others.

Radio waves are also used directly for measurements in radar, GPS, and radio astronomy. Transmitters and receivers require antennas, although these are sometimes hidden (such as the antenna inside an AM radio or inside a laptop computer equipped with Wi-Fi). Antennas can be classified as omnidirectional, radiating energy approximately equally in all directions, or Directional, where energy radiates more along one direction than others.

A completely uniform omnidirectional antenna is not physically possible. Many important antenna types have a uniform radiation pattern in the horizontal plane, but send little energy upward or downward. A "directional" antenna usually is intended to maximize its coupling to the electromagnetic field in the direction of the other station. One example of omnidirectional antennas is the very common vertical antenna or whip antenna consisting of a metal rod. A dipole antenna is similar but consists of two such conductors extending in opposite directions. Dipoles are typically oriented horizontally in which case they are weakly directional: signals are reasonably well radiated toward or received from all directions with the exception of the direction along the conductor itself; this region is called the antenna blind cone or null. Both the vertical and dipole antennas are simple in construction and relatively inexpensive. The dipole antenna, which is the basis for most antenna designs, is a balanced component, with equal but opposite voltages and currents applied at its two terminals through a balanced transmission line.

Isotropic Antenna
An isotropic antenna (isotropic radiator) is a hypothetical antenna that radiates equal signal power in all directions. It is a mathematical model that is used as the base of comparison to calculate the gain of real antennas. No real antenna can have an isotropic radiation pattern. However approximately isotropic antennas, constructed with multiple elements, are used in antenna testing.

For more information on Antennas, see the ELECTRICITY > Componentry > Passive Components > Antennas section.

Dipole

The dipole is the prototypical antenna on which a large class of antennas are based. A basic dipole antenna consists of two conductors (usually metal rods or wires) arranged symmetrically, with one side of the balanced feedline from the transmitter or receiver attached to each. The most common type, the half-wave dipole, consists of two resonant elements just under a quarter wavelength long. This antenna radiates maximally in directions perpendicular to the antenna's axis, giving it a small directive gain of 2.15 dBi. Although half-wave dipoles are used alone as omnidirectional antennas, they are also a building block of many other more complicated directional antennas.

Yagi-Uda	One of the most common directional antennas at HF, VHF, and UHF frequencies. Consists of multiple half wave dipole elements in a line, with a single driven element and multiple parasitic elements which serve to create a uni-directional or beam antenna. These typically have gains between 10–20 dBi depending on the number of elements used, and are very narrowband (with a usable bandwidth of only a few percent) though there are derivative designs which relax this limitation. Used for rooftop television antennas, point-to-point communication links, and long distance shortwave communication using skywave ("skip") reflection from the ionosphere.
Log-Periodic Dipole Array	Often confused with the Yagi-Uda, this consists of many dipole elements along a boom with gradually increasing lengths, all connected to the transmission line with alternating polarity. It is a directional antenna with a wide bandwidth. This makes it ideal for use as a rooftop television antenna, although its gain is much less than a Yagi of comparable size.
Turnstile	Two dipole antennas mounted at right angles, fed with a phase difference of 90°. This antenna is unusual in that it radiates in all directions (no nulls in the radiation pattern), with horizontal polarization in directions coplanar with the elements, circular polarization normal to that plane, and elliptical polarization in other directions. Used for receiving signals from satellites, as circular polarization is transmitted by many satellites.
Corner Reflector	A directive antenna with moderate gain of about 8 dBi often used at UHF frequencies. Consists of a dipole mounted in front of two reflective metal screens joined at an angle, usually 90°. Used as a rooftop UHF television antenna and for point-to-point data links.
Patch (Microstrip)	A type of antenna with elements consisting of metal sheets mounted over a ground plane. Similar to dipole with gain of 6–9 dBi. Integrated into surfaces such as aircraft bodies. Their easy fabrication using PCB techniques have made them popular in modern wireless devices. Often combined into arrays.

Monopole

A monopole antenna consists of a single conductor such as a metal rod, usually mounted over the ground or an artificial conducting surface (a so-called ground plane). One side of the feedline from the receiver or transmitter is connected to the conductor, and the other side to ground or the artificial ground plane. The radio waves reflected from the ground plane seem to come from an image antenna below the ground, with the monopole and its image forming a dipole, so the monopole antenna has a radiation pattern identical to the top half of the pattern of a similar dipole antenna.

Since all of the equivalent dipole's radiation is concentrated in a half-space, the antenna has twice (3 dB increase of) the gain of a similar dipole, not considering losses in the ground plane. The most common form is the quarter-wave monopole which is one-quarter of a wavelength long and has a gain of 5.12 dBi when mounted over a ground plane. Monopoles have an omnidirectional radiation pattern, so they are used for broad coverage of an area, and have vertical polarization. The ground waves used for broadcasting at low frequencies must be vertically polarized, so large vertical monopole antennas are used for broadcasting in the MF, LF, and VLF bands. Small monopoles are used as nondirectional antennas on portable radios in the HF, VHF, and UHF bands.

COMMUNICATION Antennas Monopole

Whip	Type of antenna used on mobile and portable radios in the VHF and UHF bands such as boom boxes, consists of a flexible rod, often made of telescoping segments.
Rubber Ducky	Most common antenna used on portable two way radios and cordless phones due to its compactness, consists of an electrically short wire helix. The helix adds inductance to cancel the capacitive reactance of the short radiator, making it resonant. Very low gain.
Ground Plane	A whip antenna with several rods extending horizontally from base of whip attached to the ground side of the feedline. Since whips are mounted above ground, the horizontal rods form an artificial ground plane under the antenna to increase its gain. Used as base station antennas for land mobile radio systems such as police, ambulance and taxi dispatchers.
Mast Radiator	A radio tower in which the tower structure itself serves as the antenna. Common form of transmitting antenna for AM radio stations and other MF and LF transmitters. At its base the tower is usually, but not necessarily, mounted on a ceramic insulator to isolate it from the ground.
T / Inverted L	Consist of a long horizontal wire suspended between two towers with insulators, with a vertical wire hanging down from it, attached to a feedline to the receiver or transmitter. Used on LF and VLF bands. The vertical wire serves as the radiator. Since at these frequencies the vertical wire is electrically short, much shorter than a quarter wavelength, the horizontal wire(s) serve as a capacitive "hat" to increase the current in the vertical radiator, increasing the gain. Very narrow bandwidth, requires loading coil to tune out any remaining capacitive reactance. Requires low resistance ground (electricity).
Inverted F	Combines the advantages of the compactness of inverted-L antenna, and the good matching of the F-type antenna. The antenna is grounded at the base and fed at some intermediate point. The position of the feed point determines the antenna impedance. Thus, matching can be achieved without the need for an extraneous matching network.
Umbrella	Very large wire transmitting antennas used on VLF bands. Consists of a central mast radiator tower attached at the top to multiple wires extending out radially from the mast to ground, like a tent or umbrella, insulated at the ends. Extremely narrow bandwidth, requires large loading coil and low resistance counterpoise ground. Used for long range military communications.

Array

COMMUNICATION Antennas Array

Array antennas consist of multiple antennas working as a single antenna. Typically they consist of arrays of identical driven elements, usually dipoles fed in phase, giving increased gain over that of a single dipole.

Collinear	Consist of a number of dipoles in a vertical line. It is a high gain omnidirectional antenna, meaning more of the power is radiated in horizontal directions and less into the sky or ground and wasted. Gain of 8 to 10 dBi. Used as base station antennas for land mobile radio systems such as police, fire, ambulance, and taxi dispatchers, and sector antennas for cellular base stations.
Reflective Array	multiple dipoles in a two-dimensional array mounted in front of a flat reflecting screen. Used for radar and UHF television transmitting and receiving antennas.
Phased Array	A high gain antenna used at UHF and microwave frequencies which is electronically steerable. It consists of multiple dipoles in a two-dimensional array, each fed through an electronic phase shifter, with the phase shifters controlled by a computer control system. The beam can be instantly pointed in any direction over a wide angle in front of the antenna. Used for military radar and jamming systems.
Curtain Array	Large directional wire transmitting antenna used at HF by shortwave broadcasting stations. It consists of a vertical rectangular array of wire dipoles suspended in front of a flat reflector screen consisting of a vertical "curtain" of parallel wires, all supported between two metal towers. It radiates a horizontal beam of radio waves into the sky above the horizon, which is reflected by the ionosphere to Earth beyond the horizon.
Batwing / Superturnstile	A specialized antenna used in television broadcasting consisting of perpendicular pairs of dipoles with radiators resembling bat wings. Multiple batwing antennas are stacked vertically on a mast to make VHF television broadcast antennas. Omnidirectional radiation pattern with high gain in horizontal directions. The batwing shape gives them wide bandwidth.
Microstrip	An array of patch antennas on a substrate fed by microstrip feedlines. Microwave antenna that can achieve large gains in compact space. Ease of fabrication by PCB techniques have made them popular in modern wireless devices. Beamwidth and polarization can be actively reconfigurable.

Loop

COMMUNICATION Antennas Loop

Loop antennas consist of a loop (or coil) of wire. There are essentially two broad categories of loop antennas: big loops and small loops. Loops with circumference of a wavelength are naturally resonant and act somewhat similarly to the half-wave dipole, and when it is necessary to distinguish them from small loops, they are called “full-wave” loops. (The popular “quad” antenna design is necessarily a full-wave loop, so no other distinction is needed.) If the loop is small in comparison to the wavelength it must be modified in some way to make it resonant if that is necessary. Small loops are called “magnetic loops” or “tuned loops”. They function quite differently from full-wave loops. This antenna interacts directly with the magnetic field of the radio wave, making it relatively insensitive to nearby electrical noise. However it has a very small radiation resistance, typically much smaller than the loss resistance, making it inefficient and thus undesirable for transmitting. They are used as receiving antennas at low frequencies, and also as direction finding antennas.

Ferrite (Loopstick)	These are used as the receiving antenna in most consumer AM radios operating in the medium wave broadcast band (and lower frequencies), a notable exception being car radios. Wire is coiled around a ferrite core which greatly increases the coil's inductance. Radiation pattern is maximum at directions perpendicular to the ferrite rod. The null direction of ferrite core antennas are bi-directional and sharper than the maximal directionality. This often makes the null direction more useful than the maximal directionality because the null direction can be used to reject unwanted signals from an interfering station or noise source.
Quad	Quad antennas are made of multiple full-wave loops, lined up in a row along their axes; they resemble the frame of a box kite. One loop in the quad is connected to the feedline and functions as the driver for the antenna and the signal radiator. The other loops are “helpers”; they are not connected to the feed, but are spaced and tuned so that they intercept and reflect the rearward signal from the driven loop back forward, and focus the forward-travelling signal into a narrower beam – like mirrors and lenses in a flashlight. They are called “reflectors” or “directors”, depending on function, or in general parasitic elements since they borrow energy from the field created by the driven element. Quad antennas are the exact analogue, for loops, to a Yagi-Uda antenna made out of dipoles; in fact, a “Yagi” can be built using a mixture of loops and dipoles. Similar to Yagis, quads are used as a directional antennas on the HF bands for shortwave communication, and are sometimes preferred for longer wavelengths because (if square) they are half as wide as a Yagi.

Aperture

ICATION Antennas

Aperture antennas are the main type of directional antennas used at microwave frequencies and above. They consist of a small dipole or loop feed antenna inside a three-dimensional guiding structure large compared to a wavelength, with an aperture to emit the radio waves. Since the antenna structure itself is nonresonant they can be used over a wide frequency range by replacing or tuning the feed antenna.

Parabolic	The most widely used high gain antenna at microwave frequencies and above. Consists of a dish-shaped metal parabolic reflector with a feed antenna at the focus. It can have some of the highest gains of any antenna type, up to 60 dBi, but the dish must be large compared to a wavelength. Used for radar antennas, point-to-point data links, satellite communication, and radio telescopes.
Horn	Simple antenna with moderate gains of 15 to 25 dBi consists of a flaring metal horn attached to a waveguide. Used for applications such as radar guns, radiometers and as feed antennas for parabolic dishes.
Slot	Consist of a waveguide with one or more slots cut in it to emit the microwaves. Linear slot antennas emit narrow fan-shaped beams. Used as UHF broadcast antennas and marine radar antennas.
Dielectric Resonator	Consists of small ball or puck-shaped piece of dielectric material excited by aperture in waveguide Used at millimetre wave frequencies.

Travelling Wave

Unlike the above antennas, travelling wave antennas are nonresonant so they have inherently broad bandwidth. They are typically wire antennas multiple wavelengths long, through which the voltage and current waves travel in one direction, instead of bouncing back and forth to form standing waves as in resonant antennas. They have linear polarization (except for the helical antenna). Unidirectional travelling wave antennas are terminated by a resistor at one end equal to the antenna's characteristic resistance, to absorb the waves from one direction. This makes them inefficient as transmitting antennas.

Random Wire	This describes the typical antenna used to receive shortwave radio, consisting of a random length of wire either strung outdoors between supports or indoors in a zigzag pattern along walls, connected to the receiver at one end. Can have complex radiation patterns with several lobes at angles to the wire.
Beverage	Simplest unidirectional travelling wave antenna. Consists of a straight wire one to several wavelengths long, suspended near the ground, connected to the receiver at one end and terminated by a resistor equal to its characteristic impedance, 400 to 800Ω at the other end. Its radiation pattern has a main lobe at a shallow angle in the sky off the terminated end. It is used for reception of skywaves reflected off the ionosphere in long distance "skip" shortwave.
Rhombic	Consists of four equal wire sections shaped like a rhombus. It is fed by a balanced feedline at one of the acute corners, and the two sides are connected to a resistor equal to the characteristic resistance of the antenna at the other. It has a main lobe in a horizontal direction off the terminated end of the rhombus. Used for skywave communication on shortwave bands.
Helical (Axial Mode)	Consists of a wire in the shape of a helix mounted above a reflecting screen. It radiates circularly polarized waves in a beam off the end, with a typical gain of 15 dBi. It is used at VHF and UHF frequencies. Often used for satellite communication, which uses circular polarization because it is insensitive to the relative rotation on the beam axis.
Leaky Wave	Microwave antennas consisting of a waveguide or coaxial cable with a slot or apertures cut in it so it radiates continuously along its length.

4 Observation

The devices below can be used for viewing distant communication or observing threats.

Binoculars & Monoculars

Binoculars or field glasses are two telescopes mounted side-by-side and aligned to point in the same direction, allowing the viewer to use both eyes (binocular vision) when viewing distant objects. Most are sized to be held using both hands, although sizes vary widely from opera glasses to large pedestal mounted military models. Unlike a (monocular) telescope, binoculars give users a three-dimensional (3D) image: for nearer objects the two views, presented to each of the viewer's eyes from slightly different viewpoints, produce a merged view with an impression of depth.

These are excellent for pinpointing locations, looking at objectives or approaching threats. You will generally only need a monocular, and you'll save about 50% of the space in a backpack or allow you to get a larger version to allow more light in.

Size	Full Size - 8x42, 10x50 Heavy, large, best night vision. Mid Size - 7x35, 10x32 Possible for backpacking. Compact - 8x25, 10x25 Ideal for backpacking.
Magnification	7x35 binoculars have a magnification power of 7. The object will appear 7x closer to you.
Lens Diameter	7x35 binoculars have a lens diameter of 35mm and calculates how much light it gathers.
Exit Pupil	Brightness of an object in low-light conditions. Calculated by lens diameter divided by Magnification. 7x35 - 35 / 7 = 5mm
Exit Pupil Brightness	0-2mm = Bright Light 2-4mm = Daylight (Cloudy) 4-6mm = Dawn/Dusk 6mm+ = Night time

Telescope: Best used for looking at the constellations but can also be used to look at great distances from an elevated position.

Night Vision Goggles

A night-vision device (NVD), also known as night optical/observation device (NOD) and night-vision goggles (NVG), is an optoelectronic device that allows images to be produced in levels of light approaching total darkness. The image may be a conversion to visible light of both visible light and near-infrared, while by convention detection of thermal infrared is denoted thermal imaging. The image produced is typically monochrome, e.g. shades of green. NVDs are most often used by the military and law enforcement agencies, but are available to civilian users. The term usually refers to a complete unit, including an image intensifier tube, a protective and generally water-resistant housing, and some type of mounting system. Many NVDs include a protective sacrificial lens, or optical components such as telescopic lenses or mirrors. An NVD may have an IR illuminator, making it an active as opposed to passive night-vision device.

Generations

Generation 1	1st generation is currently the most popular type of night vision in the world. Utilizing the basic principles described earlier, a 1st generation unit will amplify the existing light several thousand times letting you clearly see in the dark. These units provide a bright and sharp image at a low cost, which is perfect, whether you are boating, observing wildlife, or providing security for your home. You may notice the following when you are looking through a 1st Gen. unit.	**Features** ● A slight high-pitched whine when the unit is on. ● The image you see may be slightly blurry around the edges. This is known as Geometric Distortion. ● When you turn a 1st Gen. unit off it may glow green for some time. ● These are inherent characteristics of a 1st Gen. unit and are normal.
Generation 2	2nd generation is primarily used by law enforcement or for professional applications. This is because the cost of a 2nd Gen. unit is approximately $500.00 to $1000.00 more then a 1st Gen. The main difference between a 1st and a 2nd generation unit is the addition of a micro-channel plate, commonly referred to as a MCP. The MCP works as an electron amplifier and is placed directly behind the photocathode. The MCP consists of millions of short parallel glass tubes. When the electrons pass through these short tubes, thousands more electrons are released. This extra process allows 2nd generation units to amplify the light many more times then 1st generation giving you a brighter and sharper image.	
Generation 3	3rd generation By adding a sensitive chemical, gallium arsenide to the photocathode a brighter and sharper image has been achieved over 2nd generation units. An ion barrier film was also added to increase tube life. 3rd Gen provides the user with good to excellent low light performance.	
Generation 4	4th generation Gated/Filmless technology represents the biggest technological breakthrough in image intensification of the past 10 years. By removing the ion barrier film and "Gating" the system Gen 4 demonstrates substantial increases in target detection range and resolution, particularly at extremely low light levels. The use of film less technology and auto-gated power supply in 4th generation image intensifiers result in:	● Up to 100% improvement in photo response. ● Superb performance in extremely low light level (better S/N and EBI). ● At least triple high light level resolution (a minimum of 36 lp/mm compared to 12 lp/mm).

5 Technology

This section covers all the types of communication technology from GPS devices, Satellites, Mobile Phones and Radios.

GPS	The Global Positioning System (GPS), originally Navstar GPS, is a satellite-based radionavigation system owned by the United States government and operated by the United States Air Force. It is a global navigation satellite system that provides geolocation and time information to a GPS receiver anywhere on or near the Earth where there is an unobstructed line of sight to four or more GPS satellites. Obstacles such as mountains and buildings block the relatively weak GPS signals.
Mobile Phone	A mobile phone, known as a cell phone in North America, is a portable telephone that can make and receive calls over a radio frequency link while the user is moving within a telephone service area. The radio frequency link establishes a connection to the switching systems of a mobile phone operator, which provides access to the public switched telephone network (PSTN).
Airband Portable Transceiver	Handheld transceiver for air traffic, useful for air drops or monitoring air traffic.
Night Vision Goggles	A night vision device (NVD), also known as night optical/observation device (NOD) and night vision goggles (NVG), is an optoelectronic device that allows images to be produced in levels of light approaching total darkness. The image may be a conversion to visible light of both visible light and near-infrared, while by convention detection of thermal infrared is denoted thermal imaging. The image produced is typically monochrome, e.g. shades of green. NVDs are most often used by the military and law enforcement agencies, but are available to civilian users.
VHF Radio	Radio is the technology of using radio waves to carry information, such as sound, by systematically modulating properties of electromagnetic energy waves transmitted through space, such as their amplitude, frequency, phase, or pulse width. When radio waves strike an electrical conductor, the oscillating fields induce an alternating current in the conductor. The information in the waves can be extracted and transformed back into its original form.
Satellite Phone / Iridium	A satellite telephone, satellite phone, or satphone is a type of mobile phone that connects to orbiting satellites instead of terrestrial cell sites. They provide similar functionality to terrestrial mobile telephones; voice, SMS and low-bandwidth Internet access are supported through most systems.
VHF / UHF Car Comms	

Handheld GPS

For location tracking, finding north, getting elevation, saving waypoints and looking at terrain. A highly useful piece of kit if the GPS satellites are still functioning - otherwise it will just be a topographic map viewer. Know how to use it extremely well prior to needing it. Try out all the features. Know how to read the topographic maps and the individual markings on the terrain.

Getting a Signal	

Mobile Phone

Probably the most versatile piece of technology you will possess. Use it to store encrypted personal files, terrain maps, use it as a GPS and more. Download useful apps such as knot tying and the SAS manual. The cell towers most likely won't be available during SHTF so also have a couple of two way radios. You can also transfer files via bluetooth and wifi if the grid is down and use them for short range text or voice communication.

Increasing the Signal

If you want a mobile signal but can't get any reception, try some of the following.	**Exit the Building** Get out of, or get to the roof of the building if possible.	**Move Towards a Tower** Try to get closer to a mobile tower if you know where the nearest one is. They are generally found on tall buildings or hills.	**Get to Higher Ground** Head to the top of a hill or mountain.	**Get to Open Ground** If you're surrounded by buildings or trees, try to find a flat open area.	**Attach an Antenna** If you have access inside the phone, solder a piece of metal or wire to the antenna port to increase it's receiving capability.

Decreasing the Signal

If you don't want to be tracked or receive calls, do the following.	**Removing the Battery** Generally removing the battery works, but some phones can still be located without power.	**Faraday Cage** Put the phone in a completely sealed metal container or faraday bag.	**Abandon It** If you feel you're being tracked, abandon the phone on something that moves - a bus, a car or even a wild animal.	**Smash It** As an absolute last resort, smash the phone, however abandoning it is usually a much better plan as it will throw off pursuers.	

Best Prepper Device

Have you thought about the prospects of using your mobile phone as a tool in a survival situation and how it would work? This section looks at whether your current device is up to the task of serving your off-grid needs, completely devoid of an internet connection ever again. Most people haven't thought about what exactly on their mobile would break in the event the internet was switched off. You may be surprised to find out that as time ticks by without it, more and more features of the phone would cease to operate. I have cataloged multiple options below for choosing the most optimal offline device(s) for the collapse, assuming there's no EMP.

You would typically want more than one device with the exact same data in case one of them fails as well and perhaps another of a different variety to make watching content or reading eBooks easier. This is written with the assumption that you want a smart phone rather than a old-school Nokia brick or something similar, since you would likely want apps which can support your prepping rather than just a 'phone'.

Device Types

To choose the best device that suits your needs first you need to decide on a type of device:

Phone	These are jack of all trade devices which provide a good medium between functionality, entertainment and portability. They are generally pretty frustrating to read e-books on and aren't the best at watching video content either, but the small package means it's lightweight and easy to transport. Today, a phone is pretty much an essential part of your Every Day Carry (EDC) kit since we all probably carry one everywhere we go anyway.
Note Devices (Phablet)	Larger smartphone devices which often come with a pen for note-taking. They are generally 6-8 inches in size which also accommodates space to insert the pen into the device.
Tablet	A larger device which is usually focused more on entertainment rather than functionality – such as phone calls. This device would be great to watch and store prepper related videos on as well as reading e-books and yes, watching movies on as well. Tablets can be pretty light and therefore one could make it into your Bug Out Bag or INCH Bag without too much weight gain – although I would recommend the next device for that instead…
E-Ink Reader	These are similar to tablets but use a screen which can hold an image on it without using any battery which makes them amazing for reading e-books and PDFs during a Bug-Out situation. This is what you want if you are going to be reading documents and other informative e-books often as it will use the battery at a MUCH slower rate to a tablet. The Linux based e-Readers retain batter for longer periods over their Android counterparts. They are generally lighter than tablets and are more durable too. They can also be used for drawing and sketching which may come in handy, but is no substitute for a pen an paper, because at some point you will run out of power.
Laptop	This is probably a bit too large and heavy to use as a prepping device, but someone may find a use for a powerful device and large screen such as this. This is a tool better stored in a Bug-Out location in an EMP proof cage than being carried on you.

My choices: Personally, I have a few Samsung S10+ phones (my primary preparedness devices) with one in an EMP proof bag, a Samsung S5e tablet for watching videos, playing games and reading ebooks and I'm looking at buying an E-Ink device for the long term reading of educational eBooks if electricity is scarce. I also have a laptop as my 'prepper hub' to sync the files between all the devices and to be able to much more easily type blogs such as this. It's alsos also used to flash firmware to the portable devices as the other devices aren't capable of this.

Remember that your usage patterns of the device will vastly change during an emergency. You probably currently spend some time on social medias and chatting to friends on various platforms. However when SHTF, you will pretty much only be looking at maps, reading preparedness manuals and books and watching saved prepper content, with the occasional game if you are stressed. Due to this, don't choose a device with the best online capabilities or 50 fancy cameras, but instead focus on the aspects you really will need in your personal situation.

Hardware

Before we start looking at actual devices, we need to consider what features it should possess. Have a look at my list below on what I wanted in my prepper phone, and then start your own list rating them on how important they are to you.

Screen	Generally the device type you choose above will dictate the screen size you have, although you still have a bit of leeway up or down. Pick a size that suits what you will be doing the most of. Remember that higher density is not always better as it will drain the battery faster – even if you set it to display at a lower resolution. e-Readers should have as high a screen resolution as possible since they update the screen infrequently it won't make much of a difference to the battery life, but you will also be able to read text much more clearly. My choice: About a 6.4 inch screen at 1080p or 1440p.
Repairable	How easily can the device be opened and repaired or maintained if a component in it breaks? Also how readily available are parts for it? Have a look on iFixit.com to see scores on how easily a specific device is to repair. If it's complex, you may want to practice and open it before a disaster hits so you know you can do it without damaging any components – such as the fragile screen. My choice: The iFixit score doesn't matter to me much as I'm quite adept at repairing technology.

Battery	You are going to want a decent battery in any modern device so it can last as long as possible. This is also one of the primary components you will want backups of when the original fails. Ideally you want a removable battery, but most phones today don't give you that option. My choice: My S10+ has a 4000mah battery and I have 2 spares. I also have an ifixit kit to open the phone to do the battery replacement.
Phone Status	Locked/Unlocked My choice: This won't matter in a grid-down situation, but for now I prefer to have it carrier unlocked so I can use any network SIMs in it. When the grid does go down, I will be removing the SIM anyway.
Camera	Wide, Telephoto, Ultrawide etc. My choice: I don't mind what camera a phone has, as long as it has a single one on the back. If it has a front camera, I don't want it using up screen real estate. (One of my main annoyances with my S10+)
Storage	You want to look for the biggest storage space possible to keep all the files you'll end up saving to the device. Generally people regret not going up in size, rarely do they say they wish they bought the smaller model, plus when you start loading up the storage with prepper videos, maps, books and entertainment you will find it runs out pretty quickly. My choice: For my S10+, I look for a 512Gb or 1TB phone.
Micro SD Slot	In my opinion, this is an essential feature for any preparedness phone I'm looking for, since I can plug in a 1TB MicroSD card and instantly have a huge volume of space to do whatever I need. My choice: Absolutely need this. I also have an array of MicroSD cards full of different prepper content which I can plug in and transition between at ease.
Port Type	Do you want a USB-C, Micro USB, Mini USB or another type of charging jack? My choice: Type-C port since I can also plug in my 1TB T1 Samsung portable SSDs into my phone to access a huge array of prepper videos if required. With all the above storage plugged into my phone, this essentially brings the total storage space up to 2.5Tb (512Gb Phone, 1TB MicroSD, 1TB USB-C SSD) – more than enough…. for now.
3.5mm Audio Jack	Used to plug old-school headphones or earbuds into. My choice: I like to have this if possible to avoid wireless devices when in the field which could give away my position. The audio jack is often used as an antenna by wired earphones for the on-board radio in some devices – so if it doesn't have the audio jack, it most likely doesn't have radio capabilities.
Loudspeaker	This may be useful if you want to play wildlife calls to attract animals, otherwise you are likely never going to need a loudspeaker and it may be wise to physically disconnect it from the motherboard to avoid accidentally playing music and giving away your location.
Network Type	3G / 4G / 5G My choice: I avoid 5G phones, so I stick with older models of Samsung phones before 2020. The older phones also have better compatibility with custom roms due to being tried and tested over the years.
Sensors	Fingerprint, accelerometer, gyro, proximity, compass, barometer, heart rate, SpO2 etc. My choice: I just look for the compass and barometer primarily, the rest generally just come with every device today.
Positioning	GPS, GLONASS, BDS, GALILEO, QZSS etc. My choice: I try to get all of the above to make it easier to find my position in offline apps. Most devices today come with at least one type of positioning, however be sure to check the specs on as older tablets may not have any.
Charging	Cable, Wireless (Qi), Reverse Wireless, Fast Charging My choice: Grid-up, my choice is to use wireless charging to save the USB-C port (since each time you plug in the cable, it gets ever so slightly damaged until the port eventually fails and you have to hold the cable at a particular angle to get it to charge). Grid-down I will use cable charging as wireless charging is inefficient due to some power being lost during transmission.
Flip Devices	As a prepping device, you want to avoid anything that can cause your device to break prematurely, and a big cause of failure is any device that can fold. This technology is still relatively new and over time the folding mechanisms have been known to fail, either partially or catastrophically. Even though your screen is more protected when flipped shut, you don't want water somehow seeping into the seam and causing the entire device to stop working. The less points of failure you have – the better. My choice: Avoid flip & folding devices.
Waterproofing	Ideally you will want your device to be usable in heavy rain and also be submersible in water up to a meter or two (in case you drop it into a river). Look for an IP67 or IP68 rating when choosing a phone. My choice: Look for an IP68 device.
Toughness	Finally consider the toughness of the phone. Will it easily break if dropped? Are you the kind of person who drops their phone often? I'm EXTREMELY protective of my phone and always ensure I put it fully on a flat surface, double check it's in my pocket before exiting the car (since I hopped out of the car with it on my lap once – RIP S7 Edge) and I don't carry anything else in my pocket when the phone is in there to prevent it getting scratched by keys etc. Even then, I have cracked 2 phones, so either choose a tough device that can handle the stress of a SHTF world, or carry backups and spare parts. My choice: Being highly 'precious' with my phone, I opted for a device with a large screen and curved edges, but also have backups of the same phone as well.

Have a think about any additional features you would like your prepper phone to have and add to the list above. Consider whether they should be essential, useful or nice-to-have features.

Device Manufacturer

Next you want to look at the which manufacturer you would like to go with which has all the features you listed above. At the same time, you also want to have in mind the next step, which is the operating system you want to use.

Samsung Devices	Cutting edge devices that generally have it all. A couple of things to gripe about such as the recent removal of the MicroSD card slots and the 3.5mm ports from their newest generation phones (from 2010 onwards). Some models have ugly camera cutouts as well, such as the S10+. Samsung phones are not easy to repair yourself and generally don't have user replaceable batteries. (LOS – Lineage OS & EOS – eFoundation Compatible)

Google Devices	The hardware of the Google devices is highly secure, but we want to avoid big tech companies operating systems running on top of that. If you choose a Google device, make sure you flash a new OS onto it such as Graphene – if not, try to avoid Google devices. Also google have dropped a lot of the best prepper related hardware such as the MicroSD slot and the 3.5mm audio jack. (LOS, EOS, Graphene Compatible)
Apple Devices	Avoid! You can't install custom ROMs on iPhones so you're stuck with the apple iOS which is terrible for a number of reasons listed in the section below.
Sony Devices	Generally pretty nice devices. (LOS & EOS Compatible)
LG Devices	A little lackluster in the 'wow' department like Samsung phones, but LG's phones are generally pretty rugged and have the features I need such as a MicroSD card slot. (LOS & EOS Compatible)
ASUS Devices	Another decent phone manufacturer which has some pretty cutting edge features on their devices such as pop-up cameras. (LOS & EOS Compatible)
Fairphone Devices	A very privacy focused company. Some of their phones are a bit plain but they work. (EOS & LOS Compatible)
Motorola Devices	(LOS & EOS Compatible)
Xiaomi Devices	(LOS & EOS Compatible)

My choice: I went with a Samsung device as I'm already familiar with their operating systems and there is such a huge range of phones to choose from I could get nearly exactly what I was looking for in a phone. Also due to their ubiquitous nature modding flagship phones is fairly straightforward. If you need help choosing a company to go with, first decide what operating system you prefer and look up their website to see what phones their OS currently supports.

Operating System

Choose your device's operating system.

Android	This is probably the most ubiquitous operating system out there, but there are so many variants of it that you have to look deeply into what features it provides and what 'bloatware' the manufacturer has installed. Different manufacturers also have varying policies on tracking their users, such as Google and Samsung which you may want to look into.
iOS (Apple)	I would avoid apple products AT ALL COSTS due to their closed source, non-privacy friendly behaviour. There's so much more, so I'll summarize it quickly: They have a culture of cloud storage and synced devices. Devices have limited storage space – compared with other devices with expandable storage. Very difficult/impossible to sideload content. They gather and store information on their users. You can get 'locked' into the iOS environment. Their devices are essentially 'glued' to the internet. You can't customize or expand the storage space. There are no audio ports anymore. The software is locked down. It's difficult and also fairly pointless to jailbreak.
Lineage OS (LOS)	A deGoogled operating system for a variety of phones and tablets. It's a powerful and privacy focuses OS and can be greatly customized and also features a very large user base. The code is open source so there's less likely to be shifty things going on under the hood.
eFoundation (EOS)	Another deGoogled operating system for a larger selection of phones and tablets than the above. EOS is a little more user friendly than Lineage OS for those starting out. It's also open source with their mantra being "Your data is YOUR Data".
Others (Graphene, Ubuntu, Ubuntu Touch, CalyxOS, POP! OS)	Feel free to look into using any other operating systems which take your fancy. Ubuntu and POP! OS are operating systems for laptops if you're going down that route.

My choice: I went with EOS for its privacy friendly and open source nature. I also have files to be able to flash Lineage OS onto my phone at any point in the future without needing the internet. Both of them are pretty much the same, but EOS is slightly more user friendly and Lineage is slightly more secure.

Superuser

There is a degree of skill required to build a prepping phone from scratch due to the need to flash a new operating system (OS) onto the device and the requirement to root it – which if you do either of them wrong can 'brick' the device and cause it to be unusable. Don't worry though, I've made some mistakes flashing my device and there always seems to be a way to recover from it.

If you don't want to go down this route, or don't feel that you have the skills to do this you can always stick with the original OS and not modify anything – just be sure that you will be more vulnerable if there was ever a cyber hack or the 'powers that be' decide they want to track your phone. Below are the four different levels of manipulations which you can modify your phone. Rooting a phone makes it a little more susceptible to being infiltrated.

Stock OS – No Root	This is the default operating system that comes with the phone without root privileges. Most people have this setup by default. There is nothing you need to do to achieve this as phones just come 'stock standard'.
Rooted Stock OS	The default OS with root privileges. This gives you superuser access and allows you to modify pretty much whatever you want. At the very least I recommend rooting your stock operating system to gain the ability to perform superuser functions like backing up and restoring apps.
Custom OS – No Root	The existing operating system has been replaced with a new one, but the phone is not rooted. This is a pretty rate occurrence as rooting can easily occur during the installation of a custom OS.
Rooted Custom OS	In my opinion this is the best setup for privacy and the ability to modify your phone to suit your needs. It requires some skill to do and the process is different for each device, but generally there are complete guides to follow online for most of them – at least for the most popular phone models. There's really only a few more steps to this over the step above, so you might as well go the full way if you're modifying your phone.

Apps

For a list of recommended prepper apps, see the ADDENDUM > Media section.

Recommendations

COMMUNICATION | Technology | Mobile Phone | Best Prepper Device

To make device selection easier, I have included a list of recommended prepper phones that have been suggested by notable figures on the web.

Modern Smartphone Pick: Samsung Galaxy S10/S10+	This phone is a modern all-rounder, featuring the latest technologies (for its time) such as a nice screen, microSD card slot, 3.5mm audio jack, wireless charging, a radio (in USA/Canada), no 5G and more. Although I use the S10+ model, really any Samsung phones around the 2019 era have a great array of useful features needed for prepping. Have a look at the S8+, S9+ as well, as they are all similar with slightly different designs, features and batter sizes, so you will probably find one that suits your needs. The S8/S8+ is smaller and much lighter phone to the S10 if that interests you. Even though I have (and use) the S10+ model, I find it frustrating having a large cutout on the screen taking up screen real estate. The only difference between the S10 and S10+ is the size of the screen, the battery size and the RAM – out of which I only really care about the battery. The negatives of my S10+ is the screen cutout – I wish there was just a small circle, or nothing at all. Also the non-user replaceable battery is frustrating as there's quite a lot of steps opening the phone before you get to the actual battery. Finally, I would have liked an FM radio in mine. (U.S. Version Only) Note: Only the Exynos model of the S10 can have the operating system modified.
Cheap Smartphone Pick LG G4 (Canadian Prepper Recommended)	This 5.5 inch phone features a user replaceable battery, a microSDXC slot, a decent 1440×2560 screen, a 3.5mm audio jack and an FM Radio which is rare on phones. Downsides are that there's only 32Gb internal memory, only 3000mah battery, it has a microUSB port and the phone is now discontinued so it may be hard obtaining one. This is a fairly old recommendation so there are likely to be better models now which have more modern hardware.
Ultra-Privacy Centered Pick: Librem 5	This unique phone has 3 kill switches on the side to physically disconnect the 1. WiFi/Bluetooth, 2. Cellular Networks, and 3. Microphone and Camera for maximum privacy. Each switch will also disable the GPS when flicked as well, which may not be ideal if you are trying to navigate while 'stealthed'. It also has a user replaceable battery and a microSD card slot. It has a low resolution screen coming in at 720×1440, it doesn't have an FM radio and it costs $999+ USD.
Best Privacy & Security Pick: Google Pixel 5/6/7/8	A Google Pixel phone running GrapheneOS is arguably the best private and secure smartphone. Even though Google as a company is highly dubious regarding user privacy, the security hardware on the Pixel phones is unmatched. Additionally, Google makes it easy to install your own operating systems onto their phones which removes a layer of stress which usually comes with flashing a phone like the Samsung S10+ with its many layers of security to try to deter you. Unfortunately Pixels don't come with a MicroSD card slot or a 3.5mm audio jack.
FOSS Pick (Free Open Source Software): Pinephone and Pinephone Pro	These neat little 6" 1440×720 phones are a blend of open source software and privacy focused hardware. They have physical buttons which allow you to disable the cameras, microphone, WiFi, Bluetooth, and the mobile connection at will. It's fully repairable and therefore allows easy access to the hardware modules including the battery. They have MicroSD card slots supporting up to 2TB – which will help you store all those prepper videos, maps and eBooks you'll need.
Ultra Tough Pick: Unihertz Tank	This ultra-rugged phone will withstand even the harshest elements. It has a 22,000mah battery inside which is about 5.5x larger than the average smartphone battery. It has a 3.5mm audio jack and an FM radio which is nice to see. As for negatives, it weights a hefty 560g, the battery isn't removable and there's no MicroSD card.
Tactical Pick: Ulefone Power Armor 19T	A phone with built-in FLIR thermal imaging, a hefty 9,600mah battery, microSD card slot, IP68 & IP69K waterproofing, a 120hz screen and "180MP" camera.

COMMUNICATION | Technology | VHF

VHF Radio

COMMUNICATION | Technology

Airband Portable Transceiver

COMMUNICATION | Technology

Satellite Phone

Useful in SHTF if the satellites are still functioning and you know the numbers of people with other satellite phones.

COMMUNICATION | Technology | International Calling Codes

International Calling Codes

Country calling codes or country dial in codes are telephone dialling prefixes for the member countries or regions of the International Telecommunication Union (ITU). They are defined by the ITU-T in standards E.123 and E.164. The prefixes enable international direct dialling (IDD), and are also referred to as international subscriber dialling (ISD) codes. Country codes are a component of the international telephone numbering plan, and are necessary only when dialling a telephone number to establish a call to another country. Country codes are dialled before the national telephone number. By convention, international telephone numbers are represented by prefixing the country code with a plus sign (+), which also indicates to the subscriber that the local international call prefix must first be dialled.

Calling	**Calls From the US/Canada** For calls to most countries dial the following: 011 + country code + phone number	**Dialling Code** Dial: your country's exit code + destination country code + phone number		

Country Codes

Country calling codes or country dial in codes are telephone dialling prefixes for the member countries or regions of the International Telecommunication Union (ITU). The prefixes enable international direct dialling (IDD), and are also referred to as international subscriber dialling (ISD) codes. Country codes are a component of the international telephone numbering plan, and are necessary only when dialling a telephone number to establish a call to another country. Country codes are dialled before the national telephone number. By convention, international telephone numbers are represented by prefixing the country code with a plus sign (+), which also indicates to the subscriber that the local international call prefix must first be dialled. For example, the international call prefix in all countries belonging to the North American Numbering Plan is 011, while it is 00 in most European, Asian and African countries. On GSM (cellular) networks, the prefix may automatically be inserted when the user prefixes a dialled number with the plus sign.

A telephone keypad is the keypad installed on a push-button telephone or similar telecommunication device for dialling a telephone number. The development of the modern telephone keypad is attributed to research in the 1950s by Richard Deininger under the directorship of John Karlin at the Human Factors Engineering Department of Bell Labs. The contemporary keypad is laid out in a rectangular array of twelve push buttons arranged as four rows and three columns of keys. For military applications, a fourth, right-most column of keys was added for priority signalling in the Autovon system in the 1960s. The letters have also been used, mainly in the United States, as a technique for remembering telephone numbers easily. For example, an interior decorator might license the telephone number 1-800-724-6837, but advertise it as the more memorable phoneword 1-800-PAINTER. In mobile phones the letters on the keys are used for text entry tasks such as text messaging, entering names in the phone book, and browsing the web. To compensate for the smaller number of keys, phones used multi-tap and later predictive text processing to speed up the process. Touch-screen phones have made this method obsolete, as they can simulate as many buttons as necessary for full text entry.

Letter Mapping
In the course of telephone history, the positions of telephone dials, as well as keypads have been associated with various patterns of mapping letters and characters to numbers (keyboard layout). The use of alphanumeric codes for exchanges was abandoned in Europe when international direct dialling was introduced in the 1960s, because, for example, dialling VIC 8900 on a Danish telephone would result in a different number to dialling it on a British telephone. At the same time letters were no longer placed on the dials of new telephones. Letters did not re-appear on phones in Europe until the introduction of mobile phones, and the layout followed the new international standard. The ITU established an international standard in the mid-1990s, and that should be the layout used for any new devices. Since many newer smartphones, such as the Palm Treo and BlackBerry, have full alphanumeric keyboards instead of the traditional telephone keypads, the user must execute additional steps to dial a number containing convenience letters. On certain BlackBerry devices, a user can press the Alt key, followed by the desired letter, and the device will generate the appropriate DTMF tone.

2 Braille

Braille is a tactile writing system used by people who are visually impaired. It is traditionally written with embossed paper. Braille users can read computer screens and other electronic supports using refreshable braille displays. They can write braille with the original slate and stylus or type it on a braille writer, such as a portable braille notetaker or computer that prints with a braille embosser.

3 Morse Code

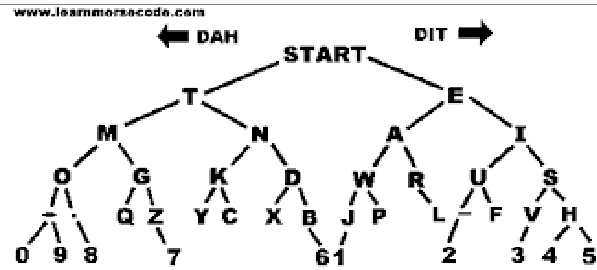
Morse code is a character encoding scheme used in telecommunication that encodes text characters as standardized sequences of two different signal durations called dots and dashes or dits and dahs. Morse code is named for Samuel F. B. Morse, an inventor of the telegraph.

The International Morse Code encodes the 26 English letters A through Z, some non-English letters, the Arabic numerals and a small set of punctuation and procedural signals (prosigns). There is no distinction between upper and lower case letters. Each Morse code symbol is formed by a sequence of dots and dashes. The dot duration is the basic unit of time measurement in Morse code transmission. The duration of a dash is three times the duration of a dot. Each dot or dash within a character is followed by period of signal absence, called a space, equal to the dot duration. The letters of a word are separated by a space of duration equal to three dots, and the words are separated by a space equal to seven dots. To increase the efficiency of encoding, Morse code was designed so that the length of each symbol is approximately inverse to the frequency of occurrence in text of the English language character that it represents. Thus the most common letter in English, the letter "E", has the shortest code: a single dot. Because the Morse code elements are specified by proportion rather than specific time durations, the code is usually transmitted at the highest rate that the receiver is capable of decoding. The Morse code transmission rate (speed) is specified in groups per minute, commonly referred to as words per minute.

One dash (—) equals about three dots worth of time. (●●●)
The space (timed gap) between parts of the same letter is one dot (●).
The space between letters is three dots (●●●).
The space between words is seven dots (●●●●●●●).

This diagram should help simplify the decoding of messages. The left side is dashes (—) and the right side is dots (•). If you hear a dot you will go to the right and if you hear a dash you go to the left. If there's a break of three dots then that's the letter you select.

For example if you hear a dot first, you head to 'E', then if you hear a dash next you will be at 'A' then another dash and you'll be on 'W'. You can continue like this until you hear the three dots silence.



Letters

Letters contain from 1 to 4 characters in their sequence. The most common letters have fewer characters.

A	•—	B	—•••	C	—•—•
D	—••	E	•	F	••—•
G	——•	H	••••	I	••
J	•———	K	—•—	L	•—••
M	——	N	—•	O	———
P	•——•	Q	——•—	R	•—•
S	•••	T	—	U	••—
V	•••—	W	•——	X	—••—
Y	—•——	Z	——••		

Numbers

Numbers always have 5 characters in their sequence so they are easy to tell apart from letters. 1-5 start with dots while 6-9 and 0 start with dashes.

1	•————	2	••———	3	•••——
4	••••—	5	•••••	6	—••••
7	——•••	8	———••	9	————•
0	—————				

Symbols

The sequences for symbols vary between different languages so these are the English versions.

.	•—•—•—	,	——••——	?	••——••
@	•——•—•	_	••——•—	"	•—••—•
!	—•—•——	;	—•—•—•	:	———•••

4 Atbash

Atbash is simply the alphabet in reverse.

A = Z	B = Y	C = X	D = W	E = V	F = U	G = T	H = S	I = R	J = Q	K = P	L = O
M = N	N = M	O = L	P = K	Q = J	R = I	S = H	T = G	U = F	V = E	W = D	X = C
Y = B	Z = A										

5 Caesar Cipher

The Caesar cipher is a code Julius Caesar invented when he mailed letters. He invented it so if his messenger was robbed of that letter and the robber wouldn't be able to read it. It is probably one of the most simple codes ever. It is 3 letters back so A would be X. The Rot Cipher is almost the same as the Caesar Cipher.

A = X	B = Y	C = Z	D = A	E = B	F = C	G = D	H = E	I = F	J = G	K = H	L = I
M = J	N = K	O = L	P = M	Q = N	R = O	S = P	T = Q	U = R	V = S	W = T	X = U
Y = V	Z = W										

Scytale

A message is wrapped around a cylindrical object which when re-wrapped decodes the message automatically. Wrap a thin piece of paper around a cylindrical object making sure there's no gaps and then write your message on multiple rows. Make sure you note the diameter of the cylinder or it will be difficult to decipher. The more lines you write and the smaller the font you use the harder the cipher is to break.

6 ASCII

ASCII, stands for American Standard Code for Information Interchange. It's a 7-bit character code where every single bit represents a unique character. On this webpage you will find 8 bits, 256 characters, ASCII table according to Windows-1252 (code page 1252) which is a superset of ISO 8859-1 in terms of printable characters. In the range 128 to 159 (hex 80 to 9F), ISO/IEC 8859-1 has invisible control characters, while Windows-1252 has writable characters. Windows-1252 is probably the most-used 8-bit character encoding in the world.

ASCII Control Characters

The first 32 characters in the ASCII-table are unprintable control codes and are used to control peripherals such as printers.

Decimal	Octal	Hexadecimal	Binary	Symbol	HTML Number	Description
0	000	00	00000000	NUL	&#000;	Null char
1	001	01	00000001	SOH	&#001;	Start of Heading
2	002	02	00000010	STX	&#002;	Start of Text
3	003	03	00000011	ETX	&#003;	End of Text
4	004	04	00000100	EOT	&#004;	End of Transmission
5	005	05	00000101	ENQ	&#005;	Enquiry
6	006	06	00000110	ACK	&#006;	Acknowledgment
7	007	07	00000111	BEL	&#007;	Bell
8	010	08	00001000	BS	&#008;	Back Space
9	011	09	00001001	HT		Horizontal Tab
10	012	0A	00001010	LF
Line Feed
11	013	0B	00001011	VT	&#011;	Vertical Tab
12	014	0C	00001100	FF		Form Feed
13	015	0D	00001101	CR
Carriage Return
14	016	0E	00001110	SO	&#014;	Shift Out / X-On
15	017	0F	00001111	SI	&#015;	Shift In / X-Off
16	020	10	00010000	DLE	&#016;	Data Line Escape
17	021	11	00010001	DC1	&#017;	Device Control 1 (oft. XON)
18	022	12	00010010	DC2	&#018;	Device Control 2
19	023	13	00010011	DC3	&#019;	Device Control 3 (oft. XOFF)
20	024	14	00010100	DC4	&#020;	Device Control 4
21	025	15	00010101	NAK	&#021;	Negative Acknowledgement
22	026	16	00010110	SYN	&#022;	Synchronous Idle
23	027	17	00010111	ETB	&#023;	End of Transmit Block
24	030	18	00011000	CAN	&#024;	Cancel
25	031	19	00011001	EM	&#025;	End of Medium
26	032	1A	00011010	SUB	&#026;	Substitute
27	033	1B	00011011	ESC	&#027;	Escape
28	034	1C	00011100	FS	&#028;	File Separator
29	035	1D	00011101	GS	&#029;	Group Separator
30	036	1E	00011110	RS	&#030;	Record Separator
31	037	1F	00011111	US	&#031;	Unit Separator

ASCII Printable Characters

Codes 32-127 are common for all the different variations of the ASCII table, they are called printable characters, represent letters, digits, punctuation marks, and a few miscellaneous symbols. You will find almost every character on your keyboard. Character 127 represents the command DEL.

Decimal	Octal	Hexadecimal	Binary	Symbol	HTML Number	Description
32	040	20	00100000			Space
33	041	21	00100001	!	!	Exclamation mark
34	042	22	00100010	"	"	Double quotes (or speech marks)
35	043	23	00100011	#	#	Number
36	044	24	00100100	$	$	Dollar
37	045	25	00100101	%	%	Per cent sign
38	046	26	00100110	&	&	Ampersand
39	047	27	00100111	'	'	Single quote
40	050	28	00101000	(	(	Open parenthesis (or open bracket)
41	051	29	00101001	)	)	Close parenthesis (or close bracket)
42	052	2A	00101010	*	*	Asterisk
43	053	2B	00101011	+	+	Plus
44	054	2C	00101100	,	,	Comma
45	055	2D	00101101	-	-	Hyphen
46	056	2E	00101110	.	.	Period, dot or full stop
47	057	2F	00101111	/	/	Slash or divide
48	060	30	00110000	0	0	Zero
49	061	31	00110001	1	1	One
50	062	32	00110010	2	2	Two
51	063	33	00110011	3	3	Three
52	064	34	00110100	4	4	Four
53	065	35	00110101	5	5	Five
54	066	36	00110110	6	6	Six
55	067	37	00110111	7	7	Seven
56	070	38	00111000	8	8	Eight
57	071	39	00111001	9	9	Nine
58	072	3A	00111010	:	:	Colon
59	073	3B	00111011	;	;	Semicolon
60	074	3C	00111100	<	<	Less than (or open angled bracket)
61	075	3D	00111101	=	=	Equals
62	076	3E	00111110	>	>	Greater than (or close angled bracket)
63	077	3F	00111111	?	?	Question mark
64	100	40	01000000	@	@	At symbol
65	101	41	01000001	A	A	Uppercase A

66	102	42	01000010	B	B	Uppercase B
67	103	43	01000011	C	C	Uppercase C
68	104	44	01000100	D	D	Uppercase D
69	105	45	01000101	E	E	Uppercase E
70	106	46	01000110	F	F	Uppercase F
71	107	47	01000111	G	G	Uppercase G
72	110	48	01001000	H	H	Uppercase H
73	111	49	01001001	I	I	Uppercase I
74	112	4A	01001010	J	J	Uppercase J
75	113	4B	01001011	K	K	Uppercase K
76	114	4C	01001100	L	L	Uppercase L
77	115	4D	01001101	M	M	Uppercase M
78	116	4E	01001110	N	N	Uppercase N
79	117	4F	01001111	O	O	Uppercase O
80	120	50	01010000	P	P	Uppercase P
81	121	51	01010001	Q	Q	Uppercase Q
82	122	52	01010010	R	R	Uppercase R
83	123	53	01010011	S	S	Uppercase S
84	124	54	01010100	T	T	Uppercase T
85	125	55	01010101	U	U	Uppercase U
86	126	56	01010110	V	V	Uppercase V
87	127	57	01010111	W	W	Uppercase W
88	130	58	01011000	X	X	Uppercase X
89	131	59	01011001	Y	Y	Uppercase Y
90	132	5A	01011010	Z	Z	Uppercase Z
91	133	5B	01011011	[	[	Opening bracket
92	134	5C	01011100	\	\	Backslash
93	135	5D	01011101	]	]	Closing bracket
94	136	5E	01011110	^	^	Caret - circumflex
95	137	5F	01011111	_	_	Underscore
96	140	60	01100000	`	`	Grave accent
97	141	61	01100001	a	a	Lowercase a
98	142	62	01100010	b	b	Lowercase b
99	143	63	01100011	c	c	Lowercase c
100	144	64	01100100	d	d	Lowercase d
101	145	65	01100101	e	e	Lowercase e
102	146	66	01100110	f	f	Lowercase f
103	147	67	01100111	g	g	Lowercase g
104	150	68	01101000	h	h	Lowercase h
105	151	69	01101001	i	i	Lowercase i
106	152	6A	01101010	j	j	Lowercase j
107	153	6B	01101011	k	k	Lowercase k
108	154	6C	01101100	l	l	Lowercase l
109	155	6D	01101101	m	m	Lowercase m
110	156	6E	01101110	n	n	Lowercase n
111	157	6F	01101111	o	o	Lowercase o
112	160	70	01110000	p	p	Lowercase p
113	161	71	01110001	q	q	Lowercase q
114	162	72	01110010	r	r	Lowercase r
115	163	73	01110011	s	s	Lowercase s
116	164	74	01110100	t	t	Lowercase t
117	165	75	01110101	u	u	Lowercase u
118	166	76	01110110	v	v	Lowercase v
119	167	77	01110111	w	w	Lowercase w
120	170	78	01111000	x	x	Lowercase x
121	171	79	01111001	y	y	Lowercase y
122	172	7A	01111010	z	z	Lowercase z
123	173	7B	01111011	{	{	Opening brace
124	174	7C	01111100	|			Vertical bar
125	175	7D	01111101	}	}	Closing brace
126	176	7E	01111110	~	~	Equivalency sign - tilde
127	177	7F	01111111		&#127;	Delete

ASCII Extended Codes

There are several different variations of the 8-bit ASCII table. The table below is according to Windows-1252 (CP-1252) which is a superset of ISO 8859-1, also called ISO Latin-1, in terms of printable characters, but differs from the IANA's ISO-8859-1 by using displayable characters rather than control characters in the 128 to 159 range. Characters that differ from ISO-8859-1 is marked by light blue colour.

Decimal	Octal	Hexadecimal	Binary	Symbol	HTML Number	Description
128	200	80	10000000	€	€	Euro sign
129	201	81	10000001			
130	202	82	10000010	‚	‚	Single low-9 quotation mark
131	203	83	10000011	ƒ	ƒ	Latin small letter f with hook
132	204	84	10000100	„	„	Double low-9 quotation mark

133	205	85	10000101	…	…	Horizontal ellipsis
134	206	86	10000110	†	†	Dagger
135	207	87	10000111	‡	‡	Double dagger
136	210	88	10001000	ˆ	ˆ	Modifier letter circumflex accent
137	211	89	10001001	‰	‰	Per mille sign
138	212	8A	10001010	Š	Š	Latin capital letter S with caron
139	213	8B	10001011	‹	‹	Single left-pointing angle quotation
140	214	8C	10001100	Œ	Œ	Latin capital ligature OE
141	215	8D	10001101			
142	216	8E	10001110	Ž	Ž	Latin capital letter Z with caron
143	217	8F	10001111			
144	220	90	10010000			
145	221	91	10010001	‘	‘	Left single quotation mark
146	222	92	10010010	’	’	Right single quotation mark
147	223	93	10010011	“	“	Left double quotation mark
148	224	94	10010100	”	”	Right double quotation mark
149	225	95	10010101	•	•	Bullet
150	226	96	10010110	–	–	En dash
151	227	97	10010111	—	—	Em dash
152	230	98	10011000	˜	˜	Small tilde
153	231	99	10011001	™	™	Trade mark sign
154	232	9A	10011010	š	š	Latin small letter S with caron
155	233	9B	10011011	›	›	Single right-pointing angle quotation mark
156	234	9C	10011100	œ	œ	Latin small ligature oe
157	235	9D	10011101			
158	236	9E	10011110	ž	ž	Latin small letter z with caron
159	237	9F	10011111	Ÿ	Ÿ	Latin capital letter Y with diaeresis
160	240	A0	10100000			Non-breaking space
161	241	A1	10100001	¡	¡	Inverted exclamation mark
162	242	A2	10100010	¢	¢	Cent sign
163	243	A3	10100011	£	£	Pound sign
164	244	A4	10100100	¤	¤	Currency sign
165	245	A5	10100101	¥	¥	Yen sign
166	246	A6	10100110	¦	¦	Pipe, Broken vertical bar
167	247	A7	10100111	§	§	Section sign
168	250	A8	10101000	¨	¨	Spacing diaeresis - umlaut
169	251	A9	10101001	©	©	Copyright sign
170	252	AA	10101010	ª	ª	Feminine ordinal indicator
171	253	AB	10101011	«	«	Left double angle quotes
172	254	AC	10101100	¬	¬	Not sign
173	255	AD	10101101			Soft hyphen
174	256	AE	10101110	®	®	Registered trade mark sign
175	257	AF	10101111	¯	¯	Spacing macron - overline
176	260	B0	10110000	°	°	Degree sign
177	261	B1	10110001	±	±	Plus-or-minus sign
178	262	B2	10110010	²	²	Superscript two - squared
179	263	B3	10110011	³	³	Superscript three - cubed
180	264	B4	10110100	´	´	Acute accent - spacing acute
181	265	B5	10110101	µ	µ	Micro sign
182	266	B6	10110110	¶	¶	Pilcrow sign - paragraph sign
183	267	B7	10110111	·	·	Middle dot - Georgian comma
184	270	B8	10111000	¸	¸	Spacing cedilla
185	271	B9	10111001	¹	¹	Superscript one
186	272	BA	10111010	º	º	Masculine ordinal indicator
187	273	BB	10111011	»	»	Right double angle quotes
188	274	BC	10111100	¼	¼	Fraction one quarter
189	275	BD	10111101	½	½	Fraction one half
190	276	BE	10111110	¾	¾	Fraction three quarters
191	277	BF	10111111	¿	¿	Inverted question mark
192	300	C0	11000000	À	À	Latin capital letter A with grave
193	301	C1	11000001	Á	Á	Latin capital letter A with acute
194	302	C2	11000010	Â	Â	Latin capital letter A with circumflex
195	303	C3	11000011	Ã	Ã	Latin capital letter A with tilde
196	304	C4	11000100	Ä	Ä	Latin capital letter A with diaeresis
197	305	C5	11000101	Å	Å	Latin capital letter A with ring above
198	306	C6	11000110	Æ	Æ	Latin capital letter AE
199	307	C7	11000111	Ç	Ç	Latin capital letter C with cedilla
200	310	C8	11001000	È	È	Latin capital letter E with grave
201	311	C9	11001001	É	É	Latin capital letter E with acute
202	312	CA	11001010	Ê	Ê	Latin capital letter E with circumflex
203	313	CB	11001011	Ë	Ë	Latin capital letter E with diaeresis
204	314	CC	11001100	Ì	Ì	Latin capital letter I with grave

205	315	CD	11001101	Í	Í	Latin capital letter I with acute
206	316	CE	11001110	Î	Î	Latin capital letter I with circumflex
207	317	CF	11001111	Ï	Ï	Latin capital letter I with diaeresis
208	320	D0	11010000	Ð	Ð	Latin capital letter ETH
209	321	D1	11010001	Ñ	Ñ	Latin capital letter N with tilde
210	322	D2	11010010	Ò	Ò	Latin capital letter O with grave
211	323	D3	11010011	Ó	Ó	Latin capital letter O with acute
212	324	D4	11010100	Ô	Ô	Latin capital letter O with circumflex
213	325	D5	11010101	Õ	Õ	Latin capital letter O with tilde
214	326	D6	11010110	Ö	Ö	Latin capital letter O with diaeresis
215	327	D7	11010111	×	×	Multiplication sign
216	330	D8	11011000	Ø	Ø	Latin capital letter O with slash
217	331	D9	11011001	Ù	Ù	Latin capital letter U with grave
218	332	DA	11011010	Ú	Ú	Latin capital letter U with acute
219	333	DB	11011011	Û	Û	Latin capital letter U with circumflex
220	334	DC	11011100	Ü	Ü	Latin capital letter U with diaeresis
221	335	DD	11011101	Ý	Ý	Latin capital letter Y with acute
222	336	DE	11011110	Þ	Þ	Latin capital letter THORN
223	337	DF	11011111	ß	ß	Latin small letter sharp s - ess-zed
224	340	E0	11100000	à	à	Latin small letter a with grave
225	341	E1	11100001	á	á	Latin small letter a with acute
226	342	E2	11100010	â	â	Latin small letter a with circumflex
227	343	E3	11100011	ã	ã	Latin small letter a with tilde
228	344	E4	11100100	ä	ä	Latin small letter a with diaeresis
229	345	E5	11100101	å	å	Latin small letter a with ring above
230	346	E6	11100110	æ	æ	Latin small letter ae
231	347	E7	11100111	ç	ç	Latin small letter c with cedilla
232	350	E8	11101000	è	è	Latin small letter e with grave
233	351	E9	11101001	é	é	Latin small letter e with acute
234	352	EA	11101010	ê	ê	Latin small letter e with circumflex
235	353	EB	11101011	ë	ë	Latin small letter e with diaeresis
236	354	EC	11101100	ì	ì	Latin small letter i with grave
237	355	ED	11101101	í	í	Latin small letter i with acute

7 Binary

This is an alternative way to count using binary, different to the cardinal numbers of binary above in the ASCII section.

0 = 0	**1 = 1**	**2 = 10**	**3 = 11**	**4 = 100**	**5 = 101**	**6 = 110**	**7 = 111**	**8 = 1000**	**9 = 1001**	**10 = 1010**	
	11 = 1011	**12 = 1100**	**13 = 1101**	**14 = 1110**	**15 = 1111**	**16 = 10000**	**17 = 10001**	**18 = 10010**	**19 = 10011**	**20 = 10100**	

7 Markings

Homeless City Guide

These chalk markings are commonly used by homeless people to communicate with each other. They may be useful in a survival situation.

An Attack Happened Here 	**Danger** 	**Dangerous Neighbourhood** 	**Empty Building** 	**Friendly Place** 	**Good Food Thrown Away** 	**Good Place to Drink & Smoke** 	**Guard Dogs** 	**Message Board X Mins That Way** 	**Safe For Sleeping** 	**Security Guard** 	**Soup Run wRating** 
Squat 	**Strong Police Presence** 	**Unfriendly Place** 	**Work Potential** 	**You'll Get Moved On Here** 							

Nomad Codes

The pictographic Hobo Code is a fascinating system of symbols understood among the hobo community. Because hobos weren't typically welcomed (and were often illiterate), messages left for others in the community had to be easy for hobos to read but look like little more than random markings to everyone else to maintain an element of secrecy. The code features certain elements that appear in more than one symbol, such as the circles and arrows that made up the directional symbols. Hash marks or crossed lines usually meant danger in some form.

Afraid	At Crossroad Go This Way	Bad Water	Be Quiet	Be Ready to Defend Yourself	Beware Dogs	Camp Here	Can Sleep In Loft	Catch Out Here	Chain Gang	You'll Get Cursed Out Here	Cops Active
Cops Inactive	Courthouse or Police Station	Cowards - Will Give to Make You Leave	Danger	Dangerous Neighbourhood	Doctor No Charge	Don't Give Up	Don't Go This Way	Get Out Fast (Hobos Not Welcome)	Worth Robbing	Go	Good Road to Follow
Fresh Water & Campsite	Hobos Arrested On Sight	Hold Your Tongue	Jail	Keep Away	No Alcohol Town	Railroad	Safe Camp	Unsafe Area	Stop	Straight Ahead	Town Allows Alcohol
Tramps Here	Trolley	Turn Left Here	Turn Right Here								

Modern Hoboglyphs

Kind Lady	Kind Gentleman	Judge Lives Here	Good Place for Hand Outs	Owner is Out/Away	Agitated Homeless	Buffet of Sample Foods	Camera Perverts	Check Cashing	Companies test market here	Discover Card Accepted	Dishonest ticket scalpers here
Dog Poop	Dumpster Treasure	GPS will screw you here	High-fee ATM	Instant Parking tickets	It	Kinkos	No Oversight of public transit ticket system	No-fee ATM	Olive Trees	Open Wireless Network	Overpriced Drinks
Plan B Contraception available	Prostitution Sting	Purell Available	25 Minute Wait from Here	Thin Ice	Those aren't women	Unexpected Lawn Sprinklers	Used Frying Oil Available for Biodiesel	Vegans Beware	Well-stocked bathroom		

Other Markings

Shadowmarks (Skyrim) Shadowmarks are a fictional communications system used by the thieves guild in Skyrim, however these marks could have useful have real world applications if learnt.	**Guild** Denotes the location nearby is part of the Guild.	**Safe** Denoting the area is safe for the Guild.	**Danger** Denoting hostile person or trap nearby.	**Escape** Denoting that following this mark leads to escape.	**Protected** Denoting the area or people are under Guild protection.	**Fence** Denoting there is a buyer of stolen goods inside.	**Cache** Denoting a Cache of supplies.	**Loot** Denoting valuables or riches lie inside or nearby.	**Empty** Denoting there is nothing of value inside.
Hunting Markings Markings that hunters use.									
Societal Markings									

Language

Foreign alphabets and translations of words and phrases

"Drawing on my fine command of the English language, I said nothing."
Robert Benchley

Introduction

Being able to speak other languages can be vital in a situation where you're plunged into another country or are being invaded. Not only can it be used to communicate with other people in their native language, but also as a means of communicating in an English speaking country covertly. English isn't included below because you're likely to already excel at it. Included is a selection of the most common words and phrases in each language to be able to get by if required. Languages are sorted alphabetically and have been chosen via a combination of usefulness and number of native speakers. Ideally there's enough information in each language that you can read signs and survive in a foreign country.

Purpose	The aim of LANGUAGE is to help the reader translate signs, words and sentences in an attempt to communicate with those who don't speak their language.
Lost?	• For information about the different regions of the world, see the GEOGRAPHY section. • To understand the drive of different groups of people, see the POPULATION section. • To improve your communication with others, see the COMMUNICATION section.

2 Arabic

Arabic is a Semitic language that first emerged in the 1st to 4th centuries CE. It is now the lingua franca of the Arab world. It is named after the Arabs, a term initially used to describe peoples living in the area bounded by Mesopotamia in the east and the Anti-Lebanon mountains in the west, in north-western Arabia, and in the Sinai Peninsula. Arabic is classified as a macrolanguage comprising 30 modern varieties, including its standard form, Modern Standard Arabic, which is derived from Classical Arabic. As the modern written language, Modern Standard Arabic is widely taught in schools and universities, and is used to varying degrees in workplaces, government, and the media.

The two formal varieties are grouped together as Literary Arabic (fuṣḥā), which is the official language of 26 states, and the liturgical language of the religion of Islam, since the Quran and Hadith were written in Arabic. Modern Standard Arabic largely follows the grammatical standards of Classical Arabic, and uses much of the same vocabulary. However, it has discarded some grammatical constructions and vocabulary that no longer have any counterpart in the spoken varieties, and has adopted certain new constructions and vocabulary from the spoken varieties.
Much of the new vocabulary is used to denote concepts that have arisen in the post-classical era, especially in modern times. Due to its grounding in Classical Arabic, Modern Standard Arabic is removed over a millennium from everyday speech, which is construed as a multitude of dialects of this language. These dialects and Modern Standard Arabic are described by some scholars as not mutually comprehensible. The former are usually acquired in families, while the latter is taught in formal education settings. However, there have been studies reporting some degree of comprehension of stories told in the standard variety among preschool-aged children. The relation between Modern Standard Arabic and these dialects is sometimes compared to that of Latin and vernaculars (or today's Italian, French or Spanish) in medieval and early modern Europe.

This view though does not take into account the widespread use of Modern Standard Arabic as a medium of audio-visual communication in today's mass media—a function Latin has never performed. Classical Arabic is the liturgical language of 1.8 billion Muslims, and Modern Standard Arabic is one of six official languages of the United Nations. All varieties of Arabic combined are spoken by perhaps as many as 422 million speakers (native and non-native) in the Arab world, making it the fifth most spoken language in the world. Arabic is written with the Arabic alphabet, which is an abjad script and is written from right to left, although the spoken varieties are sometimes written in ASCII Latin from left to right with no standardized orthography.

Alphabet

The Arabic alphabet or Arabic abjad is the Arabic script as it is codified for writing Arabic. It is written from right to left in a cursive style and includes 28 letters. The following alphabet characters are written from right to left.

ل l	ك k	ي y	ط ṭ	ح ḥ	ز z	و w	ه h	د d	ج j	ب b	أ ʼ

3 Chinese

Chinese is a group of related, but in many cases not mutually intelligible, language varieties, forming the Sinitic branch of the Sino-Tibetan language family. Chinese is spoken by the ethnic Chinese majority and many minority ethnic groups in China. About 1.2 billion people (around 16% of the world's population) speak some form of Chinese as their first language. The varieties of Chinese are usually described by native speakers as dialects of a single Chinese language, but linguists note that they are as diverse as a language family. The internal diversity of Chinese has been likened to that of the Romance languages, but may be even more varied. There are between 7 and 13 main regional groups of Chinese (depending on classification scheme), of which the most spoken by far is Mandarin (about 960 million, e.g. South-western Mandarin), followed by Wu (80 million, e.g. Shanghainese), Min (70 million, e.g. Southern Min), Yue (60 million, e.g. Cantonese), etc.

Most of these groups are mutually unintelligible, and even dialect groups within Min Chinese may not be mutually intelligible. Some, however, like Xiang and certain Southwest Mandarin dialects, may share common terms and a certain degree of intelligibility. All varieties of Chinese are tonal and analytic. Standard Chinese is a standardized form of spoken Chinese based on the Beijing dialect of Mandarin. It is the official language of China and Taiwan, as well as one of the four official languages of Singapore.

Writing Systems

Pinyin	Hanyu Pinyin, often abbreviated to pinyin, is the official romanization system for Standard Chinese in mainland China and to some extent in Taiwan. It is often used to teach Standard Mandarin Chinese, which is normally written using Chinese characters. The system includes four diacritics denoting tones. Pinyin without tone marks is used to spell Chinese names and words in languages written with the Latin alphabet, and also in certain computer input methods to enter Chinese characters.
Traditional	Traditional Chinese characters are Chinese characters in any character set that does not contain newly created characters or character substitutions performed after 1946. They are most commonly the characters in the standardized character sets of Taiwan, of Hong Kong and Macau, and in the Kangxi Dictionary.
Simplified	Simplified Chinese characters are standardized Chinese characters prescribed in the Table of General Standard Chinese Characters for use in mainland China. Along with traditional Chinese characters, they are one of the two standard character sets of the contemporary Chinese written language. The government of the People's Republic of China in mainland China has promoted them for use in printing since the 1950s and 1960s to encourage literacy.
Hanzi	

Alphabet - Pinyin

Initials

A syllable in Chinese is composed of an initial, which is a consonant that begins the syllable, and a final, which covers the rest of the syllable.

	b d g j z zh	p t k q c ch	m n h x s sh	f l r
	m, f, n, l, h and sh are pronounced as in English.	d like "d" in "bed" (unaspirated) j like "g" in "genius" (unaspirated) z like "ds" in "beds" zh like "j" in "job" b like "p" in "spin" (unaspirated) g a soft unaspirated "k" sound x like "sh" in "sheep" but with the corners of the lips drawn back r somewhat like "r" in "rain"	Particular attention should be paid to the pronunciation of the so-called "aspirated" consonants. It is necessary to breath heavily after the consonant is pronounced. p like "p" in "pope" t like "t" in "tap" k like "k" in "kangaroo" q harder than "ch" in "cheap" c like "ts" in "cats"	Distinction between certain initials: b / p d / t g / k j / q z / c zh / ch

Finals

In modern Chinese, there are 38 finals besides the above-represented 21 initials.

	a o e er ai ei ao ou an en ang eng	i ia ie iao iou (iu) ian in iang ieng	ua uo uai uei (ui) uan uen (un) uang ueng	üe üan üen	
	ie like "ye" in "yes" e like "e" in "her"	er like "er" in "sister" (american pronunciation) ai like "y" in "by" (light)	ei like "ay" in "bay" ou like "o" in "go"	an like "an" in "can" (without stressing the "n") -ng (final) a nasalized soung like the "ng" in "bang" without pronouncing the "a"	uei, uen and iou when preceded by an initial, are written as ui, un and iu respectively.

Tones

Mandarin Chinese has four pitched tones and a "toneless" tone.

Tone	Mark	Description
1st	dā	High and level
2nd	dá	Starts medium in tone, then rises to the top
3rd	dǎ	Starts low, dips to the bottom, then rises toward the top
4th	dà	Starts at the top, then falls sharp and strong to the bottom
Neutral	da	Flat, with no emphasis

Tone Changes
A 3rd tone, when immediately followed by another 3rd tone, should pe pronounced in the 2nd tone.
Nǐ hǎo = Ní hǎo

Common Phrases

4 French

French is a Romance language of the Indo-European family. It descended from the Vulgar Latin of the Roman Empire, as did all Romance languages. French evolved from Gallo-Romance, the spoken Latin in Gaul, and more specifically in Northern Gaul. Its closest relatives are the other langues d'oïl—languages historically spoken in northern France and in southern Belgium, which French (Francien) has largely supplanted. French was also influenced by native Celtic languages of Northern Roman Gaul like Gallia Belgica and by the (Germanic) Frankish language of the post-Roman Frankish invaders. Today, owing to France's past overseas expansion, there are numerous French-based creole languages, most notably Haitian Creole. A French-speaking person or nation may be referred to as Francophone in both English and French. It is spoken as a first language (in descending order of the number of speakers) in France, Canadian provinces of Quebec, Ontario and New Brunswick as well as other Francophone regions, Belgium (Wallonia and the Brussels-Capital Region), western Switzerland (cantons of Bern, Fribourg, Geneva, Jura, Neuchâtel, Vaud, Valais), Monaco, parts of the United States (Louisiana, Maine, New Hampshire, and Vermont), partly in Luxembourg and in northern Italy (region of Aosta Valley), and by various communities elsewhere.

French is estimated to have about 76 million native speakers and about 235 million daily, fluent speakers and another 77 to 110 million secondary speakers who speak it as a second language to varying degrees of proficiency, mainly in Africa. According to the Organisation internationale de la Francophonie (OIF), approximately 300 million people worldwide are "able to speak the language", without specifying the criteria for this estimation or whom it encompasses. According to a demographic projection led by the Université Laval and the Réseau Démographie de l'Agence universitaire de la francophonie, the total number of French speakers will reach approximately 500 million in 2025 and 650 million by 2050. OIF estimates 700 million by 2050, 80% of whom will be in Africa.

Common Phrases

5 German

German is a West Germanic language that is mainly spoken in Central Europe. It is the most widely spoken and official or co-official language in Germany, Austria, Switzerland, South Tyrol in Italy, the German-speaking Community of Belgium, and Liechtenstein. It is also one of the three official languages of Luxembourg and a co-official language in the Opole Voivodeship in Poland. The languages which are most similar to German are the other members of the West Germanic language branch: Afrikaans, Dutch, English, the Frisian languages, Low German/Low Saxon, Luxembourgish, and Yiddish. One of the major languages of the world, German is a native language to almost 100 million people worldwide and the most widely spoken native language in the European Union. German is the third most commonly spoken foreign language in the EU after English and French, making it the second biggest language in the EU in terms of overall speakers.

German is an inflected language with four cases for nouns, pronouns and adjectives (nominative, accusative, genitive, dative), three genders (masculine, feminine, neuter), two numbers (singular, plural), and strong and weak verbs. German derives the majority of its vocabulary from the ancient Germanic branch of the Indo-European language family. A portion of German words are derived from Latin and Greek, and fewer are borrowed from French and Modern English. With slightly different standardized variants (German, Austrian and Swiss Standard German), German is a pluricentric language. It is also notable for its broad spectrum of dialects, with many unique varieties existing in Europe and also other parts of the world. Due to the limited intelligibility between certain varieties and Standard German, as well as the lack of an undisputed, scientific difference between a "dialect" and a "language", some German varieties or dialect groups (e.g. Low German or Plautdietsch) are alternatively referred to as "languages" or "dialects".

6 Hindi

Hindi, or Modern Standard Hindi is a standardised and Sanskritised register of the Hindustani language. Hindi, written in the Devanagari script, is one of the official languages of India, along with the English language. It is one of the 22 scheduled languages of the Republic of India. However, it is not the national language of India because no language was given such a status in the Indian constitution. Hindi is the lingua franca of the Hindi belt, and to a lesser extent other parts of India (usually in a simplified or pidginized variety such as Bazaar Hindustani or Haflong Hindi). Outside India, several other languages are recognized officially as "Hindi" but do not refer to the Standard Hindi language described here and instead descend from other dialects of Hindustani, such as Awadhi and Bhojpuri. As a linguistic variety, Hindi is the fourth most-spoken first language in the world, after Mandarin, Spanish and English. Alongside Urdu as Hindustani, it is the third most-spoken language in the world, after Mandarin and English.

7 Italian

Italianis a Romance language of the Indo-European language family. Italian, together with Sardinian, is by most measures the closest language to Vulgar Latin of the Romance languages. Italian is an official language in Italy, Switzerland (where it is the first language in Canton Ticino and in the districts of Moesa and Bernina in Canton Graubünden), San Marino and Vatican City. Italian is a major European language, being one of the official languages of the Organization for Security and Co-operation in Europe and one of the working languages of the Council of Europe. It is the fourth most widely spoken first language in the European Union with 69 million native speakers (13% of the EU population) and it is spoken as a second language by 16 million EU citizens (3%). Including Italian speakers in non-EU European countries (such as Switzerland and Albania) and on other continents, the total number of speakers is around 90 million.

8 Japanese

Japanese is an East Asian language spoken by about 128 million people, primarily in Japan, where it is the national language. It is a member of the Japonic (or Japanese-Ryukyuan) language family, and its relation to other languages, such as Korean, is debated. Japanese is an agglutinative, mora-timed language with simple phonotactics, a pure vowel system, phonemic vowel and consonant length, and a lexically significant pitch-accent.

Word order is normally subject–object–verb with particles marking the grammatical function of words, and sentence structure is topic–comment. Sentence-final particles are used to add emotional or emphatic impact, or make questions. Nouns have no grammatical number or gender, and there are no articles. Verbs are conjugated, primarily for tense and voice, but not person. Japanese equivalents of adjectives are also conjugated. Japanese has a complex system of honorifics with verb forms and vocabulary to indicate the relative status of the speaker, the listener, and persons mentioned.

Japanese Characters
Hiragana and katakana (collectively referred to as kana) are syllabic writing, that is, each character represents a syllable such as "ta" or "o". They're purely phonetic so they don't have direct connotations like kanji do, and both have the same set of syllables.

Hiragana	Hiragana is generally used for Japanese words when they're not written in kanji, and for all the grammatical "glue" such as conjugations and particles.
Katakana	Katakana is usually used for loanwords and onomatopoeia. There's no strict rule though, so you will see katakana used for other purposes as well, such as emphasis.
Kanji	Kanji is ideographic writing, that is, each character represents a concept or an idea. For example, 水 means "water" while 朝 means "morning". Each character also has one or more readings, and the correct one depends on which word the kanji is part of. Many kanji (such as my two examples) can also act as stand-alone words.
Rōmaji	The romanization of Japanese is the use of Latin script to write the Japanese language. This method of writing is sometimes referred to in Japanese as rōmaji (ローマ字, literally, "Roman letters"). There are several different romanization systems. The three main ones are Hepburn romanization, Kunrei-shiki romanization (ISO 3602), and Nihon-shiki romanization (ISO 3602 Strict). Variants of the Hepburn system are the most widely used.

	Dakuten Symbol	Handakuten Symbol
Character Symbols Marks placed after certain katakana that modify the way the consonant is pronounced. These marks indicate that the consonant of the syllable should be voiced.	゛	゜

Font
The font type plays an important role in how the characters are displayed like serifs in English. An alternative font is put beside the character in Times New Roman as different fonts can change the way they are displayed.

Practice If society is still functioning you can use the following websites to learn Hiragana and Katakana via a drag-and-drop interface. If there's no access to the website you could still draw the symbols and words on different post-it notes and try to match them up.	**Hiragana Practice** www.csus.edu/indiv/s/sheaa/projects/genki/hiragana-timer.html	**Katakana Practice** www.csus.edu/indiv/s/sheaa/projects/genki/katakana-timer.html

Hiragana

To learn hiragana is to create a foundation for the rest of your Japanese. By learning hiragana, you will learn the basics of Japanese pronunciation. It will also open doors in terms of the Japanese resources you can use. There are no (good) Japanese textbooks or learning resources that don't require you to know hiragana. In essence, it's the first step to learn Japanese. Many classes and individuals spend months learning hiragana. This is too long. You should be able to learn everything in a couple days.

Hiragana		K-	S-	T-	N-	H-	M-	Y-	R-	W-	N
-A	あ あ A "a" in ah	か か KA "ka" in karate	さ さ SA "sa" in sarcasm	た た TA	な な NA	は は HA	ま ま MA "ma" in mama	や や YA	ら ら RA	わ わ WA	ん ん N
-I	い い I "ee" in eel	き き KI "key" in key	し し SHI "shi" in ship	ち ち CHI	に に NI	ひ ひ HI	み み MI "mi" in middle		り り RI		
-U	う う U "ou" in you	く く KU "ku" in kudo	す す SU	つ つ TSU	ぬ ぬ NU	ふ ふ FU / HU	む む MU "moo"	ゆ ゆ YU "you"	る る RU		
-E	え え E "e" in egg	け け KE "ke" in kelp	せ せ SE "se" in set	て て TE	ね ね NE	へ へ HE	め め ME "me" in meh		れ れ RE		
-O	お お O "o" in original	こ こ KO "co" in cot	そ そ SO "so" in soh	と と TO "to" in toe	の の NO	ほ ほ HO	も も MO	よ よ YO	ろ ろ RO	を を WO	

Hiragana Dakuten

Dakuten takes hiragana and adds an additional symbol to it to change its pronunciation. This symbol either looks like a quotation mark or a small circle.

Hiragana Dakuten	-A	-I	-U	-E	-O	
G-	か → が KA > GA	き → ぎ KI > GI	く → ぐ KU > GU	け → げ KE > GE	こ → ご KO > GO	
Z-	さ → ざ SA > ZA	し → じ SHI > JI	す → ず SU > ZU	せ → ぜ SE > ZE	そ → ぞ SO > ZO	
D-	た → だ TA > DA	ち → ぢ CHI > DZI	つ → づ TSU > DZU	て → で TE > DE	と → ど TO > DO	
B-	は → ば HA > BA	ひ → び HI > BI	ふ → ぶ HU/FU > BU	へ → べ HE > BE	ほ → ぼ HO > BO	
P-	は → ぱ HA > PA	ひ → ぴ HI > PI	ふ → ぷ HU/FU > PU	へ → ぺ HE > PE	ほ → ぽ HO > PO	

Combination Hiragana

Combines different types of kana together to make new sounds. Mainly, we're going to focus on what small ゃ, ゅ, and ょ can do to kana from the い row (that includes き, し, じ, に, etc). To use these, you'll need to combine them with something from the い column. When you do this, you're essentially combining the first (English) letter of the い-kana with the small ゃ, ゅ, ょ sound.

Size Difference	やゃ	ゆゅ	よょ	つっ							
Combination	き + ゃ KIYA → KYA		じ + ょ JIYO → JYO		The "i" gets dropped and it just becomes one syllable of sound.						
Combinations - A	きゃ KYA	ぎゃ GYA	しゃ SHA	じゃ JYA / JA	ちゃ CHA	ぢゃ DZYA	にゃ NYA	ひゃ HYA	びゃ BYA	ぴゃ PYA	みゃ MYA
Combinations - U	きゅ KYU	ぎゅ GYU	しゅ SHU	じゅ JYU / JU	ちゅ CHU	ぢゅ DYZU	にゅ NYU	ひゅ HYU	びゅ BYU	ぴゅ PYU	みゅ MYU
Combinations - O	きょ KYO	ぎょ GYO	しょ SHO	じょ JYO / JO	ちょ CHO	ぢょ DYZO	にょ NYO	ひょ HYO	びょ BYO	ぴょ PYO	みょ MYO
Combinations - A	りゃ RYA										
Combinations - U	りゅ RYU										

Combinations - O	りょ RYO										

As you may have noticed, there's no いゃ sound and there's no combination kana for the Y-column. The first kana has to be a sound with a strong consonant in it, and both "i" and "yi" don't fit the bill. Also, "yi" doesn't exist in modern Japanese.

Small TSU
The small tsu is a weird little thing but we'll make sense of it. The easiest way to think of it, I think, is to call it a "double consonant." Basically, by adding a small っ to something, you are making the (English) letter that follows it double into two consonants. Luckily, you won't see a small tsu before any of the あいうえお kana, so that never becomes an issue. Let's take a look at how the following hiragana converts to romaji.

したい shitai	しったい shit_tai	かこ kako	かっこ kak_ko	いた ita	いった it_ta						

See how that worked? したい is just plain "shitai" without the small っ. But when you add it in, it becomes shittai. The small っ that comes before the "ta" causes the consonant to double, making it "shit_tai." Make sure you understand how that works with kako/kakko too. In terms of pronunciation, this is different as well. It's almost as if you add a small stop where the small っ exists, with one of the double consonants on either side.

Katakana

Katakana is used for transcribing foreign (non-japanese) words. The sounds available in the Japanese languages are not as flexible as many other languages. Therefore, words that are transcribed to katakana often don't sound like the original.

Katakana Uses
- Scientific Words
- Animal Names
- Many Foods
- Company Names
- Emphasized Text

Katakana		K-	S-	T-	N-	H-	M-	Y-	R-	W-	N
-A	ア ア A	カ カ KA	サ サ SA	タ タ TA	ナ ナ NA	ハ ハ HA	マ マ MA	ヤ ヤ YA	ラ ラ RA	ワ ワ WA	ン ン N

Combinations

Small A	Small combining form of hiragana あ (a) used to explicitly specify the vowel part of the previous hiragana character, or to show a speaker's pronunciation or extension of that vowel.	あ ア	ふぁ - the sound [ɸa] rather than [ɸɯ] (ふ) or [ha] (は) ふぁん - transliteration of English fan.
Small I	Small combining form of hiragana い (i) used to explicitly specify the vowel part of the previous hiragana character, or to show a speaker's pronunciation or extension of that vowel.	い イ	ふぃ - the sound [ɸi] rather than [ɸɯ] (ふ) or [çi] (ひ) ふぃぎゅあ - transliteration of English figure.
Small U	Small combining form of hiragana う (u) used to explicitly specify the vowel part of the previous hiragana character, or to show a speaker's pronunciation or extension of that vowel.	う ウ	でぅ - the sound [du] rather than [de] (で) or [zu] (づ) ですぅ - specifies that the final u in です (desu) should not be silent ですぅぅぅ - specifies that the final u in です (desu) should be very long.
Small E	Small combining form of katakana エ (e) used to explicitly specify the vowel part of the previous katakana character, or to show a speaker's pronunciation or extension of that vowel.	え エ	ちぇ - the sound [tɕe] rather than [tɕi] (ち) or [te] (て) ちぇんじ - transliteration of English change.
Small O	Small combining form of hiragana お (o) used to explicitly specify the vowel part of the previous hiragana character, or to show a speaker's pronunciation or extension of that vowel.	お オ	ふぉ - the sound [ɸo] rather than [ɸɯ] (ふ) or [ho] (ほ) しふぉん - transliteration of French chiffon.
Small Ka	Small combining form of hiragana か.	か カ	
Small Tsu	A symbol consisting of a small Tsu (compare with normal Tsu: ツッ). It is used to insert a slight pause. In no case is it pronounced like the full-size つ (tsu).	つ ツ	● Preceeding Consonant: If preceding a consonant, results in the following consonant being geminate; an English example is cattail. ● Word Ending: If ending a word, results in the word ending in a glottal stop. A glottal stop or "choked sound". あっ！(Ah!) ● Combination: The sokuon: a small form of つ (tsu). In romanization, this is represented by doubling the following consonant. The equivalent in katakana is ッ. (いっぱい — ippai) (もっと — motto) (すっぱい — suppai) (おっぱい — oppai)
Small Yo	Small combining form of hiragana よ (yo) used in 拗音 (yōon) morae that end in o, such as しょ (sho), ちょ (cho), and きょ (kyo). Historically not distinguished from full-size version.	よ ヨ	
Small Ya	Combining form of や, used in yōon mora (拗音) that end in the a sound.	や ヤ	This letter appears in the hiragana きゃ (kya), しゃ (sha), ちゃ (cha), にゃ (nya), ひゃ (hya), みゃ (mya), and りゃ (rya); in the dakuten (濁点) ぎゃ (gya), じゃ (ja), and びゃ (bya); and in the handakuten (半濁点) ぴゃ (pya).
Small Yu	Small combining form of hiragana ゆ (yu) used in 拗音 (yōon) morae that end in u, such as しゅ (shu), ちゅ (chu), and きゅ (kyu). Historically not distinguished from full-size version.	ゆ ユ	
Long Vowels (Chōonpu)	Unlike hiragana, which deals with long vowels by adding more vowels to things, katakana has a special vowel extender character. Luckily it's very simple: a dash.	ー	When you see this, you'll just need to extend the vowel that it comes after. ベコン → becon ベーコン → beecon

Hiragana / Katakana

A side by side comparision of the same characters in hiragana and katakana. Both symbols share the same lettering but are used differently.

Kanji

Kanji are adopted logographic Chinese characters that are used in the Japanese writing system. They are used alongside the Japanese syllabic scripts hiragana and katakana. The Japanese term kanji for the Chinese characters literally means "Han characters". It is written with the same characters in the Chinese language to refer to the character writing system, hànzì (漢字). There are 1,945 characters below sorted by grade.

Jōyō Kanji	The jōyō kanji is the guide to kanji characters announced officially by the Japanese Ministry of Education. Current jōyō kanji are those on a list of 1,945 characters issued on October 10, 1981. (This is the format below)
JLPT Kanji	The Japanese Language Proficiency Test, or JLPT, is a standardized criterion-referenced test to evaluate and certify the Japanese language proficiency of non-native speakers. It is held twice a year in East Asia and once a year in other regions. The JLPT has five levels, with Level N5 being the most basic and Level N1 the most difficult.
Frequent Kanji	2,500 kanji ordered in a list that expresses the relative frequency of occurence of a character in the modern Japanese. The survey is based on newspaper articles.
Jinmeiyō Kanji	The Jinmeiyō Kanji (Chinese characters for use in personal names) are a set of 983 Chinese characters known as the "name kanji" in English. They are a supplementary set of characters which can be legally used in registered personal names in Japan, despite not being in that country's set of "commonly used characters".

下手 heta	Bad At
馬鹿 baka	Stupid

Common Phrases

9 Korean

The Korean language is an East Asian language spoken by about 77 million people. It is a member of the Koreanic language family and is the official and national language of both Koreas: North Korea and South Korea, with different standardized official forms used in each country. It is also one of the two official languages in the Yanbian Korean Autonomous Prefecture and Changbai Korean Autonomous County of Jilin province, China. It is also spoken in parts of Sakhalin, Ukraine and Central Asia. Historical and modern linguists classify Korean as a language isolate; however, it does have a few extinct relatives, which together with Korean itself and the Jeju language (spoken in the Jeju Province and considered somewhat distinct) form the Koreanic language family. The linguistic homeland of Korean is suggested to be somewhere in Manchuria.

10 Portuguese

Portuguese (português or, in full, língua portuguesa) is a Western Romance language originating in the Iberian Peninsula. It is the sole official language of Portugal, Brazil, Cape Verde, Guinea-Bissau, Mozambique, Angola, and São Tomé and Príncipe. It also has co-official language status in East Timor, Equatorial Guinea and Macau in China. As the result of expansion during colonial times, a cultural presence of Portuguese and Portuguese creole speakers are also found in Goa, Daman and Diu in India; in Batticaloa on the east coast of Sri Lanka; in the Indonesian island of Flores; in the Malacca state of Malaysia; and the ABC islands in the Caribbean where Papiamento is spoken, while Cape Verdean Creole is the most widely spoken Portuguese-based Creole. Reintegrationists maintain that Galician is not a separate language, but a dialect of Portuguese.

Portuguese is part of the Ibero-Romance group that evolved from several dialects of Vulgar Latin in the medieval Kingdom of Galicia and the County of Portugal, and has kept some Celtic phonology and lexicon. With approximately 215 to 220 million native speakers and 250 million total speakers, Portuguese is usually listed as the sixth most natively spoken language in the world, the third-most spoken European language in the world in terms of native speakers, and the most spoken language in the Southern Hemisphere. It is also the most spoken language in South America and the second-most spoken in Latin America after Spanish, one of the 10 most spoken languages in Africa and is an official language of the European Union, Mercosur, OAS, ECOWAS and the African Union. The Community of Portuguese Language Countries is an international organization made up of all of the world's officially Lusophone nations.

11 Russian

Russian is an East Slavic language, which is official in the Russian Federation, Belarus, Kazakhstan and Kyrgyzstan, as well as being widely used throughout Eastern Europe, the Baltic states, the Caucasus and Central Asia. It was the de facto language of the Soviet Union until its dissolution on 25 December 1991. Although nearly three decades have passed since the breakup of the Soviet Union, Russian is used in official capacity or in public life in all the post-Soviet nation-states, as well as in Israel and Mongolia. Russian belongs to the family of Indo-European languages, one of the four living members of the East Slavic languages, and part of the larger Balto-Slavic branch. Written examples of Old East Slavonic are attested from the 10th century onward. Russian is the largest native language in Europe and the most geographically widespread language in Eurasia. It is the most widely spoken of the Slavic languages, with 144 million speakers in Russia, Ukraine and Belarus.

Russian is the eighth most spoken language in the world by number of native speakers and the seventh by total number of speakers. The language is one of the six official languages of the United Nations. Russian is also the second most widespread language on the Internet after English. Russian distinguishes between consonant phonemes with palatal secondary articulation and those without, the so-called soft and hard sounds. Almost every consonant has a hard or a soft counterpart, and the distinction is a prominent feature of the language. Another important aspect is the reduction of unstressed vowels. Stress, which is unpredictable, is not normally indicated orthographically though an optional acute accent may be used to mark stress, such as to distinguish between homographic words, for example замо́к (zamók, meaning a lock) and за́мок (zámok, meaning a castle), or to indicate the proper pronunciation of uncommon words or names.

12 Spanish

Spanish is a Romance language that originated in the Castile region of Spain and today has hundreds of millions of native speakers in the Americas and Spain. It is a global language and the world's second-most spoken native language, after Mandarin Chinese. Spanish is a part of the Ibero-Romance group of languages, which evolved from several dialects of Vulgar Latin in Iberia after the collapse of the Western Roman Empire in the 5th century. The oldest Latin texts with traces of Spanish come from mid-northern Iberia in the 9th century, and the first systematic written use of the language happened in Toledo, then capital of the Kingdom of Castile, in the 13th century.

Around 75% of modern Spanish vocabulary is derived from Latin and, through Latin, Ancient Greek. Spanish vocabulary has been in contact with Arabic from an early date, having developed during the Al-Andalus era in the Iberian Peninsula. With around 8% of its vocabulary being Arabic in origin, this language is the second most important influence after Latin. It has also been influenced by Basque, Iberian, Celtiberian, Visigothic, and by neighboring Ibero-Romance languages. Spanish is one of the six official languages of the United Nations. It is also used as an official language by the European Union, the Organization of American States, the Union of South American Nations, the Community of Latin American and Caribbean States, the African Union and many other international organizations. Despite its large number of speakers, the Spanish language does not feature prominently in scientific writing, with the exception of the humanities.
