Drugs	Some drugs cause excessive internal heat production. The rate of drug-induced hyperthermia is higher where use of these drugs is higher. ● Many psychotropic medications, such as selective serotonin reuptake inhibitors (SSRIs), monoamine oxidase inhibitors (MAOIs), and tricyclic antidepressants, can cause hyperthermia. Serotonin syndrome is a rare adverse reaction to overdose of these medications or the use of several simultaneously. Similarly, neuroleptic malignant syndrome is an uncommon reaction to neuroleptic agents. These syndromes are differentiated by other associated symptoms, such as tremor in serotonin syndrome and "lead-pipe" muscle rigidity in neuroleptic malignant syndrome. ● Various stimulant drugs, including amphetamines and cocaine, and hallucinogenic drugs, including PCP, LSD, and MDMA can produce hyperthermia as an adverse effect. ● Malignant hyperthermia is a rare reaction to common anesthetic agents (such as halothane) or the paralytic agent succinylcholine. Those who have this reaction, which is potentially fatal, have a genetic predisposition.

● The use of anticholinergics, more specifically muscarinic antagonists are thought to cause mild hyperthermic episodes due to its parasympatholytic effects. The sympathetic nervous system a.k.a. the "Fight or Flight Response" dominates by raising catecholamine levels by the blocked action of the Rest and Digest System.
● Drugs that decouple oxidative phosphorylation may also cause hyperthermia. From this group of drugs the most well known is 2,4-Dinitrophenol which was used as a weight loss drug until dangers from its use became apparent.

Personal Protective Equipment	Those working in industry, in the military, or as first responders may be required to wear personal protective equipment (PPE) against hazards such as chemical agents, gases, fire, small arms and even Improvised Explosive Devices (IEDs). PPE includes a range of hazmat suits, firefighting turnout gear, body armor and bomb suits, among others. Depending on design, the wearer may be encapsulated in a microclimate, due to an increase in thermal resistance and decrease in vapor permeability. As physical work is performed, the body's natural thermoregulation (i.e., sweating) becomes ineffective. This is compounded by increased work rates, high ambient temperature and humidity levels, and direct exposure to the sun. The net effect is that desired protection from some environmental threats inadvertently increases the threat of heat stress. The effect of PPE on hyperthermia has been noted in fighting the 2014 Ebola virus epidemic in Western Africa. Doctors and healthcare workers were only able to work 40 minutes at a stretch in their protective suits, fearing heat strokes.
Other	Other rare causes of hyperthermia include thyrotoxicosis and an adrenal gland tumor, called pheochromocytoma, both of which can cause increased heat production. Damage to the central nervous system, from brain hemorrhage, status epilepticus, and other kinds of injury to the hypothalamus can also cause hyperthermia.

Hyperthermia is also touched on in the SURVIVAL section.

9 Trench Foot

Trench foot is a medical condition caused by prolonged exposure of the feet to damp, unsanitary, and cold conditions. It is one of many immersion foot syndromes. The use of the word trench in the name of this condition is a reference to trench warfare, mainly associated with World War I.

Signs & Symptoms

Affected feet may become numb, by erythema (turning red) or cyanosis (turning blue) as a result of poor blood supply, and may begin emanating a decaying odor if the early stages of necrosis (tissue death) set in. As the condition worsens, feet may also begin to swell. Advanced trench foot often involves blisters and open sores, which lead to fungal infections; this is sometimes called tropical ulcer (jungle rot). If left untreated, trench foot usually results in gangrene, which may require amputation. If trench foot is treated properly, complete recovery is normal, though it is marked by severe short-term pain when feeling returns.

Causes

Unlike frostbite, trench foot does not require freezing temperatures; it can occur in temperatures up to 16° Celsius (about 60° Fahrenheit) and within as little as 13 hours. Exposure to these environmental conditions causes deterioration and destruction of the capillaries and leads to morbidity of the surrounding flesh. Excessive sweating (hyperhidrosis) has long been regarded as a contributory cause; unsanitary, cold, and wet conditions can also cause trench foot.

Prevention

Trench foot can be prevented by keeping the feet clean, warm, and dry. It was also discovered in World War I that a key preventive measure was regular foot inspections; soldiers would be paired and each made responsible for the feet of the other, and they would generally apply whale oil to prevent trench foot. If left to their own devices, soldiers might neglect to take off their own boots and socks to dry their feet each day, but if it were the responsibility of another, this became less likely. Later on in the war, instances of trench foot began to decrease, probably as a result of the introduction of the aforementioned measures; of wooden duckboards to cover the muddy, wet, cold ground of the trenches; and of the increased practice of troop rotation, which kept soldiers from prolonged time at the front.

Treatment

The mainstay of treatment, like the treatment of gangrene, is surgical debridement, and often includes amputation. Self-treatment consists of changing socks two or three times a day and usage of plenty of talcum powder. Wherever possible, shoes and socks should be taken off, feet bathed for five minutes, patted dry, talcum powder applied and feet elevated to let air get to them.

10 Seasickness (Motion Sickness)

Motion sickness is a condition in which a disagreement exists between visually perceived movement and the vestibular system's sense of movement. Depending on the cause, it can also be referred to as seasickness, car sickness, simulation sickness or airsickness. Symptoms include dizziness, fatigue, vertigo, depressed appetite, nonspecific malaise, gastrointestinal discomfort, (most commonly) nausea, and nausea-caused vomiting. If the cause of the nausea is not resolved, the sufferer will usually vomit, but vomiting may not relieve the feeling of weakness and nausea, which means the person might continue to vomit until the underlying cause of the nausea is resolved. A kind of motion sickness with similar symptoms but a possibly different etiology is known as space adaptation syndrome or space motion sickness.

Cause

At present a "fully adequate theory of motion sickness is not presently available" but contemporary sensory conflict theory, referring to "a discontinuity between either visual, proprioceptive, and somatosensory input, or semicircular canal and otolith input", is probably the most thoroughly studied. According to this theory, when the brain presents the mind with two incongruous states of motion; the result is often nausea and other symptoms of disorientation known as motion sickness. Such conditions happen when the vestibular system and the visual system do not present a synchronized and unified representation of one's body and surroundings. According to sensory conflict theory, the cause of terrestrial motion sickness is the opposite of the cause of space motion sickness. The former occurs when one perceives visually that one's surroundings are relatively immobile while the vestibular system reports that one's body is in motion relative to its surroundings. The latter can occur when the visual system perceives that one's surroundings are in motion while the vestibular system reports relative bodily immobility (as in zero gravity.) A variation of the sensory conflict theory is known as neural mismatch, implying a mismatch occurring between ongoing sensory experience and long-term memory rather than between components of the vestibular and visual systems. This theory emphasizes "the limbic system in the integration of sensory information and long-term memory, in the expression of the symptoms of motion sickness, and the impact of anti-motion-sickness drugs and stress hormones on limbic system function. The limbic system may be the neural mismatch center of the brain."

A very different alternate is the defense mechanism theory holding that motion sickness functions as a defense mechanism against neurotoxins. The area postrema in the brain is responsible for inducing vomiting when poisons are detected, and for resolving conflicts between vision and balance. When feeling motion but not seeing it (for example, in the cabin of a ship with no portholes), the inner ear transmits to the brain that it senses motion, but the eyes tell the brain that everything is still. As a result of the incongruity, the brain concludes that the individual is hallucinating and further concludes that the hallucination is due to poison ingestion. The brain responds by inducing vomiting, to clear the supposed toxin.

Treisman's indirect argument has recently been questioned via an alternative direct evolutionary hypothesis, as well as modified and extended via a direct poison hypothesis. The direct evolutionary hypothesis essentially argues that there are plausible means by which ancient real or apparent motion could have contributed directly to the evolution of aversive reactions, without the need for the co-opting of a poison response as posited by Treisman. Nevertheless, the direct poison hypothesis argues that there still are plausible ways in which the body's poison response system may have played a role in shaping the evolution of some of the signature symptoms that characterize motion sickness.

Yet another theory, also as the nystagmus hypothesis, has been proposed based on stimulation of the vagus nerve resulting from the stretching or traction of extra-ocular muscles co-occurring with eye movements caused by vestibular stimulation. There are three critical aspects to the theory: first is the close linkage between activity in the vestibular system, i.e., semicircular canals and otolith organs, and a change in tonus among various of each eye's six extra-ocular muscles. Thus, with the exception of voluntary eye movements, the vestibular and oculomotor systems are thoroughly linked. Second is the operation of Sherrington's Law describing reciprocal inhibition between agonist-antagonist muscle pairs, and by implication the stretching of extraocular muscle that must occur whenever Sherrington's Law is made to fail, thereby causing an unrelaxed (contracted) muscle to be stretched. Finally, there is the critical presence of afferent output to the Vagus nerves as a direct result of eye muscle stretch or traction. Thus, 10th nerve stimulation resulting from eye muscle stretch is proposed as the cause of motion sickness.

The theory explains why labyrinthine-defective individuals are immune to motion sickness; why symptoms emerge when undergoing various body-head accelerations; why combinations of voluntary and reflexive eye movements may challenge the proper operation of Sherrington's Law, and why many drugs that suppress eye movements also serve to suppress motion sickness symptoms. A recent theory argues that the main reason motion sickness occurs is due to an imbalance in vestibular outputs favoring the semicircular canals (nauseogenic) vs. otolith organs (anti-nauseogenic). This theory attempts to integrate previous theories of motion sickness. For example, there are many sensory conflicts that are associated with motion sickness and many that are not, but those in which canal stimulation occurs in the absence of normal otolith function (e.g., 0-g) are the most provocative. The vestibular imbalance theory is also tied to the different roles of the otoliths and canals in autonomic arousal (otolith output more sympathetic).

Susceptibility

Roughly one-third of the population is highly susceptible to motion sickness, and most of the rest may get motion sickness under extreme conditions. The incidence of space motion sickness has been estimated over the years at between forty and eighty percent of those who have entered weightless orbit. Several factors influence susceptibility to motion sickness, including sleep deprivation and the cubic footage allocated to each space traveler. Statistics indicate that women are more likely to be affected than men, and that the risk decreases with advancing age. There is some evidence that people with Asian ancestry may suffer motion sickness more frequently compared with people of European ancestry, and there are situational and behavioral factors, such as whether a passenger has a view of the road ahead, and diet and eating behaviors.

Types

Motion sickness can be divided into three categories:
1. Motion sickness caused by motion that is felt but not seen, as in terrestrial motion sickness;
2. Motion sickness caused by motion that is seen but not felt, as in space motion sickness;
3. Motion sickness caused when both systems detect motion but they do not correspond, as in either terrestrial or space motion sickness.

Carsickness	A specific form of terrestrial motion sickness, being carsick is quite common and evidenced by disorientation while reading a map, a book, or a small screen during travel. Carsickness results from the sensory conflict arising in the brain from differing sensory inputs. Motion sickness is caused by a conflict between signals arriving in the brain from the inner ear, which forms the base of the vestibular system, the sensory apparatus that deals with movement and balance, and which detects motion mechanically. If someone is looking at a stationary object within a vehicle, such as a magazine, their eyes will inform their brain that what they are viewing is not moving. Their inner ears, however, will contradict this by sensing the motion of the vehicle. Varying theories exist as to cause. The sensory conflict theory notes that the eyes view motion while riding in the moving vehicle while other body sensors sense stillness, creating conflict between the eyes and inner ear. Another suggests the eyes mostly see the interior of the car which is motionless while the vestibular system of the inner ear senses motion as the vehicle goes around corners or over hills and even small bumps.

Therefore, the effect is worse when looking down but may be lessened by looking outside of the vehicle. In the early 20th century, Austro-Hungarian scientist Robert Barany observed the back and forth movement of the eyes of railroad passengers as they looked out the side windows at the scenery whipping by. He called it "railway nystagmus." Also called "optokinetic nystagmus." It causes nausea and vomiting. His findings were published in the journal Laeger, 83:1516, Nov.17, 1921.

Airsickness	Air sickness is a kind of terrestrial motion sickness induced by certain sensations of air travel. It is a specific form of motion sickness and is considered a normal response in healthy individuals. It is essentially the same as carsickness but occurs in an airplane. An airplane may bank and tilt sharply, and unless passengers are sitting by a window, they are likely to see only the stationary interior of the plane due to the small window sizes and during flights at night. Another factor is that while in flight, the view out of windows may be blocked by clouds, preventing passengers from seeing the moving ground or passing clouds.
Seasickness	Seasickness is a form of terrestrial motion sickness characterized by a feeling of nausea and, in extreme cases, vertigo experienced after spending time on a watercraft such as a boat or ship. It is essentially the same as carsickness, though the motion of a watercraft tends to be more regular. It is typically brought on by the rocking motion of the craft or movement while the craft is immersed in water. As with airsickness, it can be difficult to visually detect motion even if one looks outside the boat since water does not offer fixed points with which to visually judge motion. Poor visibility conditions, such as fog, may worsen seasickness. The greatest contributor to seasickness is the tendency for people being affected by the rolling or surging motions of the craft to seek refuge below decks, where they are unable to relate themselves to the boat's surroundings and consequent motion. Some sufferers of carsickness are resistant to seasickness and vice versa. Adjusting to the craft's motion at sea is called "gaining one's sea legs"; it can take a significant portion of the time spent at sea after disembarking to regain a sense of stability "post-sea legs".
Centrifuge Motion Sickness	Rotating devices such as centrifuges used in astronaut training and amusement park rides such as the Rotor, Mission: Space and the Gravitron can cause motion sickness in many people. While the interior of the centrifuge does not appear to move, one will experience a sense of motion. In addition, centrifugal force can cause the vestibular system to give one the sense that downward is in the direction away from the center of the centrifuge rather than the true downward direction.
Dizziness Due to Spinning	When one spins and stops suddenly, fluid in the inner ear continues to rotate causing a sense of continued spinning while one's visual system no longer detects motion.
Virtual Reality Disorientation	Usually, VR programs would detect the motion of the user's head and abject the rotation of vision to avoid dizziness. However, some cases such as system lagging or software crashing could cause lags in the screen updates. In such cases, even some small head motions could trigger the motion sickness.

Treatment

Devices	A motion blocking eyewear device was patented (US patent 6,275,998) to prevent carsickness-related terrestrial motion sickness. Visual cues are an important contributor to land-based vehicular travel in addition to vestibular (inner ear) input. The eyewear device limits what the wearer sees outside the moving vehicle by use of an opaque shield. By removing visual cues outside the vehicle, the device normalizes the visual input dimension involved in sensory conflict, a leading theory behind motion sickness. No evidence exists that motion blocking eyewear alters or eliminates vestibular input or that of other bodily receptors. Carsickness is the most common type of motion sickness given the number of travelers traveling over land versus those traveling by air or sea. A head-worn, computer device with a transparent display can be used to mitigate the effects of motion sickness (and spatial disorientation) if visual indicators of the wearer's head position are shown. Such a device functions by providing the wearer with digital reference lines in their field of vision that indicate the horizon's position relative to the user's head. This is accomplished by combining readings from accelerometers and gyroscopes mounted in the device (US Patent 5,966,680). This technology has been implemented in both standalone devices and Google Glass. In two NIH-backed studies, greater than 90% of patients experienced a reduction in the symptoms of motion sickness while using this technology.
Activity	One common suggestion is to simply look out the window of the moving vehicle and to gaze towards the horizon in the direction of travel. This helps to re-orient the inner sense of balance by providing a visual reaffirmation of motion. In the night, or in a ship without windows, it is helpful to simply close one's eyes, or if possible, take a nap. This resolves the sensory conflict between the eyes and the inner ear. Napping also helps prevent psychogenic effects (i.e. the effect of sickness being magnified by thinking about it). Fresh, cool air can also relieve motion sickness slightly, although it is likely this is related to avoiding foul odors which can worsen nausea. While playing computer games, and mainly in first-person shooter games, some cases of simulation sickness can be resolved by changing the field of view in the game. Some games have a default setting which places a player's vision a small distance ahead of the actual object controlled, which will most likely trigger simulation sickness.
Medication	Over-the-counter and prescription medications are readily available, such as dimenhydrinate, scopolamine, meclizine, promethazine, cyclizine, and cinnarizine. Cinnarizine is not available in the United States, as it is not approved by the FDA. As these medications often have side effects, anyone involved in high-risk activities while at sea (such as SCUBA divers) must evaluate the risks versus the benefits. Promethazine is especially known to cause drowsiness, which is often counteracted by ephedrine in a combination known as "the Coast Guard cocktail." There are special considerations to be aware of when the common anti-motion sickness medications are used in the military setting where performance must be maintained at a high level. Scopolamine is effective and is sometimes used in the form of transdermal patches (1.5 mg) or as a newer tablet form (0.4 mg). The selection of a transdermal patch or scopolamine tablet is determined by a doctor after consideration of the patient's age, weight, and length of treatment time required. Many pharmacological treatments which are effective for nausea and vomiting in some medical conditions may not be effective for motion sickness.

For example, metoclopramide and prochlorperazine, although widely used for nausea, are ineffective for motion-sickness prevention and treatment. This is due to the physiology of the CNS vomiting centre and its inputs from the chemoreceptor trigger zone versus the inner ear. Sedating anti-histamine medications such as promethazine work quite well for motion sickness, although they can cause significant drowsiness. Ginger root is commonly thought to be an effective anti-emetic, but it is ineffective in treating motion sickness.

Electronic	As astronauts frequently have motion sickness, NASA has done extensive research on the causes of and treatments for motion sickness. One very promising looking treatment is for the person suffering from motion sickness to wear LCD shutter glasses that create a stroboscopic vision of 4 Hz with a dwell of 10 milliseconds.

11 Aero-otitis Media

The traumatic inflammation of the middle ear resulting from differences between atmospheric pressure and pressure in the middle ear and occurring in high-altitude flyers, caisson or tunnel workers, and deep-sea divers. AOM is an infection of rapid onset that usually presents with ear pain. In young children this may result in pulling at the ear, increased crying, and poor sleep. Decreased eating and a fever may also be present. OME is typically not associated with symptoms. Occasionally a feeling of fullness is described. It is defined as the presence of non-infectious fluid in the middle ear for more than three months. Chronic suppurative otitis media (CSOM) is middle ear inflammation of greater than two weeks that results in episodes of discharge from the ear. It may be a complication of acute otitis media. Pain is rarely present. All three may be associated with hearing loss. The hearing loss in OME, due to its chronic nature, may affect a child's ability to learn.

The cause of AOM is related to childhood anatomy and immune function. Either bacteria or viruses may be involved. Risk factors include exposure to smoke, use of pacifiers, and attending daycare. It occurs more commonly among Indigenous peoples and those who have Down syndrome. OME frequently occurs following AOM and may be related to viral upper respiratory infections, irritants such as smoke, or allergies. Looking at the eardrum is important for making the correct diagnosis.

INJURY Environmental Aero-otitis Media

Signs of AOM include bulging or a lack of movement of the tympanic membrane from a puff of air. New discharge not related to otitis externa also indicates the diagnosis. A number of measures decrease the risk of otitis media including pneumococcal and influenza vaccination, breastfeeding, and avoiding tobacco smoke. The use of pain medications for AOM is important. This may include paracetamol (acetaminophen), ibuprofen, benzocaine ear drops, or opioids. In AOM, antibiotics may speed recovery but may result in side effects.

Antibiotics are often recommended in those with severe disease or under two years old. In those with less severe disease they may only be recommended in those who do not improve after two or three days. The initial antibiotic of choice is typically amoxicillin. In those with frequent infections tympanostomy tubes may decrease recurrence. In children with otitis media with effusion antibiotics may increase resolution of symptoms, but may cause diarrhoea, vomiting and skin rash. Worldwide AOM affects about 11% of people a year (about 325 to 710 million cases). Half the cases involve children less than five years of age and it is more common among males.

Signs & Symptoms

An integral symptom of acute otitis media is ear pain; other possible symptoms include fever, and irritability (in infants). Since an episode of otitis media is usually precipitated by an upper respiratory tract infection (URTI), there are often accompanying symptoms like a cough and nasal discharge. Discharge from the ear can be caused by acute otitis media with perforation of the ear drum, chronic suppurative otitis media, tympanostomy tube otorrhea, or acute otitis externa. Trauma, such as a basilar skull fracture, can also lead to discharge from the ear due to cerebral spinal drainage from the brain and its covering (meninges).

Causes

The common cause of all forms of otitis media is dysfunction of the Eustachian tube. This is usually due to inflammation of the mucous membranes in the nasopharynx, which can be caused by a viral upper respiratory tract infection (URTI), strep throat, or possibly by allergies. By reflux or aspiration of unwanted secretions from the nasopharynx into the normally sterile middle-ear space, the fluid may then become infected — usually with bacteria. The virus that caused the initial upper respiratory infection can itself be identified as the pathogen causing the infection.

Diagnosis

As its typical symptoms overlap with other conditions, such as acute external otitis, clinical history alone is not sufficient to predict whether acute otitis media is present; it has to be complemented by visualization of the tympanic membrane. Examiners use a pneumatic otoscope with a rubber bulb attached to assess the mobility of the tympanic membrane. In more severe cases, such as those with associated hearing loss or high fever, audiometry, tympanogram, temporal bone CT and MRI can be used to assess for associated complications, such as mastoid effusion, subperiosteal abscess formation, bony destruction, venous thrombosis or meningitis. Acute otitis media in children with moderate to severe bulging of the tympanic membrane or new onset of otorrhea (drainage) is not due to external otitis. Also, the diagnosis may be made in children who have mild bulging of the ear drum and recent onset of ear pain (less than 48 hours) or intense erythema (redness) of the ear drum.

To confirm the diagnosis, middle-ear effusion and inflammation of the eardrum have to be identified; signs of these are fullness, bulging, cloudiness and redness of the eardrum. It is important to attempt to differentiate between acute otitis media and otitis media with effusion (OME), as antibiotics are not recommended for OME. It has been suggested that bulging of the tympanic membrane is the best sign to differentiate AOM from OME, with a bulging of the membrane suggesting AOM rather than OME. Viral otitis may result in blisters on the external side of the tympanic membrane, which is called bullous myringitis (myringa being Latin for "eardrum"). However, sometimes even examination of the eardrum may not be able to confirm the diagnosis, especially if the canal is small. If wax in the ear canal obscures a clear view of the eardrum it should be removed using a blunt cerumen curette or a wire loop. Also, an upset young child's crying can cause the eardrum to look inflamed due to distension of the small blood vessels on it, mimicking the redness associated with otitis media.

Acute Otitis Media	The most common bacteria isolated from the middle ear in AOM are Streptococcus pneumoniae, Haemophilus influenzae, Moraxella catarrhalis, and Staphylococcus aureus.
Otitis Media with Effusion	Otitis media with effusion (OME), also known as serous otitis media (SOM) or secretory otitis media (SOM), and colloquially referred to as 'glue ear,' is fluid accumulation that can occur in the middle ear and mastoid air cells due to negative pressure produced by dysfunction of the Eustachian tube. This can be associated with a viral URI or bacterial infection such as otitis media. An effusion can cause conductive hearing loss if it interferes with the transmission of vibrations of middle ear bones to the vestibulocochlear nerve complex that are created by sound waves. Early-onset OME is associated with feeding of infants while lying down, early entry into group child care, parental smoking, lack, or too short a period of breastfeeding and greater amounts of time spent in group child care, particularly those with a large number of children. These risk factors increase the incidence and duration of OME during the first two years of life.
Chronic Suppurative Otitis Media	Chronic suppurative otitis media (CSOM) is a chronic inflammation of the middle ear and mastoid cavity that is characterised by discharge from the middle ear through a perforated tympanic membrane for at least 6 weeks. CSOM occurs following an upper respiratory tract infection that has led to acute otitis media. This progresses to a prolonged inflammatory response causing mucosal (middle ear) oedema, ulceration and perforation. The middle ear attempts to resolve this ulceration by production of granulation tissue and polyp formation. This can lead to increased discharge and failure to arrest the inflammation, and to development of CSOM, which is also often associated with cholesteatoma. There may be enough pus that it drains to the outside of the ear (otorrhea), or the pus may be minimal enough to be seen only on examination with an otoscope or binocular microscope. Hearing impairment often accompanies this disease. People are at increased risk of developing CSOM when they have poor eustachian tube function, a history of multiple episodes of acute otitis media, live in crowded conditions, and attend paediatric day care facilities. Those with craniofacial malformations such as cleft lip and palate, Down syndrome, and microcephaly are at higher risk. Worldwide approximately 11% of the human population is affected by AOM every year, or 709 million cases. About 4.4% of the population develop CSOM. According to the World Health Organization, CSOM is a primary cause of hearing loss in children. Adults with recurrent episodes of CSOM have a higher risk of developing permanent conductive and sensorineural hearing loss.
Adhesive Otitis Media	Adhesive otitis media occurs when a thin retracted ear drum becomes sucked into the middle-ear space and stuck (i.e., adherent) to the ossicles and other bones of the middle ear.

Prevention

AOM is far less common in breastfed infants than in formula-fed infants, and the greatest protection is associated with exclusive breastfeeding (no formula use) for the first six months of life. A longer duration of breastfeeding is correlated with a longer protective effect. Pneumococcal conjugate vaccines (PCV) in early infancy decrease the risk of acute otitis media in healthy infants. PCV is recommended for all children, and, if implemented broadly, PCV would have a significant public health benefit.

Influenza vaccine is recommended annually for all children. PCV does not appear to decrease the risk of otitis media when given to high-risk infants or for older children who have previously experienced otitis media. Risk factors such as season, allergy predisposition and presence of older siblings are known to be determinants of recurrent otitis media and persistent middle-ear effusions (MEE). History of recurrence, environmental exposure to tobacco smoke, use of daycare, and lack of breastfeeding have all been associated with increased risk of development, recurrence, and persistent MEE.

Pacifier use has been associated with more frequent episodes of AOM. Long-term antibiotics, while they decrease rates of infection during treatment, have an unknown effect on long-term outcomes such as hearing loss. This method of prevention has been associated with emergence of antibiotic-resistant otitic bacteria. They are thus not recommended. There is moderate evidence that the sugar substitute xylitol may reduce infection rates in those who go to daycare. Evidence does not support zinc supplementation as an effort to reduce otitis rates except maybe in those with severe malnutrition such as marasmus.

Management

Oral and topical pain killers are effective to treat the pain caused by otitis media. Oral agents include ibuprofen, paracetamol (acetaminophen), and opiates. Topical agents shown to be effective include antipyrine and benzocaine ear drops. Decongestants and antihistamines, either nasal or oral, are not recommended due to the lack of benefit and concerns regarding side effects. Half of cases of ear pain in children resolve without treatment in three days and 90% resolve in seven or eight days. The use of steroids is not supported by the evidence for acute otitis media.

Antibiotics
It is important to weigh the benefits and harms before using antibiotics for acute otitis media. As over 82% of acute episodes settle without treatment, about 20 children must be treated to prevent one case of ear pain, 33 children to prevent one perforation, and 11 children to prevent one opposite-side ear infection. For every 14 children treated with antibiotics, one child has an episode of either vomiting, diarrhea or a rash. If pain is present, pain medications may be used. For bilateral acute otitis media in infants younger than 24 months of age, there is evidence that the benefits of antibiotics outweigh the harms. A 2015 Cochrane review concluded that watchful waiting is the preferred approach for children over six months with non severe acute otitis media.

Antibiotics Table	Outcome	Findings	Findings in Numbers	Quality of Evidence
Pain				
	Pain at 24 hours	Antibiotics causes little or no reduction to the chance of experiencing the outcome when compared with placebo for acute otitis media in children. Data are based on high quality evidence.	RR 0.89 (0.78 to 1.01)	High
	Pain at 2 to 3 days	Antibiotics slightly reduces the chance of experiencing the outcome when compared with placebo for acute otitis media in children. Data are based on high quality evidence.	RR 0.70 (0.57 to 0.86)	High
	Pain at 4 to 7 days	Antibiotics slightly reduces the chance of experiencing the outcome when compared with placebo for acute otitis media in children. Data are based on high quality evidence.	RR 0.76 (0.63 to 0.91)	High
	Pain at 10 to 12 days	Antibiotics probably reduces the chance of experiencing the outcome when compared with placebo for acute otitis media in children. Data are based on moderate quality evidence.	RR 0.33 (0.17 to 0.66)	Moderate
Abnormal Tympanometry				
	2 to 4 weeks	Antibiotics slightly reduces the chance of experiencing the outcome when compared with placebo for acute otitis media in children. Data are based on high quality evidence.	RR 0.82 (0.74 to 0.90)	High
	3 months	Antibiotics causes little or no reduction to the chance of experiencing the outcome when compared with placebo for acute otitis media in children. Data are based on high quality evidence.	RR 0.97 (0.76 to 1.24)	High
Vomiting				
	Diarrhoea or rash	Antibiotics slightly increases the chance of experiencing the outcome when compared with placebo for acute otitis media in children. Data are based on high quality evidence.	RR 1.38 (1.19 to 1.59)	High

Summary
The evidence indicates that most children older than 6 months of age who have acute otitis media do not benefit from treatment with antibiotics. If antibiotics are used, amoxicillin is generally recommended. If there is resistance or use of amoxicillin in the last 30 days then amoxicillin-clavulanate or another penicillin derivative plus beta lactamase inhibitor is recommended. Taking amoxicillin once a day may be as effective as twice or three times a day. While less than 7 days of antibiotics have fewer side effects, more than seven days appear to be more effective. If there is no improvement after 2–3 days of treatment a change in therapy may be considered. A treatment option for chronic suppurative otitis media with discharge is topical antibiotics. A Cochrane review found that topical quinolone antibiotics can improve discharge better than oral antibiotics. Safety is not really clear.

Tympanostomy Tube
Tympanostomy tubes (also called "grommets") are recommended with three or more episodes of acute otitis media in 6 months or four or more in a year, with at least one episode or more attacks in the preceding 6 months. There is tentative evidence of reduced recurrence rates in the 6 months after placement. Evidence does not support an effect on long-term hearing or language development. A common complication of having a tympanostomy tube is otorrhea, which is a discharge from the ear. Oral antibiotics should not be used to treat uncomplicated acute tympanostomy tube otorrhea. Oral antibiotics are not a sufficient response to bacteria that cause this condition and have significant side effects including increased risk of opportunistic infection. In contrast, topical antibiotic eardrops can treat this condition.

Otitis Media with Effusion
The decision to treat is usually made after a combination of physical exam and laboratory diagnosis, with additional testing including audiometry, tympanogram, temporal bone CT and MRI. Decongestants, glucocorticoids, and topical antibiotics are generally not effective as treatment for non-infectious, or serous, causes of mastoid effusion. Moreover, it is recommended against using antihistamines and decongestants in children with OME. In less severe cases or those without significant hearing impairment, the effusion can resolve spontaneously or with more conservative measures such as autoinflation. In more severe cases, tympanostomy tubes can be inserted, possibly with adjuvant adenoidectomy as it shows a significant benefit as far as the resolution of middle ear effusion in children with OME is concerned.

Alternative Medicine
Complementary and alternative medicine is not recommended for otitis media with effusion because there is no evidence of benefit. Homeopathic treatments have not been proven to be effective for acute otitis media in a study with children. An osteopathic manipulation technique called the Galbreath technique was evaluated in one randomized controlled clinical trial; one reviewer concluded that it was promising, but a 2010 evidence report found the evidence inconclusive.

Outcomes
Complications of acute otitis media consists of perforation of the ear drum, infection of the mastoid space behind the ear (mastoiditis), and more rarely intracranial complications can occur, such as bacterial meningitis, brain abscess, or dural sinus thrombosis. It is estimated that each year 21,000 people die due to complications of otitis media.

Membrane Rupture
In severe or untreated cases, the tympanic membrane may perforate, allowing the pus in the middle-ear space to drain into the ear canal. If there is enough, this drainage may be obvious. Even though the perforation of the tympanic membrane suggests a highly painful and traumatic process, it is almost always associated with a dramatic relief of pressure and pain. In a simple case of acute otitis media in an otherwise healthy person, the body's defenses are likely to resolve the infection and the ear drum nearly always heals. An option for severe acute otitis media in which analgesics are not controlling ear pain is to perform a tympanocentesis, i.e., needle aspiration through the tympanic membrane to relieve the ear pain and to identify the causative organism(s).

Hearing Loss
Children with recurrent episodes of acute otitis media and those with otitis media with effusion or chronic suppurative otitis media have higher risks of developing conductive and sensorineural hearing loss. Globally approximately 141 million people have mild hearing loss due to otitis media (2.1% of the population). This is more common in males (2.3%) than females (1.8%). This hearing loss is mainly due to fluid in the middle ear or rupture of the tympanic membrane. Prolonged duration of otitis media is associated with ossicular complications and, together with persistent tympanic membrane perforation, contributes to the severity of the disease and hearing loss. When a cholesteatoma or granulation tissue is present in the middle ear, the degree of hearing loss and ossicular destruction is even greater.

Epidemiology
Acute otitis media is very common in childhood. It is the most common condition for which medical care is provided in children under five years of age in the US. Acute otitis media affects 11% of people each year (709 million cases) with half occurring in those below five years. Chronic suppurative otitis media affects about 5% or 31 million of these cases with 22.6% of cases occurring annually under the age of five years. Otitis media resulted in 2,400 deaths in 2013—down from 4,900 deaths in 1990.

12 Aerosinusitis

Aerosinusitis, also called barosinusitis, sinus squeeze or sinus barotrauma is a painful inflammation and sometimes bleeding of the membrane of the paranasal sinus cavities, normally the frontal sinus. It is caused by a difference in air pressures inside and outside the cavities.

Signs & Symptoms

Typically, sinus barotrauma is preceded by an upper respiratory tract infection or allergy. The affected person suffers a sudden sharp facial pain or headache during descent, which increases as the aircraft approaches ground level. The pain can ultimately become disabling unless the ambient pressure is reversed.

The pressure difference causes the mucosal lining of the sinuses to become swollen and submucosal bleeding follows with further difficulties ventilating the sinus, especially if the orifices are involved. Ultimately fluid or blood will fill the space.

In most cases of sinus barotrauma, localized pain to the frontal area is the predominant symptom. This is due to pain originating from the frontal sinus, it being above the brow bones. Less common is pain referred to the temporal, occipital, or retrobulbar region. Epistaxis or serosanguineous secretion from the nose may occur. Neurological symptoms may affect the adjacent fifth cranial nerve and especially the infraorbital nerve.

Most cases occur in scuba divers and fliers, and is easily diagnosed when presented to physicians immediately after exposure. On the other hand, the problem may remain undiagnosed when the history fails to relate the symptoms to exposure to environmental pressure changes or if the focus is on other etiologies.

Weissman defined three grades of sinus barotraumas according to symptomatology.
- Grade I includes cases with mild transient sinus discomfort without changes visible on X-ray.
- Grade II is characterized by severe pain for up to 24 h, with some mucosal thickening on X-ray.
- Patients with grade III have severe pain lasting for more than 24 h and X-ray shows severe mucosal thickening or opacification of the affected sinus; epistaxis or subsequent sinusitis may be observed.

Causes

Diagnosis

Typically, sinus barotrauma is preceded by an upper respiratory tract infection or allergy. The affected person suffers a sudden sharp facial pain or headache during descent, which increases as the aircraft approaches ground level. The pain can ultimately become disabling unless the ambient pressure is reversed.

The pressure difference causes the mucosal lining of the sinuses to become swollen and submucosal bleeding follows with further difficulties ventilating the sinus, especially if the orifices are involved. Ultimately fluid or blood will fill the space.

In most cases of sinus barotrauma, localized pain to the frontal area is the predominant symptom. This is due to pain originating from the frontal sinus, it being above the brow bones. Less common is pain referred to the temporal, occipital, or retrobulbar region. Epistaxis or serosanguineous secretion from the nose may occur. Neurological symptoms may affect the adjacent fifth cranial nerve and especially the infraorbital nerve.

Prevention

Treatment

Mild cases of barotrauma are readily treated by topical decongestants and painkillers. In severe cases or cases resistant to local treatment, functional endoscopic sinus surgery is indicated in order to re-establish drainage and ventilation of the sinuses. This treatment has shown good results in aviators suffering from recurrent sinus barotrauma. Computer-aided surgery has re-established the drainage of affected sinuses, especially with regard to the sphenoid sinuses. When the sphenoids were entered endoscopically, mucosal petechia and hematoma were clearly seen.

6 Atmosphere & Air

Any injuries that can happen due to air, atmosphere or lack of air.

1 Asphyxiation & Suffocation

Asphyxia or asphyxiation is a condition of deficient supply of oxygen to the body that arises from abnormal breathing. An example of asphyxia is choking. Asphyxia causes generalized hypoxia, which affects primarily the tissues and organs. There are many circumstances that can induce asphyxia, all of which are characterized by an inability of an individual to acquire sufficient oxygen through breathing for an extended period of time. Asphyxia can cause coma or death.

Signs & Symptoms

Causes

Situations that can cause asphyxia include but are not limited to: the constriction or obstruction of airways, such as from asthma, laryngospasm, or simple blockage from the presence of foreign materials; from being in environments where oxygen is not readily accessible: such as underwater, in a low oxygen atmosphere, or in a vacuum; environments where sufficiently oxygenated air is present, but cannot be adequately breathed because of air contamination such as excessive smoke.

Other causes of oxygen deficiency include but are not limited to:

- Acute respiratory distress syndrome
- Carbon monoxide inhalation, such as that from a car exhaust and the smoke's emission from a lighted cigarette: carbon monoxide has a higher affinity than oxygen to the hemoglobin in the blood's red blood corpuscles, bonding with it tenaciously, and, in the process, displacing oxygen and preventing the blood from transporting oxygen around the body
- Contact with certain chemicals, including pulmonary agents (such as phosgene) and blood agents (such as hydrogen cyanide)
- Drowning
- Drug overdose
- Exposure to extreme low pressure or vacuum from spacesuit damage (see space exposure)
- Hanging, whether suspension or short drop hanging
- Self-induced hypocapnia by hyperventilation, as in shallow water or deep water blackout and the choking game
- Inert gas asphyxiation
- Congenital central hypoventilation syndrome, or primary alveolar hypoventilation, a disorder of the autonomic nervous system in which a patient must consciously breathe; although it is often said that persons with this disease will die if they fall asleep, this is not usually the case
- Respiratory diseases
- Sleep apnea
- A seizure which stops breathing activity
- Strangling
- Breaking the wind pipe
- Prolonged exposure to chlorine gas

Prevention

Treatment

2 Drowning

Drowning is defined as respiratory impairment as a result of being in or under a liquid. Drowning typically occurs silently, with only a few people able to wave their hands or call for help. Symptoms following rescue may include breathing problems, vomiting, confusion, or unconsciousness. Occasionally symptoms may not appear until up to six hours afterwards. Drowning may be complicated by low body temperature, aspiration of vomit, or acute respiratory distress syndrome.

Signs & Symptoms

Drowning is most often quick and unspectacular. Its media depictions as a loud, violent struggle have much more in common with distressed non-swimmers, who may well drown but have not yet begun to do so. In particular, an asphyxiating person is seldom able to call for help. The instinctive drowning response covers many signs or behaviors associated with drowning or near-drowning:

- Head low in the water, mouth at water level
- Head tilted back with mouth open
- Eyes glassy and empty, unable to focus
- Eyes open, with fear evident on the face
- Hyperventilating or gasping
- Trying to swim in a particular direction but not making headway
- Trying to roll over on the back to float
- Uncontrollable movement of arms and legs, rarely out of the water.

Drowning begins at the point a person is unable to keep their mouth above water; inhalation of water takes place at a later stage. Most people demonstrating the instinctive drowning response do not show obvious prior evidence of distress.

A person drowning is generally unable to call for help, or seek attention, as they cannot obtain enough air. The instinctive drowning response is the final set of autonomic reactions in the 20–60 seconds before sinking underwater, and to the untrained eye can look similar to calm safe behavior. Lifeguards and other persons trained in rescue learn to recognize drowning people by watching for these movements.

Causes

Drowning mainly happens due to the inability to swim in a circumstance: lack of skill, state of the waters, physical condition, loss of consciousness, and others. Anxiety can lead to exhaustion, precipitating the drowning.

Approximately 90% of drownings take place in freshwater (rivers, lakes and swimming pools) and 10% in seawater. Drownings in other fluids are rare, and often relate to industrial accidents. In New Zealand's early colonial history, so many settlers died while trying to cross rivers that drowning was known as "The New Zealand death".

People have drowned in as little as 30 mm of water lying face down. Children have drowned in baths, buckets and toilets; inebriates or those under the influence of drugs have died in puddles.

Drowning can also happen after the drowning incident itself, due to further complications. The inhaled fluid can act as an irritant inside the lungs. Physiological responses to even small quantities include the extrusion of liquid into the lungs (pulmonary edema) over the following hours, but this reduces the ability to exchange air and can lead to a person "drowning in their own body fluid". Certain poisonous vapors or gases (as for example in chemical warfare), or vomit can have a similar effect. The reaction can take place up to 72 hours after the drowning incident, and may lead to a serious condition or death.

Many factors, behavioral and physical, are related to drowning:
● Worldwide, drowning is the most common cause of death for persons with seizure disorders, largely in the bathtub (by unintentional injury). People with epilepsy are more likely to die due to accidents such as drowning. However, this risk is especially elevated in low- and middle-income countries compared to high-income countries.
● The use of alcohol increases the risk for drowning across developed and developing nations. Alcohol is involved in approximately 50% of fatal drownings, and 35% of non-fatal drownings. Among adolescents and adults, alcohol use is involved in almost a quarter of emergency department visits for drowning.
● Inability to swim: Participation in formal swimming lessons can reduce the risk of drowning. The optimal age to start the lessons is childhood, between 1 and 4 years old.

● Feeling too tired reduces the swimming performance. This exhaustion can appear because of the anxious movements motivated by fear during drowning. Otherwise, a bad calculation of the own physical capabilities can leave oneself exhausted before reaching the shore.
● Free access to water: Effective barriers prevent young children from gaining access to the water.
● Ineffective supervision: Drowning can occur anywhere there is water, and even in the presence of lifeguards.
● Risk can vary with location depending on age. Children between 1 and 4 usually drown in home swimming pools. Drownings in natural water settings increase with age. More than half of drownings among those 15 years and older occurred in natural water environments.
● Failure to wear life jackets or personal flotation devices was implicated in 88% of the boating related drownings in the US during 2010.

Population groups at risk in the US are:
● Children and young adults: Drowning rates are highest for children under 5 years of age and persons 15–24 years of age.
● Males: Nearly 80% of people who die from drowning are male.
● Minorities: The fatal unintentional drowning rate for African Americans between 2005 and 2009 was significantly higher than that of whites across all ages. The fatal drowning rate of African American children of ages from 5 to 14 is almost three times that of white children in the same age range, and 5.5 times higher in swimming pools. These disparities might be associated with lack of basic swimming skills in some minority populations.

Freediving
Some special causes of drowning can also happen during freediving activities:
● Ascent blackout, also called deep water blackout – caused by latent hypoxia during ascent from depth, where the partial pressure of oxygen in the lungs under pressure at the bottom of a deep freedive is adequate to support consciousness but drops below the blackout threshold as the water pressure decreases on the ascent. It usually strikes upon arriving near the surface as the pressure approaches normal atmospheric pressure.
● Shallow water blackout – caused by hyperventilation prior to swimming or diving. The primary urge to breathe is triggered by rising carbon dioxide (CO2) levels in the bloodstream. The body detects CO2 levels very accurately and relies on this to control breathing. Hyperventilation reduces the carbon dioxide content of the blood but leaves the diver susceptible to sudden loss of consciousness without warning from hypoxia. There is no bodily sensation that warns a diver of an impending blackout, and people (often capable swimmers swimming under the surface in shallow water) become unconscious and drown quietly without alerting anyone to the fact that there is a problem; they are typically found on the bottom.

Oxygen Deprivation
A conscious person will hold his or her breath (see Apnea) and will try to access air, often resulting in panic, including rapid body movement. This uses up more oxygen in the blood stream and reduces the time to unconsciousness. The person can voluntarily hold his or her breath for some time, but the breathing reflex will increase until the person tries to breathe, even when submerged.

The breathing reflex in the human body is weakly related to the amount of oxygen in the blood but strongly related to the amount of carbon dioxide (see Hypercapnia). During apnea, the oxygen in the body is used by the cells, and excreted as carbon dioxide. Thus, the level of oxygen in the blood decreases, and the level of carbon dioxide increases. Increasing carbon dioxide levels lead to a stronger and stronger breathing reflex, up to the breath-hold breakpoint, at which the person can no longer voluntarily hold his or her breath. This typically occurs at an arterial partial pressure of carbon dioxide of 55 mm Hg, but may differ significantly between people.

The breath-hold break point can be suppressed or delayed either intentionally or unintentionally. Hyperventilation before any dive, deep or shallow, flushes out carbon dioxide in the blood resulting in a dive commencing with an abnormally low carbon dioxide level; a potentially dangerous condition known as hypocapnia. The level of carbon dioxide in the blood after hyperventilation may then be insufficient to trigger the breathing reflex later in the dive and a blackout may occur without warning and before the diver feels any urgent need to breathe. This can occur at any depth and is common in distance breath-hold divers in swimming pools.

Hyperventilation is often used by both deep and distance free-divers to flush out carbon dioxide from the lungs to suppress the breathing reflex for longer. It is important not to mistake this for an attempt to increase the body's oxygen store. The body at rest is fully oxygenated by normal breathing and cannot take on any more. Breath holding in water should always be supervised by a second person, as by hyperventilating, one increases the risk of shallow water blackout because insufficient carbon dioxide levels in the blood fail to trigger the breathing reflex.

A continued lack of oxygen in the brain, hypoxia, will quickly render a person unconscious usually around a blood partial pressure of oxygen of 25–30 mmHg. An unconscious person rescued with an airway still sealed from laryngospasm stands a good chance of a full recovery. Artificial respiration is also much more effective without water in the lungs. At this point the person stands a good chance of recovery if attended to within minutes. More than 10% of drownings may involve laryngospasm, but the evidence suggests that it is not usually effective at preventing water from entering the trachea. The lack of water found in lungs during autopsy does not necessarily mean there was no water at the time of drowning, as small amounts of freshwater are readily absorbed into the bloodstream. Hypercarbia and hypoxia both contribute to laryngeal relaxation, after which the airway is effectively open through the trachea. There is also bronchospasm and mucous production in the bronchi associated with laryngospasm, and these may prevent water entry at terminal relaxation.

The hypoxemia and acidosis caused by asphyxia in drowning affect various organs. There can be central nervous system damage, cardiac arhythmias, pulmonary injury, reperfusion injury, and multiple-organ secondary injury with prolonged tissue hypoxia.

A lack of oxygen or chemical changes in the lungs may cause the heart to stop beating. This cardiac arrest stops the flow of blood and thus stops the transport of oxygen to the brain. Cardiac arrest used to be the traditional point of death but at this point there is still a chance of recovery. The brain cannot survive long without oxygen and the continued lack of oxygen in the blood combined with the cardiac arrest will lead to the deterioration of brain cells causing first brain damage and eventually brain death from which recovery is generally considered impossible. The brain will die after approximately six minutes without oxygen at normal body temperature, but hypothermia of the central nervous system may prolong this.

The extent of central nervous system injury to a large extent determines the survival and long term consequences of drowning, In the case of children, most survivors are found within 2 minutes of immersion, and most fatalities are found after 10 minutes or more.

Water Aspiration
If water enters the airways of a conscious person, the person will try to cough up the water or swallow it, often inhaling more water involuntarily. When water enters the larynx or trachea, both conscious and unconscious persons experience laryngospasm, in which the vocal cords constrict, sealing the airway. This prevents water from entering the lungs. Because of this laryngospasm, in the initial phase of drowning, water generally enters the stomach and very little water enters the lungs. Though laryngospasm prevents water from entering the lungs, it also interferes with breathing. In most persons, the laryngospasm relaxes some time after unconsciousness and water can then enter the lungs causing a "wet drowning". However, about 7–10% of people maintain this seal until cardiac arrest. This has been called "dry drowning", as no water enters the lungs. In forensic pathology, water in the lungs indicates that the person was still alive at the point of submersion. Absence of water in the lungs may be either a dry drowning or indicates a death before submersion.

Aspirated water that reaches the alveoli destroys the pulmonary surfactant, which causes pulmonary oedema and decreased lung compliance which compromises oxygenation in affected parts of the lungs. This is associated with metabolic acidosis, and secondary fluid and electrolyte shifts. During alveolar fluid exchange, diatoms present in the water may pass through the alveolar wall into the capillaries to be carried to internal organs. Presence of these diatoms may be diagnostic of drowning.

Of people who have survived drowning, almost one third will experience complications such as acute lung injury (ALI) or acute respiratory distress syndrome (ARDS). ALI/ARDS can be triggered by pneumonia, sepsis and water aspiration and are life-threatening disorders that can result in death if not treated promptly. During drowning, aspirated water enters the lung tissues, causes a reduction in alveolar surfactant, obstructs ventilation and triggers a release of inflammatory mediators which ultimately results in hypoxia.

Specifically, upon reaching the alveoli, hypotonic liquid found in fresh water dilutes pulmonary surfactant, destroying the substance. Comparatively, aspiration of hypertonic seawater draws liquid from the plasma into the alveoli and similarly causes damage to surfactant by disrupting the alveolar-capillary membrane. Still, there is no clinical difference between salt and freshwater drowning. Once someone has reached definitive care, supportive care strategies such as mechanical ventilation can help to reduce the complications of ALI/ARDS.

Whether a person drowns in fresh water versus salt water makes no difference in the respiratory management or the outcome of the person. People who drown in fresh water may experience worse hypoxemia early in their treatment, however, this initial difference is short-lived and the management of both fresh water and salt water drowning is essentially the same.

Cold Water Immersion
Submerging the face in water cooler than about 21°C (70°F) triggers the diving reflex, common to air-breathing vertebrates, especially marine mammals such as whales and seals. This reflex protects the body by putting it into energy saving mode to maximize the time it can stay under water. The strength of this reflex is greater in colder water and has three principal effects:

● Bradycardia, a slowing of the heart rate by up to 50% in humans.
● Peripheral vasoconstriction, the restriction of the blood flow to the extremities to increase the blood and oxygen supply to the vital organs, especially the brain.
● Blood Shift, the shifting of blood to the thoracic cavity, the region of the chest between the diaphragm and the neck, to avoid the collapse of the lungs under higher pressure during deeper dives.

The reflex action is automatic and allows both a conscious and an unconscious person to survive longer without oxygen under water than in a comparable situation on dry land. The exact mechanism for this effect has been debated and may be a result of brain cooling similar to the protective effects seen in people who are treated with deep hypothermia.

The actual cause of death in cold or very cold water is usually lethal bodily reactions to increased heat loss and to freezing water, rather than any loss of core body temperature. Of those who die after plunging into freezing seas, around 20% die within 2 minutes from cold shock (uncontrolled rapid breathing and gasping causing water inhalation, massive increase in blood pressure and cardiac strain leading to cardiac arrest, and panic), another 50% die within 15 – 30 minutes from cold incapacitation (loss of use and control of limbs and hands for swimming or gripping, as the body 'protectively' shuts down the peripheral muscles of the limbs to protect its core), and exhaustion and unconsciousness cause drowning, claiming the rest within a similar time. A notable example of this occurred during the sinking of the Titanic, in which most people who entered the −2 °C (28 °F) water died within 15–30 minutes.

Submersion into cold water can induce cardiac arrhythmias (abnormal heart rates) in healthy people, sometimes causing strong swimmers to drown. The physiological effects caused by the diving reflex conflict with the body's cold shock response, which includes a gasp and uncontrollable hyperventilation leading to aspiration of water. While breath-holding triggers a slower heart rate, cold shock activates tachycardia, an increase in heart rate. It is thought that this conflict of these nervous system responses may account for the arrhythmias of cold water submersion.

Heat transfers very well into water, and body heat is therefore lost extremely quickly in water compared to air, even in merely 'cool' swimming waters around 70F (~20C). A water temperature of 10 °C (50 °F) can lead to death in as little as one hour, and water temperatures hovering at freezing can lead to death in as little as 15 minutes. This is because cold water can have other lethal effects on the body, so hypothermia is not usually a reason for drowning or the clinical cause of death for those who drown in cold water.

Upon submersion into cold water, remaining calm and preventing loss of body heat is paramount. While awaiting rescue, swimming or treading water should be limited to conserve energy and the person should attempt to remove as much of the body from the water as possible; attaching oneself to a buoyant object can improve the chance of survival should unconsciousness occur.

Hypothermia (and also cardiac arrest) present a risk for survivors of immersion, as for survivors of exposure; in particular the risk increases if the survivor, feeling well again, tries to get up and move, not realizing their core body temperature is still very low and will take a long time to recover.

Most people who experience cold-water drowning do not develop hypothermia quickly enough to decrease cerebral metabolism before ischemia and irreversible hypoxia occur. The neuroprotective effects appear to require water temperatures below about 5 °C.

Diagnosis

Drowning can be considered as going through four stages:
1. Breath-hold under voluntary control until the urge to breathe due to hypercapnia becomes overwhelming
2. Fluid is aspirated into the airways and/or swallowed
3. Cerebral anoxia stops breathing and aspiration
4. Cerebral injury due to anoxia becomes irreversible

Generally, in the early stages of drowning a person holds their breath to prevent water from entering their lungs. When this is no longer possible a small amount of water entering the trachea causes a muscular spasm that seals the airway and prevents further passage of water. If the process is not interrupted, loss of consciousness due to hypoxia is followed rapidly by cardiac arrest.

Experts differentiate between distress and drowning.
- Distress – people in trouble, but who still have the ability to keep afloat, signal for help and take actions.
- Drowning – people suffocating and in imminent danger of death within seconds.

Prevention

It is estimated that more than 85% of drownings could be prevented by supervision, training in water skills, normatives, technology, and public education.

Surveillance of the Swimmers	Watching the swimmers is a basic task, especially in the case of children. More than 500 children die from drowning each day. Young children must be supervised, regardless of if they can already swim. The danger increases when they are alone. A baby can drown in the bathtub, in the toilet, and even in a small bucket filled with less than an inch of water. It only takes around 2 minutes underwater for an adult to lose consciousness, and only between 30 seconds and 2 minutes for a small child to die. Choosing supervised swimming places is safer. Many pools and bathing areas either have lifeguards or a pool safety camera system for local or remote monitoring. Some others have a computer-aided drowning detection. However, normal bystanders can also play an important role in drowning detection, and in performing an intervention or notification to lifeguards or any other authority by any method (phone, alarm, etc.) Lifeguards may be unaware of a drowning due to "the intrusion of non-lifeguard duties upon lifeguards' primary task: preventive lifeguarding" and because of "the distraction from surveillance duties". For example, they could be diverted by using the mobile phone for leisure purposes upon the watching operations. About the alarms in pools, evidence shows that they are poor for any utility. The World Health Organization recommends to analyze what are the most crowded hours in the swimming zones, to increase the number of lifeguards at those moments (the more people is swimming, the more work is distributed to each lifeguard.)
Learning to Swim	Being able to swim is one of the best defenses against drowning. The studies recommend that children learn to swim when they are between 1 and 4 years old, but in a safe environment and being supervised. Learning to swim is also possible in adults, equally taking the classes in a safe environment and under supervision. After being able to swim, it's still possible to drown (because of the state of the water and other circumstances), so it is recommended to choose swimming places that are safe and kept under surveillance.
Additional Education	The WHO recommends to train the general public in first-aid for the drowned, cardiopulmonar resuscitation (CPR), and to behave in a safe manner when being in the water. In addition, it is convenient to give some advices to the minors so they avoid drowning. If they can not swim, it is recommended to teach them to keep themselves away from deep waters.
Fencing the Pools	Every swimming pool, private or public, should be fenced and enclosed, on every side, so no child nor any other person can access inside. The "Raffarin law", applied in France in 2003, that forced to fence any pool, reduced the drowning of children by 75%. It is also convenient to check that there are no objects left on the surface of the pools, so children don't approach attracted by them.
Absorbed by Pool Drains	Swimming pools usually have drainage systems to absorb and beam the water. If they work badly, they can drain to the swimmers themselves, causing injuries or even trapping their hair or any extremity, which could lead to immobilize and drown them. To avoid it, drainage holes and sumps are covered with grates and lids (according to the case), and, besides, they must suction with not too much strength. This require to make a good installation of the pool, and to check it, and to review it periodically. It is also recommended that the pool has many drainage holes, small and spaced, instead of only a big one, but the most important factor is that the system work well.
Caution in Problematic Diseases	Some illnesses require prudence when water is near. Epilepsy and all seizure disorders are problematic to swim, dive and bathe because of the possibility of drowning during a convulsion. Moreover, drowning is the most common cause of unintentional death for the people which suffers from that sort of diseases. For the epileptics, it is recommended to take showers rather than using a bath tub for bathing.
Alcohol or Drugs	Alcohol and drugs increase the probability of drowning. This danger is greater in the bars located near the water, in the parties of boat-clubs, etc.
Use of Lifejacket	The children that can not swim, the disabled, an other people in risk of drowning, would have to wear a fastened lifejacket when they are in the water, and even near the water. There exist some other floating devices (inflatable inner tubes, arm floaties -water wings-, foam tubes, etc.) which can be more or less useful (depending of how is each one of them); however they are not considerated safety instruments by the institutions, but "toys". The instrument that is considerated safe to float on water is the lifejacket, when is homologated and well fastened around the body. Besides, there are some other flotation instruments that are considerated safe: the professional circle-shaped lifebuoy (hoop-buoy, ring-buoy, life-ring, life-donut, lifesaver or lifepreserver), which is mainly designed to be thrown, and some other professional variants that are designed to be used by lifeguards in their rescues.
Keeping Calm in Water	This is to avoid getting tired, because it difficults swimming. Exhaustion can appear because of the anxious movements motivated by fear during drowning. In other sense, a bad calculation of the own physical capabilities can leave oneself exhausted before reaching the water's edge. Lowering the rhythm helps to reduce exhaustion. In case of suffering a tug, cramp or contracture (muscle spasm), it is useful to keep calm and swimming towards the shore, asking for help if necessary. If oneself is stung by a jellyfish, it is possible to get out of the water without major problems even with some itching or pain. When a problem makes swimming more difficult, it is possible to float by laying on the own back (in a completely horizontal position face up), because that position allows to float without effort.
Not to Jump into Water before Knowing the Depth	It is convenient to know if there are, or could be, rocks that stand out too much. Headfirst jumps cause more than 70% of all spinal injuries related to sports and recreational activities. A fall from a great height on shallow water (in a swimming pool or in the sea) can cause a serious impact against the bottom. This could kill the person immediately, or later, in case of suffering a brain or body injury followed by drowning. If the person does not die, the injury could cause a permanent paralysis.
Avoid Dangerous Waters	Avoid swimming in turbulent waters, with very large waves, with dangerous animals, and in those that are too cold. Also avoid dragging currents. These currents may have any characteristic that allows to recognize them, such as being more turbulent, more foamy, dragging things or debris, etc. In case of being caught by one of these currents, swim out from it (it is possible to move out gradually, in a diagonal direction until arriving to the shore).

Navigating Safely	Many people who die by drowning die in navigation accidents. A safe navigation includes being informed of the state of the sea, and equipping the boat with regulatory instruments to keep people afloat. These instruments are lifejackets (see above) and professional lifebuoys with the shape of a circle (ring-buoy, hoop-buoy, life-ring, life-donut, lifesaver or lifepreserver).
Use the "Buddy System"	It consists in not to swim alone, but near a buddy, who can help in case of any problem.
Heed the Rules	Most people who drown did not follow the safety normatives. It is important to pay attention to the banners, the flags that indicate if swimming is possible and the indications of the authorities (lifeguards, coastguards, etc.).

Treatment

Rescue

Many people who are drowning manage to save themselves, or are assisted by bystanders or professional rescuers. Less than 6% of people rescued by lifeguards need medical attention, and only 0.5% need CPR. The statistics are not as good for rescue by bystanders, but even there, a minority require CPR.

When a drowning occurs, or a swimmer becomes missing, bystanders should immediately call for help. A lifeguard should be called, if present. If not, emergency medical services and paramedics should be contacted as soon as possible. Rescue, and where necessary, resuscitation, should be started as early as possible. So the person should be taken out of the water as soon as possible.

Rescuers should avoid endangering themselves unnecessarily and, when possible, should assist from a safe position (such as a boat or the shore). This assistance usually consists in throwing with precision a flotation instrument (as a hoop-shaped lifebuoy). In other cases, the manner to help could be by holding out an object (as a rope or pole, even the own arm. etc.) towards the person, but, doing this, the rescuer's body should be laying down, well secured to the ground, to avoid falling to the water too.

In a direct swimming rescue, the initial grasp is important and must be well managed by the rescuer. If something goes wrong, it could happen that an anxious drowning person clings to the rescuer to stand out of the water, submerging the rescuer in the process. To avoid this, it is recommended that the rescuer approaches to the panicking person with a buoyant object, or offering one hand, or even from behind and bending the person's arm against the back to restrict movement.

Anyway, if the person pushes the rescuer towards below the water, the rescuer can usually escape diving downwards (because people who are unable to swim tend to move up, searching the water surface). After escaping in that manner, it is possible to come back and try a new approach to the drowning person. When the rescuer accomplishes a successful approach, the negatively buoyant objects (used in diving, such the weight belt) should be removed. Next, the priority is to transport the person to the water's edge using a tow maneuver. The rescuer usually approaches to the drowning person from behind, and then the person's body is turned face up, and grasped with a secure grip.

There are many grips that can be used, but it is common that they grasp the person around the jaw area. The person's mouth and nose must be kept above the water surface. If the person is cooperative, the towing may be in a similar fashion held at the armpits. Unconscious people may be pulled in another similar fashion held at the chin and cheeks, and ensuring that the mouth and nose are well kept above the water. Special care has to be taken for people with suspected spinal injuries, they can require a more specific grip, and a back board (spinal board) may be needed for their rescue.

In unconscious people, an in-water resuscitation could increase the chances of survival by a factor of about three, but this procedure require both medical and swimming skills, and only the breaths of the rescue ventilation are practicable in the water. Chest compressions require a suitable platform, so in-water assessment of circulation is pointless. If the person does not respond after a few breaths, cardiac arrest may be assumed, and getting them out of the water becomes the priority.

First Aid

The checks for responsiveness and breathing are carried out with the person horizontally supine. If unconscious but breathing, the recovery position is appropriate.

If not breathing, rescue ventilation is necessary. Drowning can produce a gasping pattern of apnea while the heart is still beating, and ventilation alone may be sufficient. The airway-breathing-circulation (ABC) sequence should be followed, rather than starting with compressions as is typical in cardiac arrest, because the basic problem is lack of oxygen.

Five initial breaths are recommended, as the initial ventilation may be difficult because of water in the airways which can interfere with effective alveolar inflation. Thereafter a continual sequence of 2 breaths and 30 chest compressions is recommended. This alternance is repeated until vital signs are re-established, the rescuers are unable to continue, or advanced life support is available. For babies (very small sized infants), the procedure is slightly modified. In the rescue breaths, the rescuer's mouth covers the baby's mouth and nose at the same time (because a baby's face is too small). Besides, the chest compressions are applied pressing with only with two fingers (due to the body of the babies is more fragile) on the chest bone (approximately on the lower part).

Attempts to actively expel water from the airway by abdominal thrusts, Heimlich maneuver or positioning head downwards should be avoided as there is no obstruction by solids, and they delay the start of ventilation and increase the risk of vomiting, with a significantly increased risk of death, as aspiration of stomach contents is a common complication of resuscitation efforts.

Treatment for hypothermia may also be necessary. However, in those who are unconscious, it is recommended their temperature not be increased above 34 degrees C. Because of the diving reflex, people submerged in cold water and apparently drowned may revive after a relatively long period of immersion. Rescuers retrieving a child from water significantly below body temperature should attempt resuscitation even after protracted immersion.

Medical Care

People with a near-drowning experience who have normal oxygen levels and no respiratory symptoms should be observed in a hospital environment for a period of time to ensure there are no delayed complications. The target of ventilation is to achieve 92% to 96% arterial saturation and adequate chest rise. Positive end-expiratory pressure will generally improve oxygenation. Drug administration via peripheral veins is preferred over endotracheal administration. Hypotension remaining after oxygenation may be treated by rapid crystalloid infusion. Cardiac arrest in drowning usually presents as asystole or pulseless electrical activity. Ventricular fibrillation is more likely to be associated with complications of pre-existing coronary artery disease, severe hypothermia, or the use of epinephrine or norepinephrine.

While surfactant may be used no high quality evidence exist that looks at this practice. Extracorporeal membrane oxygenation may be used in those who cannot be oxygenated otherwise. Steroids are not recommended.

Prognosis

People who have drowned who arrive at a hospital with spontaneous circulation and breathing usually recover with good outcomes. Early provision of basic and advanced life support improve probability of positive outcome. Longer duration of submersion is associated with lower probability of survival and higher probability of permanent neurological damage. Contaminants in the water can cause bronchospasm and impaired gas exchange, and can cause secondary infection with delayed severe respiratory compromise.

Low water temperature can cause ventricular fibrillation, but hypothermia during immersion can also slow the metabolism, allowing a longer hypoxia before severe damage occurs. Hypothermia which reduces brain temperature significantly can improve outcome. A reduction of brain temperature by 10 °C decreases ATP consumption by approximately 50%, which can double the time that the brain can survive.

The younger the person, the better the chances of survival. In one case, a child submerged in cold (37 °F (3 °C)) water for 66 minutes was resuscitated without apparent neurological damage. However, over the long term significant deficits were noted, including a range of cognitive difficulties, particularly general memory impairment, although recent magnetic resonance imaging (MRI) and magnetoencephalography (MEG) were within normal range.

3 Choking

Choking is a life-threatening medical emergency characterized by the blockage of air passage into the lungs secondary to the inhalation or ingestion of food or another object. Choking is caused by a mechanical obstruction of the airway that prevents normal breathing.

Signs & Symptoms

Causes

Choking is often caused by an object from outside the body, also called a foreign body, blocking the airway. The object can block the upper or lower airway passages. The airway obstruction is usually partial, but can also be complete.

Among children, the most common causes of choking are food, coins, toys, and balloons. In one study, peanuts were the most common object found in the airway of children evaluated for suspected foreign body aspiration. Foods that pose a high risk of choking include hot dogs, hard candy, nuts, seeds, whole grapes, raw carrots, apples, popcorn, peanut butter, marshmallows, chewing gum, and sausages. The most common cause of choking death in children is latex balloons. Small, round non-food objects such as balls, marbles, toys, and toy parts are also associated with a high risk of choking death because of their potential to completely block a child's airway.

Children younger than age three are especially at risk of choking because they explore their environment by putting objects in their mouth. Also, young children are still developing the ability to chew food completely. Molar teeth, which come in around 1.5 years of age, are necessary for grinding food. Even after molar teeth are present, children continue developing the ability to chew food completely and swallow throughout early childhood. In addition, a child's airway is smaller in diameter than an adult's airway, which means that smaller objects can cause an airway obstruction in children. Infants and young children generate a less forceful cough than adults, so coughing may not be as effective in relieving an airway obstruction. Finally, children with neuromuscular disorders, developmental delay, traumatic brain injury, and other conditions that affect swallowing are at an increased risk of choking.

In adults, choking often involves food blocking the airway. Risk factors include using alcohol or sedatives, undergoing a procedure involving the oral cavity or pharynx, wearing oral appliances, or having a medical condition that causes difficulty swallowing or impairs the cough reflex. Conditions that can cause difficulty swallowing and/or impaired coughing include neurological conditions such as strokes, Alzheimer's disease, or Parkinson's disease. In older adults, risk factors also include living alone, wearing dentures, and having difficulty swallowing.

Children and adults with neurological, cognitive, or psychiatric disorders may experience a delay in diagnosis because there may not be a known history of a foreign body entering the airway.

Prevention

In choking, the time to react is quite short, and the worst cases are deadly. For these reasons, it is convenient to prevent it, so it does not even happen.

Basic Prevention
Choking typically happens when swallowing too large or too abundant mouthfuls that are badly chewed. This risk disappears when one obtains the discipline to split the food in pieces of moderated size, and to chew them completely, not swallowing them before. If a food can be chewed, it must be chewed, whatever it is, even if it is very soft or gelatinous, such as spreads and soft desserts. Eating in handfuls (it can happen with foods as popcorn, different peeled nuts, etc.), requires to chew with more control than normal, and not exceeding in the amounts that enter into the mouth. Having at hand some liquid to drink is useful to help to finish swallowing (before the choking has happened).To swallow well, it is recommended that the neck is in a normal position, straight for the eater's body, with the head looking forward, being seated or standing up (not lying or too reclined).

Dangerous Foods
The foods that produce the most complicated choking are those whose shape adapts to the shape of the pharynx or trachea: hot dogs and sausages, bananas, food in blocks, etc. It is easier to choke on foods that dry the mouth (overcooked meat, sponge cake, cold pizza, etc.), which require the help of drinking liquid, or to be accompanied of purees or sauces. It is also easier to choke on foods that are tough (meat of octopus or cuttlefish, major size animals, some reptiles, etc.), they may need to be eaten together with something that helps the teeth to grind them (as loaf bread), or any concrete way to be prepared or cooked.

Groups of Risk
Some population groups have a higher choking risk, as: the elderly, the children, the disabled (physically or mentally), people under the effects of alcohol or drugs, people who have taken medications that seriously reduce the ability to salivate or react, patients with difficulties to swallow (dysphagia), suicidal people, epileptics, people on the autism spectrum, individuals with disorders such as pica that lead them to consume inedible objects, etc. They may require more assistance to feed themselves and it may be necessary to supervise them while they eat. If they are unable to chew properly, their food can not be hard nor tough. If they have difficulty eating normally, it is not recommended to give them food that may cause issues, or to separate it into very small pieces. In cases where a person is unable to safely eat, food can be supplied by feeding syringes that pour a liquid content into the patient's mouth. If the problem is that they have taken any medication or substance that reduces saliva, they cannot eat solid food until their salivation is restored.

Prevention in Babies and Children
All little children require care in eating. They must learn to chew their food completely to avoid choking. Feeding them while they do another activity (when they run, play, laugh, etc.) increases the risk of choking. Caregivers can supervise children while eating or playing. Providers such as pediatricians and dentists can provide information to parents and caregivers about what food and toys are appropriate by age to prevent choking. The American Academy of Pediatricians recommends waiting until 6 months of age before introducing solid foods to infants. Caregivers can avoid giving children, when they are younger than 5 years-old, foods that pose a high risk of choking such as hot dog pieces, bananas, cheese sticks, cheese chunks, hard candy, nuts, grapes, marshmallows or popcorn. Later, when they are accustomed to these foods, it is normal to give them split into small pieces. For example: if they are going to eat hot dogs, it is possible to split the sausage lengthwise, sliced, or both. And the same in the case of bananas, grapes, grains, etc. Parents, teachers, child care providers and other caregivers for children are advised to be trained in choking first-aid and cardiopulmonary resuscitation (CPR).

Children can put small objects into their mouths (deflated balloons, marbles, small pieces, buttons, coins, button batteries, etc.), which could lead to the child swallowing or choking on them. When babies choke on deflated balloons or plastic bags (as the sacks for wrapping the dirty diapers, the nappy sacks, which are a sort of bag sometimes dangerously placed near the babies), it produces a complicated obstruction that would require it to be directly removed with the fingers, if it is visible. To prevent children from swallowing things, it is needed to take precautions on their environment by placing dangerous objects out of their reach. Besides, they must be supervised, paying enough attention to what they do. It is necessary to teach the children to avoid putting things into their mouths. They may try to eat small pieces of toys. Toys and games may indicate on their packages the ages for which they are safe. In the US, manufacturers of children's toys and products are required by law to apply appropriate warning labels to their packaging. However, toys that are resold may not be marked with warning labels. Caregivers can try to prevent choking by considering the features of a toy (such as size, shape, consistency, small parts) before giving it to a child. Children's products that are found to pose a choking risk can be taken off the market.

Treatment

Choking is treated with a number of different procedures, which form the airway management. This consist in basic techniques available for first aiders and more advanced techniques available for health professionals.

Basic Treatment (First-Aid)
Basic treatment of choking includes a number of non-invasive techniques to help remove foreign bodies from the airways. Most modern protocols, including those of the American Heart Association and the American Red Cross, recommend several stages, designed to apply increasingly more pressure. For the conscious choking victim, most protocols recommend encouraging the victim to cough, followed by hard back slaps and, if none of these things work, abdominal thrusts (Heimlich maneuver) or chest thrusts. Once the choking victims loses consciousness, initiating CPR is recommended.

Cough
If the choking individual is conscious and coughing, the American Red Cross recommends encouraging the individual to stay calm and continue coughing freely, and it may be easier to take air through the nose to refill the lungs. If the person choking is unable to cough or if coughing is not effective, the American Red Cross recommends to move onto other methods, detailed below.

Back Blows (Back Slaps)
Many associations, as the American Red Cross and the Mayo Clinic, recommend the use of back blows (back slaps) to aid in the rescue of choking victims. This technique starts by bending the choking victim forward as much as possible, even trying to place his head lower than the chest, to avoid the risk of the slaps could drive the object deeper into the person's throat. The bending is in the back, the neck should not be excessively bent. Back blows are performed by delivering forceful slaps with the heel of the hand on the victim's back, between the shoulder blades.

The back slaps push behind the blockage, being able to dislodge the foreign object. In some cases, the physical vibration of the action may cause enough movement of the object to assist the patient in clearing the airway.

Abdominal Thrusts (Heimlich Maneuver)
Abdominal thrusts are performed with the rescuer standing behind the choking victim. The rescuer closes his skillful hand, grasps it with the other hand, and presses forcefully inwards and upwards with both of them on the area located between the chest and the belly button of the victim. The pressure is not focused directly against the ribs, to avoid breaking any of them. If the first thrust doesn't solve the choking, it can be repeated several times. Usage of abdominal thrusts is not recommended in infants under 1 year of age due to risk of causing injury; there exist adapted techniques for them (see more further below). Abdominal thrusts should not be used, either, when the patient's abdomen presents problems to receive them, like pregnancy or excessive size; then chest thrusts are advised (see further below).

The purpose of abdominal thrusts is to create a pressure capable to expel the object lodged upwards in the airway, relieving the obstruction. This method was discovered by Dr. Henry Heimlich in 1974, so it is referred to as "The Heimlich Maneuver." Dr. Henry Heimlich claimed that his maneuver was better than the back blows, arguing that back blows could cause the obstruction to become more deeply lodged in the victim's airway. That claim started a debate into the medical community, that ended up with the recommendation of alternating both techniques, but making the patient to bend the back before receiving the slaps. So the Heimlich Maneuver itself uses only abdominal thrusts, but is also part of anti-choking protocols that include the back blows (back slaps) technique.

Chest Thrusts
When abdominal thrusts can not be performed on the victim (in case of pregnant or too obese victims, and others) chest thrusts are advised instead. Chest thrusts are performed with the rescuer standing behind the choking victim. The rescuer closes his skillful hand and grasp it with the other hand. This can produce several kinds of fists, but any of them can be valid if it can be placed on the chest of the victim without sinking there a knuckle too painfully. Keeping the fist with both hands, the rescuer uses it to press forcefully inwards on the lower half of the chest bone (approximately), but not in the very endpoint (which is the xiphoid process). It can be noted, as a general reference, that, when the victim is a woman, the zone of pressure of the chest thrusts would be normally upper than the level of the breasts. The pressure is not focused against the xiphoid process, to avoid breaking it. If the first thrust doesn't solve the choking, it can be repeated several times.

"**Five and Five" Strategy**
The American Red Cross recommends a protocol of alternating five back blows and five abdominal thrusts for conscious choking victims until the object blocking the airway is dislodged. For pregnant or too obese victims, the protocol is the same, but chest thrusts are advised instead of the abdominal ones. If the victim becomes unconscious, basic CPR is recommended. Anyway, it's convenient to make someone call to emergency medical services before it happens.

The Red Cross does not specifically refer to its choking victim protocol as the "Five and Five Technique", and it differs from the Heimlich Maneuver since it includes administering back blows to the victim, contrary to Dr. Heimlich's procedure which specifically omitted back blows and was based only on his technique.

Anti-choking Devices
During the 2010-2020 decade, some effective anti-choking devices have been developed and released to the market. They have superseded primitive inventions appeared during the 20th century. The current anti-choking devices have some advantages compared with manual techniques. The usage of these devices is always quite easy. They can be especially useful in difficult cases, like disabled patients, elderly people, unconscious victims or when the victim is oneself. Also, they can be helpful in public places and crowded events. And, finally, they achieve levels of pressure in suction that can not be matched by manual methods. In the worst choking cases, no manual technique would dislodge the foreign object, being necessary the usage of one of these devices or a sort of surgery. That's why physicians recommend to put some care in eating.

The design of these devices is based in a vacuum mechanical effect, with no need of batteries or electric current. They usually present an attached mask, in order to make a vacuum from the patient's nose and mouth. The current models of anti-choking devices are quite similar: a direct plunger tool (LifeVac), or a vacuum syringe (backward syringe) that keeps the tongue in place by inserting a tube in the mouth (Dechoker). Both have received certifications and have been proven effective in many real cases reported by the media. Some other mechanical models are in development, this is the case of Lifewand (now being released to market), which makes the vacuum by direct pressure against patient's face, and the prototype of Dr. De Luca (now seeking funds), which uses a button. The challenges for the future of the anti-choking inventions are just to improve their portability reducing more their size and to develop a device that specifically works in babies (despite all the previous ones have any model for little children).

Unconscious Victims
When a choking victim becomes unconscious, it's mandatory to call to emergency medical services if this has not been done yet. For the rest, an unconscious choking victim should receive a first-aid treatment that is similar to the case of any other non-breathing patient: a cardiopulmonary resuscitation (CPR), alternating series of around 30 compressions (on the lower half of the chest bone) with series of 2 rescue breaths (pinching the victim's nose and puffing air inside of the mouth; it's also possible to tilt the victim's head up or down and give 2 additional breaths, so the air could find an entrance through the blockage).

The difference between CPR in choking victims and a normal CPR is that CPR in choking victims includes an attempt to remove the obstructing object (mainly using finger sweeping when the object is already visible) at the end of each compressions serie. The chest compressions of cardiopulmonary resuscitation (CPR) produce coincidentally the same anti-choking effect than the chest thrusts technique, so the CPR itself could expel the object. If the object is expelled and followingly removed, CPR must continue until the victim recovers breathing. Babies (infants under 1 year old) require a special adaptation of the procedure (described further below).

An anti-choking device can unblock the airway on unconscious victims, but not necessarily can take the obstructing object out of the mouth (it may need a manual removal). Anyway, the victim will require cardiopulmonary resuscitation (CPR) after that, as it has been described above, but only alternating the 30 compressions and the 2 rescue breaths.

The Finger Sweeping in Unconscious Victims
In unconscious victims of choking, the American Medical Association advocates sweeping the fingers across the back of the throat to attempt to dislodge airway obstructions. However, many modern protocols recommend against the use of the finger sweep. Red Cross procedures specifically direct rescuers not to perform a finger sweep unless an object can be clearly seen in the victim's mouth due to the risk of driving the obstruction deeper into the victim's airway. Other protocols suggest that if the patient is conscious they will be able to remove the foreign object themselves, or if they are unconscious, the rescuer should simply place them in the recovery position as this allows (to a certain extent) the drainage of fluids out of the mouth instead of down the trachea due to gravity. There is also a risk of causing further damage (for instance inducing vomiting) by using a finger sweep technique. There are no studies that have examined the usefulness of the finger sweep technique when there is no visible object in the airway. Recommendations for the use of the finger sweep have been based on anecdotal evidence.

Babies (under 1 year old)
For babies (infants under 1 year old), the American Heart Association recommends to perform cycles of back blows (5 back slaps) followed by chest thrusts (5 chest compressions, that are adapted).

In the back blows, it's recommended that, before applying them, the baby is slightly leaned upside-down, being supported by a forearm of the rescuer and its respective hand (the baby's head must be carefully held in this maneuver, usually from the jaw). To achieve this position, the rescuer can sit down on any seat with the baby, so the baby's body (supported by the forearm and hand of the rescuer) can be leaned along the rescuer's thighs. As an alternative to this (in case of the baby is too big or any other problem), the rescuer can sit on a bed or sofa, or even on the floor (when no seat is near), supporting on the lap the baby's body, to make the upside-down leaning from the lap, at the right or at the left. If the rescuer can not sit down, at least could try to do the maneuver low over a soft surface (to reduce a possible fall). In case of the previous options are not possible, but the rescuer is skillful enough, the rescuer can still kneel on a knee, and place the baby's body along the thigh that is higher (with the forearm still supporting between the thigh and the baby), so the baby can be leaned a bit moving forward that thigh. When the baby is already leaned (using any of the systems), the rescuer applies the slaps.

In the chest thrusts maneuver, the baby's body is placed laying. Then the rescuer does the compressions on the chest bone, pressing with only two fingers on its lower half (the nearer to the abdomen). Abdominal thrusts are not recommended in children less than 1 year, because they can cause liver damage. The cycles of 5 back blows and 5 chest compressions are alternated until the object comes out of the infant's airway or until the infant becomes unconscious.

If the infant becomes unconscious, the American Heart Association recommends starting a cardiopulmonary resuscitation (CPR), which must be adapted to babies. In that procedure, the baby is placed face up on a horizontal surface, with the head in straight position (tilting too much a baby's head backwards can close the access to the trachea). Then it must be applied an alternating cycle of 30 chest compressions (but modified: the rescuer presses with only two fingers in the lower part of the chest bone), and 2 rescue breaths (also modified: the rescuer's mouth puffs air covering the baby's mouth and nose at the same time). Between chest compressions and rescue breaths, the rescuer looks into the mouth searching if the obstructing object has come out (because of the effect of the compressions) and, if it is visible, attempts to extract it (mainly using a finger sweeping). If the object is extracted, the cardiopulmonary resuscitation continues until the baby's breath is successfully recovered or until medical services arrive.

Pregnant or Too Obese People
The American Heart Association recommends the chest thrusts rather than the abdominal thrusts for pregnant or too obese persons who are choking. Chest thrusts are performed in a similar way to the abdominal thrusts, but with the hands placed on the lower part of the choking victim's chest, at the lower half of the breast bone (sternum), rather than over the middle of the abdomen, as in the traditional abdominal thrusts. Strong inward thrusts are then applied. As a reference, in women, the zone of pressure of the chest thrusts (the lower half of sternum) would be normally upper than the level of the breasts. The chest thrusts can be alternated with back blows (back slaps), which are applied on the back of the victim when it is very bent forward.

Disabled People in Wheelchair
If the choking victim is a disabled person and is using a wheelchair, the first-aid procedure is quite similar than in the case of the other victims. The difference is in trying to apply the techniques directly, while the victim is still seated on the wheelchair.

The back blows (back slaps) can be used after bending forward the back of the victim very much, as much as possible. To perform the abdominal thrusts (Heimlich maneuver), the back of the victim must be bent too, and the rescuer has to get behind the wheelchair. Then, the rescuer can embrace the victim's abdomen from behind and up, leaning over the top of the wheelchair's backrest. If this is too difficult, the rescuer can get down to embrace the victim's abdomen and the wheelchair's backrest all together. The same can be tried from a side or in another way. Finally, the rescuer has to apply the sudden inward and upward pressures on the abdomen. It must be remembered that, if the victim can not receive abdominal thrusts (this is the case of the pregnant or too obese people), chest thrusts must be used instead. They are applied while the victim is in the wheelchair too, but making sudden inward pressures on the lower part of the chest bone against the wheelchair's backrest and the rescuer's body. If there are difficulties for this, the same maneuver can be tried from a side or in another way.

Due to the additional difficulties in helping to the disabled, it is convenient to avoid placing them in too narrow and encased spaces at the mealtimes. The opened spaces give an easier access to them for the rescuers. The presence of an anti-choking device at hand can be specially useful when a disabled person is near.

Self-Treatment
The Heimlich Maneuver (abdominal thrusts) can be performed or can be self-administered. Self-administration of this maneuver requires positioning of one's own abdomen over a chair, railing, or countertop and driving the abdomen upon the object with sharp, upward thrust. This serves as a substitute for thrusts made with the hands by another person. One study showed that these self-administered abdominal thrusts were just as effective as those performed by another person, although obese individuals were not included in the study. Alternatively, multiple sources of evidence suggest that one of promising approaches for self treatment during choking could be by applying the head-down (inverse) position.

On the other hand, using a modern anti-choking device is one the best, and most realistic, options for self-treatment in case of suffering a serious choking episode.

Advanced Treatment
There are many advanced medical treatments to relieve choking or airway obstruction. These include inspection of the airway with a laryngoscope or bronchoscope and removal of the object under direct vision. Severe cases where there is an inability to remove the object may require cricothyrotomy (emergency tracheostomy). Cricothyrotomy involves making an incision in a patient's neck and inserting a tube into the trachea in order to bypass the upper airways. The procedure is usually only performed when other methods have failed. In many cases, an emergency tracheostomy can save a patient's life, but if performed incorrectly, it may end the patient's life.

4 Barotrauma

Barotrauma is physical damage to body tissues caused by a difference in pressure between a gas space inside, or in contact with the body, and the surrounding gas or fluid.

Signs & Symptoms

Examples of organs or tissues easily damaged by barotrauma are:
- Middle ear (barotitis or aerotitis)
- Paranasal sinuses (causing aerosinusitis)
- Lungs
- Eyes (the under-pressure air space is inside the diving mask)
- Skin (when wearing a diving suit which creates an air space)
- Brain and cranium (temporal lobe injury secondary to temporal bone rupture)
- Teeth (causing Barodontalgia, i.e., barometric pressure related dental pain, or dental fractures)
- Genital (squeeze and associated complications of P-valve use)

Causes

Pressure Differences while Diving	When diving, the pressure differences which cause the barotrauma are changes in hydrostatic pressure: There are two components to the surrounding pressure acting on the diver: the atmospheric pressure and the water pressure. A descent of 10 metres (33 feet) in water increases the ambient pressure by an amount approximately equal to the pressure of the atmosphere at sea level. So, a descent from the surface to 10 metres (33 feet) underwater results in a doubling of the pressure on the diver. This pressure change will reduce the volume of a gas filled space by half. Boyle's law describes the relationship between the volume of the gas space and the pressure in the gas.

Barotraumas of descent are caused by preventing the free change of volume of the gas in a closed space in contact with the diver, resulting in a pressure difference between the tissues and the gas space, and the unbalanced force due to this pressure difference causes deformation of the tissues resulting in cell rupture. Barotraumas of ascent are also caused when the free change of volume of the gas in a closed space in contact with the diver is prevented. In this case the pressure difference causes a resultant tension in the surrounding tissues which exceeds their tensile strength. Besides tissue rupture, the overpressure may cause ingress of gases into the tissues and further afield through the circulatory system.

This pulmonary barotrauma (PBt) of ascent is also known as pulmonary over-inflation syndrome (POIS), lung over-pressure injury (LOP) and burst lung. Consequent injuries may include arterial gas embolism, pneumothorax, mediastinal, interstitial and subcutaneous emphysemas, not usually all at the same time.

Breathing gas at depth from underwater breathing apparatus results in the lungs containing gas at a higher pressure than atmospheric pressure. So a free-diver can dive to 10 metres (33 feet) and safely ascend without exhaling, because the gas in the lungs had been inhaled at atmospheric pressure, whereas a diver who inhales at 10 metres and ascends without exhaling has lungs containing twice the amount of gas at atmospheric pressure and is very likely to suffer life-threatening lung damage.

Explosive decompression of a hyperbaric environment can produce severe barotrauma, followed by severe decompression bubble formation and other related injury. The Byford Dolphin incident is an example.

Blast-Induced Barotrauma	An explosive blast and explosive decompression create a pressure wave that can induce barotrauma. The difference in pressure between internal organs and the outer surface of the body causes injuries to internal organs that contain gas, such as the lungs, gastrointestinal tract, and ear. Lung injuries can also occur during rapid decompression, although the risk of injury is lower than with explosive decompression.
Ventilator-Induced Barotrauma	Mechanical ventilation can lead to barotrauma of the lungs. This can be due to either: ● Absolute pressures used in order to ventilate non-compliant lungs. ● Shearing forces, particularly associated with rapid changes in gas velocity. The resultant alveolar rupture can lead to pneumothorax, pulmonary interstitial emphysema (PIE) and pneumomediastinum. Barotrauma is a recognised complication of mechanical ventilation that can occur in any patient receiving mechanical ventilation, but is most commonly associated with acute respiratory distress syndrome. It used to be the most common complication of mechanical ventilation but can usually be avoided by limiting tidal volume and plateau pressure to less than 30 to 50 cm water column (30 to 50 mb). As an indicator of transalveolar pressure, which predicts alveolar distention, plateau pressure or peak airway pressure (PAP) may be the most effective predictor of risk, but there is no generally accepted safe pressure at which there is no risk.

Risk also appears to be increased by aspiration of stomach contents and pre-existing disease such as necrotising pneumonia and chronic lung disease. Status asthmaticus is a particular problem as it requires relatively high pressures to overcome bronchial obstruction. When lung tissues are damaged by alveolar over-distension, the injury may be termed volutrauma, but volume and transpulmonary pressure are closely related. Ventilator induced lung injury is often associated with high tidal volumes (Vt).

Use of a Hyperbaric Chamber	Patients undergoing hyperbaric oxygen therapy must equalize their ears to avoid barotrauma. High risk of otic barotrauma is associated with unconscious patients.

Diagnosis

Ear Barotrauma	Barotrauma can affect the external, middle, or inner ear. Middle ear barotrauma (MEBT) is the most common being experienced by between 10% and 30% of divers and is due to insufficient equilibration of the middle ear. External ear barotrauma may occur on ascent if high pressure air is trapped in the external auditory canal either by tight fitting diving equipment or ear wax. Inner ear barotrauma (IEBT), though much less common than MEBT, shares a similar mechanism. Mechanical trauma to the inner ear can lead to varying degrees of conductive and sensorineural hearing loss as well as vertigo. It is also common for conditions affecting the inner ear to result in auditory hypersensitivity.
Barosinusitis	The sinuses similar to other air-filled cavities are susceptible to barotrauma if their openings become obstructed. This can result in pain as well as epistaxis (nosebleed).
Mask Squeeze	If a diver's mask is not equalized during descent the relative negative pressure can produce petechial hemorrhages in the area covered by the mask along with subconjunctival hemorrhages.
Helmet Squeeze	A problem mostly of historical interest, but still relevant to surface supplied divers who dive with the helmet sealed to the dry suit. If the air supply hose is ruptured near or above the surface, the pressure difference between the water around the diver and the air in the hose can be several bar. The non-return valve at the connection to the helmet will prevent backflow if it is working correctly, but if absent, as in the early days of helmet diving, or if it fails, the pressure difference will tend to squeeze the diver into the rigid helmet, which can result in severe trauma. The same effect can result from a large and rapid increase in depth if the air supply is insufficient to keep up with the increase in ambient pressure.

Pulmonary Barotrauma	Lung over-pressure injury in ambient pressure divers using underwater breathing apparatus is usually caused by breath-holding on ascent. The compressed gas in the lungs expands as the ambient pressure decreases causing the lungs to over-expand and rupture unless the diver allows the gas to escape by maintaining an open airway, as in normal breathing. The lungs do not sense pain when over-expanded giving the diver little warning to prevent the injury. This does not affect breath-hold divers as they bring a lungful of air with them from the surface, which merely re-expands safely to near its original volume on ascent. The problem only arises if a breath of ambient pressure gas is taken at depth, which may then expand on ascent to more than the lung volume. Pulmonary barotrauma may also be caused by explosive decompression of a pressurised aircraft.

Prevention

In Divers	Barotrauma may be caused when diving, either from being crushed, or squeezed, on descent or by stretching and bursting on ascent; both can be avoided by equalising the pressures. A negative, unbalanced pressure is known as a squeeze, crushing eardrums, dry suit, lungs or mask inwards and can be equalised by putting air into the squeezed space. A positive unbalanced pressure expands internal spaces rupturing tissue and can be equalised by letting air out, for example by exhaling. Both may cause barotrauma. There are a variety of techniques depending on the affected area and whether the pressure inequality is a squeeze or an expansion:

● Ears and sinuses: There is a risk of stretched or burst eardrums, usually crushed inwards during descent but sometimes stretched outwards on ascent. The diver can use a variety of methods to let air into or out of the middle ears via the Eustachian tubes. Sometimes swallowing will open the Eustachian tubes and equalise the ears.

● Lungs: There is a risk of pneumothorax, arterial gas embolism, and mediastinal and subcutanous emphysemas during ascent, which are commonly called burst lung or lung overpressure injury by divers. To equalise the lungs, all that is necessary is not to hold the breath during ascent. This risk does not occur when breath-hold diving from the surface, unless the diver breathes from an ambient pressure gas source underwater; breath-hold divers do suffer squeezed lungs on descent, crushing in the chest cavity, but, while uncomfortable, this rarely causes lung injury and returns to normal at the surface. Some people have pathologies of the lung which prevent rapid flow of excess air through the passages, which can lead to lung barotrauma even if the breath is not held during rapid depressurisation. These people should not dive as the risk is unacceptably high. Most commercial or military diving medical examinations will look specifically for signs of this pathology.

● Diving mask squeeze enclosing the eyes and nose: The main risk is rupture of the capillaries of the eyes and facial skin because of the negative pressure difference between the gas space and blood pressure, or orbital emphysema from higher pressures. This can be avoided by breathing air into the mask through the nose. Goggles covering only the eyes are not suitable for deep diving as they cannot be equalised.

● Dry suit squeeze. The main risk is skin getting pinched and bruised by folds of the dry suit when squeezed on descent. Most dry suits can be equalised against squeeze via a manually operated valve fed from a low pressure gas supply. Air must be manually injected during the descent to avoid squeeze and is manually or automatically vented on the ascent to maintain buoyancy control.

● Diving helmet squeeze: Helmet squeeze will occur if the gas supply hose is severed above the diver and the non-return valve at the helmet gas inlet fails or is not fitted. Severity will depend on the hydrostatic pressure difference. A very rapid descent, usually by accident, may exceed the rate at which the breathing gas supply can equalise the pressure causing a temporary squeeze. The introduction of the non-return valve and high maximum gas supply flow rates have all but eliminated both these risks. In helmets fitted with a neck dam, the dam will admit water into the helmet if the internal pressure gets too low; this is less of a problem than helmet squeeze but the diver may drown if the gas supply is not reinstated quickly. This form of barotrauma is avoidable by controlled descent rate, which is standard practice for commercial divers, who will use shotlines, diving stages and wet bells to control descent and ascent rates.

Professional divers are screened for risk factors during initial and periodical medical examination for fitness to dive. In most cases recreational divers are not medically screened, but are required to provide a medical statement before acceptance for training in which the most common and easy to identify risk factors must be declared. If these factors are declared, the diver may be required to be examined by a medical practitioner, and may be disqualified from diving if the conditions indicate.

Asthma, Marfan syndrome, and COPD pose a very high risk of pneumothorax. In some countries these may be considered absolute contraindications, while in others the severity may be taken into consideration. Asthmatics with a mild and well controlled condition may be permitted to dive under restricted circumstances.

A significant part of entry level diver training is focused on understanding the risks and procedural avoidance of barotrauma. Professional divers and recreational divers with rescue training are trained in the basic skills of recognizing and first aid management of diving barotrauma.

In Mechanical Ventilation	Isolated mechanical forces may not adequately explain ventilator induced lung injury (VILI). The damage is affected by the interaction of these forces and the pre-existing state of the lung tissues, and dynamic changes in alveolar structure may be involved. Factors such as plateau pressure and positive end-expiratory pressure (PEEP) alone do not adequately predict injury. Cyclic deformation of lung tissue may play a large part in the cause of VILI, and contributory factors probably include tidal volume, positive end-expiratory pressure and respiratory rate. There is no protocol guaranteed to avoid all risk in all applications.

Treatment

Treatment of diving barotrauma depends on the symptoms. Lung over-pressure injury may require a chest drain to remove air from the pleura or mediastinum. Recompression with hyperbaric oxygen therapy is the definitive treatment for arterial gas embolism, as the raised pressure reduces bubble size, low inert gas partial pressure accelerates inert gas solution and high oxygen partial pressure helps oxygenate tissues compromised by the emboli. Care must be taken when recompressing to avoid a tension pneumothorax. Barotraumas that do not involve gas in the tissues are generally treated according to severity and symptoms for similar trauma from other causes.

First Aid	Pre-hospital care for lung barotrauma includes basic life support of maintaining adequate oxygenation and perfusion, assessment of airway, breathing and circulation, neurological assessment, and managing any immediate life-threatening conditions. High-flow oxygen up to 100% is considered appropriate for diving accidents. Large-bore venous access with isotonic fluid infusion is recommended to maintain blood pressure and pulse.
Emergency Treatment	**Pulmonary Barotrauma:** ● Endotracheal intubation may be required if the airway is unstable or hypoxia persists when breathing 100% oxygen. ● Needle decompression or tube thoracostomy may be necessary to drain a pneumothorax or haemothorax ● Foley catheterization may be necessary for spinal cord AGE if the person is unable to urinate. ● Intravenous hydration may be required to maintain adequate blood pressure. ● Therapeutic recompression is indicated for severe AGE. The diving medical practitioner will need to know the vital signs and relevant symptoms, along with the recent pressure exposure and breathing gas history of the patient. Air transport should be below 1,000 feet (300 m) if possible, or in a pressurized aircraft which should be pressurised to as low an altitude as reasonably possible. Sinus squeeze and middle ear squeeze are generally treated with decongestants to reduce the pressure differential, with anti-inflammatory medications to treat the pain. For severe pain, narcotic analgesics may be appropriate. Suit, helmet and mask squeeze are treated as trauma according to symptoms and severity.
Medication	The primary medications for lung barotrauma are oxygen, oxygen-helium or nitrox, isotonic fluids, anti-inflammatory medications, decongestants, and analgesics.
Outcomes	Following barotrauma of the ears or lungs from diving the diver should not dive again until cleared by a diving doctor. After ear injury examination will include a hearing test and a demonstration that the middle ear can be autoinflated. Recovery can take weeks to months.

5 Compression Arthralgia

Compression arthralgia is pain in the joints caused by exposure to high ambient pressure at a relatively high rate of compression, experienced by underwater divers. Also referred to in the US Navy diving Manual as compression pains.

Signs & Symptoms

Compression arthralgia has been recorded as deep aching pain in the knees, shoulders, fingers, back, hips, neck and ribs. Pain may be sudden and intense in onset and may be accompanied by a feeling of roughness in the joints.

Onset commonly occurs around 60 msw (meters of sea water), and symptoms are variable depending on depth, compression rate and personal susceptibility. Intensity increases with depth and may be aggravated by exercise. Compression arthralgia is generally a problem of deep diving, particularly deep saturation diving, where at sufficient depth even slow compression may produce symptoms. Peter B. Bennett et al. showed that the use of trimix could reduce the symptoms.

Causes

Fast compression (descent) may produce symptoms as shallow as 30 msw. Saturation divers generally compress much more slowly, and symptoms are unlikely at less than around 90 msw. At depths beyond 180m even very slow compression may produce symptoms. Spontaneous improvement may occur over time at depth, but this is unpredictable, and pain may persist into decompression. They may be distinguished from decompression sickness as they are present before starting decompression, and resolve with decreasing pressure, the opposite of decompression sickness. The pain may be sufficiently severe to limit the diver's capacity for work, and may also limit travel rate and depth of downward excursions.

Prevention

A slow descent when diving.

Treatment

The symptoms generally resolve during decompression and require no further treatment.

6 Decompression Sickness

Decompression sickness (DCS; also known as divers' disease, the bends, aerobullosis, or caisson disease) describes a condition arising from dissolved gases coming out of solution into bubbles inside the body on depressurisation. DCS most commonly refers to problems arising from underwater diving decompression (i.e., during ascent), but may be experienced in other depressurisation events such as emerging from a caisson, flying in an unpressurised aircraft at altitude, and extravehicular activity from spacecraft. DCS and arterial gas embolism are collectively referred to as decompression illness.

Since bubbles can form in or migrate to any part of the body, DCS can produce many symptoms, and its effects may vary from joint pain and rashes to paralysis and death. Individual susceptibility can vary from day to day, and different individuals under the same conditions may be affected differently or not at all. The classification of types of DCS by its symptoms has evolved since its original description over a hundred years ago. The severity of symptoms varies from barely noticeable to rapidly fatal.

Risk of DCS caused by diving can be managed through proper decompression procedures and contracting it is now uncommon. Its potential severity has driven much research to prevent it and divers almost universally use dive tables or dive computers to limit their exposure and to control their ascent speed. If DCS is suspected, it is treated by hyperbaric oxygen therapy in a recompression chamber. Diagnosis is confirmed by a positive response to the treatment. If treated early, there is a significantly higher chance of successful recovery.

Signs & Symptoms

While bubbles can form anywhere in the body, DCS is most frequently observed in the shoulders, elbows, knees, and ankles. Joint pain ("the bends") accounts for about 60% to 70% of all altitude DCS cases, with the shoulder being the most common site for altitude and bounce diving, and the knees and hip joints for saturation and compressed air work. Neurological symptoms are present in 10% to 15% of DCS cases with headache and visual disturbances being the most common symptom. Skin manifestations are present in about 10% to 15% of cases. Pulmonary DCS ("the chokes") is very rare in divers and has been observed much less frequently in aviators since the introduction of oxygen pre-breathing protocols. The table below shows symptoms for different DCS types.

Signs and symptoms of decompression sickness:

DCS type	Bubble Location	Signs & Symptoms (clinical manifestations)
Musculoskeletal	Mostly large joints of the limbs (elbows, shoulders, hip, wrists, knees, ankles)	● Localized deep pain, ranging from mild to excruciating. Sometimes a dull ache, more rarely a sharp pain. ● Active and passive motion of the joint may aggravate the pain. ● The pain may be reduced by bending the joint to find a more comfortable position. ● If caused by altitude, pain can occur immediately or up to many hours later.
Cutaneous	Skin	● Itching, usually around the ears, face, neck, arms, and upper torso ● Sensation of tiny insects crawling over the skin (formication) ● Mottled or marbled skin usually around the shoulders, upper chest and abdomen, with itching (cutis marmorata) ● Swelling of the skin, accompanied by tiny scar-like skin depressions (pitting edema)
Neurologic	Brain	● Altered sensation, tingling or numbness (paresthesia), increased sensitivity (hyperesthesia) ● Confusion or memory loss (amnesia) ● Visual abnormalities ● Unexplained mood or behaviour changes ● Seizures, unconsciousness

Neurologic	Spinal cord	● Ascending weakness or paralysis in the legs ● Urinary incontinence and fecal incontinence ● Girdling (also referred to as girdle, banding, or tightening feeling) around the abdominal region and/or chest
Constitutional	Whole body	● Headache ● Unexplained fatigue ● Generalised malaise, poorly localised aches
Audiovestibular	Inner Ear	● Loss of balance ● Dizziness, vertigo, nausea, vomiting ● Hearing loss
Pulmonary	Lungs	● Dry persistent cough ● Burning chest pain under the sternum, aggravated by breathing ● Shortness of breath

Frequency
The relative frequencies of different symptoms of DCS observed by the U.S. Navy are as follows:

Symptoms - Frequency
- Local Joint Pain 89%
- Arm Symptoms 70%
- Leg Symptoms 30%
- Dizziness 5.3%
- Paralysis 2.3%
- Shortness of Breath 1.6%
- Extreme Fatigue 1.3%
- Collapse/Unconsciousness 0.5%

Onset
Although onset of DCS can occur rapidly after a dive, in more than half of all cases symptoms do not begin to appear for at least an hour. In extreme cases, symptoms may occur before the dive has been completed. The U.S. Navy and Technical Diving International, a leading technical diver training organization, have published a table that documents time to onset of first symptoms. The table does not differentiate between types of DCS, or types of symptom.

Onset of DCS symptoms
Time to onset - Percentage of cases
- within 1 hour 42%
- within 3 hours 60%
- within 8 hours 83%
- within 24 hours 98%
- within 48 hours 100%

Causes

DCS is caused by a reduction in ambient pressure that results in the formation of bubbles of inert gases within tissues of the body. It may happen when leaving a high-pressure environment, ascending from depth, or ascending to altitude.

Ascent from Depth

DCS is best known as a diving disorder that affects divers having breathed gas that is at a higher pressure than the surface pressure, owing to the pressure of the surrounding water. The risk of DCS increases when diving for extended periods or at greater depth, without ascending gradually and making the decompression stops needed to slowly reduce the excess pressure of inert gases dissolved in the body.

The specific risk factors are not well understood and some divers may be more susceptible than others under identical conditions. DCS has been confirmed in rare cases of breath-holding divers who have made a sequence of many deep dives with short surface intervals; and it may be the cause of the disease called taravana by South Pacific island natives who for centuries have dived by breath-holding for food and pearls.

Two principal factors control the risk of a diver suffering DCS:
1. The rate and duration of gas absorption under pressure – the deeper or longer the dive the more gas is absorbed into body tissue in higher concentrations than normal (Henry's Law);
2. The rate and duration of outgassing on depressurization – the faster the ascent and the shorter the interval between dives the less time there is for absorbed gas to be offloaded safely through the lungs, causing these gases to come out of solution and form "micro bubbles" in the blood. Even when the change in pressure causes no immediate symptoms, rapid pressure change can cause permanent bone injury called dysbaric osteonecrosis (DON). DON can develop from a single exposure to rapid decompression.

Leaving a high-Pressure Environment

When workers leave a pressurized caisson or a mine that has been pressurized to keep water out, they will experience a significant reduction in ambient pressure. A similar pressure reduction occurs when astronauts exit a space vehicle to perform a space-walk or extra-vehicular activity, where the pressure in their spacesuit is lower than the pressure in the vehicle.

The original name for DCS was "caisson disease". This term was introduced in the 19th century, when caissons under pressure were used to keep water from flooding large engineering excavations below the water table, such as bridge supports and tunnels. Workers spending time in high ambient pressure conditions are at risk when they return to the lower pressure outside the caisson if the pressure is not reduced slowly. DCS was a major factor during construction of Eads Bridge, when 15 workers died from what was then a mysterious illness, and later during construction of the Brooklyn Bridge, where it incapacitated the project leader Washington Roebling. On the other side of the Manhattan island during construction of the Hudson River Tunnel contractor's agent Ernest William Moir noted in 1889 that workers were dying due to decompression sickness and pioneered the use of an airlock chamber for treatment.

Ascent to Altitude

The most common health risk on ascent to altitude is not decompression sickness but altitude sickness, or acute mountain sickness (AMS), which has an entirely different and unrelated set of causes and symptoms. AMS results not from the formation of bubbles from dissolved gasses in the body but from exposure to a low partial pressure of oxygen and alkalosis. However, passengers in unpressurized aircraft at high altitude may also be at some risk of DCS. Altitude DCS became a problem in the 1930s with the development of high-altitude balloon and aircraft flights but not as great a problem as AMS, which drove the development of pressurized cabins, which coincidentally controlled DCS. Commercial aircraft are now required to maintain the cabin at or below a pressure altitude of 2,400 m (7,900 ft) even when flying above 12,000 m (39,000 ft). Symptoms of DCS in healthy individuals are subsequently very rare unless there is a loss of pressurization or the individual has been diving recently. Divers who drive up a mountain or fly shortly after diving are at particular risk even in a pressurized aircraft because the regulatory cabin altitude of 2,400 m (7,900 ft) represents only 73% of sea level pressure.

INJURY Air & Atmosphere Decompression Sickness Causes

Ascent to Altitude	Generally, the higher the altitude the greater the risk of altitude DCS but there is no specific, maximum, safe altitude below which it never occurs. There are very few symptoms at or below 5,500 m (18,000 ft) unless patients had predisposing medical conditions or had dived recently. There is a correlation between increased altitudes above 5,500 m (18,000 ft) and the frequency of altitude DCS but there is no direct relationship with the severity of the various types of DCS. A US Air Force study reports that there are few occurrences between 5,500 m (18,000 ft) and 7,500 m (24,600 ft) and 87% of incidents occurred at or above 7,500 m (24,600 ft). High altitude parachutists may reduce the risk of altitude DCS if they flush nitrogen from the body by pre-breathing pure oxygen.

Predisposing Factors

INJURY Air & Atmosphere Decompression Sickness Predisposing Factors

Although the occurrence of DCS is not easily predictable, many predisposing factors are known. They may be considered as either environmental or individual. Decompression sickness and arterial gas embolism in recreational diving are associated with certain demographic, environmental, and dive style factors. A statistical study published in 2005 tested potential risk factors: age, gender, body mass index, smoking, asthma, diabetes, cardiovascular disease, previous decompression illness, years since certification, dives in the last year, number of diving days, number of dives in a repetitive series, last dive depth, nitrox use, and drysuit use.

No significant associations with risk of decompression sickness or arterial gas embolism were found for asthma, diabetes, cardiovascular disease, smoking, or body mass index. Increased depth, previous DCI, larger number of consecutive days diving, and being male were associated with higher risk for decompression sickness and arterial gas embolism. Nitrox and drysuit use, greater frequency of diving in the past year, increasing age, and years since certification were associated with lower risk, possibly as indicators of more extensive training and experience.

Environmental
The following environmental factors have been shown to increase the risk of DCS:
● The magnitude of the pressure reduction ratio – a large pressure reduction ratio is more likely to cause DCS than a small one.
● Repetitive exposures – repetitive dives within a short period of time (a few hours) increase the risk of developing DCS. Repetitive ascents to altitudes above 5,500 metres (18,000 ft) within similar short periods increase the risk of developing altitude DCS.
● The rate of ascent – the faster the ascent the greater the risk of developing DCS. The U.S. Navy Diving Manual indicates that ascent rates greater than about 20 m/min (66 ft/min) when diving increase the chance of DCS, while recreational dive tables such as the Bühlmann tables require an ascent rate of 10 m/min (33 ft/min) with the last 6 m (20 ft) taking at least one minute. An individual exposed to a rapid decompression (high rate of ascent) above 5,500 metres (18,000 ft) has a greater risk of altitude DCS than being exposed to the same altitude but at a lower rate of ascent.
● The duration of exposure – the longer the duration of the dive, the greater is the risk of DCS. Longer flights, especially to altitudes of 5,500 m (18,000 ft) and above, carry a greater risk of altitude DCS.

INJURY Air & Atmosphere Decompression Sickness Predisposing Factors

● Underwater diving before flying – divers who ascend to altitude soon after a dive increase their risk of developing DCS even if the dive itself was within the dive table safe limits. Dive tables make provisions for post-dive time at surface level before flying to allow any residual excess nitrogen to outgas. However, the pressure maintained inside even a pressurized aircraft may be as low as the pressure equivalent to an altitude of 2,400 m (7,900 ft) above sea level. Therefore, the assumption that the dive table surface interval occurs at normal atmospheric pressure is invalidated by flying during that surface interval, and an otherwise-safe dive may then exceed the dive table limits.
● Diving before travelling to altitude – DCS can occur without flying if the person moves to a high-altitude location on land immediately after diving, for example, scuba divers in Eritrea who drive from the coast to the Asmara plateau at 2,400 m (7,900 ft) increase their risk of DCS.
● Diving at altitude – diving in water whose surface altitude is above 300 m (980 ft) — for example, Lake Titicaca is at 3,800 m (12,500 ft) — without using versions of decompression tables or dive computers that are modified for high-altitude.

INJURY Air & Atmosphere Decompression Sickness Predisposing Factors

Individual
The following individual factors have been identified as possibly contributing to increased risk of DCS:
● Dehydration – Studies by Walder concluded that decompression sickness could be reduced in aviators when the serum surface tension was raised by drinking isotonic saline, and the high surface tension of water is generally regarded as helpful in controlling bubble size. Maintaining proper hydration is recommended.
● Patent foramen ovale – a hole between the atrial chambers of the heart in the fetus is normally closed by a flap with the first breaths at birth. In about 20% of adults the flap does not completely seal, however, allowing blood through the hole when coughing or during activities that raise chest pressure. In diving, this can allow venous blood with microbubbles of inert gas to bypass the lungs, where the bubbles would otherwise be filtered out by the lung capillary system, and return directly to the arterial system (including arteries to the brain, spinal cord and heart). In the arterial system, bubbles (arterial gas embolism) are far more dangerous because they block circulation and cause infarction (tissue death, due to local loss of blood flow). In the brain, infarction results in stroke, and in the spinal cord it may result in paralysis.
● A person's age – there are some reports indicating a higher risk of altitude DCS with increasing age.

● Previous injury – there is some indication that recent joint or limb injuries may predispose individuals to developing decompression-related bubbles.
● Ambient temperature – there is some evidence suggesting that individual exposure to very cold ambient temperatures may increase the risk of altitude DCS. Decompression sickness risk can be reduced by increased ambient temperature during decompression following dives in cold water.
● Body type – typically, a person who has a high body fat content is at greater risk of DCS. This is due to nitrogen's five times greater solubility in fat than in water, leading to greater amounts of total body dissolved nitrogen during time at pressure. Fat represents about 15–25 percent of a healthy adult's body, but stores about half of the total amount of nitrogen (about 1 litre) at normal pressures.
● Alcohol consumption – although alcohol consumption increases dehydration and therefore may increase susceptibility to DCS, a 2005 study found no evidence that alcohol consumption increases the incidence of DCS.

Diagnosis

INJURY Air & Atmosphere Decompression Sickness Diagnosis

Decompression sickness should be suspected if any of the symptoms associated with the condition occurs following a drop in pressure, in particular, within 24 hours of diving. In 1995, 95% of all cases reported to Divers Alert Network had shown symptoms within 24 hours. This window can be extended to 36 hours for ascent to altitude and 48 hours for prolonged exposure to altitude following diving. An alternative diagnosis should be suspected if severe symptoms begin more than six hours following decompression without an altitude exposure or if any symptom occurs more than 24 hours after surfacing. The diagnosis is confirmed if the symptoms are relieved by recompression. Although MRI or CT can frequently identify bubbles in DCS, they are not as good at determining the diagnosis as a proper history of the event and description of the symptoms.

Symptoms of DCS and arterial gas embolism can be virtually indistinguishable. The most reliable way to tell the difference is based on the dive profile followed, as the probability of DCS depends on duration of exposure and magnitude of pressure, whereas AGE depends entirely on the performance of the ascent. In many cases it is not possible to distinguish between the two, but as the treatment is the same in such cases it does not usually matter.

Other conditions which may be confused with DCS include skin symptoms cutis marmorata due to DCS and skin barotrauma due to dry suit squeeze, for which no treatment is necessary. Dry suit squeeze produces lines of redness with possible bruising where the skin was pinched between folds of the suit, while the mottled effect of cutis marmorata is usually on skin where there is subcutaneous fat, and has no linear pattern.

Transient episodes of severe neurological incapacitation with rapid spontaneous recovery shortly after a dive may be attributed to hypothermia, but may be symptomatic of short term CNS involvement, which may have residual problems or relapses. These cases are thought to be under-diagnosed.

Inner ear DCS can be confused with alternobaric vertigo and reverse squeeze. The history of difficulty in equalising during the dive makes ear barotrauma more likely, but does not always eliminate the possibility of inner ear DCS, which is associated with deep, mixed gas dives with decompression stops. Numbness and tingling are associated with spinal DCS, but can also be caused by pressure on nerves (compression neurapraxia). In DCS the numbness or tingling is generally confined to one or a series of dermatomes, while pressure on a nerve tends to produce characteristic areas of numbness associated with the specific nerve on only one side of the body distal to the pressure point. A loss of strength or function is likely to be a medical emergency. A loss of feeling that lasts more than a minute or two indicates a need for immediate medical attention. It is only partial sensory changes, or paraesthesias, where this distinction between trivial and more serious injuries applies.

Large areas of numbness with associated weakness or paralysis, especially if a whole limb is affected, are indicative of probable brain involvement and require urgent medical attention. Paraesthesias or weakness involving a dermatome indicate probable spinal cord or spinal nerve root involvement. Although it is possible that this may have other causes, such as an injured intervertebral disk, these symptoms indicate an urgent need for medical assessment. In combination with weakness, paralysis or loss of bowel or bladder control, they indicate a medical emergency.

Prevention

Underwater Diving

To prevent the excess formation of bubbles that can lead to decompression sickness, divers limit their ascent rate—the recommended ascent rate used by popular decompression models is about 10 metres (33 ft) per minute—and carry out a decompression schedule as necessary. This schedule requires the diver to ascend to a particular depth, and remain at that depth until sufficient gas has been eliminated from the body to allow further ascent. Each of these is termed a "decompression stop", and a schedule for a given bottom time and depth may contain one or more stops, or none at all. Dives that contain no decompression stops are called "no-stop dives", but divers usually schedule a short "safety stop" at 3 m (10 ft), 4.6 m (15 ft), or 6 m (20 ft), depending on the training agency.

The decompression schedule may be derived from decompression tables, decompression software, or from dive computers, and these are commonly based upon a mathematical model of the body's uptake and release of inert gas as pressure changes. These models, such as the Bühlmann decompression algorithm, are designed to fit empirical data and provide a decompression schedule for a given depth and dive duration.

Since divers on the surface after a dive still have excess inert gas in their bodies, decompression from any subsequent dive before this excess is fully eliminated needs to modify the schedule to take account of the residual gas load from the previous dive. This will result in a shorter allowable time under water without obligatory decompression stops, or an increased decompression time during the subsequent dive. The total elimination of excess gas may take many hours, and tables will indicate the time at normal pressures that is required, which may be up to 18 hours.

Decompression time can be significantly shortened by breathing mixtures containing much less inert gas during the decompression phase of the dive (or pure oxygen at stops in 6 metres (20 ft) of water or less). The reason is that the inert gas outgases at a rate proportional to the difference between the partial pressure of inert gas in the diver's body and its partial pressure in the breathing gas; whereas the likelihood of bubble formation depends on the difference between the inert gas partial pressure in the diver's body and the ambient pressure. Reduction in decompression requirements can also be gained by breathing a nitrox mix during the dive, since less nitrogen will be taken into the body than during the same dive done on air.

Following a decompression schedule does not completely protect against DCS. The algorithms used are designed to reduce the probability of DCS to a very low level, but do not reduce it to zero. The mathematical implications of all current decompression models are that provided that no tissue is ingassing, longer decompression stops will decrease decompression risk, or at worst not increase it.

Exposure to Altitude

One of the most significant breakthroughs in the prevention of altitude DCS is oxygen pre-breathing. Breathing pure oxygen significantly reduces the nitrogen loads in body tissues by reducing the partial pressure of nitrogen in the lungs, which induces diffusion of nitrogen from the blood into the breathing gas, and this effect eventually lowers the concentration of nitrogen in the other tissues of the body. If continued for long enough, and without interruption, this provides effective protection upon exposure to low-barometric pressure environments. However, breathing pure oxygen during flight alone (ascent, en route, descent) does not decrease the risk of altitude DCS as the time required for ascent is generally not sufficient to significantly desaturate the slower tissues.

Pure aviator oxygen which has moisture removed to prevent freezing of valves at altitude is readily available and routinely used in general aviation mountain flying and at high altitudes. Most small general aviation aircraft are not pressurized, therefore oxygen use is an FAA requirement at higher altitudes.

Although pure oxygen pre-breathing is an effective method to protect against altitude DCS, it is logistically complicated and expensive for the protection of civil aviation flyers, either commercial or private. Therefore, it is currently used only by military flight crews and astronauts for protection during high-altitude and space operations. It is also used by flight test crews involved with certifying aircraft, and may also be used for high-altitude parachute jumps.

Astronauts aboard the International Space Station preparing for extra-vehicular activity (EVA) "camp out" at low atmospheric pressure, 10.2 psi (0.70 bar), spending eight sleeping hours in the Quest airlock chamber before their spacewalk. During the EVA they breathe 100% oxygen in their spacesuits, which operate at 4.3 psi (0.30 bar), although research has examined the possibility of using 100% O_2 at 9.5 psi (0.66 bar) in the suits to lessen the pressure reduction, and hence the risk of DCS.

Treatment

All cases of decompression sickness should be treated initially with 100% oxygen until hyperbaric oxygen therapy (100% oxygen delivered in a high-pressure chamber) can be provided. Mild cases of the "bends" and some skin symptoms may disappear during descent from high altitude; however, it is recommended that these cases still be evaluated. Neurological symptoms, pulmonary symptoms, and mottled or marbled skin lesions should be treated with hyperbaric oxygen therapy if seen within 10 to 14 days of development.

Recompression on air was shown to be an effective treatment for minor DCS symptoms by Keays in 1909. Evidence of the effectiveness of recompression therapy utilizing oxygen was first shown by Yarbrough and Behnke, and has since become the standard of care for treatment of DCS. Recompression is normally carried out in a recompression chamber. At a dive site, a riskier alternative is in-water recompression.

Oxygen first aid has been used as an emergency treatment for diving injuries for years. If given within the first four hours of surfacing, it increases the success of recompression therapy as well as decreasing the number of recompression treatments required. Most fully closed-circuit rebreathers can deliver sustained high concentrations of oxygen-rich breathing gas and could be used as a means of supplying oxygen if dedicated equipment is not available.

It is beneficial to give fluids, as this helps reduce dehydration. It is no longer recommended to administer aspirin, unless advised to do so by medical personnel, as analgesics may mask symptoms. People should be made comfortable and placed in the supine position (horizontal), or the recovery position if vomiting occurs. In the past, both the Trendelenburg position and the left lateral decubitus position (Durant's maneuver) have been suggested as beneficial where air emboli are suspected, but are no longer recommended for extended periods, owing to concerns regarding cerebral edema.

Treatment

The duration of recompression treatment depends on the severity of symptoms, the dive history, the type of recompression therapy used and the patient's response to the treatment. One of the more frequently used treatment schedules is the US Navy Table 6, which provides hyperbaric oxygen therapy with a maximum pressure equivalent to 60 feet (18 m) of seawater for a total time under pressure of 288 minutes, of which 240 minutes are on oxygen and the balance are air breaks to minimise the possibility of oxygen toxicity.

A multiplace chamber is the preferred facility for treatment of decompression sickness as it allows direct physical access to the patient by medical personnel, but monoplace chambers are more widely available and should be used for treatment if a multiplace chamber is not available or transportation would cause significant delay in treatment, as the interval between onset of symptoms and recompression is important to the quality of recovery. It may be necessary to modify the optimum treatment schedule to allow use of a monoplace chamber, but this is usually better than delaying treatment. A US Navy treatment table 5 can be safely performed without air breaks if a built-in breathing system is not available. In most cases the patient can be adequately treated in a monoplace chamber at the receiving hospital.

Prognosis

Immediate treatment with 100% oxygen, followed by recompression in a hyperbaric chamber, will in most cases result in no long-term effects. However, permanent long-term injury from DCS is possible. Three-month follow-ups on diving accidents reported to DAN in 1987 showed 14.3% of the 268 divers surveyed had ongoing symptoms of Type II DCS, and 7% from Type I DCS. Long-term follow-ups showed similar results, with 16% having permanent neurological sequelae.

Long term effects are dependent on both initial injury, and treatment. While almost all cases will resolve more quickly with treatment, milder cases may resolve adequately over time without recompression, where the damage is minor and the damage is not significantly aggravated by lack of treatment. In some cases the cost, inconvenience, and risk to the patient may make it appropriate not to evacuate to a hyperbaric treatment facility. These cases should be assessed by a specialist in diving medicine, which can generally be done remotely by telephone or internet.

For joint pain, the likely tissues affected depend on the symptoms, and the urgency of hyperbaric treatment will depend largely on the tissues involved.

- Sharp, localised pain that is affected by movement suggests tendon or muscle injury, both of which will usually fully resolve with oxygen and anti-inflammatory medication.
- Sharp, localised pain that is not affected by movement suggests local inflammation, which will also usually fully resolve with oxygen and anti-inflammatory medication.
- Deep, non-localised pain affected by movement suggests joint capsule tension, which is likely to fully resolve with oxygen and anti-inflammatory medication, though recompression will help it to resolve faster.
- Deep, non-localised pain not affected by movement suggests bone medulla involvement, with ischaemia due to blood vessel blockage and swelling inside the bone, which is mechanistically associated with osteonecrosis, and therefore it has been strongly recommended that these symptoms are treated with hyperbaric oxygen.

7 Dysbaric Osteonecrosis

Dysbaric osteonecrosis or DON is a form of avascular necrosis where there is death of a portion of the bone that is thought to be caused by nitrogen embolism (blockage of the blood vessels by a bubble of nitrogen coming out of solution) in divers.

Signs & Symptoms

The lesion begins as a localised area of infarction, usually without symptoms. Early identification of lesions by radiography is not possible, but over time areas of radiographic opacity develop in association with the damaged bone. Symptomatic lesions usually involve joint surfaces, and fracture where attempted healing occurs. This process takes place over months to years and eventually causes disabling arthritis, particularly of the femoral head (hip).

Dysbaric osteonecrosis lesions are typically bilateral and usually occur at both ends of the femur and at the proximal end of the humerus Symptoms are usually only present when a joint surface is involved, which typically does not occur until a long time after the causative exposure to a hyperbaric environment. The initial damage is attributed to the formation of bubbles, and one episode can be sufficient, however incidence is sporadic and generally associated with relatively long periods of hyperbaric exposure and aetiology is uncertain.

Causes

Although the definitive pathologic process is poorly understood, there are several hypotheses:
- Intra- or extravascular nitrogen in bones, "nitrogen embolism".
- Osmotic gas effects due to intramedullary pressure effects.
- Fat embolism
- Hemoconcentration and increased coagulability.

Diagnosis

The diagnosis is made by x-ray/MRI appearance and has five juxta-articular classifications and forehead, neck, and shaft classifications indicating early radiological signs.

Early on there is flattening of articular surfaces, thinning of cartilage with osteophyte (spur) formation. In juxta-articular lesions without symptoms, there is dead bone and marrow separated from living bone by a line of dense collagen. Microscopic cysts form, fill with necrotic material and there is massive necrosis with replacement by cancellous bone with collapse of the lesions.

The following staging system is sometimes useful when managing lesions.
- Stage 0 - Intravascular coagulation
- Stage 1 - Dead Bone without repair
- Stage 2 - Dead Bone with repair but without collapse
- Stage 3 - Dead Bone with repair and with collapse
- Stage 4 - Secondary degenerative arthritis

In a study of bone lesions in 281 compressed air workers done by Walder in 1969, 29% of the lesions were in the humeral head (shoulder), 16% in the femoral head (hip), 40% in the lower end of the femur (lower thigh at the knee) and 15% in the upper tibia (knee below the knee cap).

Worsening of the condition from continued decompression in an asymptomatic x-ray finding may occur.

Prevention

Prevention is a more successful strategy than treatment. By using the most conservative decompression schedule reasonably practicable, and by minimizing the number of major decompression exposures, the risk of DON may be reduced. Prompt treatment of any symptoms of decompression sickness (DCS) with recompression and hyperbaric oxygen also reduce the risk of subsequent DON.

Treatment

Treatment is difficult, often requiring a joint replacement. Spontaneous improvement occasionally happens and some juxta-articular lesions do not progress to collapse. Other treatments include immobilization and osteotomy of the femur.

Prognosis

If the diver has not been exposed to excessive depth and decompression and presents as DON, there may be a predisposition for the condition. Diving should be restricted to shallow depths. Divers who have suffered from DON are at increased risk of future fracture of a juxta-articular lesion during a dive, and may face complications with future joint replacements. Because of the young age of the population normally affected, little data is available regarding joint replacement complications.

There is the potential for worsening of DON for any diving where there might be a need for decompression, experimental or helium diving. Physically stressful diving should probably be restricted, both in sport diving and work diving due to the possibility of unnecessary stress to the joint. Any diving should be less than 40 feet/12 meters. These risks are affected by the degree of disability and by the type of lesion (juxta-articular or shaft).

8 High Pressure Nervous Syndrome

High-pressure nervous syndrome (HPNS – also known as high-pressure neurological syndrome) is a neurological and physiological diving disorder that results when a diver descends below about 500 feet (150 m) using a breathing gas containing helium.

Signs & Symptoms

Symptoms of HPNS include tremors, myoclonic jerking, somnolence, EEG changes, visual disturbance, nausea, dizziness, and decreased mental performance.

Causes

HPNS has two components, one resulting from the speed of compression and the other from the absolute pressure. The compression effects may occur when descending below 500 feet (150 m) at rates greater than a few metres per minute, but reduce within a few hours once the pressure has stabilised. The effects from depth become significant at depths exceeding 1,000 feet (300 m) and remain regardless of the time spent at that depth. All of the effects are completely reversible on ascent to shallower depths. The susceptibility of divers and animals to HPNS varies over a wide range depending on the individual, but has little variation between different dives by the same diver.

The effect of dissolved helium on an embedded trans-membrane channel has also been studied by molecular modeling tools. Those suggest that helium might cause substantial lipid membrane distortion. The high hydrostatic pressure itself has a less damaging influence on the membrane, reducing molecular volumes, but leaving the molecular boundary intact.

Diagnosis

Prevention

It is likely that HPNS cannot be entirely prevented but there are effective methods to delay or change the development of the symptoms. Utilizing slow rates of compression or adding stops to the compression have been found to prevent large initial decrements in performance.

Including other gases in the helium–oxygen mixture, such as nitrogen (creating trimix) or hydrogen (producing hydreliox) suppresses the neurological effects. Alcohol, anesthetics and anticonvulsant drugs have had varying results in suppressing HPNS with animals. None are currently in use for humans.

Treatment

9 Nitrogen Narcosis

Narcosis while diving (also known as nitrogen narcosis, inert gas narcosis, raptures of the deep, Martini effect) is a reversible alteration in consciousness that occurs while diving at depth. It is caused by the anesthetic effect of certain gases at high pressure. Narcosis produces a state similar to drunkenness (alcohol intoxication), or nitrous oxide inhalation. It can occur during shallow dives, but does not usually become noticeable at depths less than 30 meters (100 ft).

Signs & Symptoms

Due to its perception-altering effects, the onset of narcosis may be hard to recognize. At its most benign, narcosis results in relief of anxiety – a feeling of tranquility and mastery of the environment. These effects are essentially identical to various concentrations of nitrous oxide. They also resemble (though not as closely) the effects of alcohol or cannabis and the familiar benzodiazepine drugs such as diazepam and alprazolam. Such effects are not harmful unless they cause some immediate danger to go unrecognized and unaddressed. Once stabilized, the effects generally remain the same at a given depth, only worsening if the diver ventures deeper.

The most dangerous aspects of narcosis are the impairment of judgement, multi-tasking and coordination, and the loss of decision-making ability and focus. Other effects include vertigo and visual or auditory disturbances. The syndrome may cause exhilaration, giddiness, extreme anxiety, depression, or paranoia, depending on the individual diver and the diver's medical or personal history. When more serious, the diver may feel overconfident, disregarding normal safe diving practices.

Slowed mental activity, as indicated by increased reaction time and increased errors in cognitive function, are effects which increase the risk of a diver mismanaging an incident. Narcosis reduces both the perception of cold discomfort and shivering and thereby affects the production of body heat and consequently allows a faster drop in the core temperature in cold water, with reduced awareness of the developing problem.

The relation of depth to narcosis is sometimes informally known as "Martini's law", the idea that narcosis results in the feeling of one martini for every 10 m (33 ft) below 20 m (66 ft) depth. Professional divers use such a calculation only as a rough guide to give new divers a metaphor, comparing a situation they may be more familiar with. Reported signs and symptoms are summarized against typical depths in meters and feet of sea water in the following table, closely adapted from Deeper into Diving by Lippman and Mitchell:

Pressure (bar)	Depth (m)	Depth (ft)	Comments
1–2	0–10	0–33	• Unnoticeable minor symptoms, or no symptoms at all
2–4	10–30	33–100	• Mild impairment of performance of unpracticed tasks • Mildly impaired reasoning • Mild euphoria possible
4–6	30–50	100–165	• Delayed response to visual and auditory stimuli • Reasoning and immediate memory affected more than motor coordination • Calculation errors and wrong choices • Idea fixation • Over-confidence and sense of well-being • Laughter and loquacity (in chambers) which may be overcome by self-control • Anxiety (common in cold murky water)
6–8	50–70	165–230	• Sleepiness, impaired judgment, confusion • Hallucinations • Severe delay in response to signals, instructions and other stimuli • Occasional dizziness • Uncontrolled laughter, hysteria (in chamber) • Terror in some
8–10	70–90	230–300	• Poor concentration and mental confusion • Stupefaction with some decrease in dexterity and judgment • Loss of memory, increased excitability
10+	90+	300+	• Hallucinations • Increased intensity of vision and hearing • Sense of impending blackout or of levitation • Dizziness, euphoria, manic or depressive states • Disorganization of the sense of time, changes in facial appearance • Unconsciousness, (approximate inspired partial pressure of nitrogen for anaesthesia is 33 atm) • Death

Causes

The cause of narcosis is related to the increased solubility of gases in body tissues, as a result of the elevated pressures at depth (Henry's law). Modern theories have suggested that inert gases dissolving in the lipid bilayer of cell membranes cause narcosis. More recently, researchers have been looking at neurotransmitter receptor protein mechanisms as a possible cause of narcosis. The breathing gas mix entering the diver's lungs will have the same pressure as the surrounding water, known as the ambient pressure. After any change of depth, the pressure of gases in the blood passing through the brain catches up with ambient pressure within a minute or two, which results in a delayed narcotic effect after descending to a new depth. Rapid compression potentiates narcosis owing to carbon dioxide retention.

A divers' cognition may be affected on dives as shallow as 10 m (33 ft), but the changes are not usually noticeable. There is no reliable method to predict the depth at which narcosis becomes noticeable, or the severity of the effect on an individual diver, as it may vary from dive to dive even on the same day.

Significant impairment due to narcosis is an increasing risk below depths of about 30 m (100 ft), corresponding to an ambient pressure of about 4 bar (400 kPa). Most sport scuba training organizations recommend depths of no more than 40 m (130 ft) because of the risk of narcosis. When breathing air at depths of 90 m (300 ft) – an ambient pressure of about 10 bar (1,000 kPa) – narcosis in most divers leads to hallucinations, loss of memory, and unconsciousness. A number of divers have died in attempts to set air depth records below 120 m (400 ft). Because of these incidents, Guinness World Records no longer reports on this figure.

Narcosis has been compared with altitude sickness regarding its variability of onset (though not its symptoms); its effects depend on many factors, with variations between individuals. Thermal cold, stress, heavy work, fatigue, and carbon dioxide retention all increase the risk and severity of narcosis. Carbon dioxide has a high narcotic potential and also causes increased blood flow to the brain, increasing the effects of other gases. Increased risk of narcosis results from increasing the amount of carbon dioxide retained through heavy exercise, shallow or skip breathing, or because of poor gas exchange in the lungs.

Narcosis is known to be additive to even minimal alcohol intoxication. Other sedative and analgesic drugs, such as opiate narcotics and benzodiazepines, add to narcosis.

Diagnosis

Prevention

The most straightforward way to avoid nitrogen narcosis is for a diver to limit the depth of dives. Since narcosis becomes more severe as depth increases, a diver keeping to shallower depths can avoid serious narcosis. Most recreational dive schools will only certify basic divers to depths of 18 m (60 ft), and at these depths narcosis does not present a significant risk. Further training is normally required for certification up to 30 m (100 ft) on air, and this training should include a discussion of narcosis, its effects, and cure. Some diver training agencies offer specialized training to prepare recreational divers to go to depths of 40 m (130 ft), often consisting of further theory and some practice in deep dives under close supervision.

Scuba organizations that train for diving beyond recreational depths, may forbid diving with gases that cause too much narcosis at depth in the average diver, and strongly encourage the use of other breathing gas mixes containing helium in place of some or all of the nitrogen in air – such as trimix and heliox – because helium has no narcotic effect. The use of these gases forms part of technical diving and requires further training and certification.

While the individual diver cannot predict exactly at what depth the onset of narcosis will occur on a given day, the first symptoms of narcosis for any given diver are often more predictable and personal. For example, one diver may have trouble with eye focus (close accommodation for middle-aged divers), another may experience feelings of euphoria, and another feelings of claustrophobia. Some divers report that they have hearing changes, and that the sound their exhaled bubbles make becomes different. Specialist training may help divers to identify these personal onset signs, which may then be used as a signal to ascend to avoid the narcosis, although severe narcosis may interfere with the judgement necessary to take preventive action.

Deep dives should be made only after a gradual training to test the individual diver's sensitivity to increasing depths, with careful supervision and logging of reactions. Scientific evidence does not show that a diver can train to overcome any measure of narcosis at a given depth or become tolerant of it.

Treatment

Narcosis may be completely reversed in a few minutes by ascending to a shallower depth, with no long-term effects. Thus narcosis while diving in open water rarely develops into a serious problem as long as the divers are aware of its symptoms, and are able to ascend to manage it. Diving much beyond 40 m (130 ft) is generally considered outside the scope of recreational diving.

10 Oxygen Toxicity

Oxygen toxicity is a condition resulting from the harmful effects of breathing molecular oxygen (O2) at increased partial pressures. It is also known as oxygen toxicity syndrome, oxygen intoxication, and oxygen poisoning. Severe cases can result in cell damage and death, with effects most often seen in the central nervous system, lungs, and eyes. Historically, the central nervous system condition was called the Paul Bert effect, and the pulmonary condition the Lorrain Smith effect, after the researchers who pioneered the discoveries and descriptions in the late 19th century. Oxygen toxicity is a concern for underwater divers, those on high concentrations of supplemental oxygen (particularly premature babies), and those undergoing hyperbaric oxygen therapy.

Signs & Symptoms

Central Nervous System
Central nervous system oxygen toxicity manifests as symptoms such as visual changes (especially tunnel vision), ringing in the ears (tinnitus), nausea, twitching (especially of the face), behavioural changes (irritability, anxiety, confusion), and dizziness. This may be followed by a tonic–clonic seizure consisting of two phases: intense muscle contraction occurs for several seconds (tonic phase); followed by rapid spasms of alternate muscle relaxation and contraction producing convulsive jerking (clonic phase). The seizure ends with a period of unconsciousness (the postictal state). The onset of seizure depends upon the partial pressure of oxygen in the breathing gas and exposure duration. However, exposure time before onset is unpredictable, as tests have shown a wide variation, both amongst individuals, and in the same individual from day to day. In addition, many external factors, such as underwater immersion, exposure to cold, and exercise will decrease the time to onset of central nervous system symptoms. Decrease of tolerance is closely linked to retention of carbon dioxide. Other factors, such as darkness and caffeine, increase tolerance in test animals, but these effects have not been proven in humans.

Lungs
Pulmonary toxicity symptoms result from an inflammation that starts in the airways leading to the lungs and then spreads into the lungs (tracheobronchial tree). The symptoms appear in the upper chest region (substernal and carinal regions). This begins as a mild tickle on inhalation and progresses to frequent coughing. If breathing increased partial pressures of oxygen continues, patients experience a mild burning on inhalation along with uncontrollable coughing and occasional shortness of breath (dyspnoea). Physical findings related to pulmonary toxicity have included bubbling sounds heard through a stethoscope (bubbling rales), fever, and increased blood flow to the lining of the nose (hyperaemia of the nasal mucosa). X-rays of the lungs show little change in the short term, but extended exposure leads to increasing diffuse shadowing throughout both lungs. Pulmonary function measurements are reduced, as noted by a reduction in the amount of air that the lungs can hold (vital capacity) and changes in expiratory function and lung elasticity. Tests in animals have indicated a variation in tolerance similar to that found in central nervous system toxicity, as well as significant variations between species. When the exposure to oxygen above 0.5 bar (50 kPa) is intermittent, it permits the lungs to recover and delays the onset of toxicity.

Eyes
In premature babies, signs of damage to the eye (retinopathy of prematurity, or ROP) are observed via an ophthalmoscope as a demarcation between the vascularised and non-vascularised regions of an infant's retina. The degree of this demarcation is used to designate four stages: (I) the demarcation is a line; (II) the demarcation becomes a ridge; (III) growth of new blood vessels occurs around the ridge; (IV) the retina begins to detach from the inner wall of the eye (choroid).

Oxygen poisoning at 90 feet (27 m) in the dry in 36 subjects in order of performance

Exposure (mins.)	Num. of subjects	Symptoms
96	1	Prolonged dazzle; severe spasmodic vomiting
60–69	3	Severe lip-twitching; Euphoria; Nausea and vertigo; arm twitch
50–55	4	Severe lip-twitching; Dazzle; Blubbering of lips; fell asleep; Dazed
31–35	4	Nausea, vertigo, lip-twitching; Convulsed
21–30	6	Convulsed; Drowsiness; Severe lip-twitching; epigastric aura; twitch L arm; amnesia
16–20	8	Convulsed; Vertigo and severe lip twitching; epigastric aura; spasmodic respiration;
11–15	4	Inspiratory predominance; lip-twitching and syncope; Nausea and confusion
6–10	6	Dazed and lip-twitching; paraesthesiae; vertigo; "Diaphragmatic spasm"; Severe nausea

Causes

Oxygen toxicity is caused by exposure to oxygen at partial pressures greater than those to which the body is normally exposed. This occurs in three principal settings: underwater diving, hyperbaric oxygen therapy, and the provision of supplemental oxygen, particularly to premature infants. In each case, the risk factors are markedly different.

Central Nervous System Toxicity
Exposures, from minutes to a few hours, to partial pressures of oxygen above 1.6 bars (160 kPa)—about eight times normal atmospheric partial pressure—are usually associated with central nervous system oxygen toxicity and are most likely to occur among patients undergoing hyperbaric oxygen therapy and divers. Since sea level atmospheric pressure is about 1 bar (100 kPa), central nervous system toxicity can only occur under hyperbaric conditions, where ambient pressure is above normal. Divers breathing air at depths beyond 60 m (200 ft) face an increasing risk of an oxygen toxicity "hit" (seizure). Divers breathing a gas mixture enriched with oxygen, such as nitrox, can similarly suffer a seizure at shallower depths, should they descend below the maximum operating depth allowed for the mixture.

INJURY Atmosphere & Air Oxygen Toxicity Causes

Lung Toxicity
The lungs and the remainder of the respiratory tract are exposed to the highest concentration of oxygen in the human body and are therefore the first organs to show toxicity. Pulmonary toxicity occurs only with exposure to partial pressures of oxygen greater than 0.5 bar (50 kPa), corresponding to an oxygen fraction of 50% at normal atmospheric pressure.

The earliest signs of pulmonary toxicity begin with evidence of tracheobronchitis, or inflammation of the upper airways, after an asymptomatic period between 4 and 22 hours at greater than 95% oxygen, with some studies suggesting symptoms usually begin after approximately 14 hours at this level of oxygen.

At partial pressures of oxygen of 2 to 3 bar (200 to 300 kPa)—100% oxygen at 2 to 3 times atmospheric pressure—these symptoms may begin as early as 3 hours after exposure to oxygen. Experiments on rats breathing oxygen at pressures between 1 and 3 bars (100 and 300 kPa) suggest that pulmonary manifestations of oxygen toxicity may not be the same for normobaric conditions as they are for hyperbaric conditions.

Evidence of decline in lung function as measured by pulmonary function testing can occur as quickly as 24 hours of continuous exposure to 100% oxygen, with evidence of diffuse alveolar damage and the onset of acute respiratory distress syndrome usually occurring after 48 hours on 100% oxygen. Breathing 100% oxygen also eventually leads to collapse of the alveoli (atelectasis), while—at the same partial pressure of oxygen—the presence of significant partial pressures of inert gases, typically nitrogen, will prevent this effect.

Preterm newborns are known to be at higher risk for bronchopulmonary dysplasia with extended exposure to high concentrations of oxygen. Other groups at higher risk for oxygen toxicity are patients on mechanical ventilation with exposure to levels of oxygen greater than 50%, and patients exposed to chemicals that increase risk for oxygen toxicity such the chemotherapeutic agent bleomycin. Therefore, current guidelines for patients on mechanical ventilation in intensive care recommends keeping oxygen concentration less than 60%. Likewise, divers who undergo treatment of decompression sickness are at increased risk of oxygen toxicity as treatment entails exposure to long periods of oxygen breathing under hyperbaric conditions, in addition to any oxygen exposure during the dive.

Ocular Toxicity
Prolonged exposure to high inspired fractions of oxygen causes damage to the retina. Damage to the developing eye of infants exposed to high oxygen fraction at normal pressure has a different mechanism and effect from the eye damage experienced by adult divers under hyperbaric conditions. Hyperoxia may be a contributing factor for the disorder called retrolental fibroplasia or retinopathy of prematurity (ROP) in infants. In preterm infants, the retina is often not fully vascularised. Retinopathy of prematurity occurs when the development of the retinal vasculature is arrested and then proceeds abnormally. Associated with the growth of these new vessels is fibrous tissue (scar tissue) that may contract to cause retinal detachment. Supplemental oxygen exposure, while a risk factor, is not the main risk factor for development of this disease. Restricting supplemental oxygen use does not necessarily reduce the rate of retinopathy of prematurity, and may raise the risk of hypoxia-related systemic complications.

Hyperoxic myopia has occurred in closed circuit oxygen rebreather divers with prolonged exposures. It also occurs frequently in those undergoing repeated hyperbaric oxygen therapy. This is due to an increase in the refractive power of the lens, since axial length and keratometry readings do not reveal a corneal or length basis for a myopic shift. It is usually reversible with time.

Diagnosis

Diagnosis of central nervous system oxygen toxicity in divers prior to seizure is difficult as the symptoms of visual disturbance, ear problems, dizziness, confusion and nausea can be due to many factors common to the underwater environment such as narcosis, congestion and coldness. However, these symptoms may be helpful in diagnosing the first stages of oxygen toxicity in patients undergoing hyperbaric oxygen therapy. In either case, unless there is a prior history of epilepsy or tests indicate hypoglycaemia, a seizure occurring in the setting of breathing oxygen at partial pressures greater than 1.4 bar (140 kPa) suggests a diagnosis of oxygen toxicity.

Prevention

The prevention of oxygen toxicity depends entirely on the setting. Both underwater and in space, proper precautions can eliminate the most pernicious effects. Premature infants commonly require supplemental oxygen to treat complications of preterm birth. In this case prevention of bronchopulmonary dysplasia and retinopathy of prematurity must be carried out without compromising a supply of oxygen adequate to preserve the infant's life.

Underwater
Oxygen toxicity is a catastrophic hazard in diving, because a seizure results in near certain death by drowning. The seizure may occur suddenly and with no warning symptoms. The effects are sudden convulsions and unconsciousness, during which victims can lose their regulator and drown. One of the advantages of a full-face diving mask is prevention of regulator loss in the event of a seizure. As there is an increased risk of central nervous system oxygen toxicity on deep dives, long dives and dives where oxygen-rich breathing gases are used, divers are taught to calculate a maximum operating depth for oxygen-rich breathing gases, and cylinders containing such mixtures must be clearly marked with that depth.

In some diver training courses for these types of diving, divers are taught to plan and monitor what is called the oxygen clock of their dives. This is a notional alarm clock, which ticks more quickly at increased oxygen pressure and is set to activate at the maximum single exposure limit recommended in the National Oceanic and Atmospheric Administration Diving Manual.

For the following partial pressures of oxygen the limits are: 45 minutes at 1.6 bar (160 kPa), 120 minutes at 1.5 bar (150 kPa), 150 minutes at 1.4 bar (140 kPa), 180 minutes at 1.3 bar (130 kPa) and 210 minutes at 1.2 bar (120 kPa), but it is impossible to predict with any reliability whether or when toxicity symptoms will occur. Many nitrox-capable dive computers calculate an oxygen loading and can track it across multiple dives.

The aim is to avoid activating the alarm by reducing the partial pressure of oxygen in the breathing gas or by reducing the time spent breathing gas of greater oxygen partial pressure. As the partial pressure of oxygen increases with the fraction of oxygen in the breathing gas and the depth of the dive, the diver obtains more time on the oxygen clock by diving at a shallower depth, by breathing a less oxygen-rich gas, or by shortening the duration of exposure to oxygen-rich gases.

Diving below 56 m (184 ft) on air would expose a diver to increasing danger of oxygen toxicity as the partial pressure of oxygen exceeds 1.4 bar (140 kPa), so a gas mixture must be used which contains less than 21% oxygen (a hypoxic mixture). Increasing the proportion of nitrogen is not viable, since it would produce a strongly narcotic mixture. However, helium is not narcotic, and a usable mixture may be blended either by completely replacing nitrogen with helium (the resulting mix is called heliox), or by replacing part of the nitrogen with helium, producing a trimix.

Pulmonary oxygen toxicity is an entirely avoidable event while diving. The limited duration and naturally intermittent nature of most diving makes this a relatively rare (and even then, reversible) complication for divers. Established guidelines enable divers to calculate when they are at risk of pulmonary toxicity.

Treatment

INJURY Atmosphere & Air Oxygen Toxicity Treatment

During hyperbaric oxygen therapy, the patient will usually breathe 100% oxygen from a mask while inside a hyperbaric chamber pressurised with air to about 2.8 bar (280 kPa). Seizures during the therapy are managed by removing the mask from the patient, thereby dropping the partial pressure of oxygen inspired below 0.6 bar (60 kPa).

A seizure underwater requires that the diver be brought to the surface as soon as practicable. Although for many years the recommendation has been not to raise the diver during the seizure itself, owing to the danger of arterial gas embolism (AGE), there is some evidence that the glottis does not fully obstruct the airway. This has led to the current recommendation by the Diving Committee of the Undersea and Hyperbaric Medical Society that a diver should be raised during the seizure's clonic (convulsive) phase if the regulator is not in the diver's mouth – as the danger of drowning is then greater than that of AGE – but the ascent should be delayed until the end of the clonic phase otherwise. Rescuers ensure that their own safety is not compromised during the convulsive phase. They then ensure that where the victim's air supply is established it is maintained, and carry out a controlled buoyant lift. Lifting an unconscious body is taught by most diver training agencies.

Upon reaching the surface, emergency services are always contacted as there is a possibility of further complications requiring medical attention. The U.S. Navy has procedures for completing the decompression stops where a recompression chamber is not immediately available.

The occurrence of symptoms of bronchopulmonary dysplasia or acute respiratory distress syndrome is treated by lowering the fraction of oxygen administered, along with a reduction in the periods of exposure and an increase in the break periods where normal air is supplied. Where supplemental oxygen is required for treatment of another disease (particularly in infants), a ventilator may be needed to ensure that the lung tissue remains inflated. Reductions in pressure and exposure will be made progressively, and medications such as bronchodilators and pulmonary surfactants may be used.

Retinopathy of prematurity may regress spontaneously, but should the disease progress beyond a threshold (defined as five contiguous or eight cumulative hours of stage 3 retinopathy of prematurity), both cryosurgery and laser surgery have been shown to reduce the risk of blindness as an outcome. Where the disease has progressed further, techniques such as scleral buckling and vitrectomy surgery may assist in re-attaching the retina.

11 Hypoxia

Hypoxia is a condition in which the body or a region of the body is deprived of adequate oxygen supply at the tissue level. Hypoxia may be classified as either generalized, affecting the whole body, or local, affecting a region of the body.

Hypoxia differs from hypoxemia and anoxemia in that hypoxia refers to a state in which oxygen supply is insufficient, whereas hypoxemia and anoxemia refer specifically to states that have low or zero arterial oxygen supply. Hypoxia in which there is complete deprivation of oxygen supply is referred to as anoxia.

Generalized hypoxia occurs in healthy people when they ascend to high altitude, where it causes altitude sickness leading to potentially fatal complications: high altitude pulmonary edema (HAPE) and high altitude cerebral edema (HACE). Hypoxia also occurs in healthy individuals when breathing mixtures of gases with a low oxygen content, e.g. while diving underwater especially when using closed-circuit rebreather systems that control the amount of oxygen in the supplied air. Mild, non-damaging intermittent hypoxia is used intentionally during altitude training to develop an athletic performance adaptation at both the systemic and cellular level.

Hypoxia is a common complication of preterm birth in newborn infants. Because the lungs develop late in pregnancy, premature infants frequently possess underdeveloped lungs. To improve lung function, doctors frequently place infants at risk of hypoxia inside incubators (also known as humidicribs) that provide warmth, humidity, and oxygen. More serious cases are treated with continuous positive airway pressure.

Signs & Symptoms

Generalized Hypoxia
The symptoms of generalized hypoxia depend on its severity and acceleration of onset. In the case of altitude sickness, where hypoxia develops gradually, the symptoms include fatigue, numbness / tingling of extremities, nausea, and cerebral anoxia. These symptoms are often difficult to identify, but early detection of symptoms can be critical. In severe hypoxia, or hypoxia of very rapid onset, ataxia, confusion / disorientation / hallucinations / behavioral change, severe headaches / reduced level of consciousness, papilloedema, breathlessness, pallor, tachycardia, and pulmonary hypertension eventually leading to the late signs cyanosis, slow heart rate / cor pulmonale, and low blood pressure followed by heart failure eventually leading to shock and death.

Because hemoglobin is a darker red when it is not bound to oxygen (deoxyhemoglobin), as opposed to the rich red color that it has when bound to oxygen (oxyhemoglobin), when seen through the skin it has an increased tendency to reflect blue light back to the eye. In cases where the oxygen is displaced by another molecule, such as carbon monoxide, the skin may appear 'cherry red' instead of cyanotic. Hypoxia can cause premature birth, and injure the liver, among other deleterious effects.

Local Hypoxia
If tissue is not being perfused properly, it may feel cold and appear pale; if severe, hypoxia can result in cyanosis, a blue discoloration of the skin. If hypoxia is very severe, a tissue may eventually become gangrenous. Extreme pain may also be felt at or around the site.

Tissue hypoxia from low oxygen delivery may be due to low haemoglobin concentration (anaemic hypoxia), low cardiac output (stagnant hypoxia) or low haemoglobin saturation (hypoxic hypoxia). The consequence of oxygen deprivation in tissues is a switch to anaerobic metabolism at the cellular level. As such, reduced systemic blood flow may result in increased serum lactate. Serum lactate levels have been correlated with illness severity and mortality in critically ill adults and in ventilated neonates with respiratory distress.

Causes

Oxygen passively diffuses in the lung alveoli according to a pressure gradient. Oxygen diffuses from the breathed air, mixed with water vapour, to arterial blood, where its partial pressure is around 100 mmHg (13.3 kPa). In the blood, oxygen is bound to hemoglobin, a protein in red blood cells. The binding capacity of hemoglobin is influenced by the partial pressure of oxygen in the environment, as described in the oxygen–hemoglobin dissociation curve. A smaller amount of oxygen is transported in solution in the blood.

In peripheral tissues, oxygen again diffuses down a pressure gradient into cells and their mitochondria, where it is used to produce energy in conjunction with the breakdown of glucose, fats, and some amino acids.

Hypoxia can result from a failure at any stage in the delivery of oxygen to cells. This can include decreased partial pressures of oxygen, problems with diffusion of oxygen in the lungs, insufficient available hemoglobin, problems with blood flow to the end tissue, and problems with breathing rhythm.

Experimentally, oxygen diffusion becomes rate limiting (and lethal) when arterial oxygen partial pressure falls to 60 mmHg (5.3 kPa) or below.

Almost all the oxygen in the blood is bound to hemoglobin, so interfering with this carrier molecule limits oxygen delivery to the periphery. Hemoglobin increases the oxygen-carrying capacity of blood by about 40-fold, with the ability of hemoglobin to carry oxygen influenced by the partial pressure of oxygen in the environment, a relationship described in the oxygen–hemoglobin dissociation curve. When the ability of hemoglobin to carry oxygen is interfered with, a hypoxic state can result.

Ischemia
Ischemia, meaning insufficient blood flow to a tissue, can also result in hypoxia. This is called 'ischemic hypoxia'. This can include an embolic event, a heart attack that decreases overall blood flow, or trauma to a tissue that results in damage. An example of insufficient blood flow causing local hypoxia is gangrene that occurs in diabetes.

Diseases such as peripheral vascular disease can also result in local hypoxia. For this reason, symptoms are worse when a limb is used. Pain may also be felt as a result of increased hydrogen ions leading to a decrease in blood pH (acidity) created as a result of anaerobic metabolism.

Hypoxemic Hypoxia
This refers specifically to hypoxic states where the arterial content of oxygen is insufficient. This can be caused by alterations in respiratory drive, such as in respiratory alkalosis, physiological or pathological shunting of blood, diseases interfering in lung function resulting in a ventilation-perfusion mismatch, such as a pulmonary embolus, or alterations in the partial pressure of oxygen in the environment or lung alveoli, such as may occur at altitude or when diving.

Carbon Monoxide Poisoning
Carbon monoxide competes with oxygen for binding sites on hemoglobin molecules. As carbon monoxide binds with hemoglobin hundreds of times tighter than oxygen, it can prevent the carriage of oxygen. Carbon monoxide poisoning can occur acutely, as with smoke intoxication, or over a period of time, as with cigarette smoking. Due to physiological processes, carbon monoxide is maintained at a resting level of 4–6 ppm. This is increased in urban areas (7–13 ppm) and in smokers (20–40 ppm). A carbon monoxide level of 40 ppm is equivalent to a reduction in hemoglobin levels of 10 g/L.

Altitude (See: Altitude Sickness)
Atmospheric pressure reduces with altitude and with it, the amount of oxygen. The reduction in the partial pressure of inspired oxygen at higher altitudes lowers the oxygen saturation of the blood, ultimately leading to hypoxia. The clinical features of altitude sickness include: sleep problems, dizziness, headache and oedema.

Hypoxic Breathing Gases
The breathing gas in underwater diving may contain an insufficient partial pressure of oxygen, particularly in malfunction of rebreathers. Such situations may lead to unconsciousness without symptoms since carbon dioxide levels are normal and the human body senses pure hypoxia poorly. Hypoxic breathing gases can be defined as mixtures with a lower oxygen fraction than air, though gases containing sufficient oxygen to reliably maintain consciousness at normal sea level atmospheric pressure may be described as normoxic even when slightly hypoxic. Hypoxic mixtures in this context are those which will not reliably maintain consciousness at sea level pressure. Gases with as little as 2% oxygen by volume in a helium diluent are used for deep diving operations. The ambient pressure at 190 msw is sufficient to provide a partial pressure of about 0.4 bar, which is suitable for saturation diving. As the divers are decompressed, the breathing gas must be oxygenated to maintain a breathable atmosphere.

Inert gas asphyxiation may be deliberate with use of a suicide bag. Accidental death has occurred in cases where concentrations of nitrogen in controlled atmospheres, or methane in mines, has not been detected or appreciated.

Anemia
Hemoglobin plays a substantial role in carrying oxygen throughout the body, and when it is deficient, anemia can result, causing 'anaemic hypoxia' if tissue perfusion is decreased. Iron deficiency is the most common cause of anemia. As iron is used in the synthesis of hemoglobin, less hemoglobin will be synthesised when there is less iron, due to insufficient intake, or poor absorption.

Anemia is typically a chronic process that is compensated over time by increased levels of red blood cells via upregulated erythropoetin. A chronic hypoxic state can result from a poorly compensated anaemia.

Cyanide Poisoning
Histotoxic hypoxia results when the quantity of oxygen reaching the cells is normal, but the cells are unable to use the oxygen effectively as a result of disabled oxidative phosphorylation enzymes. This may occur in cyanide poisoning.

Diagnosis

Prevention

Ensure an adequate air supply. Do not use carbon monxide generating machines such as generators in enclosed spaces.

Treatment

To counter the effects of high-altitude diseases, the body must return arterial pO2 toward normal. Acclimatization, the means by which the body adapts to higher altitudes, only partially restores pO2 to standard levels. Hyperventilation, the body's most common response to high-altitude conditions, increases alveolar pO2 by raising the depth and rate of breathing.

However, while pO2 does improve with hyperventilation, it does not return to normal. Studies of miners and astronomers working at 3000 meters and above show improved alveolar pO2 with full acclimatization, yet the pO2 level remains equal to or even below the threshold for continuous oxygen therapy for patients with chronic obstructive pulmonary disease (COPD). In addition, there are complications involved with acclimatization. Polycythemia, in which the body increases the number of red blood cells in circulation, thickens the blood, raising the danger that the heart can't pump it.

In high-altitude conditions, only oxygen enrichment can counteract the effects of hypoxia. By increasing the concentration of oxygen in the air, the effects of lower barometric pressure are countered and the level of arterial pO2 is restored toward normal capacity. A small amount of supplemental oxygen reduces the equivalent altitude in climate-controlled rooms. At 4000 m, raising the oxygen concentration level by 5 percent via an oxygen concentrator and an existing ventilation system provides an altitude equivalent of 3000 m, which is much more tolerable for the increasing number of low-landers who work in high altitude.

In a study of astronomers working in Chile at 5050 m, oxygen concentrators increased the level of oxygen concentration by almost 30 percent (that is, from 21 percent to 27 percent). This resulted in increased worker productivity, less fatigue, and improved sleep.

Oxygen concentrators are uniquely suited for this purpose. They require little maintenance and electricity, provide a constant source of oxygen, and eliminate the expensive, and often dangerous, task of transporting oxygen cylinders to remote areas. Offices and housing already have climate-controlled rooms, in which temperature and humidity are kept at a constant level. Oxygen can be added to this system easily and relatively cheaply.

A prescription renewal for home oxygen following hospitalization requires an assessment of the patient for ongoing hypoxemia.

12 Swimming Induced Pulmonary Edema

Swimming induced pulmonary edema (SIPE), also known as immersion pulmonary edema, occurs when fluids from the blood leak abnormally from the small vessels of the lung (pulmonary capillaries) into the airspaces (alveoli).

15 Carbon Monoxide Poisoning

Carbon monoxide poisoning typically occurs from breathing in too much carbon monoxide (CO). Symptoms are often described as "flu-like" and commonly include headache, dizziness, weakness, vomiting, chest pain, and confusion. Large exposures can result in loss of consciousness, arrhythmias, seizures, or death. Breathing air with more than 3% CO2 can quickly lead to headaches, dizziness, increased heart rate and difficulty breathing. At mixing ratios exceeding about 15%, carbon dioxide quickly causes unconsciousness and death.

Carbon monoxide poisoning can occur accidentally, as an attempt to end one's own life, or as an attempt to end another's life. CO is a colorless and odorless gas which is initially non-irritating. It is produced during incomplete burning of organic matter. This can occur from motor vehicles, heaters, or cooking equipment that run on carbon-based fuels. It can also occur from exposure to methylene chloride. Carbon monoxide primarily causes adverse effects by combining with hemoglobin to form carboxyhemoglobin (HbCO) preventing the blood from carrying oxygen. Additionally, myoglobin and mitochondrial cytochrome oxidase are affected. Diagnosis is based on a HbCO level of more than 3% among nonsmokers and more than 10% among smokers.

Efforts to prevent poisoning include carbon monoxide detectors, proper venting of gas appliances, keeping chimneys clean, and keeping exhaust systems of vehicles in good repair. Treatment of poisoning generally consists of giving 100% oxygen along with supportive care. This should generally be carried out until symptoms are no longer present and the HbCO level is less than 10%. While hyperbaric oxygen therapy is used for severe poisonings, the benefit over standard oxygen delivery is unclear. The risk of death among those affected is between 1 and 30%.

Signs & Symptoms

Carbon monoxide is not toxic to all forms of life. Its harmful effects are due to binding with hemoglobin so its danger to organisms that do not use this compound is doubtful. It thus has no effect on photosynthesising plants. It is easily absorbed through the lungs. Inhaling the gas can lead to hypoxic injury, nervous system damage, and even death. Different people and populations may have different carbon monoxide tolerance levels. On average, exposures at 100 ppm or greater is dangerous to human health. In the United States, the OSHA limits long-term workplace exposure levels to less than 50 ppm averaged over an 8-hour period; in addition, employees are to be removed from any confined space if an upper limit ("ceiling") of 100 ppm is reached. Carbon monoxide exposure may lead to a significantly shorter life span due to heart damage. The carbon monoxide tolerance level for any person is altered by several factors, including activity level, rate of ventilation, a pre-existing cerebral or cardiovascular disease, cardiac output, anemia, sickle cell disease and other hematological disorders, barometric pressure, and metabolic rate.

Concentration	Symptoms
35 ppm (0.0035%), (0.035‰)	Headache and dizziness within six to eight hours of constant exposure
100 ppm (0.01%), (0.1‰)	Slight headache in two to three hours
200 ppm (0.02%), (0.2‰)	Slight headache within two to three hours; loss of judgment
400 ppm (0.04%), (0.4‰)	Frontal headache within one to two hours
800 ppm (0.08%), (0.8‰)	Dizziness, nausea, and convulsions within 45 min; insensible within 2 hours
1,600 ppm (0.16%), (1.6‰)	Headache, increased heart rate, dizziness, and nausea within 20 min; death in less than 2 hours
3,200 ppm (0.32%), (3.2‰)	Headache, dizziness and nausea in five to ten minutes. Death within 30 minutes.
6,400 ppm (0.64%), (6.4‰)	Headache and dizziness in one to two minutes. Convulsions, respiratory arrest, and death in less than 20 minutes.
12,800 ppm (1.28%), (12.8‰)	Unconsciousness after 2–3 breaths. Death in less than three minutes.

Acute Poisoning
The main manifestations of carbon monoxide poisoning develop in the organ systems most dependent on oxygen use, the central nervous system and the heart. The initial symptoms of acute carbon monoxide poisoning include headache, nausea, malaise, and fatigue. These symptoms are often mistaken for a virus such as influenza or other illnesses such as food poisoning or gastroenteritis. Headache is the most common symptom of acute carbon monoxide poisoning; it is often described as dull, frontal, and continuous. Increasing exposure produces cardiac abnormalities including fast heart rate, low blood pressure, and cardiac arrhythmia; central nervous system symptoms include delirium, hallucinations, dizziness, unsteady gait, confusion, seizures, central nervous system depression, unconsciousness, respiratory arrest, and death. Less common symptoms of acute carbon monoxide poisoning include myocardial ischemia, atrial fibrillation, pneumonia, pulmonary edema, high blood sugar, lactic acidosis, muscle necrosis, acute kidney failure, skin lesions, and visual and auditory problems.

One of the major concerns following acute carbon monoxide poisoning is the severe delayed neurological manifestations that may occur. Problems may include difficulty with higher intellectual functions, short-term memory loss, dementia, amnesia, psychosis, irritability, a strange gait, speech disturbances, Parkinson's disease-like syndromes, cortical blindness, and a depressed mood. Depression may occur in those who did not have pre-existing depression. These delayed neurological sequelae may occur in up to 50% of poisoned people after 2 to 40 days. It is difficult to predict who will develop delayed sequelae; however, advanced age, loss of consciousness while poisoned, and initial neurological abnormalities may increase the chance of developing delayed symptoms.

One classic sign of carbon monoxide poisoning is more often seen in the dead rather than the living – people have been described as looking red-cheeked and healthy. However, since this "cherry-red" appearance is more common in the dead, it is not considered a useful diagnostic sign in clinical medicine. In autopsy examinations, the ruddy appearance of carbon monoxide poisoning is notable because unembalmed dead persons are normally bluish and pale, whereas dead carbon-monoxide poisoned people may appear unusually lifelike in coloration. The colorant effect of carbon monoxide in such postmortem circumstances is thus analogous to its use as a red colorant in the commercial meat-packing industry.

Chronic Poisoning
Chronic exposure to relatively low levels of carbon monoxide may cause persistent headaches, lightheadedness, depression, confusion, memory loss, nausea, hearing disorders and vomiting. It is unknown whether low-level chronic exposure may cause permanent neurological damage. Typically, upon removal from exposure to carbon monoxide, symptoms usually resolve themselves, unless there has been an episode of severe acute poisoning. However, one case noted permanent memory loss and learning problems after a three-year exposure to relatively low levels of carbon monoxide from a faulty furnace. Chronic exposure may worsen cardiovascular symptoms in some people. Chronic carbon monoxide exposure might increase the risk of developing atherosclerosis. Long-term exposures to carbon monoxide present the greatest risk to persons with coronary heart disease and in females who are pregnant. In experimental animals, carbon monoxide appears to worsen noise-induced hearing loss at noise exposure conditions that would have limited effects on hearing otherwise. In humans, hearing loss has been reported following carbon monoxide poisoning. Unlike the findings in animal studies, noise exposure was not a necessary factor for the auditory problems to occur.

Causes

Carbon monoxide is a product of combustion of organic matter under conditions of restricted oxygen supply, which prevents complete oxidation to carbon dioxide (CO_2). Sources of carbon monoxide include cigarette smoke, house fires, faulty furnaces, heaters, wood-burning stoves, internal combustion vehicle exhaust, electrical generators, propane-fueled equipment such as portable stoves, and gasoline-powered tools such as leaf blowers, lawn mowers, high-pressure washers, concrete cutting saws, power trowels, and welders. Exposure typically occurs when equipment is used in buildings or semi-enclosed spaces.

Riding in the back of pickup trucks has led to poisoning in children. Idling automobiles with the exhaust pipe blocked by snow has led to the poisoning of car occupants. Any perforation between the exhaust manifold and shroud can result in exhaust gases reaching the cabin. Generators and propulsion engines on boats, especially houseboats, has resulted in fatal carbon monoxide exposures.

Poisoning may also occur following the use of a self-contained underwater breathing apparatus (SCUBA) due to faulty diving air compressors.

In caves carbon monoxide can build up in enclosed chambers due to the presence of decomposing organic matter. In coal mines incomplete combustion may occur during explosions resulting in the production of afterdamp. The gas is up to 3% CO and may be fatal after just a single breath. Following an explosion in a colliery, adjacent interconnected mines may become dangerous due to the afterdamp leaking from mine to mine. Such an incident followed the Trimdon Grange explosion which killed men in the Kelloe mine.

Another source of poisoning is exposure to the organic solvent dichloromethane, also known as methylene chloride, found in some paint strippers, as the metabolism of dichloromethane produces carbon monoxide. In November 2019, an EPA ban on dichloromethane in paint strippers for consumer use took effect in the United States.

Diagnosis

As many symptoms of carbon monoxide poisoning also occur with many other types of poisonings and infections (such as the flu), the diagnosis is often difficult. A history of potential carbon monoxide exposure, such as being exposed to a residential fire, may suggest poisoning, but the diagnosis is confirmed by measuring the levels of carbon monoxide in the blood. This can be determined by measuring the amount of carboxyhemoglobin compared to the amount of hemoglobin in the blood.

The ratio of carboxyhemoglobin to hemoglobin molecules in an average person may be up to 5%, although cigarette smokers who smoke two packs per day may have levels up to 9%. In symptomatic poisoned people they are often in the 10–30% range, while persons who die may have postmortem blood levels of 30–90%.

As people may continue to experience significant symptoms of CO poisoning long after their blood carboxyhemoglobin concentration has returned to normal, presenting to examination with a normal carboxyhemoglobin level (which may happen in late states of poisoning) does not rule out poisoning.

There are many conditions to be considered in the differential diagnosis of carbon monoxide poisoning. The earliest symptoms, especially from low level exposures, are often non-specific and readily confused with other illnesses, typically flu-like viral syndromes, depression, chronic fatigue syndrome, chest pain, and migraine or other headaches. Carbon monoxide has been called a "great mimicker" due to the presentation of poisoning being diverse and nonspecific. Other conditions included in the differential diagnosis include acute respiratory distress syndrome, altitude sickness, lactic acidosis, diabetic ketoacidosis, meningitis, methemoglobinemia, or opioid or toxic alcohol poisoning.

Prevention

Detectors
Prevention remains a vital public health issue, requiring public education on the safe operation of appliances, heaters, fireplaces, and internal-combustion engines, as well as increased emphasis on the installation of carbon monoxide detectors. Carbon monoxide is tasteless, odourless, and colourless, and therefore can not be detected by visual cues or smell.

The United States Consumer Product Safety Commission has stated, "carbon monoxide detectors are as important to home safety as smoke detectors are," and recommends each home have at least one carbon monoxide detector, and preferably one on each level of the building. These devices, which are relatively inexpensive and widely available, are either battery- or AC-powered, with or without battery backup. In buildings, carbon monoxide detectors are usually installed around heaters and other equipment. If a relatively high level of carbon monoxide is detected, the device sounds an alarm, giving people the chance to evacuate and ventilate the building. Unlike smoke detectors, carbon monoxide detectors do not need to be placed near ceiling level.

The use of carbon monoxide detectors has been standardized in many areas. In the US, NFPA 720-2009, the carbon monoxide detector guidelines published by the National Fire Protection Association, mandates the placement of carbon monoxide detectors/alarms on every level of the residence, including the basement, in addition to outside sleeping areas. In new homes, AC-powered detectors must have battery backup and be interconnected to ensure early warning of occupants at all levels. NFPA 720-2009 is the first national carbon monoxide standard to address devices in non-residential buildings. These guidelines, which now pertain to schools, healthcare centers, nursing homes and other non-residential buildings, include three main points:

1. A secondary power supply (battery backup) must operate all carbon monoxide notification appliances for at least 12 hours,
2. Detectors must be on the ceiling in the same room as permanently installed fuel-burning appliances, and
3. Detectors must be located on every habitable level and in every HVAC zone of the building.

Gas organizations will often recommend to get gas appliances serviced at least once a year.

Treatment

Initial treatment for carbon monoxide poisoning is to immediately remove the person from the exposure without endangering further people. Those who are unconscious may require CPR on site. Administering oxygen via non-rebreather mask shortens the half-life of carbon monoxide from 320 minutes, when breathing normal air, to only 80 minutes. Oxygen hastens the dissociation of carbon monoxide from carboxyhemoglobin, thus turning it back into hemoglobin. Due to the possible severe effects in the baby, pregnant women are treated with oxygen for longer periods of time than non-pregnant people.

Hyperbaric Oxygen
Hyperbaric oxygen is also used in the treatment of carbon monoxide poisoning, as it may hasten dissociation of CO from carboxyhemoglobin and cytochrome oxidase to a greater extent than normal oxygen. Hyperbaric oxygen at three times atmospheric pressure reduces the half life of carbon monoxide to 23 (~80/3 minutes) minutes, compared to 80 minutes for oxygen at regular atmospheric pressure. It may also enhance oxygen transport to the tissues by plasma, partially bypassing the normal transfer through hemoglobin. However, it is controversial whether hyperbaric oxygen actually offers any extra benefits over normal high flow oxygen, in terms of increased survival or improved long-term outcomes. There have been randomized controlled trials in which the two treatment options have been compared; of the six performed, four found hyperbaric oxygen improved outcome and two found no benefit for hyperbaric oxygen. Some of these trials have been criticized for apparent flaws in their implementation. A review of all the literature concluded that the role of hyperbaric oxygen is unclear and the available evidence neither confirms nor denies a medically meaningful benefit. The authors suggested a large, well designed, externally audited, multicentre trial to compare normal oxygen with hyperbaric oxygen.

Other
Further treatment for other complications such as seizure, hypotension, cardiac abnormalities, pulmonary edema, and acidosis may be required. Increased muscle activity and seizures should be treated with dantrolene or diazepam; diazepam should only be given with appropriate respiratory support. Hypotension requires treatment with intravenous fluids; vasopressors may be required to treat myocardial depression. Cardiac dysrhythmias are treated with standard advanced cardiac life support protocols. If severe, metabolic acidosis is treated with sodium bicarbonate. Treatment with sodium bicarbonate is controversial as acidosis may increase tissue oxygen availability. Treatment of acidosis may only need to consist of oxygen therapy. The delayed development of neuropsychiatric impairment is one of the most serious complications of carbon monoxide poisoning. Brain damage is confirmed following MRI or CAT scans. Extensive follow up and supportive treatment is often required for delayed neurological damage. Outcomes are often difficult to predict following poisoning, especially people who have symptoms of cardiac arrest, coma, metabolic acidosis, or have high carboxyhemoglobin levels. One study reported that approximately 30% of people with severe carbon monoxide poisoning will have a fatal outcome. It has been reported that electroconvulsive therapy (ECT) may increase the likelihood of delayed neuropsychiatric sequelae (DNS) after carbon monoxide (CO) poisoning. A device that also provides some carbon dioxide to stimulate faster breathing (sold under the brand name ClearMate) may also be used.

16 Lipid Pneumonia

Lipid pneumonia is a specific form of lung inflammation (pneumonia) that develops when lipids enter the bronchial tree.

Signs & Symptoms

The pneumonia presents as a foreign body reaction causing cough, dyspnea, and often fever. Hemoptysis has also been reported.

Causes

Sources of such lipids could be either exogenous or endogenous.

Exogenous: from outside the body. For example, inhaled nose drops with an oil base, or accidental inhalation of cosmetic oil. Amiodarone is an anti-arrythmic known to cause this condition. Oil pulling has also been shown to be a cause. Fire breather's pneumonia from the inhalation of hydrocarbon fuel is a specific variant. At risk populations include the elderly, developmentally delayed or persons with gastroesophageal reflux. Switching to water-soluble alternatives may be helpful in some situations.

Endogenous: from the body itself, for example, when an airway is obstructed, it is often the case that distal to the obstruction, lipid-laden macrophages and giant cells fill the lumen of the disconnected airspace.

Diagnosis

The gross appearance of a lipid pneumonia is that in which there is an ill-defined, pale yellow area on the lung. This yellow appearance explains the colloquial term "golden" pneumonia. At the microscopic scale foamy macrophages and giant cells are seen in the airways, and the inflammatory response is visible in the parenchyma.

Prevention

Treatment

Treatment is with corticosteroids and possibly intravenous immunoglobulins.

7 Animal & Plant

This section includes all the unique stings and bites from animals and plants.

Subheadings

1. Ant Bites	**2. Bee Stings**	**3. Wasp Stings**	**4. Caterpillar Stings**
5. Scorpion Stings	**6. Snake Bites**	**7. Spider Bites**	**8. Plant Stings**

1 Ant Bites

If attacked by fire ants, treat the bites by washing the affected area with soap and water. You can also apply ice to reduce the swelling and pain or use topical over-the-counter steroid or aloe vera-based creams. Antihistamines can help reduce the itching sensation and lessen the reaction to the bite. Avoid scratching, though, as doing so can cause bites to become infected. If left alone, bites should heal in about a week's time. Signs of a dangerous allergic reaction include difficulty breathing and swallowing, nausea and dizziness. These symptoms will develop quickly after bitten. If you or a family member is experiencing such symptoms, seek medical attention immediately.

2 Bee Stings

A bee sting is a wound caused by the stinger from a bee (honey bee, bumblebee, sweat bee, etc.) being injected into one's flesh. The stings of most of these species can be quite painful, and are therefore keenly avoided by many people.

Bee stings differ from insect bites, and the venom or toxin of stinging insects is quite different. Therefore, the body's reaction to a bee sting may differ significantly from one species to another. In particular, bee stings are acidic, whereas wasp stings are alkaline, so the body's reaction to a bee sting may be very different from its reaction to a wasp sting.

The most aggressive stinging insects are vespid wasps (including bald-faced hornets and other yellowjackets) and hornets (especially the Asian giant hornet). All of these insects aggressively defend their nests. Although for most people a bee sting is painful but otherwise relatively harmless, in people with insect sting allergy, stings may trigger a dangerous anaphylactic reaction that is potentially deadly. Additionally, honey bee stings release pheromones that prompt other nearby bees to attack.

Signs & Symptoms

Causes

A honey bee that is away from the hive foraging for nectar or pollen will rarely sting, except when stepped on or roughly handled. Honey bees will actively seek out and sting when they perceive the hive to be threatened, often being alerted to this by the release of attack pheromones (below).

Although it is widely believed that a worker honey bee can sting only once, this is a partial misconception: although the stinger is in fact barbed so that it lodges in the victim's skin, tearing loose from the bee's abdomen and leading to its death in minutes, this only happens if the skin of the victim is sufficiently thick, such as a mammal's. Honey bees are the only hymenoptera with a strongly barbed sting, though yellow jackets and some other wasps have small barbs.

Bees with barbed stingers can often sting other insects without harming themselves. Queen honeybees and bees of many other species, including bumblebees and many solitary bees, have smoother stingers with smaller barbs, and can sting mammals repeatedly.

The sting's injection of apitoxin into the victim is accompanied by the release of alarm pheromones, a process which is accelerated if the bee is fatally injured. The release of alarm pheromones near a hive may attract other bees to the location, where they will likewise exhibit defensive behaviors until there is no longer a threat, typically because the victim has either fled or been killed. (Note: A bee swarm, seen as a mass of bees flying or clumped together, is generally not hostile; it has deserted its hive and has no comb or young to defend.) These pheromones do not dissipate or wash off quickly, and if their target enters water, bees will resume their attack as soon as it leaves the water. The alarm pheromone emitted when a bee stings another animal smells like a banana.

Drone bees, the males, are larger and do not have stingers. The female bees (worker bees and queens) are the only ones that can sting, and their stinger is a modified ovipositor. The queen bee has a barbed but smoother stinger and can, if need be, sting skin-bearing creatures multiple times, but the queen does not leave the hive under normal conditions. Her sting is not for defense of the hive; she only uses it for dispatching rival queens, ideally before they can emerge from their cells. Queen breeders who handle multiple queens and have the queen odor on their hands are sometimes stung by a queen.

The main component of bee venom responsible for pain in vertebrates is the toxin melittin; histamine and other biogenic amines may also contribute to pain and itching. In one of the alternative medical uses of honey bee products, apitherapy, bee venom has been used to treat arthritis and other painful conditions. All currently available evidence supporting this practice is either anecdotal, animal studies, or preliminary evidence, most of which has poor methodology. While a preliminary, in-vitro proof of concept has demonstrated that isolated melittin may attenuate the infectivity of two specific HIV strains, apitherapy is not currently accepted as a viable medical treatment for any condition or disease; the risk of allergic reaction and anaphylaxis outweighs any benefits.

The stinger consists of three parts: a stylus and two barbed slides (or lancets), one on either side of the stylus. The bee does not push the stinger in but it is drawn in by the barbed slides. The slides move alternately up and down the stylus so when the barb of one slide has caught and retracts, it pulls the stylus and the other barbed slide into the wound. When the other barb has caught, it also retracts up the stylus pulling the sting further in. This process is repeated until the sting is fully in and even continues after the sting and its mechanism is detached from the bee's abdomen.

When a honey bee stings a person, it cannot pull the barbed stinger back out. It leaves behind not only the stinger, but also part of its abdomen and digestive tract, plus muscles and nerves. This massive abdominal rupture kills the honey bee. Honey bees are the only bees to die after stinging.

Diagnosis

Prevention

Treatment

The first step in treatment following a honey bee sting is removal of the stinger itself. The stinger should be removed as quickly as possible without regard to method: a study has shown the amount of venom delivered does not differ whether the sting is pinched or scraped off and even a delay of a few seconds leads to more venom being injected. Once the stinger is removed, pain and swelling should be reduced with a cold compress. A topical anesthetic containing benzocaine will kill pain quickly and menthol is an effective anti-itch treatment. Itching can also be relieved by antihistamine or by a steroid cream.

Many traditional remedies have been suggested for bee stings including damp pastes of tobacco, salt, baking soda, papain, toothpaste, clay, garlic, urine, onions, aspirin or even application of copper coins. As with jellyfish stings, ammonia and ammonia-containing liquids, such as window cleaner, are often suggested as a way to immediately cleanse the skin and remove excess venom, and sweat itself (which also contains small amounts of ammonia) may provide some small relief.

Bee venom is acidic, and these interventions are often recommended to neutralize the venom; however, neutralizing a sting is unlikely to be effective as the venom is injected under the skin and deep into the tissues, where a topically applied alkali is unable to reach, so neutralization is unlikely to occur. In any case, the amount of venom injected is typically very small (between 5 and 50 micrograms of fluid) and placing large amounts of alkali near the sting site is unlikely to produce a perfectly neutral pH to stop the pain. Many people do claim benefit from these home remedies but it is doubtful they have any real physical effect on how much a sting hurts or continues hurting.

The effect is probably related to rubbing the area or the mind perceiving benefit. Furthermore, none of these interventions have been proven to be effective in scientific studies and a randomized trial of aspirin paste and topical ice packs showed that aspirin was not effective in reducing the duration of swelling or pain in bee and wasp stings, and significantly increased the duration of redness. The study concluded that ice alone is a better treatment for bee and wasp stings than aspirin.

The sting may be painful for a few hours. Swelling and itching may persist for a week. The area should not be scratched as it will only increase the itching and swelling. If swelling persists for over a week or covers an area greater than 7–10 cm (3–4 inches), medical attention should be sought. Doctors often recommend a tetanus immunization. For about 2 percent of people, a hypersensitivity can develop after being stung, creating a more severe reaction when stung again later. This sensitisation may happen after a single sting, or after a series of stings where they reacted normally. A highly allergic person may suffer anaphylactic shock from certain proteins in the venom, which can be life-threatening and requires emergency treatment. People known to be highly allergic may carry around epinephrine (adrenaline) in the form of a self-injectable EpiPen for the treatment of an anaphylactic shock.

For patients who experience severe or life-threatening reactions to insect stings, allergy injections composed of increasing concentrations of naturally occurring venom may provide protections against future insect stings.

8 Foreign Bodies

Any kind of wound where an external object enters the body such as a bullet or a nail.

Splinters

A splinter is a fragment of a larger object (especially wood), or a foreign body that penetrates or is purposely injected into a body. The foreign body must be lodged inside tissue to be considered a splinter.

According to the AAFP, the most common foreign bodies contracted by people fall into two official classes: biological splinters, and nonbiological splinters. In the biological class, splinters include bone, fish spines, teeth, and wood. In the nonbiological class, common splinters contracted are glass, metal, aluminum, fishhooks, pencil graphite, and plastic. Rarely, people may become infected with splinters from more unusual sources. Common cases of exotic foreign bodies include sea urchins, insect stings, stingray spines, and even grenade shrapnel.

Signs & Symptoms

Generally, a splinter causes an initial feeling of pain as the sharp object makes its initial penetration through the body. Through this penetration, the object cuts through the cutaneous layer of the skin, and settles in the subcutaneous layer of the skin, and can even penetrate further down, breaking the sub-cutaneous layer, settling in muscle tissue, or even the bone. Some splinters will remain in place, but most will continue to migrate through the body, further damaging their surroundings.

Causes

Common splinter types:

Wood	This type of splinter is contracted from lumber or other vegetative materials. Wood splinters must be removed from wounds because they are associated with inflammation and risk of infection. Larger or deeper splinters can result in difficult removal, or localization of the foreign body.
Fishhooks	Fishhooks that become lodged in the skin are problematic because of the barbs found on the ends of most fishhooks. These barbs are designed to make removal difficult, and if care is not taken, the victim can experience tearing of not only the flesh, but the muscle as well. The most common injuries caused by fishhooks occur in the hand, face, scalp, foot, and eye.
Glass	One study found that patients were more likely to feel sensations from glass present in their skin than from any other kind of splinter. Though glass is generally detectable by radiography and is radiopaque, there is limited ability for radiography to detect glass fragments smaller than 2mm. Most glass splinters are inert, and generally lack the ability to migrate to other regions of the body.
Other	Pencil lead and other graphite foreign bodies, once lodged in the cutaneous layer of the skin, can cause permanent pigment tattooing if not removed immediately. Metallic bodies range from BB pellets to grenade shrapnel. Smaller objects can be removed without much difficulty if the depth of the wound remains superficial, but if the wound does not protrude past the subcutaneous layers of the skin, and remains inert, the object can actually remain in place. In larger objects, fragments that remain superficial in one's body may be removed without much trouble, but if wounds protrude past the subcutaneous layers of the skin and even into the muscular area or near vital organs, such objects must be left alone and immediate medical attention must be sought.
Hair	Short lengths of hair, especially stiff hair such as trimmed beard hair or pet hair, can work its way under the skin of the feet or hands. So-called "hair splinters" are commonly experienced by hairdressers and dog groomers. This is distinct from an ingrown hair, where a hair still attached to its follicle grows back under (or fails to emerge from) the skin.

Diagnosis

Signs of a hidden foreign body
- Puncture wound
- Blood-stained injury track of a fresh wound
- Sharp pain with deep palpation over a puncture wound
- Discoloration beneath the epidermis
- Wound that elicits pain with movement
- Wound that fails to heal
- Abscess (with sterile culture)
- Pain associated with a mass
- Mass under the epidermis
- Chronically draining purulent wound
- Cyst
- Granuloma formation
- Sterile monoarticular arthritis
- Periosteal reactions
- Osteomyelitis
- Pseudo tumors of bone
- Delayed tendon or nerve injury

Prevention

Wear gloves and other protective equipment.

INJURY Foreign Body Splinters

Treatment

There are many medical techniques to remove splinters safely. Common medical techniques include the Elliptical Technique and the String Technique. In the elliptical technique the surrounding area of the splinter is sliced in an elliptical formation. From there the flesh in the elliptical area is cut (in the shape of an upside-down cone) and the whole chunk of flesh containing the splinter is removed. The Needle Cover Technique is limited to fishhook removal. A string is looped around the base of the hook, and as the hook is pressed further into the skin, the string is pulled, allowing the barbs to be unhooked from muscle and follow the path of the rest of the hook out of the body without snagging any additional flesh.

Since the splinter has penetrated through a physical barrier of the body it allows for an individual to get an infection. The opening from the splinter will make it easier for bacteria to get into the body. It is strongly encourage for the removal or a splinter before falling victim to an Infection.

Infection
Infection is usually determined by the duration of time that the foreign object remains lodged in the human body. Objects that have included poison, deep penetration, dirt, or bite injuries generally result in a shorter time until infection is notable. According to the AAFP patients that are older, or have diabetes, or have wounds that are longer, wider, more jagged or deeper, have a much higher risk of infection. Simply the easiest way to avoid infection is to completely remove the splinters or foreign body as soon as possible. Though infection is generally the largest complication encountered with splinters, ranging from 1.1 to 12 percent presence, the use of antibiotics in non-bite cases is generally deemed unnecessary by the medical community. Though cases are rare, infection of foreign body wounds can result in cases of tetanus.

Since splinters are made of organic matter, they are much more dangerous than other types of things puncturing the body. Splinters are usually infected with many bacteria which then turn into an infection such as tetanus. Due to a splinter being made of organic matter, it makes it much more difficult for the body to get rid of it.

Impalement & Piercing

Impalement is the penetration of a human by an object such as a stake, pole, spear, or hook, often by complete or partial perforation of the torso.

Treatment

Gunshot Wound

A gunshot wound (GSW), also known as ballistic trauma, is a form of physical trauma sustained from the discharge of arms or munitions. Damage may include bleeding, broken bones, organ damage, infection of the wound, or loss of the ability to move part of the body. Damage depends on the part of the body hit, the path the bullet follows through the body, and the type and speed of the bullet. Long-term complications can include lead poisoning and post traumatic stress disorder (PTSD).

Signs & Symptoms

Trauma from a gunshot wound varies widely based on the bullet, velocity, mass, entry point, trajectory, and affected anatomy. Gunshot wounds can be particularly devastating compared to other penetrating injuries because the trajectory and fragmentation of bullets can be unpredictable after entry. Additionally, gunshot wounds typically involve a large degree of nearby tissue disruption and destruction due to the physical effects of the projectile correlated with the bullet velocity classification.

The immediate damaging effect of a gunshot wound is typically severe bleeding, and with it the potential for hypovolemic shock, a condition characterized by inadequate delivery of oxygen to vital organs. In the case of traumatic hypovolemic shock, this failure of adequate oxygen delivery is due to blood loss, as blood is the means of delivering oxygen to the body's constituent parts. Devastating effects can result when a bullet strikes a vital organ such as the heart, lungs or liver, or damages a component of the central nervous system such as the spinal cord or brain.

Common causes of death following gunshot injury include bleeding, low oxygen caused by pneumothorax, catastrophic injury to the heart and major blood vessels, and damage to the brain or central nervous system. Non-fatal gunshot wounds frequently have mild to severe long-lasting effects, typically some form of major disfigurement such as amputation due to a severe bone fracture, and may cause permanent disability.

Causes

Diagnosis

Classification

Gunshot wounds are classified according to the speed of the projectile:

- Low-velocity: < 1,100 ft/s (340 m/s)
- Medium-velocity: 1,100 ft/s (340 m/s) to 2,000 ft/s (610 m/s)
- High-velocity: 2,000 ft/s (610 m/s) to 3,500 ft/s (1,100 m/s)
- Hyper velocity: > 3,500 ft/s (1,100 m/s)

Bullets from handguns are sometimes less than 1,000 ft/s (300 m/s) but with modern pistol loads, they usually are slightly above 1,000 ft/s (300 m/s), while bullets from most modern rifles exceed 2,500 ft/s (760 m/s). One recently developed class of firearm projectiles is the hyper-velocity bullet, such cartridges are usually either wildcats made for achieving such high speed or purpose built factory ammunition with the same goal in mind. Examples of hyper velocity cartridges include the .220 Swift, .17 Remington and .17 Mach IV cartridges. The US military commonly uses 5.56mm bullets, which have a relatively low mass as compared with other bullets (40-62 grains); however, the speed of these bullets is relatively fast (Approximately 2,800 ft/s (850 m/s), placing them in the high velocity category). As a result, they produce a larger amount of kinetic energy, which is transmitted to the tissues of the target.

However, one must remember that high kinetic energy does not necessarily equate to high stopping power, as incapacitation usually results from remote wounding effects such as bleeding, rather than raw energy transfer. High energy does indeed result in more tissue disruption, which plays a role in incapacitation, but other factors such as wound size and shot placement play as big of, if not a bigger role in stopping power and thus, effectiveness. Muzzle velocity does not consider the effect of aerodynamic drag on the flight of the bullet for the sake of ease of comparison.

Prevention

Medical organizations in the United States recommend criminal background check before people can buy a gun and those who are guilty of crimes of violence should be prevented from buying them. Safe storage of firearms is also recommended as is better mental health care and removal of guns from those at risk of suicide. In an effort to prevent mass shootings greater regulations on guns that can rapidly fire many bullets is recommended.

Treatment

Before management begins it should be verified the area is safe. This is followed by stopping major bleeding, then assessing and supporting the airway, breathing, and circulation. Firearm laws, particularly background checks and permit to purchase, decrease the risk of death from firearms. Safer firearm storage may decrease the risk of firearm-related deaths in children.

Initial assessment for a gunshot wound is approached in the same way as other acute trauma using the advanced trauma life support (ATLS) protocol. These include:

A) Airway - Assess and protect airway and potentially the cervical spine
B) Breathing - Maintain adequate ventilation and oxygenation
C) Circulation - Assess for and control bleeding to maintain organ perfusion including focused assessment with sonography for trauma (FAST)
D) Disability - Perform basic neurological exam including Glasgow Coma Scale (GCS)
E) Exposure - Expose entire body and search for any missed injuries, entry points, and exit points while maintaining body temperature

Depending on the extent of injury, management can range from urgent surgical intervention to observation. As such, any history from the scene such as gun type, shots fired, shot direction and distance, blood loss on scene, and pre-hospital vitals signs can be very helpful in directing management. Unstable people with signs of bleeding that cannot be controlled during the initial evaluation require immediate surgical exploration in the operating room. Otherwise, management protocols are generally dictated by anatomic entry point and anticipated trajectory.

Neck

A gunshot wound to the neck can be particularly dangerous because of the high number of vital anatomical structures contained within a small space. The neck contains the larynx, trachea, pharynx, esophagus, vasculature (carotid, subclavian, and vertebral arteries; jugular, brachiocephalic, and vertebral veins; thyroid vessels), and nervous system anatomy (spinal cord, cranial nerves, peripheral nerves, sympathetic chain, brachial plexus). Gunshots to the neck can thus cause severe bleeding, airway compromise, and nervous system injury.

Initial assessment of a gunshot wound to the neck involves non-probing inspection of whether the injury is a penetrating neck injury (PNI), classified by violation of the platsyma muscle. If the platsyma is intact, the wound is considered superficial and only requires local wound care. If the injury is a PNI, surgery should be consulted immediately while the case is being managed. Of note, wounds should not be explored on the field or in the emergency department given the risk of exacerbating the wound.

Due to the advances in diagnostic imaging, management of PNI has been shifting from a "zone-based" approach, which uses anatomical site of injury to guide decisions, to a "no-zone" approach which uses a symptom-based algorithm. The no-zone approach uses a hard signs and imaging system to guide next steps. Hard signs include airway compromise, unresponsive shock, diminished pulses, uncontrolled bleeding, expanding hematoma, bruits/thrill, air bubbling from wound or extensive subcutaneous air, stridor/hoarseness, neurological deficits.

If any hard signs are present, immediate surgical exploration and repair is pursued alongside airway and bleeding control. If there are no hard signs, the person receives a multi-detector CT angiography for better diagnosis. A directed angiography or endoscopy may be warranted in a high-risk trajectory for the gunshot. A positive finding on CT leads to operative exploration. If negative, the person may be observed with local wound care.

Chest

Important anatomy in the chest includes the chest wall, ribs, spine, spinal cord, intercostal neurovascular bundles, lungs, bronchi, heart, aorta, major vessels, esophagus, thoracic duct, and diaphragm. Gunshots to the chest can thus cause severe bleeding (hemothorax), respiratory compromise (pneumothorax, hemothorax, pulmonary contusion, tracheobronchial injury), cardiac injury (pericardial tamponade), esophageal injury, and nervous system injury.

Initial workup as outlined in the Workup section is particularly important with gunshot wounds to the chest because of the high risk for direct injury to the lungs, heart, and major vessels. Important notes for the initial workup specific for chest injuries are as follows. In people with pericardial tamponade or tension pneumothorax, the chest should be evacuated or decompressed if possible prior to attempting tracheal intubation because the positive pressure ventilation can cause hypotention or cardiovascular collapse. Those with signs of a tension pneumothorax (asymmetric breathing, unstable blood flow, respiratory distress) should immediately receive a chest tube (> French 36) or needle decompression if chest tube placement is delayed. FAST exam should include extended views into the chest to evaluate for hemopericardium, pneumothorax, hemothorax, and peritoneal fluid.

Those with cardiac tamponade, uncontrolled bleeding, or a persistent air leak from a chest tube all require surgery. Cardiac tamponade can be identified on FAST exam. Blood loss warranting surgery is 1–1.5 L of immediate chest tube drainage or ongoing bleeding of 200-300 mL/hr. Persistent air leak is suggestive of tracheobronchial injury which will not heal without surgical intervention. Depending on the severity of the person's condition and if cardiac arrest is recent or imminent, the person may require surgical intervention in the emergency department, otherwise known as an emergency department thoracotomy (EDT).

However, not all gunshot to the chest require surgery. Asymptomatic people with a normal chest X-ray can be observed with a repeat exam and imaging after 6 hours to ensure no delayed development of pneumothorax or hemothorax. If a person only has a pneumothorax or hemothorax, a chest tube is usually sufficient for management unless there is large volume bleeding or persistent air leak as noted above. Additional imaging after initial chest X-ray and ultrasound can be useful in guiding next steps for stable people. Common imaging modalities include chest CT, formal echocardiography, angiography, esophagoscopy, esophagography, and bronchoscopy depending on the signs and symptoms.

Abdomen

Important anatomy in the abdomen includes the stomach, small bowel, colon, liver, spleen, pancreas, kidneys, spine, diaphragm, descending aorta, and other abdominal vessels and nerves. Gunshots to the abdomen can thus cause severe bleeding, release of bowel contents, peritonitis, organ rupture, respiratory compromise, and neurological deficits.

The most important initial evaluation of a gunshot wound to the abdomen is whether there is uncontrolled bleeding, inflammation of the peritoneum, or spillage of bowel contents. If any of these are present, the person should be transferred immediately to the operating room for laparotomy. If it is difficult to evaluate for those indications because the person is unresponsive or incomprehensible, it is up to the surgeon's discretion whether to pursue laparotomy, exploratory laparoscopy, or alternative investigative tools.

Although all people with abdominal gunshot wounds were taken to the operating room in the past, practice has shifted in recent years with the advances in imaging to non-operative approaches in more stable people. If the person's vital signs are stable without indication for immediate surgery, imaging is done to determine the extent of injury.

Ultrasound (FAST) and help identify intra-abdominal bleeding and X-rays can help determine bullet trajectory and fragmentation. However, the best and preferred mode of imaging is high-resolution multi-detector CT (MDCT) with IV, oral, and sometimes rectal contrast. Severity of injury found on imaging will determine whether the surgeon takes an operative or close observational approach.

Extremities

The four main components of extremities are bones, vessels, nerves, and soft tissues. Gunshot wounds can thus cause severe bleeding, fractures, nerve deficits, and soft tissue damage. The Mangled Extremity Severity Score (MESS) is used to classify the severity of injury and evaluates for severity of skeletal and/or soft tissue injury, limb ischemia, shock, and age. Depending on the extent of injury, management can range from superficial wound care to limb amputation.

Vital sign stability and vascular assessment are the most important determinants of management in extremity injuries. As with other traumatic cases, those with uncontrolled bleeding require immediate surgical intervention. If surgical intervention is not readily available and direct pressure is insufficient to control bleeding, tourniquets or direct clamping of visible vessels may be used temporarily to slow active bleeding. People with hard signs of vascular injury also require immediate surgical intervention. Hard signs include active bleeding, expanding or pulsatile hematoma, bruit/thrill, absent distal pulses and signs of extremity ischemia.

For stable people without hard signs of vascular injury, an injured extremity index (IEI) should be calculated by comparing the blood pressure in the injured limb compared to an uninjured limb in order to further evaluate for potential vascular injury. If the IEI or clinical signs are suggestive of vascular injury, the person may undergo surgery or receive further imaging including CT angiography or conventional arteriography.

In addition to vascular management, people must be evaluated for bone, soft tissue, and nerve injury. Plain films can be used for fractures alongside CTs for soft tissue assessment. Fractures must be debrided and stabilized, nerves repaired when possible, and soft tissue debrided and covered. This process can often require multiple procedures over time depending on the severity of injury.

9 Poisoning

Poisoning is a condition or a process in which an organism becomes chemically harmed severely (poisoned) by a toxic substance or venom of an animal. In biology, poisons are substances that cause disturbances in organisms, usually by chemical reaction or other activity on the molecular scale, when an organism absorbs a sufficient quantity. The fields of medicine (particularly veterinary) and zoology often distinguish a poison from a toxin, and from a venom. Toxins are poisons produced by organisms in nature, and venoms are toxins injected by a bite or sting (this is exclusive to animals). The difference between venom and other poisons is the delivery method. Industry, agriculture, and other sectors use poisons for reasons other than their toxicity. Pesticides are one group of substances whose toxicity to various insects and other animals deemed to be pests (e.g., rats and cockroaches) is their prime purpose. Acute poisoning is exposure to a poison on one occasion or during a short period of time. Symptoms develop in close relation to the exposure. Absorption of a poison is necessary for systemic poisoning. In contrast, substances that destroy tissue but do not absorb, such as lye, are classified as corrosives rather than poisons.

Types

Hemlock	The plant is poisonous to animals that graze on it. Studies have reported cases of intoxication in cattle, pigs, sheep, goats, donkeys, rabbits, and horses. A short time after ingestion, the alkaloids produce potentially fatal neuromuscular dysfunction due to failure of the respiratory muscles. Acute toxicity, if not lethal, may resolve in spontaneous recovery, provided further exposure is avoided. The onset of symptoms is similar to that caused by curare, with an ascending muscular paralysis leading to paralysis of the respiratory muscles, causing death from oxygen deprivation. Death can be prevented by artificial ventilation until the effects have worn off 48–72 hours later. For an adult, the ingestion of more than 100 mg (0.1 gram) of coniine (about six to eight fresh leaves, or a smaller dose of the seeds or root) may be fatal. Since no specific antidote is available, prevention is the only way to deal with the production losses caused by the plant. Control with herbicides and grazing with less-susceptible animals (such as sheep) have been suggested. It is a common myth that C. maculatum alkaloids can enter the human food chain via milk and fowl, but scientific studies have disproven these claims.
Aconite	
Belladonna	
Dimethylmercury	
Tetrodotoxin	
Polonium	The element polonium is the ultimate poison and has been linked to the deaths of infamous people. It is intensely toxic to living things and as such has no known biological role. In its commonest form, Polonium 210 it is reportedly 250,000 times more toxic than hydrogen cyanide. This toxicity is radioactive in nature and caused by the release of alpha particles which damage organic tissue. Alpha particles cannot penetrate the skin but if the polonium is ingested, inhaled or injected it is lethal in the tiniest of doses. In theory a single gram of polonium 210 could kill 10 million people. If the acute effects of radiation poisoning don't kill you then some form of cancer probably will.
Mercury	

INJURY
Poisoning
Types

Cyanide	Cyanide works by preventing cellular respiration; i.e. the body stops producing energy at the very lowest level causing what is termed "internal asphyxia". This manifests itself in rapid breathing, dizziness, nausea, headache and ultimately convulsions. Cyanide comes in two main forms hydrogen cyanide which is a gas and potassium cyanide which is a white powder. It occurs naturally in the stones of apricots, several plants and even apple pips. Whatever the source it is recognisable by a bitter-almond smell.
Botulinum Toxin	It is impractical to kill using isolated botulinum toxin. It is the most poisonous substance known to man. It is estimated that a single teaspoon of botulinum toxin would be sufficient to kill over 1 billion people. The toxin is produced by the bacterium Clostridium botulinum which can be found worldwide. In its lethal form it is most commonly encountered as botulism occurring when food contaminated with the bacteria is consumed. This form of food poisoning has killed countless people over the ages but is easily avoided by heating the food to over 100°C for a minute.
Arsenic	The superficial effects of arsenic poisoning are jaundice and a skin rash, but this tends to be after a long build up. Acute poisoning from a high dose results in intense gastric distress – basically everything goes wrong with your gut causing vomiting, diarrhea and bleeding, along with pain. Death follows convulsions and coma with circulatory failure being the ultimate cause. This may happen within a few hours of ingestion.
Strychnine	
Ricin	

Animal Poisons

INJURY
Poisoning

Arrow Poison Frog	

Poisoning Treatment

INJURY
Poisoning
Poisoning Treatment

Treatment of a recently ingested poison may involve gastric decontamination to decrease absorption.

Activated Charcoal	Treatment of choice to prevent poison absorption. Usually administered in an emergency room or by a trained Paramedic or EMT. Charcoal is ineffective against metals such as sodium, potassium, and lithium, and alcohols and glycols; it is also not recommended for ingestion of corrosive chemicals such as acids and alkalis.
Cathartics	Postulated to decrease absorption by increasing the expulsion of the poison from the gastrointestinal tract. There are two types of cathartics used in poisoned patients; saline cathartics (sodium sulfate, magnesium citrate, magnesium sulfate) and saccharide cathartics (sorbitol). They do not appear to improve patient outcome and are no longer recommended.
Emesis	(i.e. induced by ipecac) is no longer recommended in poisoning situations, because vomiting is ineffective at removing poisons.
Gastric Lavage	Commonly known as a stomach pump, is the insertion of a tube into the stomach, followed by administration of water or saline down the tube. The liquid is then removed along with the contents of the stomach. Lavage has been used for many years as a common treatment for poisoned patients. However, a recent review of the procedure in poisonings suggests no benefit. Whole bowel irrigation cleanses the bowel. This is achieved by giving the patient large amounts of a polyethylene glycol solution. The osmotically balanced polyethylene glycol solution is not absorbed into the body, having the effect of flushing out the entire gastrointestinal tract. Its major uses are to treat ingestion of sustained release drugs, toxins not absorbed by activated charcoal (e.g. lithium, iron), and for removal of ingested drug packets.

Antidotes

INJURY
Poisoning
Antidotes

This is a list of antidotes to common poisons and toxins.

Poison	Antidote
Many Oral Toxins	Activated Charcoal (Or Regular Charcoal) with Sorbitol
Adenosine Poisoning	Theophylline
Organophosphate and carbamate insecticides, nerve agents, some poison mushrooms	Atropine
Theophylline	Beta Blocker
Calcium channel blockers, black widow spider bites	Calcium Chloride
Hydrofluoric Acid	Calcium Gluconate
Heavy Metal Poisoning	Chelators such as EDTA, dimercaprol (BAL), penicillamine, and 2,3-dimercaptosuccinic acid (DMSA, succimer)
Cyanide Poisoning	Cyanide antidote (hydroxocobalamin, amyl nitrite, sodium nitrite, or thiosulfate)
Serotonin Syndrome	Cyproheptadine
Iron Poisoning	Deferoxamine Mesylate
Digoxin Poisoning	Digoxin Immune Fab antibody (Digibind and Digifab)
Extrapyramidal reactions associated with antipsychotic	Diphenhydramine hydrochloride and benztropine mesylate
Ethylene glycol poisoning and methanol poisoning	Ethanol or Fomepizole
Benzodiazepine Overdose	Flumazenil
Beta blocker poisoning and calcium channel blocker poisoning	Glucagon
Carbon monoxide poisoning and cyanide poisoning	100% oxygen or hyperbaric oxygen therapy (HBOT)
Reversal of dabigatran etexilate, an anticoagulant	Idarucizumab
Beta blocker poisoning and calcium channel blocker poisoning	Insulin with Glucagon
Methotrexate and Trimethoprim	Leucovorin

Treatment of conditions that cause methemoglobinemia	Methylene Blue
Opioid Overdose	Naloxone Hydrochloride
Paracetamol (acetaminophen) Poisoning	N-acetylcysteine
Oral Hypoglycemic Agents	Octreotide
Organophosphate insecticides, followed after atropine	Pralidoxime Chloride (2-PAM)
Heparin Poisoning	Protamine Sulfate
Thallium Poisoning	Prussian Blue
Anticholinergic Poisoning	Physostigmine Sulfate
Isoniazid poisoning, ethylene glycol	Pyridoxine
Warfarin poisoning and indanedione	Phytomenadione (vitamin K) and fresh frozen plasma
Aspirin, TCAs with a wide QRS	Sodium Bicarbonate
Lead Poisoning	Succimer, chemical name Dimercaptosuccinic acid (DMSA)

10 Other

Any other kind of wounds or injuries such as a stroke, seizure or childbirth.

Subheadings

1. Electrocution	**2. Cardiac Arrest**	**3. Stroke**	**4. Seizure**
5. Childbirth	**6. Hyperglycemia**	**7. Hypoglycemia**	**8. Toothache**

1 Electrical Injury & Electrocution

Electrical injury is a physiological reaction caused by electric current passing through the body. Electric shock occurs upon contact of a (human) body part with any source of electricity that causes a sufficient magnitude of current to pass through the victim's flesh, viscera or hair. Electrocution is death or serious injury caused by electric shock, electric current passing through the body.

Signs & Symptoms

Burns	Heating due to resistance can cause extensive and deep burns. When applied to the hand, electricity can cause involuntary muscle contraction, producing the "no-let-go" phenomenon, and increasing the risk for serious burns. Voltage levels of 500 to 1000 volts tend to cause internal burns due to the large energy (which is proportional to the duration multiplied by the square of the voltage divided by resistance) available from the source. Damage due to current is through tissue heating and/or electroporation injury. For most cases of high-energy electrical trauma, the Joule heating in the deeper tissues along the extremity will reach damaging temperatures in a few seconds.
Ventricular Fibrillation	A domestic power supply voltage (110 or 230 V), 50 or 60 Hz alternating current (AC) through the chest for a fraction of a second may induce ventricular fibrillation at currents as low as 30 milliamperes (mA). With direct current (DC), 300 to 500 mA is required. If the current has a direct pathway to the heart (e.g., via a cardiac catheter or other kind of electrode), a much lower current of less than 1 mA (AC or DC) can cause fibrillation. If not immediately treated by defibrillation, fibrillation is usually lethal because all of the heart muscle fibres move independently instead of in the coordinated pulses needed to pump blood and maintain circulation. Above 200 mA, muscle contractions are so strong that the heart muscles cannot move at all, but these conditions prevent fibrillation.
Neurological Effects	Electrical current can cause interference with nervous control, especially over the heart and lungs. electric shock which does not lead to death has been shown to cause neuropathy at the site where the current entered the body. The neurologic symptoms of electrical injury may occur immediately, which traditionally have a higher likelihood for healing, though they may also be delayed by days to years. The delayed neurologic consequences of electrical injury have a worse prognosis. When the patch of electrical current proceeds through the head, it appears that, with sufficient current applied, loss of consciousness almost always occurs swiftly. (This is borne out by some limited self-experimentation by early designers of the electric chair and by research from the field of animal husbandry, where electric stunning has been extensively studied). If ventricular fibrillation occurs (as above), the blood supply to the brain is diminished, which may cause cerebral hypoxia (and its associated neurologic consequences).
Psychiatric Effects	There are a variety of psychiatric effects that may occur due to electrical injuries. Recent research has found that functional differences in neural activation during spatial working memory and implicit learning oculomotor tasks have been identified in electrical shock victims. Frank behavioral changes can occur as well, even if the path of electrical current did not proceed through the head. Symptoms may include: ● Depression, including feelings of low self-esteem and guilt ● Anxiety spectrum disorders, including posttraumatic stress disorder and fear of electricity ● Moodiness, including a lower threshold for frustration and "losing one's temper" ● Memory loss, decreased attention span, and difficulty learning
Arc-Flash Hazards	OSHA found that up to 80 percent of its electrical injuries involve thermal burns due to arcing faults. The arc flash in an electrical fault produces the same type of light radiation from which electric welders protect themselves using face shields with dark glass, heavy leather gloves, and full-coverage clothing. The heat produced may cause severe burns, especially on unprotected flesh. The arc blast produced by vaporizing metallic components can break bones and damage internal organs. The degree of hazard present at a particular location can be determined by a detailed analysis of the electrical system, and appropriate protection worn if the electrical work must be performed with the electricity on.

Causes

Physical contact with energized wiring or devices is the most common cause of an electric shock. In cases of exposure to high voltages, such as on a power transmission tower, physical contact with energized wiring or objects may not be necessary to cause electric shock, as the voltage may be sufficient to "jump" the air gap between the electrical device and the victim. The United States National Library of Medicine states: "Contact with 20 mA of current can be fatal".

The minimum current a human can feel depends on the current type (AC or DC) as well as frequency for AC. A person can feel at least 1 mA (rms) of AC at 60 Hz, while at least 5 mA for DC. At around 10 mA, AC current passing through the arm of a 68-kilogram (150 lb) human can cause powerful muscle contractions; the victim is unable to voluntarily control muscles and cannot release an electrified object. This is known as the "let go threshold" and is a criterion for shock hazard in electrical regulations.

The current may, if it is high enough and is delivered at sufficient voltage, cause tissue damage or fibrillation which can cause cardiac arrest; more than 30 mA of AC (rms, 60 Hz) or 300 – 500 mA of DC at high voltage can cause fibrillation. A sustained electric shock from AC at 120 V, 60 Hz is an especially dangerous source of ventricular fibrillation because it usually exceeds the let-go threshold, while not delivering enough initial energy to propel the person away from the source. However, the potential seriousness of the shock depends on paths through the body that the currents take.

If the voltage is less than 200 V, then the human skin, more precisely the stratum corneum, is the main contributor to the impedance of the body in the case of a macroshock—the passing of current between two contact points on the skin. The characteristics of the skin are non-linear however. If the voltage is above 450–600 V, then dielectric breakdown of the skin occurs. The protection offered by the skin is lowered by perspiration, and this is accelerated if electricity causes muscles to contract above the let-go threshold for a sustained period of time.

Point of Entry
Macroshock: Current across intact skin and through the body. Current from arm to arm, or between an arm and a foot, is likely to traverse the heart, therefore it is much more dangerous than current between a leg and the ground. This type of shock by definition must pass into the body through the skin.
Microshock: Very small current source with a pathway directly connected to the heart tissue. The shock is required to be administered from inside the skin, directly to the heart i.e. a pacemaker lead, or a guide wire, conductive catheter etc. connected to a source of current. This is a largely theoretical hazard as modern devices used in these situations include protections against such currents.

Diagnosis

Prevention

Treatment

2 Cardiac Arrest

Cardiac arrest is a sudden loss of blood flow resulting from the failure of the heart to effectively pump. Symptoms include loss of consciousness and abnormal or absent breathing.

Signs & Symptoms

Cardiac arrest is preceded by no warning symptoms in approximately 50 percent of people. For those who do experience symptoms, they will be non-specific, such as new or worsening chest pain, fatigue, blackouts, dizziness, shortness of breath, weakness and vomiting. When cardiac arrest occurs, the most obvious sign of its occurrence will be the lack of a palpable pulse in the victim. Also, as a result of loss of cerebral perfusion (blood flow to the brain), the victim will rapidly lose consciousness and will stop breathing. The main criterion for diagnosing a cardiac arrest, as opposed to respiratory arrest, which shares many of the same features, is lack of circulation; however, there are a number of ways of determining this. Near-death experiences are reported by 10 to 20 percent of people who survived cardiac arrest.

Certain types of prompt intervention can often reverse a cardiac arrest, but without such intervention, death is all but certain. In certain cases, cardiac arrest is an anticipated outcome of a serious illness where death is expected.

Causes

The most common cause of cardiac arrest is coronary artery disease. Less common causes include major blood loss, lack of oxygen, very low potassium, heart failure, and intense physical exercise. A number of inherited disorders may also increase the risk including long QT syndrome. The initial heart rhythm is most often ventricular fibrillation. The diagnosis is confirmed by finding no pulse. While a cardiac arrest may be caused by heart attack or heart failure, these are not the same.

Sudden cardiac arrest (SCA) and sudden cardiac death (SCD) occur when the heart abruptly begins to beat in an abnormal or irregular rhythm (arrhythmia). Without organized electrical activity in the heart muscle, there is no consistent contraction of the ventricles, which results in the heart's inability to generate an adequate cardiac output (forward pumping of blood from heart to rest of the body). There are many different types of arrhythmias, but the ones most frequently recorded in SCA and SCD are ventricular tachycardia (VT) or ventricular fibrillation (VF). Less common causes of dysrhythmias in cardiac arrest include pulseless electrical activity (PEA) or asystole. Such rhythms are seen when there is prolonged cardiac arrest, progression of ventricular fibrillation, or due to efforts such as defibrillation to resuscitate the person.

Sudden cardiac arrest can result from cardiac and non-cardiac causes including the following:

Coronary Artery Disease	Coronary artery disease (CAD), also known as ischemic heart disease, is responsible for 62 to 70 percent of all SCDs. CAD is a much less frequent cause of SCD in people under the age of 40. Cases have shown that the most common finding at postmortem examination of sudden cardiac death (SCD) is chronic high-grade stenosis of at least one segment of a major coronary artery, the arteries that supply the heart muscle with its blood supply.
Structural Heart Disease	Structural heart diseases not related to CAD account for 10% of all SCDs. Examples of these include: cardiomyopathies (hypertrophic, dilated, or arrythmogenic), cardiac rhythm disturbances, congenital coronary artery anomalies, myocarditis, hypertensive heart disease, and congestive heart failure. Left ventricular hypertrophy is thought to be a leading cause of SCD in the adult population. This is most commonly the result of longstanding high blood pressure which has caused secondary damage to the wall of the main pumping chamber of the heart, the left ventricle. A 1999 review of SCDs in the United States found that this accounted for over 30% of SCDs for those under 30 years. A study of military recruits age 18-35 found that this accounted for over 40% of SCDs. Congestive heart failure increases the risk of SCD fivefold.

Inherited Arrhythmia Syndromes	Arrhythmias that are not due to structural heart disease account for 5 to 10% of sudden cardiac arrests. These are frequently caused by genetic disorders that lead to abnormal heart rhythms. The genetic mutations often affect specialised proteins known as ion channels that conduct electrically charged particles across the cell membrane, and this group of conditions are therefore often referred to as channelopathies. Examples of these inherited arrhythmia syndromes include Long QT syndrome, Brugada Syndrome, Catecholaminergic polymorphic ventricular tachycardia, and Short QT syndrome. Other conditions that promote arrhythmias but are not caused by genetic mutations include Wolff-Parkinson-White syndrome. Long QT syndrome, a condition often mentioned in young people's deaths, occurs in one of every 5000 to 7000 newborns and is estimated to be responsible for 3000 deaths each year compared to the approximately 300,000 cardiac arrests seen by emergency services. These conditions are a fraction of the overall deaths related to cardiac arrest but represent conditions which may be detected prior to arrest and may be treatable.

Non-Cardiac Causes
SCA due to non-cardiac causes accounts for the remaining 15 to 25%. The most common non-cardiac causes are trauma, major bleeding (gastrointestinal bleeding, aortic rupture, or intracranial hemorrhage), hypovolemic shock, overdose, drowning, and pulmonary embolism. Cardiac arrest can also be caused by poisoning (for example, by the stings of certain jellyfish), or through electrocution, lightning.

Mnemonic for Reversible Causes
"Hs and Ts" is the name for a mnemonic used to aid in remembering the possible treatable or reversible causes of cardiac arrest:

Hs
- **H**ypovolemia – A lack of blood volume
- **H**ypoxia – A lack of oxygen
- **H**ydrogen ions (Acidosis) – An abnormal pH in the body
- **H**yperkalemia or **H**ypokalemia – Both increased or decreased potassium can be life-threatening.
- **H**ypothermia – A low core body temperature
- **H**ypoglycemia or **H**yperglycemia – Low or high blood glucose

Ts
- **T**ablets or Toxins such as drug overdose
- Cardiac **T**amponade – Fluid building up around the heart
- **T**ension pneumothorax – A collapsed lung
- **T**hrombosis (Myocardial infarction) – Heart attack
- **T**hromboembolism (Pulmonary embolism) – A blood clot in the lung
- **T**raumatic cardiac arrest

Diagnosis

Cardiac arrest is synonymous with clinical death. Historical information and a physical exam diagnosis cardiac arrest, as well as provides information regarding the potential cause and the prognosis. The history should aim to determine if the episode was observed by anyone else, what time the episode took place, what the person was doing (in particular if there was any trauma), and involvement of drugs.

The physical examination portion of diagnosis cardiac arrest focuses on the absence of a pulse clinically. In many cases lack of carotid pulse is the gold standard for diagnosing cardiac arrest, as lack of a pulse (particularly in the peripheral pulses) may result from other conditions (e.g. shock), or simply an error on the part of the rescuer. Nonetheless, studies have shown that rescuers often make a mistake when checking the carotid pulse in an emergency, whether they are healthcare professionals or lay persons.

Owing to the inaccuracy in this method of diagnosis, some bodies such as the European Resuscitation Council (ERC) have de-emphasised its importance. The Resuscitation Council (UK), in line with the ERC's recommendations and those of the American Heart Association, have suggested that the technique should be used only by healthcare professionals with specific training and expertise, and even then that it should be viewed in conjunction with other indicators such as agonal respiration.

Various other methods for detecting circulation have been proposed. Guidelines following the 2000 International Liaison Committee on Resuscitation (ILCOR) recommendations were for rescuers to look for "signs of circulation", but not specifically the pulse. These signs included coughing, gasping, colour, twitching, and movement. However, in face of evidence that these guidelines were ineffective, the current recommendation of ILCOR is that cardiac arrest should be diagnosed in all casualties who are unconscious and not breathing normally. Another method is to use molecular autopsy or postmortem molecular testing which uses a set of molecular techniques to find the ion channels that are cardiac defective.

Location	Findings	Possible Causes
General	Pale skin	• Hemorrhage
General	Decreased body temperature	• Hypothermia
Airway	Presence of secretions, vomit, blood	• Aspiration
Airway	Inability to provide positive pressure ventilation	• Tension pneumothorax • Airway obstruction
Neck	Distension of the neck veins	• Tension pneumothorax • Cardiac tamponade • Pulmonary embolism
Chest	Trachea shifted to one side	• Tension pneumothorax
Chest	Scar in the middle of the sternum	• Cardiac disease • Tension pneumothorax
Chest	No breath sounds or distant breath sounds	• Esophageal intubation • Airway obstruction
Chest	Wheezing	• Aspiration • Bronchospasm • Pulmonary edema
Chest	Rales	• Aspiration • Pulmonary edema • Pneumonia
Heart	Decreased heart sounds	• Cardiac tamponade • Tension pneumothorax • Pulmonary embolus
Abdomen	Distended and dull	• Ruptured abdominal aortic aneurysm • Ruptured ectopic pregnancy
Abdomen	Distended and tympanic	• Esophageal intubation
Rectal	Blood present	• Gastrointestinal hemorrhage

Extremities	Asymmetrical pulses	• Aortic dissection
Skin	Needle tracks	• Drug abuse

Prevention

With positive outcomes following cardiac arrest unlikely, an effort has been spent in finding effective strategies to prevent cardiac arrest. With the prime causes of cardiac arrest being ischemic heart disease, efforts to promote a healthy diet, exercise, and smoking cessation are important. For people at risk of heart disease, measures such as blood pressure control, cholesterol lowering, and other medico-therapeutic interventions are used. A Cochrane review published in 2016 found moderate-quality evidence to show that blood pressure-lowering drugs do not appear to reduce sudden cardiac death.

Implantable Cardioverter Defibrillator	An implantable cardioverter defibrillator (ICD) is a battery-powered device that monitors electrical activity in the heart and when an arrhythmia or asystole is detected is able to deliver an electrical shock to terminate the abnormal rhythm. ICDs are used to prevent sudden cardiac death (SCD) in those that have survived a prior episode of sudden cardiac arrest (SCA) due to ventricular fibrillation or ventricular tachycardia (secondary prevention). ICD's are also used prophylactically to prevent sudden cardiac death in certain high risk patient populations (primary prevention). Numerous studies have been conducted on the use of ICDs for the secondary prevention of SCD. These studies have shown improved survival with ICD's compared to the use of anti-arrhythmic drugs. ICD therapy is associated with a 50% relative risk reduction in death caused by an arrhythmia and a 25% relative risk reduction in all cause mortality.
Diet	Marine-derived omega-3 polyunsaturated fatty acids (PUFAs) have been promoted for the prevention of sudden cardiac death due to their postulated ability to lower triglyceride levels, prevent arrhythmias, decrease platelet aggregation, and lower blood pressure. However, according to a recent systematic review, omega-3 PUFA supplementation are not being associated with a lower risk of sudden cardiac death.
Risk Factors	The risk factors for SCD are similar to those of coronary artery disease and include age, cigarette smoking, high blood pressure, high cholesterol, lack of physical exercise, obesity, diabetes, and family history. A prior episode of sudden cardiac arrest also increases the risk of future episodes. Air pollution is also associated with the risk of cardiac arrest. Current cigarette smokers with coronary artery disease were found to have a two to threefold increase in the risk of sudden death between ages 30 and 59. Furthermore, it was found that former smokers' risk was closer to that of those who had never smoked.

Treatment

Sudden cardiac arrest may be treated via attempts at resuscitation. This is usually carried out based upon basic life support, advanced cardiac life support (ACLS), pediatric advanced life support (PALS), or neonatal resuscitation program (NRP) guidelines.

Cardiopulmonary Resuscitation
Early cardiopulmonary resuscitation (CPR) is essential to surviving cardiac arrest with good neurological function. It is recommended that it be started as soon as possible with minimal interruptions once begun. The components of CPR that make the greatest difference in survival are chest compressions and defibrillating shockable rhythms. After defibrillation, chest compressions should be continued for two minutes before a rhythm check is again done. This is based off a compression rate of 100-120 compressions per minute, a compression depth of 5–6 centimeters into the chest, full chest recoil, and a ventilation rate of 10 breath ventilations per minute. Correctly performed bystander CPR has been shown to increase survival; however, it is performed in less than 30% of out of hospital arrests as of 2007. If high-quality CPR has not resulted in return of spontaneous circulation and the person's heart rhythm is in asystole, discontinuing CPR and pronouncing the person's death is reasonable after 20 minutes. Exceptions to this include certain cases with hypothermia or who have drowned. Some of these cases should have longer and more sustained CPR until they are nearly normothermic. Longer durations of CPR may be reasonable in those who have cardiac arrest while in hospital. Bystander CPR, by the lay public, before the arrival of EMS also improves outcomes.

Either a bag valve mask or an advanced airway may be used to help with breathing. High levels of oxygen are generally given during CPR. Tracheal intubation has not been found to improve survival rates or neurological outcome in cardiac arrest and in the prehospital environment may worsen it. Endotracheal tube and supraglottic airways appear equally useful. When done by EMS 30 compressions followed by two breaths appear better than continuous chest compressions and breaths being given while compressions are ongoing.

For bystanders, CPR which involves only chest compressions results in better outcomes as compared to standard CPR for those who have gone into cardiac arrest due to heart issues. Mechanical chest compressions (as performed by a machine) are no better than chest compressions performed by hand. It is unclear if a few minutes of CPR before defibrillation results in different outcomes than immediate defibrillation. If cardiac arrest occurs after 20 weeks of pregnancy someone should pull or push the uterus to the left during CPR. If a pulse has not returned by four minutes emergency Cesarean section is recommended.

Defibrillation
In addition, there is increasing use of public access defibrillation. This involves placing an automated external defibrillator in public places, and training staff in these areas how to use them. This allows defibrillation to take place prior to the arrival of emergency services and has been shown to lead to increased chances of survival. Some defibrillators even provide feedback on the quality of CPR compressions, encouraging the lay rescuer to press the person's chest hard enough to circulate blood. In addition, it has been shown that those who have arrests in remote locations have worse outcomes following cardiac arrest.

Defibrillation is indicated if a shockable rhythm is present. The two shockable rhythms are ventricular fibrillation and pulseless ventricular tachycardia. In children 2 to 4 J/Kg is recommended.

Medications
As of 2016, medications other than epinephrine (adrenaline), while included in guidelines, have not been shown to improve survival to hospital discharge following out-of-hospital cardiac arrest. This includes the use of atropine, lidocaine, and amiodarone. Epinephrine in adults, as of 2019, appears to improve survival but does not appear to improve neurologically normal survival. It is generally recommended every five minutes. Vasopressin overall does not improve or worsen outcomes compared to epinephrine. The combination of epinephrine, vasopressin, and methylprednisolone appears to improve outcomes. Some of the lack of long-term benefit may be related to delays in epinephrine use. While evidence does not support its use in children, guidelines state its use is reasonable. Lidocaine and amiodarone are also deemed reasonable in children with cardiac arrest who have a shockable rhythm. The general use of sodium bicarbonate or calcium is not recommended. The use of calcium in children has been associated with poor neurological function as well as decreased survival. Correct dosing of medications in children is dependent on weight. To minimize time spent calculating medication doses, the use of a Broselow tape is recommended.

The 2010 guidelines from the American Heart Association no longer contain the recommendation for using atropine in pulseless electrical activity and asystole for want of evidence for its use. Neither lidocaine nor amiodarone, in those who continue in ventricular tachycardia or ventricular fibrillation despite defibrillation, improves survival to hospital discharge but both equally improve survival to hospital admission.

Thrombolytics when used generally may cause harm but may be of benefit in those with a confirmed pulmonary embolism as the cause of arrest. Evidence for use of naloxone in those with cardiac arrest due to opioids is unclear but it may still be used. In those with cardiac arrest due to local anesthetic, lipid emulsion may be used.

Targeted Temperature Management
Cooling adults after cardiac arrest who have a return of spontaneous circulation (ROSC) but no return of consciousness improves outcomes. This procedure is called targeted temperature management (previously known as therapeutic hypothermia). People are typically cooled for a 24-hour period, with a target temperature of 32–36 °C (90–97 °F). There are a number of methods used to lower the body temperature, such as applying ice packs or cold-water circulating pads directly to the body, or infusing cold saline. This is followed by gradual rewarming over the next 12 to 24 hrs.

Recent meta-analysis found that the use of therapeutic hypothermia after out-of-hospital cardiac arrest is associated with improved survival rates and better neurological outcomes.

Chain of Survival
Several organizations promote the idea of a chain of survival. The chain consists of the following "links":
● Early recognition If possible, recognition of illness before the person develops a cardiac arrest will allow the rescuer to prevent its occurrence. Early recognition that a cardiac arrest has occurred is key to survival for every minute a patient stays in cardiac arrest, their chances of survival drop by roughly 10%.
● Early CPR improves the flow of blood and of oxygen to vital organs, an essential component of treating a cardiac arrest. In particular, by keeping the brain supplied with oxygenated blood, chances of neurological damage are decreased.
● Early defibrillation is effective for the management of ventricular fibrillation and pulseless ventricular tachycardia
● Early advanced care
● Early post-resuscitation care which may include percutaneous coronary intervention
If one or more links in the chain are missing or delayed, then the chances of survival drop significantly.

These protocols are often initiated by a code blue, which usually denotes impending or acute onset of cardiac arrest or respiratory failure, although in practice, code blue is often called in less life-threatening situations that require immediate attention from a physician.

Other
Resuscitation with extracorporeal membrane oxygenation devices has been attempted with better results for in-hospital cardiac arrest (29% survival) than out-of-hospital cardiac arrest (4% survival) in populations selected to benefit most. Cardiac catheterization in those who have survived an out-of-hospital cardiac arrest appears to improve outcomes although high quality evidence is lacking. It is recommended that it is done as soon as possible in those who have had a cardiac arrest with ST elevation due to underlying heart problems.

The precordial thump may be considered in those with witnessed, monitored, unstable ventricular tachycardia (including pulseless VT) if a defibrillator is not immediately ready for use, but it should not delay CPR and shock delivery or be used in those with unwitnessed out of hospital arrest.

Prognosis

The overall chance of survival among those who have cardiac arrest outside hospital is 10%. Among those who have an out-of-hospital cardiac arrest, 70% occur at home and their survival rate is 6%. For those who have an in-hospital cardiac arrest, the survival rate is estimated to be 24%. Among children rates of survival are 3 to 16% in North America. For in hospital cardiac arrest survival to discharge is around 22%. However, some may have neurological injury that can range from mild memory problems to coma.

Prognosis is typically assessed 72 hours or more after cardiac arrest. Rates of survival are better in those who someone saw collapse, got bystander CPR, or had either ventricular tachycardia or ventricular fibrillation when assessed. Survival among those with Vfib or Vtach is 15 to 23%. Women are more likely to survive cardiac arrest and leave hospital than men.

A 1997 review found rates of survival to discharge of 14% although different studies varied from 0 to 28%. In those over the age of 70 who have a cardiac arrest while in hospital, survival to hospital discharge is less than 20%. How well these individuals are able to manage after leaving hospital is not clear.

A study of survival rates from out-of-hospital cardiac arrest found that 14.6% of those who had received resuscitation by paramedics survived as far as admission to hospital. Of these, 59% died during admission, half of these within the first 24 hours, while 46% survived until discharge from hospital. This reflects an overall survival following cardiac arrest of 6.8%. Of these 89% had normal brain function or mild neurological disability, 8.5% had moderate impairment, and 2% had major neurological disability. Of those who were discharged from hospital, 70% were still alive four years later.

3 Stroke

A stroke is a medical condition in which poor blood flow to the brain results in cell death. There are two main types of stroke: ischemic, due to lack of blood flow, and hemorrhagic, due to bleeding. Both result in parts of the brain not functioning properly.

Signs & Symptoms

Stroke symptoms typically start suddenly, over seconds to minutes, and in most cases do not progress further. The symptoms depend on the area of the brain affected. The more extensive the area of the brain affected, the more functions that are likely to be lost. Some forms of stroke can cause additional symptoms. For example, in intracranial hemorrhage, the affected area may compress other structures. Most forms of stroke are not associated with a headache, apart from subarachnoid hemorrhage and cerebral venous thrombosis and occasionally intracerebral hemorrhage.

Early Recognition
Various systems have been proposed to increase recognition of stroke. Different findings are able to predict the presence or absence of stroke to different degrees. Sudden-onset face weakness, arm drift (i.e., if a person, when asked to raise both arms, involuntarily lets one arm drift downward) and abnormal speech are the findings most likely to lead to the correct identification of a case of stroke, increasing the likelihood by 5.5 when at least one of these is present. Similarly, when all three of these are absent, the likelihood of stroke is decreased (– likelihood ratio of 0.39). While these findings are not perfect for diagnosing stroke, the fact that they can be evaluated relatively rapidly and easily make them very valuable in the acute setting.

A mnemonic to remember the warning signs of stroke is FAST (facial droop, arm weakness, speech difficulty, and time to call emergency services), as advocated by the Department of Health (United Kingdom) and the Stroke Association, the American Stroke Association, the National Stroke Association (US), the Los Angeles Prehospital Stroke Screen (LAPSS) and the Cincinnati Prehospital Stroke Scale (CPSS). Use of these scales is recommended by professional guidelines. FAST is less reliable in the recognition of posterior circulation strokes.

Subtypes
If the area of the brain affected includes one of the three prominent central nervous system pathways—the spinothalamic tract, corticospinal tract, and the dorsal column–medial lemniscus pathway, symptoms may include:

● Hemiplegia and muscle weakness of the face
● Numbness
● Reduction in sensory or vibratory sensation
● Initial flaccidity (reduced muscle tone), replaced by spasticity (increased muscle tone), excessive reflexes, and obligatory synergies.

In most cases, the symptoms affect only one side of the body (unilateral). Depending on the part of the brain affected, the defect in the brain is usually on the opposite side of the body. However, since these pathways also travel in the spinal cord and any lesion there can also produce these symptoms, the presence of any one of these symptoms does not necessarily indicate a stroke. In addition to the above CNS pathways, the brainstem gives rise to most of the twelve cranial nerves. A brainstem stroke affecting the brainstem and brain, therefore, can produce symptoms relating to deficits in these cranial nerves:

INJURY | Other | Stroke | Signs & Symptoms

- Altered smell, taste, hearing, or vision (total or partial)
- Drooping of eyelid (ptosis) and weakness of ocular muscles
- Decreased reflexes: gag, swallow, pupil reactivity to light
- Decreased sensation and muscle weakness of the face
- Balance problems and nystagmus
- Altered breathing and heart rate
- Weakness in sternocleidomastoid muscle with inability to turn head to one side
- Weakness in tongue (inability to stick out the tongue or move it from side to side)

If the cerebral cortex is involved, the CNS pathways can again be affected, but also can produce the following symptoms:
- Aphasia (difficulty with verbal expression, auditory comprehension, reading and writing; Broca's or Wernicke's area typically involved)
- Dysarthria (motor speech disorder resulting from neurological injury)
- Apraxia (altered voluntary movements)
- Visual field defect
- Memory deficits (involvement of temporal lobe)
- Hemineglect (involvement of parietal lobe)
- Disorganized thinking, confusion, hypersexual gestures (with involvement of frontal lobe)
- Lack of insight of his or her, usually stroke-related, disability

If the cerebellum is involved, ataxia might be present and this includes:
- Altered walking gait
- Altered movement coordination
- Vertigo and or disequilibrium

Associated Symptoms
Loss of consciousness, headache, and vomiting usually occur more often in hemorrhagic stroke than in thrombosis because of the increased intracranial pressure from the leaking blood compressing the brain. If symptoms are maximal at onset, the cause is more likely to be a subarachnoid hemorrhage or an embolic stroke.

Causes

Thrombotic Stroke
In thrombotic stroke, a thrombus (blood clot) usually forms around atherosclerotic plaques. Since blockage of the artery is gradual, onset of symptomatic thrombotic strokes is slower than that of a hemorrhagic stroke. A thrombus itself (even if it does not completely block the blood vessel) can lead to an embolic stroke if the thrombus breaks off and travels in the bloodstream, at which point it is called an embolus. Two types of thrombosis can cause stroke:

- Large vessel disease involves the common and internal carotid arteries, the vertebral artery, and the Circle of Willis. Diseases that may form thrombi in the large vessels include (in descending incidence): atherosclerosis, vasoconstriction (tightening of the artery), aortic, carotid or vertebral artery dissection, various inflammatory diseases of the blood vessel wall (Takayasu arteritis, giant cell arteritis, vasculitis), noninflammatory vasculopathy, Moyamoya disease and fibromuscular dysplasia.
- Small vessel disease involves the smaller arteries inside the brain: branches of the circle of Willis, middle cerebral artery, stem, and arteries arising from the distal vertebral and basilar artery. Diseases that may form thrombi in the small vessels include (in descending incidence): lipohyalinosis (build-up of fatty hyaline matter in the blood vessel as a result of high blood pressure and aging) and fibrinoid degeneration (a stroke involving these vessels is known as a lacunar stroke) and microatheroma (small atherosclerotic plaques).

Sickle-cell anemia, which can cause blood cells to clump up and block blood vessels, can also lead to stroke. A stroke is the second leading cause of death in people under 20 with sickle-cell anemia. Air pollution may also increase stroke risk.

Embolic Stroke
An embolic stroke refers to an arterial embolism (a blockage of an artery) by an embolus, a traveling particle or debris in the arterial bloodstream originating from elsewhere. An embolus is most frequently a thrombus, but it can also be a number of other substances including fat (e.g., from bone marrow in a broken bone), air, cancer cells or clumps of bacteria (usually from infectious endocarditis).

Because an embolus arises from elsewhere, local therapy solves the problem only temporarily. Thus, the source of the embolus must be identified. Because the embolic blockage is sudden in onset, symptoms usually are maximal at the start. Also, symptoms may be transient as the embolus is partially resorbed and moves to a different location or dissipates altogether.

Emboli most commonly arise from the heart (especially in atrial fibrillation) but may originate from elsewhere in the arterial tree. In paradoxical embolism, a deep vein thrombosis embolizes through an atrial or ventricular septal defect in the heart into the brain.

Causes of stroke related to the heart can be distinguished between high and low-risk:
- High risk: atrial fibrillation and paroxysmal atrial fibrillation, rheumatic disease of the mitral or aortic valve disease, artificial heart valves, known cardiac thrombus of the atrium or ventricle, sick sinus syndrome, sustained atrial flutter, recent myocardial infarction, chronic myocardial infarction together with ejection fraction <28 percent, symptomatic congestive heart failure with ejection fraction <30 percent, dilated cardiomyopathy, Libman-Sacks endocarditis, Marantic endocarditis, infective endocarditis, papillary fibroelastoma, left atrial myxoma and coronary artery bypass graft (CABG) surgery.
- Low risk/potential: calcification of the annulus (ring) of the mitral valve, patent foramen ovale (PFO), atrial septal aneurysm, atrial septal aneurysm with patent foramen ovale, left ventricular aneurysm without thrombus, isolated left atrial "smoke" on echocardiography (no mitral stenosis or atrial fibrillation), complex atheroma in the ascending aorta or proximal arch.

Among those who have a complete blockage of one of the carotid arteries, the risk of stroke on that side is about one percent per year. A special form of embolic stroke is the embolic stroke of undetermined source (ESUS). This subset of cryptogenetic stroke is defined as a non-lacunar brain infarct without proximal arterial stenosis or cardioembolic sources. About one out of six ischemic strokes could be classified as ESUS.

Cerebral Hypoperfusion
Cerebral hypoperfusion is the reduction of blood flow to all parts of the brain. The reduction could be to a particular part of the brain depending on the cause. It is most commonly due to heart failure from cardiac arrest or arrhythmias, or from reduced cardiac output as a result of myocardial infarction, pulmonary embolism, pericardial effusion, or bleeding. Hypoxemia (low blood oxygen content) may precipitate the hypoperfusion. Because the reduction in blood flow is global, all parts of the brain may be affected, especially vulnerable "watershed" areas—border zone regions supplied by the major cerebral arteries. A watershed stroke refers to the condition when the blood supply to these areas is compromised. Blood flow to these areas does not necessarily stop, but instead it may lessen to the point where brain damage can occur.

Venous Thrombosis
Cerebral venous sinus thrombosis leads to stroke due to locally increased venous pressure, which exceeds the pressure generated by the arteries. Infarcts are more likely to undergo hemorrhagic transformation (leaking of blood into the damaged area) than other types of ischemic stroke.

Intracerebral Hemorrhage
It generally occurs in small arteries or arterioles and is commonly due to hypertension, intracranial vascular malformations (including cavernous angiomas or arteriovenous malformations), cerebral amyloid angiopathy, or infarcts into which secondary hemorrhage has occurred. Other potential causes are trauma, bleeding disorders, amyloid angiopathy, illicit drug use (e.g., amphetamines or cocaine).

The hematoma enlarges until pressure from surrounding tissue limits its growth, or until it decompresses by emptying into the ventricular system, CSF or the pial surface. A third of intracerebral bleed is into the brain's ventricles. ICH has a mortality rate of 44 percent after 30 days, higher than ischemic stroke or subarachnoid hemorrhage (which technically may also be classified as a type of stroke).

Other
Other causes may include spasm of an artery. This may occur due to cocaine.

Silent Stroke
A silent stroke is a stroke that does not have any outward symptoms, and the patients are typically unaware they have had a stroke. Despite not causing identifiable symptoms, a silent stroke still damages the brain and places the patient at increased risk for both transient ischemic attack and major stroke in the future. Conversely, those who have had a major stroke are also at risk of having silent strokes. In a broad study in 1998, more than 11 million people were estimated to have experienced a stroke in the United States.

Approximately 770,000 of these strokes were symptomatic and 11 million were first-ever silent MRI infarcts or hemorrhages. Silent strokes typically cause lesions which are detected via the use of neuroimaging such as MRI. Silent strokes are estimated to occur at five times the rate of symptomatic strokes. The risk of silent stroke increases with age, but may also affect younger adults and children, especially those with acute anemia.

Diagnosis

Stroke is diagnosed through several techniques: a neurological examination (such as the NIHSS), CT scans (most often without contrast enhancements) or MRI scans, Doppler ultrasound, and arteriography. The diagnosis of stroke itself is clinical, with assistance from the imaging techniques. Imaging techniques also assist in determining the subtypes and cause of stroke. There is yet no commonly used blood test for the stroke diagnosis itself, though blood tests may be of help in finding out the likely cause of stroke.

Physical Examination
A physical examination, including taking a medical history of the symptoms and a neurological status, helps giving an evaluation of the location and severity of a stroke. It can give a standard score on e.g., the NIH stroke scale.

Prevention

Given the disease burden of strokes, prevention is an important public health concern. Primary prevention is less effective than secondary prevention (as judged by the number needed to treat to prevent one stroke per year). Recent guidelines detail the evidence for primary prevention in stroke. In those who are otherwise healthy, aspirin does not appear beneficial and thus is not recommended. In people who have had a myocardial infarction or those with a high cardiovascular risk, it provides some protection against a first stroke. In those who have previously had a stroke, treatment with medications such as aspirin, clopidogrel, and dipyridamole may be beneficial. The U.S. Preventive Services Task Force (USPSTF) recommends against screening for carotid artery stenosis in those without symptoms.

Risk Factors
The most important modifiable risk factors for stroke are high blood pressure and atrial fibrillation although the size of the effect is small with 833 people have to be treated for 1 year to prevent one stroke. Other modifiable risk factors include high blood cholesterol levels, diabetes mellitus, cigarette smoking (active and passive), heavy alcohol use, drug use, lack of physical activity, obesity, processed red meat consumption, and unhealthy diet. Smoking just one cigarette per day increases the risk more than 30%.

Alcohol use could predispose to ischemic stroke, as well as intracerebral and subarachnoid hemorrhage via multiple mechanisms (for example, via hypertension, atrial fibrillation, rebound thrombocytosis and platelet aggregation and clotting disturbances). Drugs, most commonly amphetamines and cocaine, can induce stroke through damage to the blood vessels in the brain and acute hypertension. Migraine with aura doubles a person's risk for ischemic stroke. Untreated, celiac disease regardless of the presence of symptoms can be an underlying cause of stroke, both in children and adults.

High levels of physical activity reduce the risk of stroke by about 26%. There is a lack of high quality studies looking at promotional efforts to improve lifestyle factors. Nonetheless, given the large body of circumstantial evidence, best medical management for stroke includes advice on diet, exercise, smoking and alcohol use. Medication is the most common method of stroke prevention; carotid endarterectomy can be a useful surgical method of preventing stroke.

Blood Pressure
High blood pressure accounts for 35–50% of stroke risk. Blood pressure reduction of 10 mmHg systolic or 5 mmHg diastolic reduces the risk of stroke by ~40%. Lowering blood pressure has been conclusively shown to prevent both ischemic and hemorrhagic strokes. It is equally important in secondary prevention. Even patients older than 80 years and those with isolated systolic hypertension benefit from antihypertensive therapy. The available evidence does not show large differences in stroke prevention between antihypertensive drugs—therefore, other factors such as protection against other forms of cardiovascular disease and cost should be considered. The routine use of beta-blockers following a stroke or TIA has not been shown to result in benefits.

Blood Lipids
High cholesterol levels have been inconsistently associated with (ischemic) stroke. Statins have been shown to reduce the risk of stroke by about 15%. Since earlier meta-analyses of other lipid-lowering drugs did not show a decreased risk, statins might exert their effect through mechanisms other than their lipid-lowering effects.

Diabetes Mellitus
Diabetes mellitus increases the risk of stroke by 2 to 3 times. While intensive blood sugar control has been shown to reduce small blood vessel complications such as kidney damage and damage to the retina of the eye it has not been shown to reduce large blood vessel complications such as stroke.

Anticoagulation Drugs
Oral anticoagulants such as warfarin have been the mainstay of stroke prevention for over 50 years. However, several studies have shown that aspirin and other antiplatelets are highly effective in secondary prevention after a stroke or transient ischemic attack. Low doses of aspirin (for example 75–150 mg) are as effective as high doses but have fewer side effects; the lowest effective dose remains unknown.

Thienopyridines (clopidogrel, ticlopidine) might be slightly more effective than aspirin and have a decreased risk of gastrointestinal bleeding, but are more expensive. Both aspirin and clopidogrel may be useful in the first few weeks after a minor stroke or high risk TIA. Clopidogrel has less side effects than ticlopidine. Dipyridamole can be added to aspirin therapy to provide a small additional benefit, even though headache is a common side effect. Low-dose aspirin is also effective for stroke prevention after having a myocardial infarction.

INJURY Other Stroke Prevention

Those with atrial fibrillation have a 5% a year risk of stroke, and this risk is higher in those with valvular atrial fibrillation. Depending on the stroke risk, anticoagulation with medications such as warfarin or aspirin is useful for prevention. Except in people with atrial fibrillation, oral anticoagulants are not advised for stroke prevention—any benefit is offset by bleeding risk. In primary prevention, however, antiplatelet drugs did not reduce the risk of ischemic stroke but increased the risk of major bleeding. Further studies are needed to investigate a possible protective effect of aspirin against ischemic stroke in women.

Surgery
Carotid endarterectomy or carotid angioplasty can be used to remove atherosclerotic narrowing of the carotid artery. There is evidence supporting this procedure in selected cases. Endarterectomy for a significant stenosis has been shown to be useful in preventing further strokes in those who have already had one. Carotid artery stenting has not been shown to be equally useful. People are selected for surgery based on age, gender, degree of stenosis, time since symptoms and the person's preferences. Surgery is most efficient when not delayed too long—the risk of recurrent stroke in a patient who has a 50% or greater stenosis is up to 20% after 5 years, but endarterectomy reduces this risk to around 5%. The number of procedures needed to cure one patient was 5 for early surgery (within two weeks after the initial stroke), but 125 if delayed longer than 12 weeks.

Screening for carotid artery narrowing has not been shown to be a useful test in the general population. Studies of surgical intervention for carotid artery stenosis without symptoms have shown only a small decrease in the risk of stroke. To be beneficial, the complication rate of the surgery should be kept below 4%. Even then, for 100 surgeries, 5 patients will benefit by avoiding stroke, 3 will develop stroke despite surgery, 3 will develop stroke or die due to the surgery itself, and 89 will remain stroke-free but would also have done so without intervention.

Diet
Nutrition, specifically the Mediterranean-style diet, has the potential for decreasing the risk of having a stroke by more than half. It does not appear that lowering levels of homocysteine with folic acid affects the risk of stroke.

Women
A number of specific recommendations have been made for women including taking aspirin after the 11th week of pregnancy if there is a history of previous chronic high blood pressure and taking blood pressure medications during pregnancy if the blood pressure is greater than 150 mmHg systolic or greater than 100 mmHg diastolic. In those who have previously had preeclampsia other risk factors should be treated more aggressively.

Previous stroke or TIA
Keeping blood pressure below 140/90 mmHg is recommended. Anticoagulation can prevent recurrent ischemic strokes. Among people with nonvalvular atrial fibrillation, anticoagulation can reduce stroke by 60% while antiplatelet agents can reduce stroke by 20%. However, a recent meta-analysis suggests harm from anticoagulation started early after an embolic stroke. Stroke prevention treatment for atrial fibrillation is determined according to the CHA2DS2–VASc score. The most widely used anticoagulant to prevent thromboembolic stroke in patients with nonvalvular atrial fibrillation is the oral agent warfarin while a number of newer agents including dabigatran are alternatives which do not require prothrombin time monitoring.

Anticoagulants, when used following stroke, should not be stopped for dental procedures.

If studies show carotid artery stenosis, and the person has a degree of residual function on the affected side, carotid endarterectomy (surgical removal of the stenosis) may decrease the risk of recurrence if performed rapidly after stroke.

Treatment

Management

Ischemic Stroke
Aspirin reduces the overall risk of recurrence by 13% with greater benefit early on. Definitive therapy within the first few hours is aimed at removing the blockage by breaking the clot down (thrombolysis), or by removing it mechanically (thrombectomy). The philosophical premise underlying the importance of rapid stroke intervention was summed up as Time is Brain! in the early 1990s. Years later, that same idea, that rapid cerebral blood flow restoration results in fewer brain cells dying, has been proved and quantified.

Tight blood sugar control in the first few hours does not improve outcomes and may cause harm. High blood pressure is also not typically lowered as this has not been found to be helpful. Cerebrolysin, a mix of pig brain tissue used to treat acute ischemic stroke in many Asian and European countries, does not improve outcomes and may increase the risk of severe adverse events.

Thrombolysis
Thrombolysis, such as with recombinant tissue plasminogen activator (rtPA), in acute ischemic stroke, when given within three hours of symptom onset, results in an overall benefit of 10% with respect to living without disability. It does not, however, improve chances of survival. Benefit is greater the earlier it is used. Between three and four and a half hours the effects are less clear. The AHA/ASA recommend it for certain people in this time frame. A 2014 review found a 5% increase in the number of people living without disability at three to six months; however, there was a 2% increased risk of death in the short term. After four and a half hours thrombolysis worsens outcomes. These benefits or lack of benefits occurred regardless of the age of the person treated. There is no reliable way to determine who will have an intracranial bleed post-treatment versus who will not. In those with findings of savable tissue on medical imaging between 4.5 hours and 9 hours or who wake up with a stroke, alteplase results in some benefit.

Its use is endorsed by the American Heart Association, the American College of Emergency Physicians and the American Academy of Neurology as the recommended treatment for acute stroke within three hours of onset of symptoms as long as there are no other contraindications (such as abnormal lab values, high blood pressure, or recent surgery). This position for tPA is based upon the findings of two studies by one group of investigators which showed that tPA improves the chances for a good neurological outcome. When administered within the first three hours thrombolysis improves functional outcome without affecting mortality. 6.4% of people with large strokes developed substantial brain bleeding as a complication from being given tPA thus part of the reason for increased short term mortality. The American Academy of Emergency Medicine had previously stated that objective evidence regarding the applicability of tPA for acute ischemic stroke was insufficient. In 2013 the American College of Emergency Medicine refuted this position, acknowledging the body of evidence for the use of tPA in ischemic stroke; but debate continues. Intra-arterial fibrinolysis, where a catheter is passed up an artery into the brain and the medication is injected at the site of thrombosis, has been found to improve outcomes in people with acute ischemic stroke.

Endovascular Treatment
Mechanical removal of the blood clot causing the ischemic stroke, called mechanical thrombectomy, is a potential treatment for occlusion of a large artery, such as the middle cerebral artery. In 2015, one review demonstrated the safety and efficacy of this procedure if performed within 12 hours of the onset of symptoms. It did not change the risk of death, but reduced disability compared to the use of intravenous thrombolysis which is generally used in people evaluated for mechanical thrombectomy. Certain cases may benefit from thrombectomy up to 24 hours after the onset of symptoms.

Craniectomy
Strokes affecting large portions of the brain can cause significant brain swelling with secondary brain injury in surrounding tissue. This phenomenon is mainly encountered in strokes affecting brain tissue dependent upon the middle cerebral artery for blood supply and is also called "malignant cerebral infarction" because it carries a dismal prognosis. Relief of the pressure may be attempted with medication, but some require hemicraniectomy, the temporary surgical removal of the skull on one side of the head. This decreases the risk of death, although some people – who would otherwise have died – survive with disability.

Hemorrhagic Stroke
People with intracerebral hemorrhage require supportive care, including blood pressure control if required. People are monitored for changes in the level of consciousness, and their blood sugar and oxygenation are kept at optimum levels. Anticoagulants and antithrombotics can make bleeding worse and are generally discontinued (and reversed if possible). A proportion may benefit from neurosurgical intervention to remove the blood and treat the underlying cause, but this depends on the location and the size of the hemorrhage as well as patient-related factors, and ongoing research is being conducted into the question as to which people with intracerebral hemorrhage may benefit.

In subarachnoid hemorrhage, early treatment for underlying cerebral aneurysms may reduce the risk of further hemorrhages. Depending on the site of the aneurysm this may be by surgery that involves opening the skull or endovascularly (through the blood vessels).

Prognosis

Disability affects 75% of stroke survivors enough to decrease their employability. Stroke can affect people physically, mentally, emotionally, or a combination of the three. The results of stroke vary widely depending on size and location of the lesion. Dysfunctions correspond to areas in the brain that have been damaged.

Some of the physical disabilities that can result from stroke include muscle weakness, numbness, pressure sores, pneumonia, incontinence, apraxia (inability to perform learned movements), difficulties carrying out daily activities, appetite loss, speech loss, vision loss and pain. If the stroke is severe enough, or in a certain location such as parts of the brainstem, coma or death can result.

Emotional problems following a stroke can be due to direct damage to emotional centers in the brain or from frustration and difficulty adapting to new limitations. Post-stroke emotional difficulties include anxiety, panic attacks, flat affect (failure to express emotions), mania, apathy and psychosis. Other difficulties may include a decreased ability to communicate emotions through facial expression, body language and voice.

Disruption in self-identity, relationships with others, and emotional well-being can lead to social consequences after stroke due to the lack of ability to communicate. Many people who experience communication impairments after a stroke find it more difficult to cope with the social issues rather than physical impairments. Broader aspects of care must address the emotional impact speech impairment has on those who experience difficulties with speech after a stroke. Those who experience a stroke are at risk of paralysis which could result in a self disturbed body image which may also lead to other social issues.

30 to 50% of stroke survivors suffer post-stroke depression, which is characterized by lethargy, irritability, sleep disturbances, lowered self-esteem and withdrawal. Depression can reduce motivation and worsen outcome, but can be treated with social and family support, psychotherapy and, in severe cases, antidepressants. Psychotherapy sessions may have a small effect on improving mood and preventing depression after a stroke, however psychotherapy does not appear to be effective at treating depression after a stroke. Antidepressant medications may be useful for treating depression after a stroke.

Emotional lability, another consequence of stroke, causes the person to switch quickly between emotional highs and lows and to express emotions inappropriately, for instance with an excess of laughing or crying with little or no provocation. While these expressions of emotion usually correspond to the person's actual emotions, a more severe form of emotional lability causes the affected person to laugh and cry pathologically, without regard to context or emotion. Some people show the opposite of what they feel, for example crying when they are happy. Emotional lability occurs in about 20% of those who have had a stroke. Those with a right hemisphere stroke are more likely to have an empathy problems which can make communication harder.

Cognitive deficits resulting from stroke include perceptual disorders, aphasia, dementia, and problems with attention and memory. A stroke sufferer may be unaware of his or her own disabilities, a condition called anosognosia. In a condition called hemispatial neglect, the affected person is unable to attend to anything on the side of space opposite to the damaged hemisphere. Cognitive and psychological outcome after a stroke can be affected by the age at which the stroke happened, pre-stroke baseline intellectual functioning, psychiatric history and whether there is pre-existing brain pathology. Up to 10% of people following a stroke develop seizures, most commonly in the week subsequent to the event; the severity of the stroke increases the likelihood of a seizure.

4 Seizure

A seizure, formally known as an epileptic seizure, is a period of symptoms due to abnormally excessive or synchronous neuronal activity in the brain. Outward effects vary from uncontrolled shaking movements involving much of the body with loss of consciousness (tonic-clonic seizure), to shaking movements involving only part of the body with variable levels of consciousness (focal seizure), to a subtle momentary loss of awareness (absence seizure). Most of the time these episodes last less than 2 minutes and it takes some time to return to normal. Loss of bladder control may occur.

Seizures may be provoked and unprovoked. Provoked seizures are due to a temporary event such as low blood sugar, alcohol withdrawal, low blood sodium, fever, brain infection, or concussion. Unprovoked seizures occur without a known or fixable cause such that ongoing seizures are likely. Unprovoked seizures may be triggered by stress or sleep deprivation. Diseases of the brain, where there has been at least one seizure and a long term risk of further seizures, are collectively known as epilepsy. Conditions that look like epileptic seizures but are not include fainting, nonepileptic psychogenic event, and tremor.

A seizure that lasts for more than a brief period is a medical emergency. Any seizure lasting longer than 5 minutes should be treated as status epilepticus. A first seizure generally does not require long-term treatment with anti-seizure medications unless a specific problem is found on electroencephalogram (EEG) or brain imaging. Typically it is safe to complete the work-up following a single seizure as an outpatient. In many, with what appears to be a first seizure, other minor seizures have previously occurred.

Up to 10% of people have at least one epileptic seizure. Provoked seizures occur in about 3.5 per 10,000 people a year while unprovoked seizures occur in about 4.2 per 10,000 people a year. After one seizure, the chance of experiencing a second is about 50%. Epilepsy affects about 1% of the population at any given time with about 4% of the population affected at some point in time. Nearly 80% of those with epilepsy live in developing countries. Many places require people to stop driving until they have not had a seizure for a specific period.

Signs & Symptoms

The signs and symptoms of seizures vary depending on the type. The most common type of seizure is convulsive (60%). Two-thirds of these begin as focal seizures and become generalized while one third begin as generalized seizures. The remaining 40% of seizures are non-convulsive, an example of which is absence seizure.

Focal Seizures
Focal seizures often begin with certain experiences, known as an aura. These may include sensory, visual, psychic, autonomic, olfactory or motor phenomena. In a complex partial seizure a person may appear confused or dazed and can not respond to questions or direction. Focal seizure may become generalized.

Jerking activity may start in a specific muscle group and spread to surrounding muscle groups—known as a Jacksonian march. Unusual activities that are not consciously created may occur. These are known as automatisms and include simple activities like smacking of the lips or more complex activities such as attempts to pick something up.

Generalized Seizures
There are six main types of generalized seizures: tonic-clonic, tonic, clonic, myoclonic, absence, and atonic seizures. They all involve a loss of consciousness and typically happen without warning.

- Tonic-clonic seizures present with a contraction of the limbs followed by their extension, along with arching of the back for 10–30 seconds. A cry may be heard due to contraction of the chest muscles. The limbs then begin to shake in unison. After the shaking has stopped it may take 10–30 minutes for the person to return to normal.
- Tonic seizures produce constant contractions of the muscles. The person may turn blue if breathing is impaired.
- Clonic seizures involve shaking of the limbs in unison.
- Myoclonic seizures involve spasms of muscles in either a few areas or generalized through the body.
- Absence seizures can be subtle, with only a slight turn of the head or eye blinking. The person often does not fall over and may return to normal right after the seizure ends, though there may also be a period of post-ictal disorientation.
- Atonic seizures involve the loss of muscle activity for greater than one second. This typically occurs bilaterally (on both sides of the body)

Duration
A seizure can last from a few seconds to more than five minutes, at which point it is known as status epilepticus. Most tonic-clonic seizures last less than two or three minutes. Absence seizures are usually around 10 seconds in duration.

Postictal
After the active portion of a seizure, there is typically a period of confusion called the postictal period before a normal level of consciousness returns. This usually lasts 3 to 15 minutes but may last for hours. Other common symptoms include: feeling tired, headache, difficulty speaking, and abnormal behavior. Psychosis after a seizure is relatively common, occurring in between 6 and 10% of people. Often people do not remember what occurred during this time.

Causes

Seizures have a number of causes. Of those who have a seizure, about 25% have epilepsy. A number of conditions are associated with seizures but are not epilepsy including: most febrile seizures and those that occur around an acute infection, stroke, or toxicity. These seizures are known as "acute symptomatic" or "provoked" seizures and are part of the seizure-related disorders. In many the cause is unknown.

Different causes of seizures are common in certain age groups.
- Seizures in babies are most commonly caused by hypoxic ischemic encephalopathy, central nervous system (CNS) infections, trauma, congenital CNS abnormalities, and metabolic disorders.
- The most frequent cause of seizures in children is febrile seizures, which happen in 2–5% of children between the ages of six months and five years.
- During childhood, well-defined epilepsy syndromes are generally seen.
- In adolescence and young adulthood, non-compliance with the medication regimen and sleep deprivation are potential triggers.
- Pregnancy and labor and childbirth, and the post-partum, or post-natal period (after birth) can be at-risk times, especially if there are certain complications like pre-eclampsia.
- During adulthood, the likely causes are alcohol related, strokes, trauma, CNS infections, and brain tumors.
- In older adults, cerebrovascular disease is a very common cause. Other causes are CNS tumors, head trauma, and other degenerative diseases that are common in the older age group, such as dementia.

Metabolic
Dehydration can trigger epileptic seizures if it is severe enough. A number of disorders including: low blood sugar, low blood sodium, hyperosmolar nonketotic hyperglycemia, high blood sodium, low blood calcium and high blood urea levels may cause seizures. As may hepatic encephalopathy and the genetic disorder porphyria.

Structural
- Cavernoma or cavernous malformation is a treatable medical condition that can cause seizures, headaches, and brain hemorrhages.
- Arteriovenous malformation (AVM) is a treatable medical condition that can cause seizures, headaches, and brain hemorrhages.
- Space-occupying lesions in the brain (abscesses, tumours). In people with brain tumours, the frequency of epilepsy depends on the location of the tumor in the cortical region.

Medications
Both medication and drug overdoses can result in seizures, as may certain medication and drug withdrawal. Common drugs involved include: antidepressants, antipsychotics, cocaine, insulin, and the local anaesthetic lidocaine. Difficulties with withdrawal seizures commonly occurs after prolonged alcohol or sedative use, a condition known as delirium tremens.

Infections
- Infection with the pork tapeworm, which can cause neurocysticercosis, is the cause of up to half of epilepsy cases in areas of the world where the parasite is common.
- Parasitic infections such as cerebral malaria. In Nigeria this is one of the most common causes of seizures among children under 5 years of age.
- Infection, such as encephalitis or meningitis

Stress
Stress can induce seizures in people with epilepsy, and is a risk factor for developing epilepsy. Severity, duration, and time at which stress occurs during development all contribute to frequency and susceptibility to developing epilepsy. It is one of the most frequently self-reported triggers in patients with epilepsy.

Stress exposure results in hormone release that mediates its effects in the brain. These hormones act on both excitatory and inhibitory neural synapses, resulting in hyper-excitability of neurons in the brain. The hippocampus is known to be a region that is highly sensitive to stress and prone to seizures. This is where mediators of stress interact with their target receptors to produce effects.

Other
Seizures may occur as a result of high blood pressure, known as hypertensive encephalopathy, or in pregnancy as eclampsia when accompanied by either seizures or a decreased level of consciousness. Very high body temperatures may also be a cause. Typically this requires a temperature greater than 42 °C (107.6 °F).

- Head injury may cause non-epileptic post-traumatic seizures or post-traumatic epilepsy
- About 3.5 to 5.5% of people with celiac disease also have seizures.
- Seizures in a person with a shunt may indicate failure
- Hemorrhagic stroke can occasionally present with seizures, embolic strokes generally do not (though epilepsy is a common later complication); cerebral venous sinus thrombosis, a rare type of stroke, is more likely to be accompanied by seizures than other types of stroke
- Multiple sclerosis may cause seizures

Electroconvulsive therapy (ECT) deliberately sets out to induce a seizure for the treatment of major depression.

Diagnosis

Seizures may be divided into provoked and unprovoked. Provoked seizures may also be known as "acute symptomatic seizures" or "reactive seizures". Unprovoked seizures may also be known as "reflex seizures". Depending on the presumed cause blood tests and lumbar puncture may be useful. Hypoglycemia may cause seizures and should be ruled out. An electroencephalogram and brain imaging with CT scan or MRI scan is recommended in the work-up of seizures not associated with a fever.

Classification
Seizure types are organized by whether the source of the seizure is localized (focal seizures) or distributed (generalized seizures) within the brain. Generalized seizures are divided according to the effect on the body and include tonic-clonic (grand mal), absence (petit mal), myoclonic, clonic, tonic, and atonic seizures. Some seizures such as epileptic spasms are of an unknown type.

Focal seizures (previously called partial seizures) are divided into simple partial or complex partial seizure. Current practice no longer recommends this, and instead prefers to describe what occurs during a seizure.

Physical Examination
Most people are in a postictal state (drowsy or confused) following a seizure. They may show signs of other injuries. A bite mark on the side of the tongue helps confirm a seizure when present, but only a third of people who have had a seizure have such a bite. When present in people thought to have had a seizure, this physical sign tentatively increases the likelihood that a seizure was the cause.

Differential Diagnosis
Differentiating an epileptic seizure from other conditions such as syncope can be difficult. Other possible conditions that can mimic a seizure include: decerebrate posturing, psychogenic seizures, tetanus, dystonia, migraine headaches, and strychnine poisoning. In addition, 5% of people with a positive tilt table test may have seizure-like activity that seems due to cerebral hypoxia. Convulsions may occur due to psychological reasons and this is known as a psychogenic non-epileptic seizure. Non-epileptic seizures may also occur due to a number of other reasons.

Prevention

A number of measures have been attempted to prevent seizures in those at risk. Following traumatic brain injury anticonvulsants decrease the risk of early seizures but not late seizures. In those with a history of febrile seizures, medications (both antipyretics and anticonvulsants) have not been found effective for prevention. Some, in fact, may cause harm.

There is no clear evidence that antiepileptic drugs are effective or not effective at preventing seizures following a craniotomy, following subdural hematoma, after a stroke, or after subarachnoid haemorrhage, for both people who have had a previous seizure, and those who have not.

Management

Potentially sharp or dangerous objects should be moved from the area around a person experiencing a seizure, so that the individual is not hurt. After the seizure if the person is not fully conscious and alert, they should be placed in the recovery position. A seizure longer than five minutes, or two or more seizures occurring within the time of five minutes is a medical emergency known as status epilepticus. Contrary to a common misconception, bystanders should not attempt to force objects into the mouth of the person suffering a seizure, as doing so may cause injury to the teeth and gums.

Treatments of a person that is actively seizing follows a progression from initial response, through first line, second line, and third line treatments. The initial response involves ensuring the person is protected from potential harms (such as nearby objects) and managing their airway, breathing, and circulation. Airway management should include placing the person on their side, known as the recovery position, to prevent them from choking. If they are unable to breathe because something is blocking their airway, they may require treatments to open their airway.

Medication
The first line medication for an actively seizing person is a benzodiazepine, with most guidelines recommending lorazepam. Diazepam and midazolam are alternatives. This may be repeated if there is no effect after 10 minutes. If there is no effect after two doses, barbiturates or propofol may be used. Benzodiazepines given by a non-intravenous route appear better than those given by intravenous, as the intravenous takes longer to have an effect.

Second-line therapy for adults is phenytoin or fosphenytoin and phenobarbital for children. Third-line medications include phenytoin for children and phenobarbital for adults.

Ongoing anti-epileptic medications are not typically recommended after a first seizure except in those with structural lesions in the brain. They are generally recommended after a second one has occurred. Approximately 70% of people can obtain full control with continuous use of medication. Typically one type of anticonvulsant is preferred. Following a first seizure, while immediate treatment with an anti-seizure drug lowers the probability of seizure recurrence up to five years it does not change the risk of death and there are potential side effects.

In seizures related to toxins, up to two doses of benzodiazepines should be used. If this is not effective pyridoxine is recommended. Phenytoin should generally not be used. There is a lack of evidence for preventative anti-epileptic medications in the management of seizures related to intracranial venous thrombosis.

Other
Helmets may be used to provide protection to the head during a seizure. Some claim that seizure response dogs, a form of service dog, can predict seizures. Evidence for this, however, is poor. At present there is not enough evidence to support the use of cannabis for the management of seizures, although this is an ongoing area of research. There is low quality evidence that a ketogenic diet may help in those who have epilepsy and is reasonable in those who do not improve following typical treatments.

5 Childbirth

Childbirth, also known as labour and delivery, is the ending of a pregnancy by one or more babies leaving a woman's uterus by vaginal passage or Caesarean section.

The most common way of childbirth is a vaginal delivery. It involves three stages of labour: the shortening and opening of the cervix, descent and birth of the baby, and the delivery of the placenta. The first stage typically lasts 12 to 19 hours, the second stage 20 minutes to two hours, and the third stage five to 30 minutes. The first stage begins with crampy abdominal or back pain that last around half a minute and occur every 10 to 30 minutes. The pain becomes stronger and closer together over time. During the second stage, pushing with contractions may occur. In the third stage, delayed clamping of the umbilical cord is generally recommended. A number of methods can help with pain, such as relaxation techniques, opioids, and spinal blocks.

Most babies are born head first; however about 4% are born feet or buttock first, known as breech. Typically the head enters the pelvis facing to one side, and then rotates to face down. During labour, a woman can generally eat and move around as she likes. However, pushing is not recommended during the first stage or during delivery of the head, and enemas are not recommended. While making a cut to the opening of the vagina, known as an episiotomy, is common, it is generally not needed. In 2012, about 23 million deliveries occurred by Caesarean section, an operation on the abdomen. C-sections may be recommended for twins, signs of distress in the baby, or breech position. This method of delivery can take longer to heal from.

Each year, complications from pregnancy and childbirth result in about 500,000 maternal deaths, seven million women have serious long term problems, and 50 million women have negative health outcomes following delivery. Most of these occur in the developing world. Specific complications include obstructed labour, postpartum bleeding, eclampsia, and postpartum infection. Complications in the baby may include lack of oxygen at birth, birth trauma, prematurity, and infections.

Signs & Symptoms

The most prominent sign of labour is strong repetitive uterine contractions. The distress levels reported by labouring women vary widely. They appear to be influenced by fear and anxiety levels, experience with prior childbirth, cultural ideas of childbirth and pain, mobility during labour, and the support received during labour. Personal expectations, the amount of support from caregivers, quality of the caregiver-patient relationship, and involvement in decision-making are more important in women's overall satisfaction with the experience of childbirth than are other factors such as age, socioeconomic status, ethnicity, preparation, physical environment, pain, immobility, or medical interventions.

Descriptions
Pain in contractions has been described as feeling similar to very strong menstrual cramps. Women are often encouraged to refrain from screaming. However, moaning and grunting may be encouraged to help lessen pain. Crowning may be experienced as an intense stretching and burning. Even women who show little reaction to labour pains, in comparison to other women, show a substantially severe reaction to crowning (the appearance of the baby's head).

Back labour is a term for specific pain occurring in the lower back, just above the tailbone, during childbirth.

Psychological
During the later stages of gestation there is an increase in abundance of oxytocin, a hormone that is known to evoke feelings of contentment, reductions in anxiety, and feelings of calmness and security around the mate. Oxytocin is further released during labour when the fetus stimulates the cervix and vagina, and it is believed that it plays a major role in the bonding of a mother to her infant and in the establishment of maternal behavior. The act of nursing a child also causes a release of oxytocin.

Between 70% and 80% of mothers in the United States report some feelings of sadness or "baby blues" after giving birth. The symptoms normally occur for a few minutes up to few hours each day and they should lessen and disappear within two weeks after delivery. Postpartum depression may develop in some women; about 10% of mothers in the United States are diagnosed with this condition. Preventive group therapy has proven effective as a prophylactic treatment for postpartum depression.

Vaginal Birth

Humans are bipedal with an erect stance. The erect posture causes the weight of the abdominal contents to thrust on the pelvic floor, a complex structure which must not only support this weight but allow, in women, three channels to pass through it: the urethra, the vagina and the rectum. The infant's head and shoulders must go through a specific sequence of maneuvers in order to pass through the ring of the mother's pelvis.

Six phases of a typical vertex or cephalic (head-first presentation) delivery:
1. Engagement of the fetal head in the transverse position. The baby's head is facing across the pelvis at one or other of the mother's hips.
2. Descent and flexion of the fetal head.
3. Internal rotation. The fetal head rotates 90 degrees to the occipito-anterior position so that the baby's face is towards the mother's rectum.
4. Delivery by extension. The fetal head is bowed, chin on chest, so that the back or crown of its head leads the way through the birth canal, until the back of its neck presses against the pubic bone and its chin leaves its chest, extending the neck—as if to look up, and the rest of its head passes out of the birth canal.
5. Restitution. The fetal head turns through 45 degrees to restore its normal relationship with the shoulders, which are still at an angle.
6. External rotation. The shoulders repeat the corkscrew movements of the head, which can be seen in the final movements of the fetal head.

The vagina is called a 'birth canal' when the baby enters this passage.

Station refers to the relationship of the fetal presenting part to the level of the ischial spines. When the presenting part is at the ischial spines the station is 0 (synonymous with engagement). If the presenting fetal part is above the spines, the distance is measured and described as minus stations, which range from −1 to −4 cm. If the presenting part is below the ischial spines, the distance is stated as plus stations (+1 to +4 cm). At +3 and +4 the presenting part is at the perineum and can be seen.

The fetal head may temporarily change shape substantially (becoming more elongated) as it moves through the birth canal. This change in the shape of the fetal head is called molding and is much more prominent in women having their first vaginal delivery.

Cervical ripening is the physical and chemical changes in the cervix to prepare it for the stretching that will take place as the fetus moves out of the uterus and into the birth canal. A scoring system called a Bishop score can be used to judge the degree of cervical ripening in order to predict the timing of labor and delivery of the infant or for women at risk for preterm labor. It is also used to judge when a woman will respond to induction of labor for a postdate pregnancy or other medical reasons. There are several methods of inducing cervical ripening which will allow the uterine contractions to effectively dilate the cervix.

Onset of Labour
There are various definitions of the onset of labour, including:
- Regular uterine contractions at least every six minutes with evidence of change in cervical dilation or cervical effacement between consecutive digital examinations.
- Regular contractions occurring less than 10 minutes apart and progressive cervical dilation or cervical effacement.
- At least three painful regular uterine contractions during a 10-minute period, each lasting more than 45 seconds.

In order to avail for more uniform terminology, the first stage of labour is divided into "latent" and "active" phases, where the latent phase is sometimes included in the definition of labour, and sometimes not.

Common signs that labour, commonly spelled as labor, is about to begin may include "lightening". Lightening is the process of the baby moving down from the rib cage with the head of the baby engaging deep in the pelvis. The pregnant woman may then find breathing easier, since her lungs have more room for expansion, but pressure on her bladder may cause more frequent need to void (urinate). Lightening may occur a few weeks or a few hours before labour begins, or even not until labour has begun.

Some women also experience an increase in vaginal discharge several days before labour begins when the "mucus plug", a thick plug of mucus that blocks the opening to the uterus, is pushed out into the vagina. The mucus plug may become dislodged days before labour begins or not until the start of labour.

While inside the uterus the baby is enclosed in a fluid-filled membrane called the amniotic sac. Shortly before, at the beginning of, or during labor the sac ruptures. Once the sac ruptures, termed "the water breaks", the baby is at risk for infection and the mother's medical team will assess the need to induce labor if it has not started within the time they believe to be safe for the infant.

Many women are known to experience what has been termed the "nesting instinct". Women report a spurt of energy shortly before going into labour.

Folklore has long held that most babies are born in the late night or very early morning and recent (2018) research has found this to be correct in the US, but only for babies born at home or on Saturday or Sunday. All other births are most likely to occur between 8 a.m. and noon, a reflection of the fact that planned C-sections are generally scheduled for 8 a.m. Likewise, births from induced deliveries rose during the morning hours and peaked at 3 p.m. The most likely day of the week for a baby's birthday in the US is Monday, followed by Tuesday, likely related to scheduled deliveries as well.

First Stage: Latent Phase
The latent phase is generally defined as beginning at the point at which the woman perceives regular uterine contractions. In contrast, Braxton Hicks contractions, which are contractions that may start around 26 weeks gestation and are sometimes called "false labour", are infrequent, irregular, and involve only mild cramping.

Cervical effacement, which is the thinning and stretching of the cervix, and cervical dilation occur during the closing weeks of pregnancy. Effacement is usually complete or near complete and dilation is about 5 cm by the end of the latent phase. The degree of cervical effacement and dilation may be felt during a vaginal examination. The latent phase ends with the onset of the active first stage.

First Stage: Active Phase
The active stage of labour (or "active phase of first stage" if the previous phase is termed "latent phase of first stage") has geographically differing definitions. The World Health Organization describes the active first stage as "a period of time characterized by regular painful uterine contractions, a substantial degree of cervical effacement and more rapid cervical dilatation from 5 cm until full dilatation for first and subsequent labours. In the US, the definition of active labour was changed from 3 to 4 cm, to 5 cm of cervical dilation for multiparous women, mothers who had given birth previously, and at 6 cm for nulliparous women, those who had not given birth before. This was done in an effort to increase the rates of vaginal delivery.

Health care providers may assess a labouring mother's progress in labour by performing a cervical exam to evaluate the cervical dilation, effacement, and station. These factors form the Bishop score. The Bishop score can also be used as a means to predict the success of an induction of labour.

During effacement, the cervix becomes incorporated into the lower segment of the uterus. During a contraction, uterine muscles contract causing shortening of the upper segment and drawing upwards of the lower segment, in a gradual expulsive motion. The presenting fetal part then is permitted to descend. Full dilation is reached when the cervix has widened enough to allow passage of the baby's head, around 10 cm dilation for a term baby.

A standard duration of the latent first stage has not been established and can vary widely from one woman to another. However, the duration of active first stage (from 5 cm until full cervical dilatation) usually does not extend beyond 12 hours in first labours ("primiparae"), and usually does not extend beyond 10 hours in subsequent labours ("multiparae"). The median duration of active first stage is four hours in first labours and three hours in second and subsequent labours.

Dystocia of labor, also called "dysfunctional labor" or "failure to progress", is difficult labor or abnormally slow progress of labor, involving progressive cervical dilatation or lack of descent of the fetus. Friedman's Curve, developed in 1955, was for many years used to determine labor dystocia. However, more recent medical research suggests that the Friedman curve may not be currently applicable.

Second Stage: Fetal Expulsion
The expulsion stage begins when the cervix is fully dilated, and ends when the baby is born. As pressure on the cervix increases, women may have the sensation of pelvic pressure and an urge to begin pushing. At the beginning of the normal second stage, the head is fully engaged in the pelvis; the widest diameter of the head has passed below the level of the pelvic inlet. The fetal head then continues descent into the pelvis, below the pubic arch and out through the vaginal introitus (opening). This is assisted by the additional maternal efforts of "bearing down" or pushing. The appearance of the fetal head at the vaginal orifice is termed the "crowning". At this point, the woman will feel an intense burning or stinging sensation.

When the amniotic sac has not ruptured during labour or pushing, the infant can be born with the membranes intact. This is referred to as "delivery en caul". Complete expulsion of the baby signals the successful completion of the second stage of labour. The second stage varies from one woman to another. In first labours, birth is usually completed within three hours whereas in subsequent labours, birth is usually completed within two hours. Labours longer than three hours are associated with declining rates of spontaneous vaginal delivery and increasing rates of infection, perineal tears, and obstetric hemorrhage, as well as the need for intensive care of the neonate.

Third Stage: Placenta Delivery
The period from just after the fetus is expelled until just after the placenta is expelled is called the third stage of labour or the involution stage. Placental expulsion begins as a physiological separation from the wall of the uterus. The average time from delivery of the baby until complete expulsion of the placenta is estimated to be 10–12 minutes dependent on whether active or expectant management is employed. In as many as 3% of all vaginal deliveries, the duration of the third stage is longer than 30 minutes and raises concern for retained placenta.

Placental expulsion can be managed actively or it can be managed expectantly, allowing the placenta to be expelled without medical assistance. Active management is the administration of a uterotonic drug within one minute of fetal delivery, controlled traction of the umbilical cord and fundal massage after delivery of the placenta, followed by performance of uterine massage every 15 minutes for two hours. In a joint statement, World Health Organization, the International Federation of Gynaecology and Obstetrics and the International Confederation of Midwives recommend active management of the third stage of labour in all vaginal deliveries to help to prevent postpartum hemorrhage.

Delaying the clamping of the umbilical cord for at least one minute or until it ceases to pulsate, which may take several minutes, improves outcomes as long as there is the ability to treat jaundice if it occurs. For many years it was believed that late cord cutting led to a mother's risk of experiencing significant bleeding after giving birth, called postpartum bleeding. However a recent review found that delayed cord cutting in healthy full-term infants resulted in early haemoglobin concentration and higher birthweight and increased iron reserves up to six months after birth with no change in the rate of postpartum bleeding.

Fourth Stage
The "fourth stage of labour" is the period beginning immediately after the birth of a child and extending for about six weeks. The terms postpartum and postnatal are often used for this period. The woman's body, including hormone levels and uterus size, return to a non-pregnant state and the newborn adjusts to life outside the mother's body. The World Health Organization (WHO) describes the postnatal period as the most critical and yet the most neglected phase in the lives of mothers and babies; most deaths occur during the postnatal period.

Following the birth, if the mother had an episiotomy or a tearing of the perineum, it is stitched. The mother has regular assessments for uterine contraction and fundal height, vaginal bleeding, heart rate and blood pressure, and temperature, for the first 24 hours after birth. The first passing of urine should be documented within six hours. Afterpains (pains similar to menstrual cramps), contractions of the uterus to prevent excessive blood flow, continue for several days. Vaginal discharge, termed "lochia", can be expected to continue for several weeks; initially bright red, it gradually becomes pink, changing to brown, and finally to yellow or white. Some women experience an uncontrolled episode of shivering or postpartum chills, after the birth.

Most authorities suggest the infant be placed in skin-to-skin contact with the mother for 1–2 hours immediately after birth, putting routine cares off until later.

Until recently babies born in hospitals were removed from their mothers shortly after birth and brought to the mother only at feeding times. Mothers were told that their newborn would be safer in the nursery and that the separation would offer the mother more time to rest. As attitudes began to change, some hospitals offered a "rooming in" option wherein after a period of routine hospital procedures and observation, the infant could be allowed to share the mother's room. However, more recent information has begun to question the standard practice of removing the newborn immediately postpartum for routine postnatal procedures before being returned to the mother. Beginning around 2000, some authorities began to suggest that early skin-to-skin contact (placing the naked baby on the mother's chest) may benefit both mother and infant. Using animal studies that have shown that the intimate contact inherent in skin-to-skin contact promotes neurobehaviors that result in the fulfillment of basic biological needs as a model, recent studies have been done to assess what, if any, advantages may be associated with early skin-to-skin contact for human mothers and their babies.

A 2011 medical review looked at existing studies and found that early skin-to-skin contact, sometimes called kangaroo care, resulted in improved breastfeeding outcomes, cardio-respiratory stability, and a decrease in infant crying. A 2016 Cochrane review found that skin-to-skin contact at birth promotes the likelihood and effectiveness of breastfeeding.

As of 2014, early postpartum skin-to-skin contact is endorsed by all major organizations that are responsible for the well-being of infants, including the American Academy of Pediatrics. The World Health Organization (WHO) states that "the process of childbirth is not finished until the baby has safely transferred from placental to mammary nutrition." They advise that the newborn be placed skin-to-skin with the mother, postponing any routine procedures for at least one to two hours.

The WHO suggests that any initial observations of the infant can be done while the infant remains close to the mother, saying that even a brief separation before the baby has had its first feed can disturb the bonding process. They further advise frequent skin-to-skin contact as much as possible during the first days after delivery, especially if it was interrupted for some reason after the delivery. The National Institute for Health and Care Excellence also advises postponing procedures such as weighing, measuring, and bathing for at least one hour to insure an initial period of skin-to-skin contact between mother and infant.

Labour Induction and Elective Caesarean Section

In many cases and with increasing frequency, childbirth is achieved through induction of labour or caesarean section. Caesarean section is the removal of the neonate through a surgical incision in the abdomen, rather than through vaginal birth. Childbirth by C-Sections increased 50% in the US from 1996 to 2006. In 2011, 32.8 percent of births in the US were delivered by cesarean section. Induced births and elective cesarean before 39 weeks can be harmful to the neonate as well as harmful or without benefit to the mother. Therefore, many guidelines recommend against non-medically required induced births and elective cesarean before 39 weeks. The 2012 rate of labour induction in the United States was 23.3 percent, and has more than doubled from 1990 to 2010. Pitocin is commonly used to induce uterine contractions. A large review of methods of induction was published in 2011.

The American Congress of Obstetricians and Gynecologists (ACOG) guidelines recommend a full evaluation of the maternal-fetal status, the status of the cervix, and at least a 39 completed weeks (full term) of gestation for optimal health of the newborn when considering elective induction of labour. Per these guidelines, the following conditions may be an indication for induction, including:

- Abruptio placentae
- Chorioamnionitis
- Fetal compromise such as isoimmunization leading to hemolytic disease of the newborn or oligohydramnios
- Fetal demise
- Gestational hypertension
- Maternal conditions such as gestational diabetes or chronic kidney disease
- Preeclampsia or eclampsia

- Premature rupture of membranes
- Postterm pregnancy

Induction is also considered for logistical reasons, such as the distance from hospital or psychosocial conditions, but in these instances gestational age confirmation must be done, and the maturity of the fetal lung must be confirmed by testing. The ACOG also note that contraindications for induced labour are the same as for spontaneous vaginal delivery, including vasa previa, complete placenta praevia, umbilical cord prolapse or active genital herpes simplex infection.

Management

Deliveries are assisted by a number of professionals including: obstetricians, family physicians and midwives. For low risk pregnancies all three result in similar outcomes.

Preparation
Eating or drinking during labour is an area of ongoing debate. While some have argued that eating in labour has no harmful effects on outcomes, others continue to have concern regarding the increased possibility of an aspiration event (choking on recently eaten foods) in the event of an emergency delivery due to the increased relaxation of the esophagus in pregnancy, upward pressure of the uterus on the stomach, and the possibility of general anesthetic in the event of an emergency cesarean.

A 2013 Cochrane review found that with good obstetrical anaesthesia there is no change in harms from allowing eating and drinking during labour in those who are unlikely to need surgery. They additionally acknowledge that not eating does not mean there is an empty stomach or that its contents are not as acidic. They therefore conclude that "women should be free to eat and drink in labour, or not, as they wish."

At one time shaving of the area around the vagina, was common practice due to the belief that hair removal reduced the risk of infection, made an episiotomy (a surgical cut to enlarge the vaginal entrance) easier, and helped with instrumental deliveries. It is currently less common, though it is still a routine procedure in some countries even though a systematic review found no evidence to recommend shaving.

Side effects appear later, including irritation, redness, and multiple superficial scratches from the razor. Another effort to prevent infection has been the use of the antiseptic chlorhexidine or providone-iodine solution in the vagina. Evidence of benefit with chlorhexidine is lacking. A decreased risk is found with providone-iodine when a cesarean section is to be performed.

Active Management of Labour
A 2013 review of the active management in low-risk women found that when compared to routine care there were no differences in the use of medications for pain, maternal or neonatal complications, or rates of assisted vaginal deliveries. There was a slight reduction in the caesarean section rate, however active management was seen as "highly prescriptive and interventional."

The World Health Organization (WHO) states: "While augmentation of labour may be beneficial in preventing prolonged labour, its inappropriate use may cause harm." The WHO suggests to "avoid the systematic use of a package of interventions ("active management of labour") to prevent possible labour delay because it is highly prescriptive and can undermine women's choices and autonomy during care."

Active management of labour consists of a number of principles that aim to improve outcomes with prolonged labour. This include antenatal classes, early diagnosis of labour by senior midwives, amniotomy when membranes are intact before the onset of labour, selective use of oxytocin for slow progress (only in first time mothers), and one-to-one support from midwives and obstetricians.

There is some debate about the effectiveness of active management of labour on caesarean section rates. Active management of labour was first used in the 1960s at the Irish National Maternity Hospital in Dublin, Ireland, in what became known as "the Dublin experience".

Pain Control - Non pharmaceutical
Some women prefer to avoid analgesic medication during childbirth. Psychological preparation may be beneficial. Relaxation techniques, immersion in water, massage, and acupuncture may provide pain relief. Acupuncture and relaxation were found to decrease the number of caesarean sections required. Immersion in water has been found to relieve pain during the first stage of labor and to reduce the need for anesthesia and shorten the duration of labor, however the safety and efficacy of immersion during birth, water birth, has not been established or associated with maternal or fetal benefit.

Most women like to have someone to support them during labour and birth; such as a midwife, nurse, or doula; or a lay person such as the father of the baby, a family member, or a close friend. Studies have found that continuous support during labor and delivery reduce the need for medication and a caesarean or operative vaginal delivery, and result in an improved Apgar score for the infant

INJURY Other Childbirth Management

Pain Control - Pharmaceutical
Different measures for pain control have varying degrees of success and side effects to the woman and her baby. In some countries of Europe, doctors commonly prescribe inhaled nitrous oxide gas for pain control, especially as 53% nitrous oxide, 47% oxygen, known as Entonox; in the UK, midwives may use this gas without a doctor's prescription. Opioids such as fentanyl may be used, but if given too close to birth there is a risk of respiratory depression in the infant.

Popular medical pain control in hospitals include the regional anesthetics epidurals (EDA), and spinal anaesthesia. Epidural analgesia is a generally safe and effective method of relieving pain in labour, but is associated with longer labour, more operative intervention (particularly instrument delivery), and increases in cost. However, a recent Cochrane review suggests that the new epidural techniques have no more effect on labour time and the used instruments. Generally, pain and stress hormones rise throughout labour for women without epidurals, while pain, fear, and stress hormones decrease upon administration of epidural analgesia, but rise again later. Medicine administered via epidural can cross the placenta and enter the bloodstream of the fetus. Epidural analgesia has no statistically significant impact on the risk of caesarean section, and does not appear to have an immediate effect on neonatal status as determined by Apgar scores.

Augmentation
Augmentation is the process of stimulating the uterus to increase the intensity and duration of contractions after labour has begun. Several methods of augmentation are commonly been used to treat slow progress of labour (dystocia) when uterine contractions are assessed to be too weak. Oxytocin is the most common method used to increase the rate of vaginal delivery. The World Health Organization recommends its use either alone or with amniotomy (rupture of the amniotic membrane) but advises that it must be used only after it has been correctly confirmed that labour is not proceeding properly if harm is to be avoided. The WHO does not recommend the use of antispasmodic agents for prevention of delay in labour.

INJURY Other Childbirth Management

Episiotomy
Perineal tears can occur during childbirth, most often at the vaginal opening as the baby's head passes through, especially if the baby descends quickly. Tears can involve the perineal skin or extend to the muscles and the anal sphincter and anus. While making a cut to the opening of the vagina, known as an episiotomy is common, it is generally not needed. When needed, the midwife or obstetrician makes a surgical cut in the perineum to prevent severe tears that can be difficult to repair. A 2017 Cochrane review compared episiotomy as needed (restrictive) with routine episiotomy to determine the possible benefits and harms for mother and baby. The review found that restrictive episiotomy policies appeared to give a number of benefits compared with using routine episiotomy. Women experienced less severe perineal trauma, less posterior perineal trauma, less suturing and fewer healing complications at seven days with no difference in occurrence of pain, urinary incontinence, painful sex or severe vaginal/perineal trauma after birth.

Multiple births
In cases of a head first-presenting first twin, twins can often be delivered vaginally. In some cases twin delivery is done in a larger delivery room or in an operating theatre, in the event of complication e.g.

- Both twins born vaginally—this can occur both presented head first or where one comes head first and the other is breech and/or helped by a forceps/ventouse delivery
- One twin born vaginally and the other by caesarean section.
- If the twins are joined at any part of the body—called conjoined twins, delivery is mostly by caesarean section.

INJURY Other Childbirth Management

Support
Baby on warming tray attended to by her father.
Obstetric care frequently subjects women to institutional routines, which may have adverse effects on the progress of labour. Supportive care during labour may involve emotional support, comfort measures, and information and advocacy which may promote the physical process of labour as well as women's feelings of control and competence, thus reducing the need for obstetric intervention. The continuous support may be provided either by hospital staff such as nurses or midwives, doulas, or by companions of the woman's choice from her social network. There is increasing evidence to show that the participation of the child's father in the birth leads to better birth and also post-birth outcomes, providing the father does not exhibit excessive anxiety.

Continuous labour support may help women to give birth spontaneously, i.e. without caesarean or vacuum or forceps, with slightly shorter labours, and to have more positive feelings regarding their experience of giving birth. Continuous labour support may also reduce women's use of pain medication during labour and reduce the risk of babies having low five-minute Agpar scores.

Complications

Labour and Delivery Complications

INJURY Other Childbirth Complications

Obstructed Labour
The second stage of labour may be delayed or lengthy due to poor or uncoordinated uterine action, an abnormal uterine position such as breech or shoulder dystocia, and cephalopelvic disproportion (a small pelvis or large infant). Prolonged labour may result in maternal exhaustion, fetal distress, and other complications including obstetric fistula.

Eclampsia
Eclampsia is the onset of seizures (convulsions) in a woman with pre-eclampsia. Pre-eclampsia is a disorder of pregnancy in which there is high blood pressure and either large amounts of protein in the urine or other organ dysfunction. Pre-eclampsia is routinely screened for during prenatal care. Onset may be before, during, or rarely, after delivery. Around one percent of women with eclampsia die.

Maternal Complications

A puerperal disorder or postpartum disorder is a complication which presents primarily during the puerperium, or postpartum period. The postpartum period can be divided into three distinct stages; the initial or acute phase, six to 12 hours after childbirth; subacute postpartum period, which lasts two to six weeks, and the delayed postpartum period, which can last up to six months. In the subacute postpartum period, 87% to 94% of women report at least one health problem. Long term health problems (persisting after the delayed postpartum period) are reported by 31 percent of women

INJURY Other Childbirth Complications

Postpartum Bleeding
Postpartum bleeding is the leading cause of death of birthing mothers in the world, especially in the developing world. Globally it occurs about 8.7 million times and results in 44,000 to 86,000 deaths per year. Uterine atony, the inability of the uterus to contract, is the most common cause of postpartum bleeding. Following delivery of the placenta, the uterus is left with a large area of open blood vessels which must be constricted to avoid blood loss. Retained placental tissue and infection may contribute to uterine atony. Heavy blood loss leads to hypovolemic shock, insufficient perfusion of vital organs and death if not rapidly treated.

Postpartum Infections
Postpartum infections, also known as childbed fever and puerperal fever, are any bacterial infections of the reproductive tract following childbirth or miscarriage. Signs and symptoms usually include a fever greater than 38.0 °C (100.4 °F), chills, lower abdominal pain, and possibly bad-smelling vaginal discharge. The infection usually occurs after the first 24 hours and within the first ten days following delivery. Infection remains a major cause of maternal deaths and morbidity in the developing world. The work of Ignaz Semmelweis was seminal in the pathophysiology and treatment of childbed fever and his work saved many lives.

INJURY Other Childbirth Complications

Psychological Complications
Childbirth can be an intense event and strong emotions, both positive and negative, can be brought to the surface. Abnormal and persistent fear of childbirth is known as tokophobia. The prevalence of fear of childbirth around the world ranges between 4–25%, with 3–7% of pregnant women having clinical fear of childbirth.

Most new mothers may experience mild feelings of unhappiness and worry after giving birth. Babies require a lot of care, so it is normal for mothers to be worried about, or tired from, providing that care. The feelings, often termed the "baby blues", affect up to 80 percent of mothers. They are somewhat mild, last a week or two, and usually go away on their own.

Postpartum depression is different from the "baby blues". With postpartum depression, feelings of sadness and anxiety can be extreme and might interfere with a woman's ability to care for herself or her family. Because of the severity of the symptoms, postpartum depression usually requires treatment. The condition, which occurs in nearly 15 percent of births, may begin shortly before or any time after childbirth, but commonly begins between a week and a month after delivery.
Childbirth-related posttraumatic stress disorder is a psychological disorder that can develop in women who have recently given birth. Causes include issues such as an emergency C-section, preterm labour, inadequate care during labour, lack of social support following childbirth, and others. Examples of symptoms include intrusive symptoms, flashbacks and nightmares, as well as symptoms of avoidance (including amnesia for the whole or parts of the event), problems in developing a mother-child attachment, and others similar to those commonly experienced in posttraumatic stress disorder (PTSD). Many women who are experiencing symptoms of PTSD after childbirth are misdiagnosed with postpartum depression or adjustment disorders. These diagnoses can lead to inadequate treatment.

Postpartum psychosis is a rare psychiatric emergency in which symptoms of high mood and racing thoughts (mania), depression, severe confusion, loss of inhibition, paranoia, hallucinations and delusions set in, beginning suddenly in the first two weeks after childbirth. The symptoms vary and can change quickly. It usually requires hospitalization. The most severe symptoms last from two to 12 weeks, and recovery takes six months to a year.

Fetal Complications

Five causes make up about 80 percent of newborn deaths. They include prematurity and low-birth-weight, infections, lack of oxygen at birth, and trauma during birth.

Stillbirth
Stillbirth is typically defined as fetal death at or after 20 to 28 weeks of pregnancy. It results in a baby born without signs of life.

Worldwide prevention of most stillbirths is possible with improved health systems. About half of stillbirths occur during childbirth, with this being more common in the developing than developed world. Otherwise depending on how far along the pregnancy is, medications may be used to start labor or a type of surgery known as dilation and evacuation may be carried out. Following a stillbirth, women are at higher risk of another one; however, most subsequent pregnancies do not have similar problems.

Worldwide in 2015 there were about 2.6 million stillbirths that occurred after 28 weeks of pregnancy (about 1 for every 45 births). They occur most commonly in the developing world, particularly South Asia and Sub-Saharan Africa. In the United States for every 167 births there is one stillbirth. Stillbirth rates have declined, though more slowly since the 2000s.

Preterm Birth
Preterm birth is the birth of an infant at fewer than 37 weeks gestational age. It is estimated that one in 10 babies are born prematurely. Premature birth is the leading cause of death in children under five years of age though many that survive experience disabilities including learning defects and visual and hearing problems. Causes for early birth may be unknown or may be related to certain chronic conditions such as diabetes, infections, and other known causes. The World Health Organization has developed guidelines with recommendations to improve the chances of survival and health outcomes for preterm infants.

Neonatal Infection
Newborns are prone to infection in the first month of life. The organism S. agalactiae (Group B Streptococcus) or (GBS) is most often the cause of these occasionally fatal infections. The baby contracts the infection from the mother during labor. In 2014 it was estimated that about one in 2000 newborn babies have GBS bacterial infections within the first week of life, usually evident as respiratory disease, general sepsis, or meningitis.

Untreated sexually transmitted infections (STIs) are associated with congenital and infections in newborn babies, particularly in the areas where rates of infection remain high. The majority of STIs have no symptoms or only mild symptoms that may not be recognized. Mortality rates resulting from some infections may be high, for example the overall perinatal mortality rate associated with untreated syphilis is 30 percent.

Perinatal Asphyxia
Perinatal asphyxia is the medical condition resulting from deprivation of oxygen to a newborn infant that lasts long enough during the birth process to cause physical harm, usually to the brain. Hypoxic damage can occur to most of the infant's organs (heart, lungs, liver, gut, kidneys), but brain damage is of most concern and perhaps the least likely to quickly or completely heal.

Mechanical Fetal Injury
Risk factors for fetal birth injury include fetal macrosomia (big baby), maternal obesity, the need for instrumental delivery, and an inexperienced attendant. Specific situations that can contribute to birth injury include breech presentation and shoulder dystocia. Most fetal birth injuries resolve without long term harm, but brachial plexus injury may lead to Erb's palsy or Klumpke's paralysis.

6 Hyperglycemia

Hyperglycemia, or high blood sugar (also spelled hyperglycaemia or hyperglycæmia) is a condition in which an excessive amount of glucose circulates in the blood plasma. This is generally a blood sugar level higher than 11.1 mmol/l (200 mg/dl), but symptoms may not start to become noticeable until even higher values such as 15–20 mmol/l (~250–300 mg/dl). A subject with a consistent range between ~5.6 and ~7 mmol/l (100–126 mg/dl) (American Diabetes Association guidelines) is considered slightly hyperglycemic, while above 7 mmol/l (126 mg/dl) is generally held to have diabetes.

Signs & Symptoms

The degree of hyperglycemia can change over time depending on the metabolic cause, for example, impaired glucose tolerance or fasting glucose, and it can depend on treatment. Temporary hyperglycemia is often benign and asymptomatic. Blood glucose levels can rise well above normal and cause pathological and functional changes for significant periods without producing any permanent effects or symptoms. During this asymptomatic period, an abnormality in carbohydrate metabolism can occur which can be tested by measuring plasma glucose.

Chronic hyperglycemia at above normal levels can produce a very wide variety of serious complications over a period of years, including kidney damage, neurological damage, cardiovascular damage, damage to the retina or damage to feet and legs. Diabetic neuropathy may be a result of long-term hyperglycemia. Impairment of growth and susceptibility to certain infection can occur as a result of chronic hyperglycemia.

Acute hyperglycemia involving glucose levels that are extremely high is a medical emergency and can rapidly produce serious complications (such as fluid loss through osmotic diuresis). It is most often seen in persons who have uncontrolled insulin-dependent diabetes.

The following symptoms may be associated with acute or chronic hyperglycemia, with the first three composing the classic hyperglycemic triad:
- Polyphagia – frequent hunger, especially pronounced hunger
- Polydipsia – frequent thirst, especially excessive thirst
- Polyuria – increased volume of urination (not an increased frequency, although it is a common consequence)
- Blurred vision
- Fatigue
- Restlessness
- Weight loss
- Poor wound healing (cuts, scrapes, etc.)
- Dry mouth
- Dry or itchy skin
- Tingling in feet or heels
- Erectile dysfunction
- Recurrent infections, external ear infections (swimmer's ear)
- Cardiac arrhythmia
- Stupor
- Coma
- Seizures

Frequent hunger without other symptoms can also indicate that blood sugar levels are too low. This may occur when people who have diabetes take too much oral hypoglycemic medication or insulin for the amount of food they eat. The resulting drop in blood sugar level to below the normal range prompts a hunger response. Polydipsia and polyuria occur when blood glucose levels rise high enough to result in excretion of excess glucose via the kidneys, which leads to the presence of glucose in the urine. This produces an osmotic diuresis.
Signs and symptoms of diabetic ketoacidosis may include:
- Ketoacidosis
- Kussmaul hyperventilation (deep, rapid breathing)
- Confusion or a decreased level of consciousness
- Dehydration due to glycosuria and osmotic diuresis
- Increased thirst
- 'Fruity' smelling breath odor
- Nausea and vomiting
- Impairment of cognitive function, along with increased sadness and anxiety
- Weight loss

Hyperglycemia causes a decrease in cognitive performance, specifically in processing speed, executive function, and performance. Decreased cognitive performance may cause forgetfulness and concentration loss,

Complications
In untreated hyperglycemia, a condition called ketoacidosis may develop because decreased insulin levels increase the activity of hormone sensitive lipase. The degradation of triacylglycerides by hormone-sensitive lipase produces free fatty acids that are eventually converted to acetyl-coA by beta-oxidation.

Ketoacidosis is a life-threatening condition which requires immediate treatment. Symptoms include: shortness of breath, breath that smells fruity (such as pear drops), nausea and vomiting, and very dry mouth. Chronic hyperglycemia (high blood sugar) injures the heart in patients without a history of heart disease or diabetes and is strongly associated with heart attacks and death in subjects with no coronary heart disease or history of heart failure.

Also, life-threatening consequences of hyperglycemia is nonketotic hyperosmolar syndrome. Perioperative hyperglycemia has been associated with immunosuppression, increased infections, osmotic diuresis, delayed wound healing, delayed gastric emptying, sympatho-adrenergic stimulation, and increased mortality. In addition, it reduces skin graft success, exacerbates brain, spinal cord, and renal damage by ischemia, worsens neurologic outcomes in traumatic head injuries, and is associated with postoperative cognitive dysfunction following CABG.

Causes

Diabetes Mellitus
Chronic hyperglycemia that persists even in fasting states is most commonly caused by diabetes mellitus. In fact, chronic hyperglycemia is the defining characteristic of the disease. Intermittent hyperglycemia may be present in prediabetic states. Acute episodes of hyperglycemia without an obvious cause may indicate developing diabetes or a predisposition to the disorder.

In diabetes mellitus, hyperglycemia is usually caused by low insulin levels (Diabetes mellitus type 1) and/or by resistance to insulin at the cellular level (Diabetes mellitus type 2), depending on the type and state of the disease. Low insulin levels and/or insulin resistance prevent the body from converting glucose into glycogen (a starch-like source of energy stored mostly in the liver), which in turn makes it difficult or impossible to remove excess glucose from the blood.

With normal glucose levels, the total amount of glucose in the blood at any given moment is only enough to provide energy to the body for 20–30 minutes, and so glucose levels must be precisely maintained by the body's internal control mechanisms. When the mechanisms fail in a way that allows glucose to rise to abnormal levels, hyperglycemia is the result.

Ketoacidosis may be the first symptom of immune-mediated diabetes, particularly in children and adolescents. Also, patients with immune-mediated diabetes, can change from modest fasting hyperglycemia to severe hyperglycemia and even ketoacidosis as a result of stress or an infection.

Insulin Resistance
Obesity has been contributing to increased insulin resistance due to the population's daily caloric intake rising. Insulin resistance increases hyperglycemia because the body becomes over saturated by glucose. Insulin resistance desensitizes insulin receptors, preventing insulin from lowering blood sugar levels.

The leading cause of hyperglycemia in type 2 diabetes is the failure of insulin to suppress glucose production by glycolysis and gluconeogenesis due to insulin resistance. Insulin normally inhibits glycogenolysis, but fails to do so in a condition of insulin resistance, resulting in increased glucose production. In the liver, FOXO6 normally promotes gluconeogenesis in the fasted state, but insulin blocks Fox06 upon feeding. In a condition of insulin resistance insulin fails to block FoxO6, resulting in continued gluconeogenesis even upon feeding.

Drugs
Certain medications increase the risk of hyperglycemia, including corticosteroids, octreotide, beta blockers, epinephrine, thiazide diuretics, statins, niacin, pentamidine, protease inhibitors, L-asparaginase, and antipsychotics. The acute administration of stimulants such as amphetamines typically produces hyperglycemia; chronic use, however, produces hypoglycemia. Some of the newer psychiatric medications, such as Zyprexa (Olanzapine) and Cymbalta (Duloxetine), can also cause significant hyperglycemia.

Thiazides are used to treat type 2 diabetes but it also causes severe hyperglycemia.

INJURY Other Hyperglycemia Causes

Critical Illness
The following conditions can also cause hyperglycemia in the absence of diabetes. 1) Dysfunction of the thyroid, adrenal, and pituitary glands 2) Numerous diseases of the pancreas 3) Severe increases in blood glucose may be seen in sepsis and certain infections 4) Intracranial diseases (frequently overlooked) can also cause hyperglycemia. Encephalitis, brain tumors (especially those located near the pituitary gland), brain bleeds, and meningitis are prime examples. 5) Mild to high blood sugar levels are often seen in convulsions and terminal stages of many diseases. Prolonged, major surgeries can temporarily increase glucose levels. Certain forms of severe stress and physical trauma can increase levels for a brief time as well yet rarely exceeds 6.6 mmol/l (120 mg/dl).

Stress
A high proportion of patients suffering an acute stress such as stroke or myocardial infarction may develop hyperglycemia, even in the absence of a diagnosis of diabetes. (Or perhaps stroke or myocardial infarction was caused by hyperglycemia and undiagnosed diabetes.) Human and animal studies suggest that this is not benign, and that stress-induced hyperglycemia is associated with a high risk of mortality after both stroke and myocardial infarction.

Somatostatinomas and aldosteronoma-induced hypokalemia can cause hyperglycemia but usually disappears after the removal of the tumour.

Mechanism
Hormones such as the growth hormone, glucagon, cortisol and catecholamines, can cause hyperglycemia when they are present in the body in excess amounts. Also, increased proinflammatory cytokines that interrupt carbohydrate metabolism, leading to excessive glucose production and reduced uptake in tissues, can cause hyperglycemia.

Environmental Factors
Hyperglycemia is lower in higher income groups since there is access to better education and resources. Low-middle income groups are more likely to develop hyperglycemia due education and access to food options. Living in warmer climates can reduce hyperglycemia due to increased physical activity while people are less active in colder climates.

Population
Hyperglycemia is one of the main symptoms of diabetes and it has substantially affected the population making it an epidemic due to the population's increased calorie consumption. Healthcare providers are trying to work more closely with people allowing them more freedom with interventions that suit their lifestyle. As physical inactivity and calorie consumption increases it makes individuals more susceptible to developing hyperglycemia. Hyperglycemia is caused by type 1 diabetes and non-whites have a higher susceptibility for it.

Diagnosis

Monitoring
It is critical for patients who monitor glucose levels at home to be aware of which units of measurement their testing kit uses. Glucose levels are measured in either:

1. Millimoles per liter (mmol/l) is the SI standard unit used in most countries around the world.
2. Milligrams per deciliter (mg/dl) is used in some countries such as the United States, Japan, France, Egypt and Colombia.

Scientific journals are moving towards using mmol/l; some journals now use mmol/l as the primary unit but quote mg/dl in parentheses.

Glucose levels vary before and after meals, and at various times of day; the definition of "normal" varies among medical professionals. In general, the normal range for most people (fasting adults) is about 4 to 6 mmol/l or 80 to 110 mg/dl. (where 4 mmol/l or 80 mg/dl is "optimal".) A subject with a consistent range above 7 mmol/l or 126 mg/dl is generally held to have hyperglycemia, whereas a consistent range below 4 mmol/l or 70 mg/dl is considered hypoglycemic. In fasting adults, blood plasma glucose should not exceed 7 mmol/l or 126 mg/dL. Sustained higher levels of blood sugar cause damage to the blood vessels and to the organs they supply, leading to the complications of diabetes.

Chronic hyperglycemia can be measured via the HbA1c test. The definition of acute hyperglycemia varies by study, with mmol/l levels from 8 to 15 (mg/dl levels from 144 to 270).

Defects in insulin secretion, insulin action, or both, results in hyperglycemia. Chronic hyperglycemia can be measured by Clinical urine tests which can detect sugar in the urine or microalbuminuria which could be a symptom of diabetes

Prevention

Treatment of hyperglycemia requires elimination of the underlying cause, such as diabetes. Acute hyperglycemia can be treated by direct administration of insulin in most cases. Severe hyperglycemia can be treated with oral hypoglycemic therapy and lifestyle modification.

In diabetes mellitus (by far the most common cause of chronic hyperglycemia), treatment aims at maintaining blood glucose at a level as close to normal as possible, in order to avoid serious long-term complications. This is done by a combination of proper diet, regular exercise, and insulin or other medication such as metformin, etc.

Those with hyperglycaemia can be treated using sulphonylureas or metformin or both. These drugs help by improving glycaemic control. Dipeptidyl peptidase 4 inhibitor alone or in combination with basal insulin can be used as a treatment for hyperglycemia with patients still in hospital.

Increasing aerobic exercise to at least 30 minutes will make better use of glucose accumulated in the body since glucose is being used for energy by the muscle. Calorie restriction would be one of the main lifestyle changes because it reduces over eating which contributes to hyperglycemia.

Diets higher in healthy saturated fats and whole wheat carbohydrates such as the Mediterranean diet can help reduce carbohydrate intake to better control hyperglycemia. Diets such as intermittent fasting and ketogenic diet help reduce calorie consumption which could significantly reduce hyperglycemia.

Carbohydrates are the main cause for hyperglycemia, whole wheat items should be substituted for non whole wheat items. Fruits are a part of a complete nutritious diet, but should be limited due to its high sugar content.

7 Hypoglycemia

Hypoglycemia, also known as low blood sugar, is when blood sugar decreases to below normal levels. This may result in a variety of symptoms including clumsiness, trouble talking, confusion, loss of consciousness, seizures or death. A feeling of hunger, sweating, shakiness and weakness may also be present. Symptoms typically come on quickly. The most common cause of hypoglycemia is medications used to treat diabetes mellitus such as insulin and sulfonylureas. Risk is greater in diabetics who have eaten less than usual, exercised more than usual or have drunk alcohol. Other causes of hypoglycemia include kidney failure, certain tumors, such as insulinoma, liver disease, hypothyroidism, starvation, inborn error of metabolism, severe infections, reactive hypoglycemia and a number of drugs including alcohol.

The glucose level that defines hypoglycemia is variable. In people with diabetes, levels below 3.9 mmol/L (70 mg/dL) are diagnostic. In adults without diabetes, symptoms related to low blood sugar, low blood sugar at the time of symptoms and improvement when blood sugar is restored to normal confirm the diagnosis. Otherwise, a level below 2.8 mmol/L (50 mg/dL) after not eating or following exercise may be used. In newborns, a level below 2.2 mmol/L (40 mg/dL), or less than 3.3 mmol/L (60 mg/dL) if symptoms are present, indicates hypoglycemia. Other tests that may be useful in determining the cause include insulin and C peptide levels in the blood.

Among people with diabetes, prevention is by matching the foods eaten with the amount of exercise and the medications used. When people feel their blood sugar is low, testing with a glucose monitor is recommended. Some people have few initial symptoms of low blood sugar, and frequent routine testing in this group is recommended. Treatment of hypoglycemia is by eating foods high in simple sugars or taking dextrose. If a person is not able to take food by mouth, glucagon by injection or in the nose may help. The treatment of hypoglycemia unrelated to diabetes includes treating the underlying problem as well and a healthy diet. The term "hypoglycemia" is sometimes incorrectly used to refer to idiopathic postprandial syndrome, a controversial condition with similar symptoms that occur following eating but with normal blood sugar levels.

Signs & Symptoms

Hypoglycemic symptoms and manifestations can be divided into those produced by the counterregulatory hormones (epinephrine/adrenaline and glucagon) triggered by the falling glucose, and the neuroglycopenic effects produced by the reduced brain sugar.
● Shakiness, anxiety, nervousness
● Palpitations, tachycardia
● Sweating, feeling of warmth (sympathetic muscarinic rather than adrenergic)
● Pallor, coldness, clamminess
● Dilated pupils (mydriasis)
● Hunger, borborygmus
● Nausea, vomiting, abdominal discomfort
● Headache

Central Nervous System
● Abnormal thinking, impaired judgment
● Nonspecific dysphoria, moodiness, depression, crying, exaggerated concerns
● Feeling of numbness, pins and needles (paresthesia)
● Negativism, irritability, belligerence, combativeness, rage
● Personality change, emotional lability
● Fatigue, weakness, apathy, lethargy, daydreaming, sleep
● Confusion, memory loss, lightheadedness or dizziness, delirium
● Staring, glassy look, blurred vision, double vision
● Flashes of light in the field of vision
● Automatic behavior, also known as automatism
● Difficulty speaking, slurred speech

● Ataxia, incoordination, sometimes mistaken for drunkenness
● Focal or general motor deficit, paralysis, hemiparesis
● Headache
● Stupor, coma, abnormal breathing
● Generalized or focal seizures

Not all of the above manifestations occur in every case of hypoglycemia. There is no consistent order to the appearance of the symptoms, if symptoms even occur. Specific manifestations may also vary by age, by severity of the hypoglycemia and the speed of the decline. In young children, vomiting can sometimes accompany morning hypoglycemia with ketosis.

In older children and adults, moderately severe hypoglycemia can resemble mania, mental illness, drug intoxication, or drunkenness. In the elderly, hypoglycemia can produce focal stroke-like effects or a hard-to-define malaise. The symptoms of a single person may be similar from episode to episode, but are not necessarily so and may be influenced by the speed at which glucose levels are dropping, as well as previous incidents.

In newborns, hypoglycemia can produce irritability, jitters, myoclonic jerks, cyanosis, respiratory distress, apneic episodes, sweating, hypothermia, somnolence, hypotonia, refusal to feed, and seizures or "spells." Hypoglycemia can resemble asphyxia, hypocalcemia, sepsis, or heart failure.

In both young and old people with hypoglycemia, the brain may habituate to low glucose levels, with a reduction of noticeable symptoms despite neuroglycopenic impairment. In insulin-dependent diabetic people this phenomenon is termed hypoglycemia unawareness and is a significant clinical problem when improved glycemic control is attempted. Another aspect of this phenomenon occurs in type I glycogenosis, when chronic hypoglycemia before diagnosis may be better tolerated than acute hypoglycemia after treatment is underway.

Hypoglycemic symptoms can also occur when one is sleeping. Examples of symptoms during sleep can include damp bed sheets or clothes from perspiration. Having nightmares or the act of crying out can be a sign of hypoglycemia. Once the individual is awake they may feel tired, irritable, or confused and these may be signs of hypoglycemia as well.

In nearly all cases, hypoglycemia that is severe enough to cause seizures or unconsciousness can be reversed without obvious harm to the brain. Cases of death or permanent neurological damage occurring with a single episode have usually involved prolonged, untreated unconsciousness, interference with breathing, severe concurrent disease, or some other type of vulnerability. Nevertheless, brain damage or death has occasionally resulted from severe hypoglycemia. Research in healthy adults shows that mental efficiency declines slightly but measurably as blood glucose falls below 3.6 mM (65 mg/dL).

Hormonal defense mechanisms (adrenaline and glucagon) are normally activated as it drops below a threshold level (about 55 mg/dL (3.0 mM) for most people), producing the typical hypoglycemic symptoms of shakiness and dysphoria. Obvious impairment may not occur until the glucose falls below 40 mg/dL (2.2 mM), and many healthy people may occasionally have glucose levels below 65 in the morning without apparent effects. Since the brain effects of hypoglycemia, termed neuroglycopenia, determine whether a given low glucose is a "problem" for that person, most doctors use the term hypoglycemia only when a moderately low glucose level is accompanied by symptoms or brain effects.

Determining the presence of both parts of this definition is not always straightforward, as hypoglycemic symptoms and effects are vague and can be produced by other conditions; people with recurrently low glucose levels can lose their threshold symptoms so that severe neuroglycopenic impairment can occur without much warning, and many measurement methods (especially glucose meters) are imprecise at low levels.

It may take longer to recover from severe hypoglycemia with unconsciousness or seizure even after restoration of normal blood glucose. When a person has not been unconscious, failure of carbohydrate to reverse the symptoms in 10–15 minutes increases the likelihood that hypoglycemia was not the cause of the symptoms. When severe hypoglycemia has persisted in a hospitalized person, the amount of glucose required to maintain satisfactory blood glucose levels becomes an important clue to the underlying cause. Glucose requirements above 10 mg/kg/minute in infants, or 6 mg/kg/minute in children and adults are strong evidence for hyperinsulinism. In this context this is referred to as the glucose infusion rate (GIR). Finally, the blood glucose response to glucagon given when the glucose is low can also help distinguish among various types of hypoglycemia. A rise of blood glucose by more than 30 mg/dL (1.70 mmol/l) suggests insulin excess as the probable cause of the hypoglycemia.

Long-Term Effects
Significant hypoglycemia appears to increase the risk of cardiovascular disease.

Causes

The most common cause of hypoglycemia is medications used to treat diabetes mellitus such as insulin, sulfonylureas, and biguanides. Risk is greater in diabetics who have eaten less than usual, exercised more than usual, or drunk alcohol. Other causes of hypoglycemia include kidney failure, certain tumors, liver disease, hypothyroidism, starvation, inborn errors of metabolism, severe infections, reactive hypoglycemia, and a number of drugs including alcohol. Low blood sugar may occur in babies who are otherwise healthy who have not eaten for a few hours. Inborn errors of metabolism may include the lack of an enzyme to make glycogen (glycogen storage type 0).

Serious Illness
Serious illness may result in low blood sugar. Severe disease of nearly all major organ systems can cause hypoglycemia as a secondary problem. Hospitalized persons, especially in intensive care units or those prevented from eating, can develop hypoglycemia from a variety of circumstances related to the care of their primary disease. Hypoglycemia in these circumstances is often multifactorial or caused by the healthcare. Once identified, these types of hypoglycemia are readily reversed and prevented, and the underlying disease becomes the primary problem.

Hormone Deficiency
Not enough cortisol, such as in Addison's disease, not enough glucagon, or not enough epinephrine can result in low blood sugar. This is a more common cause in children.

Diagnosis

The glucose level that defines hypoglycemia is variable. In diabetics a level below 3.9 mmol/L (70 mg/dL) is diagnostic. In adults without diabetes, symptoms related to low blood sugar, low blood sugar at the time of symptoms, and improvement when blood sugar is restored to normal confirm the diagnosis. This is known as the Whipple's triad. Otherwise a level below 2.8 mmol/L (50 mg/dL) after not eating or following exercise may be used. In newborns a level below 2.2 mmol/L (40 mg/dL) or less than 3.3 mmol/L (60 mg/dL) if symptoms are present indicates hypoglycemia. Other tests that may be useful in determining the cause include insulin and C peptide levels in the blood. Hyperglycemia, a high blood sugar, is the opposite condition.

Throughout a 24-hour period blood plasma glucose levels are generally maintained between 4–8 mmol/L (72 and 144 mg/dL).1 Although 3.3 or 3.9 mmol/L (60 or 70 mg/dL) is commonly cited as the lower limit of normal glucose, symptoms of hypoglycemia usually do not occur until 2.8 to 3.0 mmol/L (50 to 54 mg/dL).

In cases of recurrent hypoglycemia with severe symptoms, the best method of excluding dangerous conditions is often a diagnostic fast. This is usually conducted in the hospital, and the duration depends on the age of the person and response to the fast. A healthy adult can usually maintain a glucose level above 50 mg/dL (2.8 mM) for 72 hours, a child for 36 hours, and an infant for 24 hours. The purpose of the fast is to determine whether the person can maintain his or her blood glucose as long as normal, and can respond to fasting with the appropriate metabolic changes. At the end of the fast the insulin should be nearly undetectable and ketosis should be fully established. The person's blood glucose levels are monitored and a critical specimen is obtained if the glucose falls. Despite its unpleasantness and expense, a diagnostic fast may be the only effective way to confirm or refute a number of serious forms of hypoglycemia, especially those involving excessive insulin.

The precise level of glucose considered low enough to define hypoglycemia is dependent on (1) the measurement method, (2) the age of the person, (3) presence or absence of effects, and (4) the purpose of the definition. While there is no disagreement as to the normal range of blood sugar, debate continues as to what degree of hypoglycemia warrants medical evaluation or treatment, or can cause harm.

Deciding whether a blood glucose in the borderline range of 45–75 mg/dL (2.5–4.2 mM) represents clinically problematic hypoglycemia is not always simple. This leads people to use different "cutoff levels" of glucose in different contexts and for different purposes. Because of all the variations, the Endocrine Society recommends that a diagnosis of hypoglycemia as a problem for an individual be based on the combination of a low glucose level and evidence of adverse effects.

Glucose concentrations are expressed as milligrams per deciliter (mg/dL or mg/100 mL) in Lebanon, the United States, Japan, Portugal, Spain, France, Belgium, Egypt, Turkey, Saudi Arabia, Colombia, India and Israel, while millimoles per liter (mmol/L or mM) are the units used in most of the rest of the world. Glucose concentrations expressed as mg/dL can be converted to mmol/L by dividing by 18.0 g/dmol (the molar mass of glucose). For example, a glucose concentration of 90 mg/dL is 5.0 mmol/L or 5.0 mM.

The circumstances of hypoglycemia provide most of the clues to diagnosis. Circumstances include the age of the person, time of day, time since last meal, previous episodes, nutritional status, physical and mental development, drugs or toxins (especially insulin or other diabetes drugs), diseases of other organ systems, family history, and response to treatment.

When hypoglycemia occurs repeatedly, a record or "diary" of the spells over several months, noting the circumstances of each spell (time of day, relation to last meal, nature of last meal, response to carbohydrate, and so forth) may be useful in recognizing the nature and cause of the hypoglycemia.

Age
Children's blood sugar levels are often slightly lower than adults'. Overnight fasting glucose levels are below 70 mg/dL (3.9 mM) in 5% of healthy adults, but up to 5% of children can be below 60 mg/dL (3.3 mM) in the morning fasting state. As the duration of fasting is extended, a higher percentage of infants and children will have mildly low plasma glucose levels, typically without symptoms. The normal range of newborn blood sugars continues to be debated. It has been proposed that newborn brains are able to use alternate fuels when glucose levels are low more readily than adults. Experts continue to debate the significance and risk of such levels, though the trend has been to recommend maintenance of glucose levels above 60–70 mg/dL the first day after birth.

Diabetic hypoglycemia represents a special case with respect to the relationship of measured glucose and hypoglycemic symptoms for several reasons. First, although home glucose meter readings are often misleading, the probability that a low reading, whether accompanied by symptoms or not, represents real hypoglycemia is much higher in a person who takes insulin than in someone who does not.

Prevention

The most effective means of preventing further episodes of hypoglycemia depends on the cause. The risk of further episodes of diabetic hypoglycemia can often (but not always) be reduced by lowering the dose of insulin or other medications, or by more meticulous attention to blood sugar balance during unusual hours, higher levels of exercise, or decreasing alcohol intake.

Many of the inborn errors of metabolism require avoidance or shortening of fasting intervals, or extra carbohydrates. For the more severe disorders, such as type 1 glycogen storage disease, this may be supplied in the form of cornstarch every few hours or by continuous gastric infusion.

Several treatments are used for hyperinsulinemic hypoglycemia, depending on the exact form and severity. Some forms of congenital hyperinsulinism respond to diazoxide or octreotide. Surgical removal of the overactive part of the pancreas is curative with minimal risk when hyperinsulinism is focal or due to a benign insulin-producing tumor of the pancreas. When congenital hyperinsulinism is diffuse and refractory to medications, near-total pancreatectomy may be the treatment of last resort, but in this condition is less consistently effective and fraught with more complications.

Hypoglycemia due to hormone deficiencies such as hypopituitarism or adrenal insufficiency usually ceases when the appropriate hormone is replaced. Hypoglycemia due to dumping syndrome and other post-surgical conditions is best dealt with by altering diet. Including fat and protein with carbohydrates may slow digestion and reduce early insulin secretion. Some forms of this respond to treatment with an alpha-glucosidase inhibitor, which slows starch digestion.

Reactive hypoglycemia with demonstrably low blood glucose levels is most often a predictable nuisance which can be avoided by consuming fat and protein with carbohydrates, by adding morning or afternoon snacks, and reducing alcohol intake.

Idiopathic postprandial syndrome without demonstrably low glucose levels at the time of symptoms can be more of a management challenge. Many people find improvement by changing eating patterns (smaller meals, avoiding excessive sugar, mixed meals rather than carbohydrates by themselves), reducing intake of stimulants such as caffeine, or by making lifestyle changes to reduce stress. See the following section of this article.

Treatment

Treatment of some forms of hypoglycemia, such as in diabetes, involves immediately raising the blood sugar to normal through the eating of carbohydrates such as sugars, determining the cause, and taking measures to hopefully prevent future episodes. However, this treatment is not optimal in other forms such as reactive hypoglycemia, where rapid carbohydrate ingestion may lead to a further hypoglycemic episode.

Blood glucose can be raised to normal within minutes by taking (or receiving) 10–20 grams of carbohydrate. It can be taken as food or drink if the person is conscious and able to swallow. This amount of carbohydrate is contained in about 3–4 ounces (100–120 ml) of orange, apple, or grape juice although fruit juices contain a higher proportion of fructose which is more slowly metabolized than pure dextrose. Alternatively, about 4–5 ounces (120–150 ml) of regular (non-diet) soda may also work, as will about one slice of bread, about 4 crackers, or about 1 serving of most starchy foods. Starch is quickly digested to glucose (unless the person is taking acarbose), but adding fat or protein retards digestion. Symptoms should begin to improve within 5 minutes, though full recovery may take 10–20 minutes. Overfeeding does not speed recovery and if the person has diabetes will simply produce hyperglycemia afterwards. A mnemonic used by the American Diabetes Association and others is the "rule of 15" – consuming 15 grams of carbohydrate followed by a 15-minute wait, repeated if glucose remains low (variable by individual, sometimes 70 mg/dL).
If a person has such severe effects of hypoglycemia that they cannot (due to combativeness) or should not (due to seizures or unconsciousness) be given anything by mouth, medical personnel such as paramedics, or in-hospital personnel can establish IV access and give intravenous dextrose, concentrations varying depending on age (infants are given 2 ml/kg dextrose 10%, children are given dextrose 25%, and adults are given dextrose 50%). Care must be taken in giving these solutions because they can cause skin necrosis if the IV is infiltrated, sclerosis of veins, and many other fluid and electrolyte disturbances if administered incorrectly. If IV access cannot be established, the person can be given 1 to 2 milligrams of glucagon in an intramuscular injection. More treatment information can be found in the article diabetic hypoglycemia. If a person has less severe effects, and is conscious with the ability to swallow, medical personal may administer gelatinous oral glucose. The soft drink Lucozade has been used for hypoglycemia in the United Kingdom, however it has recently replaced much of its glucose with the artificial sugars, which do not treat hypoglycemia.

One situation where starch may be less effective than glucose or sucrose is when a person is taking acarbose. Since acarbose and other alpha-glucosidase inhibitors prevents starch and other sugars from being broken down into monosaccharides that can be absorbed by the body, people taking these medications should consume monosaccharide-containing foods such as glucose tablets, honey, or juice to reverse hypoglycemia.

8 Toothache

Toothache, also known as dental pain, is pain in the teeth or their supporting structures, caused by dental diseases or pain referred to the teeth by non-dental diseases. When severe it may impact sleep, eating, and other daily activities.

Common causes include inflammation of the pulp, usually in response to tooth decay, dental trauma, or other factors, dentin hypersensitivity, apical periodontitis (inflammation of the periodontal ligament and alveolar bone around the root apex), dental abscesses (localized collections of pus, alveolar osteitis ("dry socket", a possible complication of tooth extraction), acute necrotizing ulcerative gingivitis (a gum infection), temporomandibular disorder.

Pulpitis is reversible when the pain is mild to moderate and lasts for a short time after a stimulus (for instance cold); or irreversible when the pain is severe, spontaneous, and lasts a long time after a stimulus. Left untreated, pulpitis may become irreversible, then progress to pulp necrosis (death of the pulp) and apical periodontitis. Abscesses usually cause throbbing pain. The apical abscess usually occurs after pulp necrosis, the pericoronal abscess is usually associated with acute pericoronitis of a lower wisdom tooth, and periodontal abscesses usually represent a complication of chronic periodontitis (gum disease). Less commonly, non-dental conditions can cause toothache, such as maxillary sinusitis, which can cause pain in the upper back teeth, or angina pectoris, which can cause pain in the lower teeth. Correct diagnosis can sometimes be challenging.

Proper oral hygiene helps to prevent toothaches by preventing dental disease. The treatment of a toothache depends upon the exact cause, and may involve a filling, root canal treatment, extraction, drainage of pus, or other remedial action. The relief of toothache is considered one of the main responsibilities of dentists. Toothache is the most common type of pain in the mouth or face It is one of the most common reasons for emergency dental appointments.

Signs & Symptoms

The chief complaint, and the onset of the complaint, are usually important in the diagnosis of toothache. For example, the key distinction between reversible and irreversible pulpitis is given in the history, such as pain following a stimulus in the former, and lingering pain following a stimulus and spontaneous pain in the latter. History is also important in recent filling or other dental treatment, and trauma to the teeth. Based on the most common causes of toothache (dentin hypersensitivity, periodontitis, and pulpitis), the key indicators become localization of the pain (whether the pain is perceived as originating in a specific tooth), thermal sensitivity, pain on biting, spontaneity of the pain, and factors that make the pain worse.

The various qualities of the toothache, such as the effect of biting and chewing on the pain, the effect of thermal stimuli, and the effect of the pain on sleep, are verbally established by the clinician, usually in a systematic fashion, such as using the Socrates pain assessment method (see table).

From the history, indicators of pulpal, periodontal, a combination of both, or non-dental causes can be observed. Periodontal pain is frequently localized to a particular tooth, which is made much worse by biting on the tooth, sudden in onset, and associated with bleeding and pain when brushing. More than one factor may be involved in the toothache.

For example, a pulpal abscess (which is typically severe, spontaneous and localized) can cause periapical periodontitis (which results in pain on biting). Cracked tooth syndrome may also cause a combination of symptoms. Lateral periodontitis (which is usually without any thermal sensitivity and sensitive to biting) can cause pulpitis and the tooth becomes sensitive to cold.

Causes

Toothache may be caused by dental (odontogenic) conditions (such as those involving the dentin-pulp complex or periodontium), or by non-dental (non-odontogenic) conditions (such as maxillary sinusitis or angina pectoris). There are many possible non-dental causes, but the vast majority of toothache is dental in origin.

Both the pulp and periodontal ligament have nociceptors (pain receptors), but the pulp lacks proprioceptors (motion or position receptors) and mechanoreceptors (mechanical pressure receptors). Consequently, pain originating from the dentin-pulp complex tends to be poorly localized, whereas pain from the periodontal ligament will typically be well localized, although not always.

For instance, the periodontal ligament can detect the pressure exerted when biting on something smaller than a grain of sand (10–30 µm). When a tooth is intentionally stimulated, about 33% of people can correctly identify the tooth, and about 20% cannot narrow the stimulus location down to a group of three teeth. Another typical difference between pulpal and periodontal pain is that the latter is not usually made worse by thermal stimuli.

Dental

Pulpal
The majority of pulpal toothache falls into one of the following types; however, other rare causes (which do not always fit neatly into these categories) include galvanic pain and barodontalgia.

Pulpitis
Pulpitis (inflammation of the pulp) can be triggered by various stimuli (insults), including mechanical, thermal, chemical, and bacterial irritants, or rarely barometric changes and ionizing radiation. Common causes include tooth decay, dental trauma (such as a crack or fracture), or a filling with an imperfect seal.

Because the pulp is encased in a rigid outer shell, there is no space to accommodate swelling caused by inflammation. Inflammation therefore increases pressure in the pulp system, potentially compressing the blood vessels which supply the pulp. This may lead to ischemia (lack of oxygen) and necrosis (tissue death). Pulpitis is termed reversible when the inflamed pulp is capable of returning to a state of health, and irreversible when pulp necrosis is inevitable.

Reversible pulpitis is characterized by short-lasting pain triggered by cold and sometimes heat. The symptoms of reversible pulpitis may disappear, either because the noxious stimulus is removed, such as when dental decay is removed and a filling placed, or because new layers of dentin (tertiary dentin) have been produced inside the pulp chamber, insulating against the stimulus. Irreversible pulpitis causes spontaneous or lingering pain in response to cold.

Dentin Hypersensitivity
Dentin hypersensitivity is a sharp, short-lasting dental pain occurring in about 15% of the population, which is triggered by cold (such as liquids or air), sweet or spicy foods, and beverages. Teeth will normally have some sensation to these triggers, but what separates hypersensitivity from regular tooth sensation is the intensity of the pain. Hypersensitivity is most commonly caused by a lack of insulation from the triggers in the mouth due to gingival recession (receding gums) exposing the roots of the teeth, although it can occur after scaling and root planing or dental bleaching, or as a result of erosion. The pulp of the tooth remains normal and healthy in dentin hypersensitivity.

Many topical treatments for dentin hypersensitivity are available, including desensitizing toothpastes and protective varnishes that coat the exposed dentin surface. Treatment of the root cause is critical, as topical measures are typically short lasting. Over time, the pulp usually adapts by producing new layers of dentin inside the pulp chamber called tertiary dentin, increasing the thickness between the pulp and the exposed dentin surface and lessening the hypersensitivity.

Periodontal
In general, chronic periodontal conditions do not cause any pain. Rather, it is acute inflammation which is responsible for the pain.

Apical Periodontitis
Apical periodontitis is acute or chronic inflammation around the apex of a tooth caused by an immune response to bacteria within an infected pulp. It does not occur because of pulp necrosis, meaning that a tooth that tests as if it's alive (vital) may cause apical periodontitis, and a pulp which has become non-vital due to a sterile, non-infectious processes (such as trauma) may not cause any apical periodontitis. Bacterial cytotoxins reach the region around the roots of the tooth via the apical foramina and lateral canals, causing vasodilation, sensitization of nerves, osteolysis (bone resorption) and potentially abscess or cyst formation.

The periodontal ligament becomes inflamed and there may be pain when biting or tapping on the tooth. On an X-ray, bone resporption appears as a radiolucent area around the end of the root, although this does not manifest immediately. Acute apical periodontitis is characterized by well-localized, spontaneous, persistent, moderate to severe pain. The alveolar process may be tender to palpation over the roots. The tooth may be raised in the socket and feel more prominent than the adjacent teeth.

Food Impaction
Food impaction occurs when food debris, especially fibrous food such as meat, becomes trapped between two teeth and is pushed into the gums during chewing. The usual cause of food impaction is disruption of the normal interproximal contour or drifting of teeth so that a gap is created (an open contact). Decay can lead to collapse of part of the tooth, or a dental restoration may not accurately reproduce the contact point. Irritation, localized discomfort or mild pain and a feeling of pressure from between the two teeth results. The gingival papilla is swollen, tender and bleeds when touched. The pain occurs during and after eating, and may slowly disappear before being evoked again at the next meal, or relieved immediately by using a tooth pick or dental floss in the involved area. A gingival or periodontal abscess may develop from this situation.

Periodontal Abscess
A periodontal abscess (lateral abscess) is a collection of pus that forms in the gingival crevices, usually as a result of chronic periodontitis where the pockets are pathologically deepened greater than 3mm. A healthy gingival pocket will contain bacteria and some calculus kept in check by the immune system. As the pocket deepens, the balance is disrupted, and an acute inflammatory response results, forming pus. The debris and swelling then disrupt the normal flow of fluids into and out of the pocket, rapidly accelerating the inflammatory cycle. Larger pockets also have a greater likelihood of collecting food debris, creating additional sources of infection.

Periodontal abscesses are less common than apical abscesses, but are still frequent. The key difference between the two is that the pulp of the tooth tends to be alive, and will respond normally to pulp tests. However, an untreated periodontal abscess may still cause the pulp to die if it reaches the tooth apex in a periodontic-endodontic lesion.

A periodontal abscess can occur as the result of tooth fracture, food packing into a periodontal pocket (with poorly shaped fillings), calculus build-up, and lowered immune responses (such as in diabetes). Periodontal abscess can also occur after periodontal scaling, which causes the gums to tighten around the teeth and trap debris in the pocket. Toothache caused by a periodontal abscess is generally deep and throbbing. The oral mucosa covering an early periodontal abscess appears erythematous (red), swollen, shiny, and painful to touch.

A variant of the periodontal abscess is the gingival abscess, which is limited to the gingival margin, has a quicker onset, and is typically caused by trauma from items such as a fishbone, toothpick, or toothbrush, rather than chronic periodontitis. The treatment of a periodontal abscess is similar to the management of dental abscesses in general (see: Treatment). However, since the tooth is typically alive, there is no difficulty in accessing the source of infection and, therefore, antibiotics are more routinely used in conjunction with scaling and root planing. The occurrence of a periodontal abscess usually indicates advanced periodontal disease, which requires correct management to prevent recurrent abscesses, including daily cleaning below the gumline to prevent the buildup of subgingival plaque and calculus.

Acute Necrotizing Ulcerative Gingivitis

Common marginal gingivitis in response to subgingival plaque is usually a painless condition. However, an acute form of gingivitis/periodontitis, termed acute necrotizing ulcerative gingivitis (ANUG), can develop, often suddenly. It is associated with severe periodontal pain, bleeding gums, "punched out" ulceration, loss of the interdental papillae, and possibly also halitosis (bad breath) and a bad taste. Predisposing factors include poor oral hygiene, smoking, malnutrition, psychological stress, and immunosuppression. This condition is not contagious, but multiple cases may simultaneously occur in populations who share the same risk factors (such as students in a dormitory during a period of examination). ANUG is treated over several visits, first with debridement of the necrotic gingiva, homecare with hydrogen peroxide mouthwash, analgesics and, when the pain has subsided sufficiently, cleaning below the gumline, both professionally and at home. Antibiotics are not indicated in ANUG management unless there is underlying systemic disease.

Pericoronitis

Pericoronitis is inflammation of the soft tissues surrounding the crown of a partially erupted tooth. The lower wisdom tooth is the last tooth to erupt into the mouth, and is, therefore, more frequently impacted, or stuck, against the other teeth. This leaves the tooth partially erupted into the mouth, and there frequently is a flap of gum (an operculum), overlying the tooth. Bacteria and food debris accumulate beneath the operculum, which is an area that is difficult to keep clean because it is hidden and far back in the mouth. The opposing upper wisdom tooth also tends to have sharp cusps and over-erupt because it has no opposing tooth to bite into, and instead traumatizes the operculum further.

Periodontitis and dental caries may develop on either the third or second molars, and chronic inflammation develops in the soft tissues. Chronic pericoronitis may not cause any pain, but an acute pericoronitis episode is often associated with pericoronal abscess formation. Typical signs and symptoms of a pericoronal abscess include severe, throbbing pain, which may radiate to adjacent areas in the head and neck, redness, swelling and tenderness of the gum over the tooth. There may be trismus (difficulty opening the mouth), facial swelling, and rubor (flushing) of the cheek that overlies the angle of the jaw.

Persons typically develop pericoronitis in their late teens and early 20s, as this is the age that the wisdom teeth are erupting. Treatment for acute conditions includes cleaning the area under the operculum with an antiseptic solution, painkillers, and antibiotics if indicated. After the acute episode has been controlled, the definitive treatment is usually by tooth extraction or, less commonly, the soft tissue is removed (operculectomy). If the tooth is kept, good oral hygiene is required to keep the area free of debris to prevent recurrence of the infection.

Occlusal Trauma

Occlusal trauma results from excessive biting forces exerted on teeth, which overloads the periodontal ligament, causing periodontal pain and a reversible increase in tooth mobility. Occlusal trauma may occur with bruxism, the parafunctional (abnormal) clenching and grinding of teeth during sleep or while awake. Over time, there may be attrition (tooth wear), which may also cause dentin hypersensitivity, and possibly formation of a periodontal abscess, as the occlusal trauma causes adaptive changes in the alveolar bone.

Occlusal trauma often occurs when a newly placed dental restoration is built too "high", concentrating the biting forces on one tooth. Height differences measuring less than a millimeter can cause pain. Dentists, therefore, routinely check that any new restoration is in harmony with the bite and forces are distributed correctly over many teeth using articulating paper. If the high spot is quickly eliminated, the pain disappears and there is no permanent harm. Over-tightening of braces can cause periodontal pain and, occasionally, a periodontal abscess.

Alveolar Osteitis

Alveolar osteitis is a complication of tooth extraction (especially lower wisdom teeth) in which the blood clot is not formed or is lost, leaving the socket where the tooth used to be empty, and bare bone is exposed to the mouth. The pain is moderate to severe, and dull, aching, and throbbing in character. The pain is localized to the socket, and may radiate. It normally starts two to four days after the extraction, and may last 10–40 days. Healing is delayed, and it is treated with local anesthetic dressings, which are typically required for five to seven days. There is some evidence that chlorhexidine mouthwash used prior to extractions prevents alveolar osteitis.

Dental trauma and cracked tooth syndrome

Cracked tooth syndrome refers to a highly variable set of pain-sensitivity symptoms that may accompany a tooth fracture, usually sporadic, sharp pain that occurs during biting or with release of biting pressure, or relieved by releasing pressure on the tooth. The term is falling into disfavor and has given way to the more generalized description of fractures and cracks of the tooth, which allows for the wide variations in signs, symptoms, and prognosis for traumatized teeth. A fracture of a tooth can involve the enamel, dentin, and/or pulp, and can be orientated horizontally or vertically. Fractured or cracked teeth can cause pain via several mechanisms, including dentin hypersensitivity, pulpitis (reversible or irreversible), or periodontal pain. Accordingly, there is no single test or combination of symptoms that accurately diagnose a fracture or crack, although when pain can be stimulated by causing separation of the cusps of the tooth, it's highly suggestive of the disorder. Vertical fractures can be very difficult to identify because the crack can rarely be probed or seen on radiographs, as the fracture runs in the plane of conventional films (similar to how the split between two adjacent panes of glass is invisible when facing them).

Periodontic-Endodontic Lesion

Apical abscesses can spread to involve periodontal pockets around a tooth, and periodontal pockets cause eventual pulp necrosis via accessory canals or the apical foramen at the bottom of the tooth. Such lesions are termed periodontic-endodontic lesions, and they may be acutely painful, sharing similar signs and symptoms with a periodontal abscess, or they may cause mild pain or no pain at all if they are chronic and free-draining. Successful root canal therapy is required before periodonal treatment is attempted. Generally, the long-term prognosis of perio-endo lesions is poor.

Non-Dental

Non-dental causes of toothache are much less common as compared with dental causes. In a toothache of neurovascular origin, pain is reported in the teeth in conjunction with a migraine. Local and distant structures (such as ear, brain, carotid artery, or heart) can also refer pain to the teeth. Other non-dental causes of toothache include myofascial pain (muscle pain) and angina pectoris (which classically refers pain to the lower jaw). Very rarely, toothache can be psychogenic in origin.

Disorders of the maxillary sinus can be referred to the upper back teeth. The posterior, middle and anterior superior alveolar nerves are all closely associated with the lining of the sinus. The bone between the floor of the maxillary sinus and the roots of the upper back teeth is very thin, and frequently the apices of these teeth disrupt the contour of the sinus floor. Consequently, acute or chronic maxillary sinusitis can be perceived as maxillary toothache, and neoplasms of the sinus (such as adenoid cystic carcinoma) can cause similarly perceived toothache if malignant invasion of the superior alveolar nerves occurs. Classically, sinusitis pain increases upon Valsalva maneuvers or tilting the head forward.

Painful conditions which do not originate from the teeth or their supporting structures may affect the oral mucosa of the gums and be interpreted by the individual as toothache. Examples include neoplasms of the gingival or alveolar mucosa (usually squamous cell carcinoma), conditions which cause gingivostomatitis and desquamative gingivitis. Various conditions may involve the alveolar bone, and cause non-odontogenic toothache, such as Burkitt's lymphoma, infarcts in the jaws caused by sickle cell disease, and osteomyelitis. Various conditions of the trigeminal nerve can masquerade as toothache, including trigeminal zoster (maxillary or mandibular division), trigeminal neuralgia, cluster headache, and trigeminal neuropathies. Very rarely, a brain tumor might cause toothache. Another chronic facial pain syndrome which can mimic toothache is temporomandibular disorder (temporomandibular joint pain-dysfunction syndrome), which is very common. Toothache which has no identifiable dental or medical cause is often termed atypical odontalgia, which, in turn, is usually considered a type of atypical facial pain (or persistent idiopathic facial pain). Atypical odontalgia may give very unusual symptoms, such as pain which migrates from one tooth to another and which crosses anatomical boundaries (such as from the left teeth to the right teeth).

Establishing a diagnosis of nondental toothache is initially done by careful questioning about the site, nature, aggravating and relieving factors, and referral of the pain, then ruling out any dental causes. There are no specific treatments for nondental pain (each treatment is directed at the cause of the pain, rather than the toothache itself), but a dentist can assist in offering potential sources of the pain and direct the patient to appropriate care. The most critical nondental source is the radiation of angina pectoris into the lower teeth and the potential need for urgent cardiac care.

Diagnosis

The diagnosis of toothache can be challenging, not only because the list of potential causes is extensive, but also because dental pain may be extremely variable, and pain can be referred to and from the teeth. Dental pain can simulate virtually any facial pain syndrome. However, the vast majority of toothache is caused by dental, rather than non-dental, sources. Consequently, the saying "horses, not zebras" has been applied to the differential diagnosis of orofacial pain. That is, everyday dental causes (such as pulpitis) should always be considered before unusual, non-dental causes (such as myocardial infarction). In the wider context of orofacial pain, all cases of orofacial pain may be considered as having a dental origin until proven otherwise. The diagnostic approach for toothache is generally carried out in the following sequence: history, followed by examination, and investigations. All this information is then collated and used to build a clinical picture, and a differential diagnosis can be carried out.

Non-dental sources of pain often cause multiple teeth to hurt and have an epicenter that is either above or below the jaws. For instance, cardiac pain (which can make the bottom teeth hurt) usually radiates up from the chest and neck, and sinusitis (which can make the back top teeth hurt) is worsened by bending over. As all of these conditions may mimic toothache, it is possible that dental treatment, such as fillings, root canal treatment, or tooth extraction may be carried out unnecessarily by dentists in an attempt to relieve the individual's pain, and as a result the correct diagnosis is delayed. A hallmark is that there is no obvious dental cause, and signs and symptoms elsewhere in the body may be present. As migraines are typically present for many years, the diagnosis is easier to make. Often the character of the pain is the differentiator between dental and non-dental pain.

Irreversible pulpitis progresses to pulp necrosis, wherein the nerves are non-functional, and a pain-free period following the severe pain of irreversible pulpitis may be experienced. However, it is common for irreversible pulpitis to progress to apical periodontitis, including an acute apical abscess, without treatment. As irreversible pulpitis generates an apical abscess, the character of the toothache may simply change without any pain-free period. For instance, the pain becomes well localized, and biting on the tooth becomes painful. Hot drinks can make the tooth feel worse because they expand the gases and likewise, cold can make it feel better, thus some will sip cold water.

Differential Diagnoses:

Parameter	Dentin Hypersensitivity	Dentin Hypersensitivity	Irreversible Pulpitis	Pulp Necrosis	Apical Periodontitis	Periodontal Abscess	Pericoronitis	Myofascial Pain	Maxillary Sinusitis		
Site	Poorly localized	Poorly localized	Variable; localized or diffuse	No pain	Well localized	Usually well localized	Well localized, associated with partially impacted tooth	Diffuse, often over many muscles	Back teeth top jaw		
Onset	Gradual	Variable	Variable	From pain of reversible pulpitis to no pain in days	Gradual, typically follows weeks of thermal pain in tooth	Sudden, no episode of thermal sensitivity	Sudden	Very slow; weeks to months	Sudden		
Character	Sharp, quickly reversible	Sharp, shooting	Dull, continuous pain. Can also be sharp	No pain	Dull, continuous throbbing pain	Dull, continuous throbbing pain	Sharp, with continuous dull	Dull, aching	Dull, aching, occasional thermal sensitivity in back top teeth		
Radiation	Does not cross midline	Does not cross midline	Does not cross midline	N/A	Does not cross midline	Little, well localized	Moderate, into jaw/neck	Extensive, neck/temple	Moderate, into other facial sinus areas		
Associated Symptoms	Patient may complain of receding gums and/or toothbrush abrasion cavities	Can follow restorative dental work or trauma	Follows period of pain that does not linger	Follows period of spontaneous pain	Tooth may feel raised in socket	May follow report of something getting "stuck" in gum	Tooth eruption ("cutting") or impacted tooth	Tension headaches, neck pain, periods of stress or episode of mouth open for long period	Symptoms of URTI		
Time Pattern	Hypersensitivity as long as stimulus is applied; often worse in cold weather	Pain as long as stimulus is applied	Lingering pain to hot or cold or spontaneous pain	Absence of pain following days or weeks of intense, well localized pain	Pain on biting following constant dull, aching pain development	Dull ache with acute increase in pain when tooth is moved, minimal thermal sensitivity	Constant dull ache without stimulus	Spontaneous, worse with eating, chewing, or movement of jaw	Spontaneous, worse when head is tipped forward		
Exacerbating and Relieving Factors	Exacerbating: thermal, particularly cold	Exacerbating: thermal, sweet	Simple analgesics have little effect	Prolonged heat may elicit pain	Same as irreversible pulpitis, or no response to cold, lingering pain to hot, pain with biting or lying down	Tapping tooth makes worse, cleansing area may improve pain	Cleansing area can improve pain	Rest or ice makes pain better, movement and chewing make it worse	Tilting head forward, jarring movements (jumping) make pain worse		
Severity	Less severe than pulpitis	Severe, for short periods	Variable; pain dissipates until periapical tissue affected	Severe	Severe	Severe	Mild to severe	Mild to moderate	Mild to severe		
Effect on Sleep	None	None usually	Disrupts sleep	None	Disrupts sleep	Variable, can disrupt sleep	If moderate to severe, will disrupt	Unusual	Unusual		

Prevention

Since most toothache is the result of plaque-related diseases, such as tooth decay and periodontal disease, the majority of cases could be prevented by avoidance of a cariogenic diet and maintenance of good oral hygiene. That is, reduction in the number times that refined sugars are consumed per day and brushing the teeth twice a day with fluoride toothpaste and interdental cleaning. Regular visits to a dentist also increases the likelihood that problems are detected early and averted before toothache occurs. Dental trauma could also be significantly reduced by routine use of mouthguards in contact sports.

Management

There are many causes of toothache and its diagnosis is a specialist topic, meaning that attendance at a dentist is usually required. Since many cases of toothache are inflammatory in nature, over the counter non-steroidal anti-inflammatory drugs (NSAIDs) may help (unless contraindicated, such as with a peptic ulcer). Generally, NSAIDs are as effective as aspirin alone or in combination with codeine. However, simple analgesics may have little effect on some causes of toothache, and the severe pain can drive individuals to exceed the maximum dose. For example, when acetaminophen (paracetamol) is taken for toothache, an accidental overdose is more likely to occur when compared to people who are taking acetaminophen for other reasons. Another risk in persons with toothache is a painful chemical burn of the oral mucosa caused by holding a caustic substance such as aspirin tablets and toothache remedies containing eugenol (such as clove oil) against the gum. Although the logic of placing a tablet against the painful tooth is understandable, an aspirin tablet needs to be swallowed to have any pain-killing effect. Caustic toothache remedies require careful application to the tooth only, without coming into excessive contact with the soft tissues of the mouth.

For the dentist, the goal of treatment generally is to relieve the pain, and wherever possible to preserve or restore function. The treatment depends on the cause of the toothache, and frequently a clinical decision regarding the current state and long-term prognosis of the affected tooth, as well as the individual's wishes and ability to cope with dental treatment, will influence the treatment choice. Often, administration of an intra-oral local anesthetic such as lidocaine and epinephrine is indicated in order to carry out pain-free treatment. Treatment may range from simple advice, removal of dental decay with a dental drill and subsequent placement of a filling, to root canal treatment, tooth extraction, or debridement.

INJURY Other Toothache Management

Pulpitis and its sequalae

In pulpitis, an important distinction in regard to treatment is whether the inflammation is reversible or irreversible. Treatment of reversible pulpitis is by removing or correcting the causative factor. Usually, the decay is removed, and a sedative dressing is used to encourage the pulp to return to a state of health, either as a base underneath a permanent filling or as a temporary filling intended to last for a period while the tooth is observed to see if pulpitis resolves. Irreversible pulpitis and its sequalae pulp necrosis and apical periodontitis require treatment with root canal therapy or tooth extraction, as the pulp acts as a nidus of infection, which will lead to a chronic infection if not removed. Generally, there is no difference in outcomes between whether the root canal treatment is completed in one or multiple appointments. The field of regenerative endodontics is now developing ways to clean the pulp chamber and regenerate the soft and hard tissues to either regrow or simulate pulp structure. This has proved especially helpful in children where the tooth root has not yet finished developing and root canal treatments have lower success rates.

Reversible/irreversible pulpitis is a distinct concept from whether the tooth is restorable or unrestorable, e.g. a tooth may only have reversible pulpitis, but has been structurally weakened by decay or trauma to the point that it is impossible to restore the tooth in the long term.

Dental Abscesses

A general principle concerning dental abscesses is ubi pus, ibi evacua ("where there is pus, drain it"), which applies to any case where there is a collection of pus in the tissues (such as a periodontal abscess, pericoronal abscess, or apical abscess). The pus within the abscess is under pressure, and the surrounding tissues are deformed and stretched to accommodate the swelling. This leads to a sensation of throbbing (often in time with the pulse) and constant pain. Pus may be evacuated via the tooth by drilling into the pulp chamber (an endodontic access cavity). Such a treatment is sometimes termed open drainage. Drainage can also be performed via the tooth socket, once the causative tooth is extracted. If neither of those measures succeeds, or they are impossible, incision and drainage may be required, in which a small incision is made in the soft tissues directly over the abscess at the most dependent point. A surgical instrument such as a pair of tweezers is gently inserted into the incision and opened, while the abscess is massaged to encourage the pus to drain out. Usually, the reduction in pain when the pus drains is immediate and marked as the built up pressure is relieved. If the pus drains into the mouth, there is usually a bad or offensive taste.

Antibiotics

Antibiotics tend to be extensively used for emergency dental problems. As samples for microbiologic culture and sensitivity are hardly ever carried out in general dental practice, broad-spectrum antibiotics such as amoxicillin are typically used for a short course of about three to seven days. Antibiotics are seen as a "quick fix" by both dentists, who generally only have a very short time to manage dental emergencies, and by patients, who tend to want to avoid treatments (such as tooth extraction) which are perceived negatively. However, antibiotics typically only temporarily suppress an infection, and the need for definitive treatment is only postponed for an unpredictable length of time. An estimated 10% of all antibiotic prescriptions are made by dentists, a major factor in antibiotic resistance. They are often used inappropriately, in conditions for which they are ineffective, or their risks outweigh the benefits, such as irreversible pulpitis, apical abscess, dry socket, or mild pericoronitis. However, the reality is that antibiotics are rarely needed, and they should be used restrictively in dentistry. Local measures such as incision and drainage, and removal of the cause of the infection (such as a necrotic tooth pulp) have a greater therapeutic benefit and are much more important. If abscess drainage has been achieved, antibiotics are not usually necessary.

Antibiotics tend to be used when local measures cannot be carried out immediately. In this role, antibiotics suppress the infection until local measures can be carried out. Severe trismus may occur in when the muscles of mastication are involved in an odontogenic infection, making any surgical treatment impossible. Immunocompromised individuals are less able to fight off infections, and antibiotics are usually given. Evidence of systemic involvement (such as a fever higher than 38.5 °C, cervical lymphadenopathy, or malaise) also indicates antibiotic therapy, as do rapidly spreading infections, cellulitis, or severe pericoronitis. Drooling and difficulty swallowing are signs that the airway may be threatened, and may precede difficulty in breathing. Ludwig's angina and cavernous sinus thrombosis are rare but serious complications of odontogenic infections. Severe infections tend to be managed in hospital.

Prognosis

INJURY Other Toothache Prognosis

Most dental pain can be treated with routine dentistry. In rare cases, toothache can be a symptom representing a life-threatening condition, such as a deep neck infection (compression of the airway by a spreading odontogenic infection) or something more remote like a heart attack.

Dental caries, if left untreated, follows a predictable natural history as it nears the pulp of the tooth. First it causes reversible pulpitis, which transitions to irreversible pulpitis, then to necrosis, then to necrosis with periapical periodontitis and, finally, to necrosis with periapical abscess. Reversible pulpitis can be stopped by removal of the cavity and the placement of a sedative dressing of any part of the cavity that is near the pulp chamber. Irreversible pulpitis and pulp necrosis are treated with either root canal therapy or extraction. Infection of the periapical tissue will generally resolve with the treatment of the pulp, unless it has expanded to cellulitis or a radicular cyst. The success rate of restorative treatment and sedative dressings in reversible pulpitis, depends on the extent of the disease, as well as several technical factors, such as the sedative agent used and whether a rubber dam was used. The success rate of root canal treatment also depends on the degree of disease (root canal therapy for irreversible pulpitis has a generally higher success rate than necrosis with periapical abscess) and many other technical factors.

Emotional

Recovering from emotional problems and signs to look out for

"Instead of a sign that says 'Do Not Disturb', I need one that says: 'Already Disturbed, Proceed With Caution'."
Unknown

Introduction

Being emotionally healthy does not mean you are happy all the time. It means you are aware of your emotions. You can deal with them, whether they are positive or negative. Emotionally healthy people still feel stress, anger, and sadness. But they know how to manage their negative feelings. They can tell when a problem is more than they can handle on their own.

Purpose	The aim of EMOTIONAL is to help diagnose and treat any emotional related issuses you may face in a disaster. It includes information on depression, anxiety, stress, dementia and grief.

1 Depression

Sometimes it is hard to know if what you are experiencing is sadness or depression. The symptoms, causes, management and treatment of depression are discussed along with how to get a mental health care plan from your doctor and tips on what to do if someone you know is depressed. Depression is the persistentance and extreme negative thoughts and feelings. It can stop you doing everyday activities including eating and sleeping. Depression is a serious and common illness that affects one in five people. Those with depression find it hard to function each day, physically, mentally and emotionally. Depression is different from sadness, stress, anxiety or even grief. What distinguishes depression is a combination of factors, including continuously feeling miserable or losing interest in things that you usually enjoy, to the point where you feel you are no longer functioning. While most people will experience some symptoms of depression at various stages of their life, people who are depressed experience many symptoms, often intensely. Depression significantly affects how people think, feel and act.

Symptoms	Symptoms	Thoughts	Behaviours
● Sleep disturbance: either not sleeping or 'over' sleeping ● Changes in eating: either not eating or 'over' eating ● Changes in weight: unanticipated loss or gain ● Not wanting to be intimate with others ● Empty and depressed mood most of the time ● Continuing feelings of sadness, unhappiness and tearfulness ● Irritability and/or agitation	● Loss of energy ● Tired all the time ● Tension pains ● Feelings of anxiety ● Feelings of heaviness ● Feelings of isolation ● Headaches ● Churning stomach ● Loss of motivation ● Loss of interest in sex	● "I'm a failure" ● "Everyone would be better off without me around" ● "I feel so guilty" ● '"It's all my fault" ● "Nothing good ever happens" ● "I'm worthless" ● "Life is not worth living"	● Withdrawal from social situations ● Less pleasure/interest in activities ● Loss of interest in personal appearance ● Drug and alcohol misuse ● Difficulty concentrating ● Panic attacks ● Hopelessness about yourself, the future and the world

Depression Causes

These are the most common causes of depression.

Biochemical Changes	Neurotransmitters (brain chemicals), which carry signals from one part of the brain to the next, can be disrupted and 'dull' how you feel, leading to depression.	
Hormones	Oestrogen, progesterone and testosterone may account for mood changes women can experience: ● With periods and PMS (premenstrual syndrome) ● With menopause (around 51 years) ● Postnatally	The exception to this is women who have a surgical or sudden menopause. The sudden and severe drop in hormones when menopause is induced increases the risk of developing depression.
Genetics	A family history of depression increases your risk of having depression. However, it does not automatically mean it will occur.	
Stress & Anxiety	If you have had high stress and anxiety over a long period of time this may lead to depression.	
Personality	Some personalities are more prone to depression such as being self-critical, having low self-esteem or worrying excessively.	
Traumatic Experiences	You may not feel depressed immediately after a traumatic event, but depression can build up and develop over time. This is known as post-traumatic stress disorder (PTSD).	
Health Status	Some illnesses and diseases are linked to depression, such as diabetes and cardiovascular disease. Having an illness or disease such as arthritis, breast cancer or stroke can make depression worse.	
Social Factors	Being lonely, isolated from friends and family, single, divorced or widowed can contribute to the development of depression. The experience of depression is often made worse if you are lonely or isolated. A 'cluster effect' means your mood is influenced by the mood of your social network. If someone very close to you is depressed for a long time, you are more likely to develop depression	
Cultural Expectations	Sometimes cultural expectations create added stress and if this continues for a long time, it can lead to depression.	
Lack of Daylight	During the winter months some people find they are more prone to Seasonal Affective Disorder (SAD) which is a depression caused by the impact on the brain of the lack of day and sunlight. This is more common in countries that experience long and harsh winters like Europe.	

Depression Treatment

It is important to know you can not just 'snap' out of it, nor can you just 'cheer up' or 'get over it' without help. Depression will not pass easily if ignored and may get worse, and the longer it continues without help, the more difficult it may be to shift.

Keep a Diary	Everyday write down your physical and emotional symptoms to help clarify: ● Whether the symptoms are related to your periods, menopause, anxiety and/or depression ● The things that trigger feelings of stress ● What creates positive or negative thoughts for you
Relaxation Techniques	Learn relaxation techniques to help you feel more calm through the day and to give you a coping skill in times of stress and distress.
Small Tasks/Achievements	Set small tasks so each day you feel you have achieved something. Remember the things you achieve each day – even the small ones are worth remembering.
Exercise	Exercise physically to stimulate endorphins (feel good hormones) in the brain because these can improve your mood and help you cope with stress.
Talk	Talk with trusted people if this helps to get things 'out' rather than bottling things inside.
Good Company	Spend time with the friends and family members who are easier to be with and make you feel more positive. It is okay to choose the people you want to spend time with.
Nutritious Food	Avoid the highs and lows of sugary and high carbohydrate foods.

Network	If you feel cut off from other people, try joining a sport group (e.g. Pilates, tennis, walking) or hobby group (e.g. pottery, bridge), or a book club, use the internet to connect via a reliable system such as email or Facebook or LinkedIn, volunteer with a local charity.
Herbs & Natural Remedies	Ask an accredited naturopath about some of the herbs and natural remedies that can help with depressive symptoms – these might include St John's wort, lavender, lemon balm or oat straw

Helping Someone with Depression
- Start a general conversation. Ask open-ended questions e.g. "Tell me what you have been doing lately?" Give them time to open up to you.
- Don't push them if they are not ready to talk. Offer to listen. Ask how you can help
- Ring, text or pop in. Be a presence. Encourage them to see a doctor
- Follow up with them. Reinforce any positive things they do. Try not to preach or lecture
- Look after your own wellbeing. Let them know you care
- Try to keep your own emotions in check – it can be easy to get overwhelmed; If you find you are not coping with what they are doing or how they are behaving, seek support for yourself.

2 Anxiety

Fear and anxiety are normal emotions that help alert us to, protect us from, and cause us to deal with danger. What is not healthy and not good for us is when these feelings become excessive, irrational, ongoing, distressing or interfere with daily life. Anxiety is an unpleasant feeling of nervousness, apprehension, distress and fear that something bad is happening or about to happen. You can feel anxious without necessarily having an anxiety disorder. If you would like to know if what you are experiencing is worry, anxiety or an anxiety disorder.

A variety of things can make you more at risk of developing an anxiety disorder and feeling more anxious than normal. These include:
- High stress levels
- Being physically tired or run-down
- Certain personality traits
- Experiencing lots of change
- Physical or emotional trauma
- Family history

Types

Anxiety Type: Generalised Anxiety Disorder (GAD)	GAD involves excessive, irrational and persistent anxiety or worry over common issues (eg family, work, finances or illness) This worry is out of proportion to the circumstances causing it. GAD can decrease the ability to do even the most basic everyday activities	**Symptoms** ● Excessive worry that is difficult to control ● Irritability ● Fatigue ● Restlessness	**Symptoms** ● Difficulty concentrating ● Muscle tension and pain ● Difficulty sleeping or unsatisfying sleep
Anxiety Type: Panic Disorder	A panic disorder occurs when the body's normal anxiety response to feared situations is not working properly and you: Experience frequent, unexpected panic attacks. Have a persistent concern about having more panic attacks.	**Symptoms** ● Increased heart rate ● Rapid breathing ● Tightness in the chest ● Feeling like you might faint	**Symptoms** ● Sudden intense feeling of terror ● Feeling like you are going to lose control ● Feeling like a catastrophe is about to happen
Anxiety Type: Phobias	A phobia develops when a specific fear becomes excessive or interferes with daily life. Phobias can develop from more common fears of spiders, airplanes, visits to the dentist, and social phobia. Social phobia is a fear of being embarrassed or judged negatively in social situations	**Symptoms** People who suffer from phobias: ● Avoid the feared situation ● Show obvious signs of distress at confronting it	**Symptoms** People with social phobia may fear activities where attention could be drawn to them, such as: ● Speaking in public ● Meeting new people ● Being watched whilst doing something Panic attacks may be an indicator that your fear of something has turned into a phobia.
Anxiety Type: Post-Traumatic Stress Disorder (PTSD)	PTSD can occur following a traumatic event – the event usually involves the person reacting with intense fear, horror or helplessness to actual or threatened death or injury.	These events can include: ● Car accidents ● Natural disasters ● Violence ● Assault ● Abuse ● Being diagnosed with a life threatening illness	**Symptoms** ● Nightmares, flashbacks or constant distressing thoughts relating to the traumatic event ● Avoidance of anything that triggers memories of the event ● Increased anxiety, irritability or anger ● Feeling emotionally withdrawn, sad or detached ● Difficulty concentrating ● Loss of interest in activities previously enjoyed
Anxiety Type: Obsessive Compulsive Disorder (OCD)	OCD occurs when a person cannot stop their obsessive thoughts followed by their compulsive behaviours. Whilst acting out these compulsions may temporarily relieve the anxiety of the sufferer, people with OCD often become quite distressed by the way they behave, and in time, without professional help, this anxiety develops into a disorder.		Feeling compelled to act in a certain way to ease the anxiety caused by these thoughts, for example: ● Cleaning something over and over again ● Needing to do the same task a number of times

Treatment

Medications similar to those used to treat depression may be recommended as a short–term solution. Studies have shown psychological therapies are more effective in the long–term. The following is a list of strategies or interventions recommended for the management and treatment of anxiety.

Cognitive behaviour therapy (CBT)	CBT is a psychological approach designed to help you: ● Understand the thoughts and behaviours contributing to your disorder ● Change negative thoughts into more useful ones ● Acquire coping strategies to better manage your anxiety
Challenging the way you think	To change the way you think, try to: ● Keep a diary to see what triggers your negative or irrational thoughts ● Challenge these thoughts by acknowledging they are not the whole story, they are the negative bits only ● Practise replacing the negative thoughts with more positive, supportive statements

Relaxation	When you are anxious, your body and mind become tense so releasing physical and mental tension can lower your anxiety. It is worth trying: ● Deep, slow breathing ● Controlled breathing and progressive muscle relaxation ● Listening to relaxing music ● Having a massage or a relaxing bath ● Taking time out to do something just for you
Healthy lifestyle It helps to:	● Eat a healthy diet including fresh fruit and vegetables, wholegrain foods and plenty of calcium. Calcium is a critical chemical involved in the release of neurotransmitters, chemicals that serve as messengers between cells within the nervous system ● Move as much as you can – aim for 30 minutes of moderate intensity physical activity over the day to stimulate endorphins (feel good hormones) in the brain as these can improve your mood and help you cope with stress ● Reduce your consumption of alcohol, caffeine and other stimulants.
Seek Support	Getting support is a big step towards taking control of your anxiety. Look for support from someone you feel comfortable with, such as a: ● Doctor and/or psychologist ● Friend or family member ● Support group For those experiencing social phobia, finding online support groups may be less daunting.

3 Stress

Stress occurs when you feel you are not coping with life. We all need a little stress to motivate us to achieve or get things done. However, too much stress, particularly over a long period of time, can take its toll on your health and sense of wellbeing. Extreme stress can be so overwhelming it causes physical reactions such as nausea, diarrhoea, over eating and under eating. There are many things you can do to manage stress; it is just about finding the right strategy for you.

Stress Symptoms

These are some of the symptoms of stress.

How you feel	Anxious, aggressive, apathetic, bored, tired, depressed, frustrated, guilty, irritable, tense, lonely, overwhelmed, unhappy, mood swings
How you think	Difficulty in making decisions, less creative in solving problems, forgetful, hypersensitive to criticism, poor concentration, negative or anxious thoughts, poor organisation (family, work, other interests) memory problems
How you behave	Restless, trembling, having accidents, drinking or smoking excessively, incoherent speech, eating too much or too little, nervous laughing, teary, increased use of alcohol, cigarettes or other drugs
What happens to your body	Increased heart rate, increased blood pressure, dry mouth, sweating, dilated pupils, hot and cold spells, lump in your throat, numbness, butterflies in the stomach, aches, pains, nausea, dizzy, chest tightness, increased frequency of colds and flu, changes in sleeping routine, changes in eating routine
What happens to your health	Dizziness, faintness, diarrhoea, asthma, chest and back pains, frequent urination, headaches or migraines, nightmares, loss of sexual interest, skin complaints, ulcers, coronary heart disease
How does your stress affect others around you	Increased arguments with family members, missing work, avoiding seeing friends. If these words describe what you are experiencing lately, it is likely that you are stressed. There are a number of things you can do to lessen the impact of stress on your life.

Stress Treatment

Ways you can deal with stress.

Learn what makes you stressed	List what you know causes you stress and what you suspect causes you stress – add new causes of stress if they happen Keep a diary of when you feel particularly stressed and see if there are any patterns to suggest something is causing you stress you hadn't realised was a stressor
Identify levels of stress	Rate how bad is it on a scale of 1-10 The higher the score you give to something, the more likely you need to do something about it
Challenge the strength of your stressors	Once you identify and rate your stressors, try challenging their strength: "I don't need to take that on board", "I can live with that", "I can live without that", "Is this worth getting stressed about", "I can do this" "I don't need to do that".
Get quality rest	It is important to have enough quality sleep because lack of sleep may lead to: ● Reduced alertness ● Shorter attention span ● Slower than normal reaction time ● Poorer judgment ● Which can all heighten stress levels.
Take a break	Have a mental break if you have been working for long periods – get up from your desk and move around for a few minutes. It will help to prevent stress building.
Slow down	Lighten your load of engagements where possible and give yourself a break. Each day make a list of things you want to get done, put the actions in order of priority and simply cross off the last half. Make the top half of your to do list achievable so you don't get disappointed or frustrated.
Reduce stimulants like caffeine	Caffeine stimulates the sympathetic nervous system causing stress: replace a caffeine drink with a glass of water or herbal tea.
Activity and exercise	Increase your physical activity. Moving your body, e.g. walking, increases the flow of feel good chemicals (endorphins) in your body to help you cope.

If possible, reduce working hours	Reduce the number of hours you spend at work or even prioritise your work tasks to help lighten your load.
Share your thoughts	Try to discuss the causes of your stress with people who understand your situation because they may be able to help you develop coping strategies. See a counselling psychologist if you become overwhelmed.

EMOTIONAL Confidence

4 Confidence

Confidence is believing in yourself – believing that you are capable of completing tasks and reaching goals. Confidence is knowing that you have skills and positive traits, that you are able to face challenges and deal with difficult circumstances; it is knowing that you are your best resource. Confidence levels can change throughout your life and across different areas of your life. Many things can influence your confidence levels such as your thoughts, feelings, actions and past experiences. When you feel confident you tend to make decisions that are good for you and your health. You are more likely to take care of yourself, get out and about, be active, and choose healthier foods. Confidence can also give you a positive outlook on life, increasing your mental and emotional wellbeing. However, when your confidence is low, your feelings of self-worth and self-respect may also suffer.

You may not care how others treat you or how you treat yourself. You may not care about what you eat or how you spend your time, and this can start to affect your health. It is important to remember that your confidence levels cannot be high across all areas of your life all the time. You can experience low levels of confidence at different times and in different areas of your life and sometimes it is hard to work out why. It is important to try and understand what affects your confidence because ongoing low confidence can affect your physical and emotional health, your relationships with others, and your work or school life.

Keeping your mind and brain healthy is an important part of building and maintaining confidence. Your mood, concentration levels, and memory can all affect your outlook on life so taking care of these areas is another way that can improve confidence. The wrong foods, not enough food or water, too little sleep and not being active can all affect your mind, making you depressed, sad, anxious, prone to stress, mood swings or unable to concentrate. Social connections are made up of the people you engage with and know, the friends you can confide in, the family you belong to and the community you work and live in.

Social support refers to the emotional, practical, advice, love, help, resources, information and empathy you give and receive among family, friends and community. Evidence indicates that social connectedness has an influence on physical and emotional wellbeing. Research shows that engaging with others and being part of a network, is seen as a reward by the brain and is associated with the release of one of the happiness hormones, dopamine.

Building Confidence

- Ask yourself – and list – what affects your confidence in different situations and at different times
- Focus on the things you do well and have achieved – not the things you don't do well
- Pick someone who you think is confident and list the things that you think make them confident. How do they act? What do they focus on? What words do they use to describe their successes?
- Fake it until you make it. Even women who appear confident don't feel that way all the time but they have learned ways to project the appearance of being self-confident
- Talk to other people about confidence – ask about what helps them and what is difficult for them too
- Accept compliments – this can be difficult for some people, but even saying 'thank you' is a great start
- Think of building confidence as a process. Small steps, practice and time are all part of learning to be more confident

Confidence and Social Connections
Your own level of confidence can affect whether you connect with others. You might feel shy around others and this can lower your confidence even further, particularly if it makes you feel inadequate.
The way other people have treated you in social situations can either lower or raise your confidence too. Having people in your life who are negative or who make you feel like you are not good enough can dent your confidence and make you want to hide away. Confidence to engage with others can be different for each person and change from day to day. Here are some tips to help you get social and engage:

- Be less critical of yourself and others in social situations
- Join a group or start one if there are none in your area and you have an idea for a group – this could be a book club, art group, discussion or walking group
- Try new experiences and gradually increase the amount of time you spend in building new social skills and making new connections
- Seek out groups on social media who share the same values, interests and ideas as you – Facebook, LinkedIn or Pinterest for example have lots of different groups you can join to share conversations with like-minded people
- Practise looking more confident in the mirror – eg practise maintaining eye contact
- Practise a few lines of conversation and think about a few topics of conversation before you arrive somewhere
- Volunteer to meet new people – this might be a committee, club, baking, driving older people to appointments or visiting lonely people; volunteering gives you meaning and supporting others can add to your confidence

5 Relaxation

Relax – to be calm, unwind, loosen up, de-stress, slow down, chill out. Relaxation can help increase your sense of calm and reduce anxiety and stress. Relaxation techniques can slow heart and breathing rates, reduce blood pressure and decrease muscle tension and is a good tool for stress management. Different techniques work for different people and can include anything from deep breathing, laughter, positive thinking, visualisation, meditation and mindfulness.

Practising Relaxation Can:
- Enhance energy
- Increase immunity
- Promote more restful sleep
- Increase concentration
- Lessen mood swings
- Help reduce anxiety and stress

Meditation	There is some evidence to suggest meditation may help reduce: ● Anxiety ● Stress ● Blood pressure ● Chronic pain ● Insomnia
Mindfulness	Mindfulness is about increasing your ability to stay calm and focused in the present moment rather than worrying about the past or future. Research has shown mindfulness to be effective in controlling stress and problems with mood. **Mindfulness Meditation** ● Slow breathing ● As an unhelpful thought comes into your head, you acknowledge this is a thought, nothing more, and let it go The aim is not to pay it loads of attention, rather to become an observer of your thoughts ● Thoughts will continue to flow into your head and the aim is to try and increase the time and space and time between the thoughts

Physical Activity	Research indicates that just 10 minutes of exercise is all that is needed to put people in a more positive mood. Exercise releases endorphins that give you a feeling of happiness, it keeps cortisol (a stress hormone) in check and helps your mind to relax. Rhythmic exercise such as running, walking, rowing or cycling is most effective at relieving stress and promoting relaxation because you can also focus on the repetition in your body's movement and also breath to match the movement.
Hobbies	Hobbies can offer distraction from daily routines and tensions and open your mind to life's possibilities. Become involved in a hobby like calligraphy, design, antique restoration, art galleries, archery, croquet, singing, chess, salsa dancing, camping, cycling, judo, cooking, film collecting – there are more possibilities than you might know!
Pleasure	Every day do something you enjoy and do something for someone else.Make time in your day for activities like reading, listening to music, gardening, sewing, taking a bath, lighting a candle, using a lovely hand cream, walking through a flower shop, taking a friend for coffee, giving a loved one a kiss.
Visualisation or Guided Imagery	This involves imagining a scene in which you feel at peace and are free to let go of tension and anxiety. Use each of your five senses and imagine: ● A beach, a forest, a hill, a retreat you have been to ● A candle and focus on the movement of the flame to anchor your thoughts and the scent to feel its warmth ● A river to visualise sending your worries downstream.
Relaxation Exercises	● Progressive muscle relaxation is about learning to feel the difference between tension and relaxation ● This awareness helps you to recognise and respond to the first signs of the muscular tension that accompanies stress ● Deep breathing is a simple but powerful relaxation technique that can be done anywhere, anytime ● In eastern philosophies, mastery of the breath is the key to controlling the body's life force energy With every inhalation, you draw energy into your body. With every exhalation, you let go of tension in your body. ● The technique involves methodically tensing and relaxing different muscle groups in the body ● A variation is to simply focus on the sensations in each part of your body so you become aware of where the tension is: the neck, shoulders, and head are common stress points ● Deep breathing helps focus you on the present moment by concentrating on the 'in and out' of your breaths ● Drop your shoulders and breathe in for 7 seconds and out for 11 seconds. ● Deep breathing can be combined with aromatherapy and music
Pets	Research indicates the following benefits of having a pet: ● A beautiful distraction ● Something to have and to hold ● Something to be responsible for ● A buddy to exercise with ● Do not overlook the benefit of touching and talking with your pet ● If you don't have a pet, offer to mind or walk one
Affirmations	Affirmations are positive statements you make to yourself. They need to be present tense, positive, personal and specific, e.g.: ● I can do this ● I am valuable ● I am loved ● My friends care ● It's okay to relax ● It's okay to care
Laughter	When you laugh, your body produces natural chemicals that: ● Lower blood pressure ● Lower heart rate ● Increase immune system function ● Reduce stress ● Browse through books at your local book shop ● See a show ● Laugh with your children, your family or your friends ● Get out a DVD such as Something's gotta give
Positive Thinking	Positive thinking and 'affirmations' can: ● Counter negative thoughts ● Improve confidence ● Help you to relax

6 Memory & Dementia

There are many causes of poor memory such as stress, ageing, illness, menopause or something more serious, like the onset of Alzheimer's and dementia. There are many strategies to help with memory including staying mentally and physically active, using organisational tools like a calendar or special notebook, and mnemonics – word plays and rhymes.

Memory Phases ● Encoding (filing information into your memory) ● Storing ● Retrieving Forgetting can be the result of a glitch at any one of these steps.	**Memory Health Affecters** ● Illness such as the flu ● Chronic conditions like diabetes, high blood pressure ● Vitamin B12 and folic acid deficiencies ● Smoking ● Alcohol abuse ● Lack of physical activity ● Lack of mental activity ● Stress ● Grief ● Depression and anxiety ● Social isolation	**Menopause & Memory** Perimenopause (when periods start to become irregular, and menopause symptoms begin) is known to be a time of memory lapses, poor concentration and 'foggy' thinking. Sixty per cent of women report memory complaints with menopause.

Some studies have linked a chemical imbalance (a drop in oestrogen) with memory and verbal function changes at this stage of a woman's life. However, there are many other potentially stressful issues happening at the same time that need to be considered. Coping with teenagers, ageing parents with health problems, work, hot flushes, disturbed sleep, lack of libido and the effects of that on your relationship. These are all part of the context of your life stage and can certainly affect your memory.

EMOTIONAL Memory & Dementia

Aging Memory
The ability to pay attention and focus on more than one thing at a time decreases with age. "With increasing age there are changes in the brain's blood supply and mass, as well as the richness of interconnections between nerve cells," senior lecturer of psychology at Adelaide University Lynn Ward explains. "These changes affect the speed of our mental operations. It takes more effort to learn new things and longer time to process and recall information."

Dementia

A change in your memory does not mean you have dementia. As the brain naturally ages it becomes more difficult to learn and retain new information, but most complex skills are not lost. Dementia is not a normal part of ageing. It is defined as an acquired global impairment of intellect, memory and personality without impairment of consciousness. Dementia is regarded as a syndrome and not a specific diagnosis in itself. Dementia is a collection of diseases affecting the brain. It is often seen just as a loss of memory but it can affect thinking, behaviour and ability to perform tasks. This can interfere with the normal social and working life. It is now the third leading cause of death in Australia, and as the population ages we will see more people with dementia. Dementia can happen to anybody, but is more common after the age of 65. Just because a parent has had dementia, it does not mean that you will too.

Alzheimer's Disease
- Alzheimer's disease is the most common cause of dementia
- It is a progressive, degenerative illness that attacks the brain
- It is a syndrome of unknown causes, usually presenting insidiously (gradual with few or no symptoms) and developing slowly over a period of years
- The most common early symptoms are short term memory loss, word finding difficulty and personality changes

Vascular Dementia
- Vascular dementia is the second most common form of dementia
- It is a type of dementia that is associated with problems with the flow of blood to the brain
- Many cases of vascular dementia are due to silent 'mini strokes' which are caused by high blood pressure, heart disease or smoking

Dementia with Lewy Bodies
- Not common
- It can come on quite quickly and change rapidly and is caused by the degeneration and death of nerve cells in the brain
- People with this type of dementia tend to see things (hallucinations), experience stiffness or shakiness (Parkinsonism)

Other Neurological Diseases Causing Dementia
- Parkinson's Disease- a progressive neurological disease
- Huntington's Chorea- an inherited disease
- FrontoTemporal Lobar degeneration
- Alcohol related dementia (Korsakoff's Syndrome)
- AIDS related dementia
- Brain Tumours

Signs

The early signs of dementia are often subtle and vague and can sometimes be confused for other conditions. The most obvious clue to dementia is increasingly frequent memory difficulties particularly with things you used to be good at. Some common symptoms are:

- Progressive and frequent memory loss
- Confusion
- Lack of interest and withdrawal
- Change in personality, such as becoming flat or aggressive
- Loss of ability to perform everyday tasks

Risk Factors for Dementia
The following may increase the chance of developing dementia:
- Heart disease
- Strokes
- Midlife Hypertension
- Smoking
- Diabetes
- High cholesterol
- Genetic disease
- Head injury

The following memory problems are not 'normal' and need to be investigated:
- A memory problem that affects daily living such as frequently:
- Forgetting where you are going while driving
- Losing common objects
- Putting common objects in odd places
- Progressively worsening memory
- Forgetting how to do familiar tasks
- Trouble learning new things
- Repeating phrases or stories within the same conversation
- Substituting forgotten words with inappropriate words
- Trouble making choices or handling money

- Inability to keep track of what happens each day, such as missing appointments
- Mood and personality changes

Memory Strategies

The best strategy to improve your memory and prevent memory loss is to do a range of things. Recent studies have shown activities that involve two or more components of physical, social and mental activity are better for your memory than doing one.

Stay Physically Active
Good for the heart = good for the brain.

Stay Mentally Active
Read books and newspapers, do puzzles, games and quizzes.

Stay Socially Active or Volunteer
- Socialise with friends and family
- If you are experiencing memory difficulties, socialising with just one person is better than group settings

Maintain Good Nutrition
In particular, eat 2-3 serves of fruit and 5-7 serves of vegetables daily, reduce saturated fats, increase omega 3 intake and eat foods rich in vitamin E, B12 and folate.

Start a New Hobby
This can strengthen your thinking but if you are already having memory difficulties, avoid doing dramatically new hobbies as this may make you feel frustrated.

Adopt a Positive Approach
- Don't be judgmental or hard on yourself
- Minimise stress
- Relax and take your time when you need to remember

Use Memory Strategies
Strategies to organise or categorise information can help, like using:

- Diaries
- Calendars
- Whiteboards
- Lists and reminder notes

Use Memory Strategies
- Mnemonics: word plays and rhymes
- e.g. Imogen is the one with the big imagination
- acronyms: a word formed from initial letters
- e.g. for a shopping list of bread, oranges, yoghurt and sugar: just remember BOYS
- imagery: use pictures to link objects with names
- e.g. James jumps up and down a lot
- association: linking to something you know
- e.g. Isabel is part of the local tennis club

7 Grief & Loss

EMOTIONAL Grief & Loss

There is no single way to grieve and deal with loss. How you respond is affected by the strength of your attachment to what you have lost and how that loss occurred. There are many types of loss including separation, illness, job loss and miscarriage. How you react to loss will be influenced by your personality, the way you think, your age and background. There are no rules when it comes to how you manage loss but it is important to know when to seek help.

The Language of Loss You may hear different words to describe loss and they each mean something slightly different.	● Mourning is a word used to describe the process someone goes through in adapting to the death of a person. Mourners need to understand that their feelings are not a sign of sickness or instability ● Bereavement defines the loss a person tries to adapt to and is a universal experience ● Grief is a term that can be applied to other losses like a job or relationship. Grief is a normal part of life, one that must be experienced and not denied

Types of Loss	● Separation or divorce ● Financial problems ● Life-changing events ● Career redundancies ● Significant illness or disability: ○ Disfigurement ○ Blindness/deafness ○ Amputation	● Betrayals and lost friendships ● Miscarriage ● Infertility ● Failing memory ● Loss of independence ● Unfulfilled potential ● Lost opportunities

Loss is usually complex and layered: a woman who experiences premature menopause may feel a loss of femininity, a loss of fertility, along with losses of time, choice or opportunity. Loss can be complicated if it can not be publicly acknowledged; for example a couple who keep their pregnancy secret and then experience a miscarriage. This unacknowledged loss is known as 'disenfranchised grief'.

Time Frame
There is no set time frame or order for the grieving process. Grief is individual, there's no 'normal' grieving timeframe. Acknowledging your grief is the important thing. Denying grief and loss or listening to well-meaning advice like 'get over it' is rarely useful. Instead, accepting that you'll continue to grieve at various times throughout your life can be a big relief.

Grief Affecters

Personality	People express grief and loss in different ways, some close down and need to shut themselves away and others will require action and busy-ness to help them through.
Thoughts & Beliefs	If loss can be understood as a part of the pattern or cycle of life, this can help with acceptance and recovery. This is a significant challenge, and can be a huge ask, that usually takes time and space to achieve.
Level of Attachment	Of course, the more attached you are to something the more you feel the loss. Sometimes you do not appreciate how important something is until it is lost and this can add shock to the grief.
Availability of Support	Loving friends, family and partners can help and so can grief counselling.
Age	The age and stage you are in life can affect how you view your loss and how you grieve. For example, an elderly couple may be more prepared for the death of their partner so that even though there is a loss, it is not as great a shock.
Culture	Some cultures have defined mourning periods and rituals which can help mark and support your movement through grief.
History of Loss	If you have experienced loss in your life before, it may feel a little easier compared to someone experiencing loss for the first time.
Experience of Loss	The way the loss occurred may affect how you react to it. Some people can grieve again for a past loss, when a new loss occurs. For example, a woman whose mother dies may grieve the death of her father 10 years before all over again and at the same time. She may then also grieve the loss of her identity as a daughter.

Stages of Grief

The five stages of grief model (or the Kübler-Ross model) postulates that those experiencing grief go through a series of five emotions:
● Denial
● Anger
● Bargaining
● Depression
● Acceptance

Although commonly referenced in popular culture, studies have not empirically demonstrated the existence of these stages, and the model is considered to be outdated, inaccurate, and unhelpful in explaining the grieving process.

Kübler-Ross originally developed stages to describe the process patients with terminal illness go through as they come to terms with their own deaths; it was later applied to grieving friends and family as well, who seemed to undergo a similar process. The stages, popularly known by the acronym DABDA, include:
1. Denial – The first reaction is denial. In this stage, individuals believe the diagnosis is somehow mistaken, and cling to a false, preferable reality.
2. Anger – When the individual recognizes that denial cannot continue, they become frustrated, especially at proximate individuals. Certain psychological responses of a person undergoing this phase would be: "Why me? It's not fair!"; "How can this happen to me?"; "Who is to blame?"; "Why would this happen?".
3. Bargaining – The third stage involves the hope that the individual can avoid a cause of grief. Usually, the negotiation for an extended life is made in exchange for a reformed lifestyle. People facing less serious trauma can bargain or seek compromise. Examples include the terminally ill person who "negotiates with God" to attend a daughter's wedding, an attempt to bargain for more time to live in exchange for a reformed lifestyle or a phrase such as "If I could trade their life for mine".

4. Depression – "I'm so sad, why bother with anything?"; "I'm going to die soon, so what's the point?"; "I miss my loved one; why go on?"
During the fourth stage, the individual despairs at the recognition of their mortality. In this state, the individual may become silent, refuse visitors and spend much of the time mournful and sullen.
5. Acceptance – "It's going to be okay."; "I can't fight it; I may as well prepare for it."
In this last stage, individuals embrace mortality or inevitable future, or that of a loved one, or other tragic event. People dying may precede the survivors in this state, which typically comes with a calm, retrospective view for the individual, and a stable condition of emotions.

In 2020, during the COVID-19 pandemic, Kessler applied the five stages to responses to the virus, saying: "It's not a map but it provides some scaffolding for this unknown world."

"There's denial, which we saw a lot of early on: This virus won't affect us. There's anger: You're making me stay home and taking away my activities. There's bargaining: Okay, if I social distance for two weeks everything will be better, right? There's sadness: I don't know when this will end. And finally there's acceptance. This is happening; I have to figure out how to proceed. Acceptance, as you might imagine, is where the power lies. We find control in acceptance. I can wash my hands. I can keep a safe distance. I can learn how to work virtually."

Criticisms of this five-stage model of grief center mainly on a lack of empirical research and empirical evidence supporting the stages as described by Kübler-Ross and, to the contrary, empirical support for other modes of the expression of grief. Moreover, Kübler-Ross' model is the product of a particular culture at a particular time and might not be applicable to people of other cultures. These points have been made by many experts, including Professor Robert J. Kastenbaum (1932–2013) who was a recognized expert in gerontology, aging, and death. In his writings, Kastenbaum raised the following points:

● The existence of these stages as such has not been demonstrated.
● No evidence has been presented that people actually do move from Stage 1 through Stage 5.
● The limitations of the method have not been acknowledged.
● The line is blurred between description and prescription.
● The resources, pressures, and characteristics of the immediate environment, which can make a tremendous difference, are not taken into account.

Grieving Pattern

There's no right or wrong way to grieve and no step–by–step process to follow. Your family has probably been your model. What do you remember about your mother or father's grieving? Was it secretive, did it turn into a sickness, did they ever get over their loss? Today we encourage you to be in the experience of it, know it for what it is and accept the process. The following list presents all normal reactions. You may feel some or all of the following, at any time, as a part of the grieving process:

Emotions and Feelings	● Sadness ● Anger ● Numbness ● Shock ● Irritability ● Disbelief	● Emptiness ● Hopelessness ● Despair ● Frustration ● Guilt ● Panic	● Denial ● Loneliness ● Helplessness ● Anxiety ● Relief ● Restlessness ● Depressed Mood
Physical Responses	● Decrease/increase in appetite ● Weight loss/gain ● Sleep changes ● Lack of energy or fatigue ● Nausea ● Panic attacks	● Headaches ● Stomach ache ● Difficulty breathing ● Trembling ● 'Knotting' or empty sensation in your stomach ● Muscle tension	
Thoughts	You may have thoughts like: ● 'I should have done more' ● 'It's my fault' ● 'I can't do this' ● 'This can't be happening' ● 'It's not fair' ● "I want to stop that moment from ever occurring"	Thoughts may also arise from a fear of losing control: ● 'I can't cope' ● 'I can't make it on my own'	Some people find it: ● Difficult to think ● Have repetitive thoughts ● Have thoughts of wanting to die or self-harm
Behaviours	● Withdrawing socially or from a relationship, shutting yourself away ● Transferring feelings: thinking everyone else around you is feeling sad when really you are ● Changing behaviours such as using alcohol or drugs (including prescription medications)	● Being angry at someone who doesn't deserve it ● Acting in ways that don't make sense ● Avoiding situations ● Crying	● Increasing 'risky' behaviours ● Withdrawing from personal interests ● Overeating ● Oversleeping ● Forgetfulness

Managing Grief

If you are an emotionally expressive person	You may benefit from talking to a friend or spending time with family. You may like to spend time with people who remind you that everything will be okay. Avoid people who exhaust you or who are uncomfortable talking about your grief. If you leave a conversation feeling bad or inadequate, it's time to seek other help.
If you are not an emotionally expressive person	You may prefer to spend time alone or become active and take control of other areas of your life. It's important to give yourself permission to cry, but it's also okay not to cry.
Find a private place	Some people find it useful to have a private place to sit and be. Allow yourself to cry or even wallow in your sadness. Then leave it there.
Look after yourself	Grief often leads to reduced immunity, so self-care is important. Eat and sleep as well as you can and do some exercise, even if it's a gentle, short walk. Avoid alcohol, recreational drugs and inappropriate use of prescription medications to numb the pain
Don't expect too much of yourself	There's no right or wrong time to return to work – a good indicator is to go back when it feels meaningful. Activities and distraction can help, as long as you aren't denying your loss.
Give yourself space	Give yourself space to grieve and adjust not only to your loss, but your changed life. Your changed life means a new identity, one you probably don't want and one you wonder and fear if you will be able to cope or survive with. A huge adjustment needs to occur and this takes time.
How do you know when you are getting through the grief	Although it never goes away completely, you will know you are through the grieving process when you can think and speak of the loss without enormous pain. Mourning is finished when you can reinvest your emotions into life and in the living.

Seeking Help

If you don't feel you are coping or you are suffering symptoms, seek help from your doctor and/or a psychologist. Counselling doesn't have to be long term – sometimes a few sessions are enough for someone to express their grief and find ways to cope with their grief. Psychologists can assist with short–term coping strategies and help couples if needed, as loss and grief can significantly affect relationships. It can be difficult to empathise and relate to a partner who is grieving the loss differently (or not at all). A psychologist can offer support to you both, and give couples permission to respond differently in a trusted space.

● You may feel comfortable talking with your doctor or religious adviser.
● Medicare rebates allow up to 10 visits with a psychologist, speak to your GP to get a referral.
● Community health centres may have a grief or support group. This is especially useful for people seeking support from others who have experienced a similar loss.

8 Postnatal Depression

Depression experienced after childbirth is called postnatal or postpartum depression also known as PND. About 10-13% of women experience depression when they are pregnant or after birth. Causes of PND are likely to include hormone changes, previous experience of depression and/or anxiety, personality, timing of pregnancy and many other factors.

Causes
There is debate about the causes of postnatal depression, but they are likely to include:
● Hormone changes of pregnancy and childbirth (which affect some women more than others)
● Personality
● Lack of social support
● Childhood abuse
● Timing of the pregnancy
● Previous experience of depression and anxiety
● Low income
● Low self-esteem
● Relationship quality
● Other life stressors

Recent research at Jean Hailes has found women with a partner who is caring, considerate and appreciative are less likely to have depression symptoms six months after the birth of their baby. But if they experience their partner to be very controlling and domineering then they are more likely to have symptoms at six months. The relationship is also important to getting better. "A woman's experience of the strength of the relationship with her intimate partner is closely related to recovery from the symptoms of postnatal depression," says Dr Sonia McCallum, a Research Fellow at the Jean Hailes Women's Mental Health Program. Couples also need to recognise the importance of communicating with each other at this time. Often if they sit down and talk there is a lot they didn't realise. Having a baby is a huge adjustment for both of them", says Dr McCallum. To improve maternal mental health in the postpartum (after birth) period, interventions need to address partner relationships and have to involve both partners. A lot of work in the past has focused on the mother, but this research highlights interventions need to focus on both parents.

Strategies and Support
● Know that everyone finds it challenging to learn how to care well for a baby and manage a home with a baby – you are not alone
● Ask a maternal and child health nurse for practical advice, such as how to establish a feed-play-sleep routine of care for your baby
● Talk to your partner about how to share the increased workload at home – avoid criticising each other
● Share baby tasks – babies benefits from receiving care, e.g. bathing, nappy changing and settling from both parents
● Accept practical help from friends and family if they offer
● Identify what you miss from how life used to be and work out how you can begin to replace that activity or interest, maybe in a changed way

Partners
● Be actively involved in caring for your baby
● Share increased household work in ways that feel fair
● Listen to each other's needs – be kind and encouraging
● Avoid criticism – it undermines confidence
● Help manage visitors keen to see you and meet your baby so you don't become overtired
● Support each other in having some time away from day-to-day responsibilities

Family & Friends
● Be upfront in offering help – most new parents find it difficult to ask for help with practical tasks
● Offer practical support e.g. pick up an older child from childcare, buy groceries, prepare a meal, hang out washing
● Invite them to tell you how they are finding things and help to work out solutions to difficulties
● Help them find ways to make new friends at the same life stage
● Give lots of praise and encouragement

9 New Parents

Adjusting to the changes of being a new parent can take a toll on your emotional wellbeing and your relationship. Communication, seeking help and learning strategies to cope with a new baby are important to getting through this time. If your partner is there with you:
Acknowledge the togetherness 'It's so good we've been through this together'
Thank each other often and communicate your feelings to each other:
● It's a miracle
● It's scary
● How do I know if I'm doing the right thing?
● I am bursting with joy and dying of tiredness
● I miss the 'us', don't let us lose the 'us' even though there are now three of us.

Many of us imagined that there would be more flexibility and leisure time after having a baby. For most women it's a shock to discover their unpaid work doesn't permit a lot of extra time to see friends, has no neat boundaries and may be quite lonely. Parents may also expect others will help more than they actually do. It may help to think about these sorts of questions before the birth of a baby:
● What help would I like?
● Who can I ask for help?
● Who will screen and/or time the visitors, so I can have my own time if I need it?

There is consistent evidence that the quality of a woman's relationship with her partner is associated with her mental health. Mental health is promoted when partners are empathetic, encouraging, supportive and actively involved in the care of the baby. In contrast, wellbeing is lowered if they experience criticism or irritability. When two people become a family of three, their needs as individuals and as a couple are changed. It can be helpful to think about what your needs are as an individual and as a couple. Your needs around who does an everyday task like cooking and paying the bills can change in the face of the demands of looking after your baby.

Your sex life is likely to change because you are tired, your body has changed and/or your relationship with your partner is in a state of flux as you adjust to life as a family. This can be demanding for both partners, particularly if you are not able to talk comfortably about these changes. It is true, in most instances, that a new mum will put the baby's needs before a partner's needs and even her own. It is common for partners to feel excluded in this new triangle. If this isn't discussed, it can lead to feeling of guilt and defensive behaviour. Pregnancy and childbirth are physically demanding and women have to adjust to changes in shape and appearance and also how their bodies now function (e.g. with breastfeeding). It can be more difficult to recover from a birth which has involved surgery and/or other intrusive procedures.

Having a baby means your identity, freedom and independence are changed forever. Some women experience the change as a loss. This feeling of loss can become more complex if you see your partner as not having suffered the same sort of loss.

While the work of mothering can be fulfilling, it can also feel repetitive, boring and isolating. You may find yourself coping with a huge change to your life about which you feel both joyful and appalled. Changeable emotions are a normal part of adjusting to such a major life change. Your feelings may become less changeable with time and a sense of coping. Increased familiarity about what to do and an increasingly responsive, healthy baby are key to adjusting to being parents and knowing the joy!

No matter how many books you read or classes you attend, having a baby is a change which brings unexpected emotional reactions. Use the list below to help you cope with a new baby:

- Identify and make a list of the changes that have happened to you and recognise the things that cause you the most distress – tackle these through discussions with your partner, family, friends, a doctor or a psychologist
- Recognise your losses (e.g. identity, leisure time, freedom) to help yourself adjust to your new life
- Name your needs (e.g. time alone, help with the 3am feed, someone else to cook dinner)
- If you have a partner, discuss how you plan to share the cleaning, the cooking, paying the bills and caring for the baby and make time to be alone and together
- Expect changes in your body's shape, appearance and functions
- Don't feel guilty for having negative thoughts and feelings – changeable emotions are a normal part of adjusting to a major life change

Research confirms a woman feels more capable if her baby quietens to her soothing, suckles easily, gains weight and smiles responsively. Her confidence is lower if her baby cries for long periods and is difficult to settle or feed. On top of this response, frequent overnight waking and insufficient sleep leads to fatigue, slower decision–making, poor concentration and poorer mental and emotional wellbeing.

"Unsettled" is the commonly-used term for babies (up to 12 months old) who:

- Cry for long periods
- Cry and cannot be soothed
- Have difficulties settling to sleep
- Wake after short sleeps
- Wake up often during the night

Coping with a Baby

At least one in four families experience infant crying and fussing behaviour that is distressing. Up to one in three families experiences a problem with infant sleep. Babies vary in the amount and intensity of crying in their first year. Parents most commonly assume crying means the baby is either hungry or in pain, but a lot of the time crying is difficult to explain. If you are struggling with a crying baby and feel at a loss as to what to do, seek support and help from a health professional rather than letting yourself get over tired and over stressed. Let other people, family or friends, help you. Let them in so you can rest, be by yourself in the garden or at a cafe or have time just with your partner.

10 Body Image

Many people are dissatisfied with the way they look and often say they feel guilty just for eating. Health problems, anxiety, depression, low self-esteem, and how people talk about your body can all make you feel negative about your body. It can be helpful to stop and think about how you view your own body and acknowledge it for all the wonderful things it is capable of instead of focusing on the negative parts.

Influences

- Personality
- Health
- Illness and disease
- Depression
- Anxiety
- Self-esteem (whether you value and respect yourself)

Influences

- Childhood experiences
- How important people in your life talk about and refer to your body (and their body too)
- Media
- Society and culture
- Self-talk – what are you saying or not saying to yourself about your body image (does it start with "I should"… "I ought"… "I must"… or "I wish"… ?)

Physical changes associated with menopause and ageing include changes in body shape. Shifting weight from the hips to the central tummy area, drier skin, decreased muscle tone and hot flushes change how you feel, how you think about and the actual shape of your body. Some women talk about losing control of the body they always thought they could control and rely on. Other women find greater confidence in who they are because they are less driven by worrying about whether their body is 'perfect' as they enter this stage – "I can let go of the need to be perfect, to compete with the youngies and just be me".

Body Thoughts

Do you:

- Feel proud of some aspect of your body: your hair, your eyes, your shape, your breasts, your legs, your hands?
- Focus on the parts you don't like so much: the wrinkles, the hairs, the sagging, the stretching, the bumps, the scars?
- Feel conscious of what your body can do: cycle, walk, run, swim, embrace and carry?
- Think about what you weigh, what is round, what is flat, what is large, what is small?

These questions might allow you to see whether you are negative or positive about your body. They might also allow you to see a mixture of reactions to your own body. The reality is that everyone can answer these questions and end up with both positive and negative responses. If your image of your own body is at odds with how others see you or you have an extreme view about yourself, then it is likely your body image is affecting your mental and emotional wellbeing.

You can ask your doctor about counselling to help you talk through how to have a more balanced view of your body. It is also important to focus on the physical health of your body and not compare it to others, so aim to be the healthiest you can possibly be. Treat it well.

11 Family & Friends

Social connections, friendships and relationships with others help shape who we are and how we behave. They are also one of the most significant influences on health and wellbeing. Good social support may offer greater protection from chronic disease and illness like cardiovascular disease, depression and anxiety. Sometimes it is hard to know if your relationship is healthy or when to let go of relationships, but talking to someone you trust or a health professional is important to both your physical and emotional wellbeing if you are worried. Research shows loneliness and social isolation negatively affect the health of patients with heart disease, diabetes, arthritis, liver disease, breast cancer and stroke. People who are divorced, widowed or single are often found to be more depressed than those who are in supportive relationships. The support of social networks may offer greater protection from chronic disease and illness.

EMOTIONAL Family & Friends

Apart from the effects of your own mood, the emotions of the people around you also impact on your health and wellbeing. The 'cluster effect' means your mood is influenced by the mood of your social network, so if your friends are happy, you are more likely to be happy too. If your partner is depressed for a long period of time, you are more likely to develop depression too. If you find yourself in a social network that is causing you distress or you find yourself thinking more negatively around some people, it may be time to think about connecting with people who are more positive and who share the same values as you. Often you stay in the same relationships because you think you should (for whatever reason) but if you think about the person or the group and ask yourself: 'Is this really good for me?', 'Can I give and take in this relationship or in the group? Is it a positive, authentic experience most of the time?' you may realise it is not, and it is time to move on.

Moving on means letting go and leaving a gap and then having to deal with the anxiety this may cause. Lots of relationships have a beginning, a middle and an end and so often you get stuck at the ending because it is too hard. Most people would choose and love to belong to a happy supportive family. However, you cannot choose your parents or the family to whom you marry or commit. If you are experiencing problems with your family, your awareness of the situation is the first step in managing your life in a healthier and more responsible way. It often takes time to act or change your behaviour in a positive way.

Being Connected
- Join or start a sports club or hobby group for like-minded people
- Both children and pets really help in making connections
- Play groups, pre-school and parks can help you meet new people – maybe you could suggest a coffee!
- Volunteer – not only will this get you out and connecting with others but you will also feel like you are making a difference in other people's lives
- If you have an illness or health problem, a support group offers a place to go to discuss your thoughts and feelings with people who are more likely to understand what you are going through
- Use the internet to connect with new and/or existing friends via sites such as Facebook, LinkedIn or Pinterest

EMOTIONAL Healthy

12 Healthy Living

EMOTIONAL Healthy Living

A nutritious, balanced diet and regular physical activity can positively influence your state of mind and emotional wellbeing as much as your physical wellbeing. Some herbs such as St John's wort, lavender and lemon balm may help with mental and emotional health. Also, participating in creative, spiritual and intellectual activities along with community involvement help to balance out a healthy lifestyle. While it can be difficult for people suffering from depression to feel motivated to be physically active, it can be beneficial – particularly in managing mild to moderate depression or anxiety.

Regular physical activity of light or moderate intensity can lead to a reduction in depression and anxiety symptoms of up to 50 per cent, especially in women. Becoming more active can help to block negative thoughts, distract you from daily stresses and, if you exercise with other people, the social contact can be invaluable. In a recent large population-based study assessing psychological health and exercise, young women who did not regularly exercise had higher levels of anxiety and/or depression compared to those that did.

Other research shows that walking groups have been associated with lowered postnatal depression scores and improved fitness in new mothers which is likely to impact on stress, coping strategies, confidence and sleeping patterns in a positive way. If you know you are not motivated to exercise, try things like asking a friend to join you, put your exercise gear out to wear and talk to yourself –"I want to feel better". Make sure you note how you feel after you exercise and reward your efforts with positive self talk – "I'm proud of myself". It can be helpful to regularly review these areas and give yourself a score out of 10 as to how you think you are going in them. Take time to sit and ask yourself where you want to be in relation to these areas. Do this exercise several times and listen to yourself. If you need more assistance with this you can speak to a therapist.

EMOTIONAL Healthy Living

Healthy Diet
A balanced and nutritious diet including vegetables, fruit and whole grains is as important to mental and emotional health as it is to your physical health. A nutritious breakfast can give you plenty of emotional and physical energy for the day. It can also help you to avoid the afternoon mood slump which may lead you to reach for a quick sugary fix. The highs and lows of sugary and high carbohydrate foods (such as biscuits, cakes and lollies) can cause mood swings.

Physical Activity & Exercise
- Regular exercise has been linked to improved mental and emotional health including:
- Reduced depressive symptoms
- Reduced symptoms of stress and anxiety
- Improved mood
- Improved self confidence

Alcohol
Drinking more than two standard alcoholic drinks a day puts your health at risk. While short-term affects include poor sleep, headaches, dehydration, potential for accidents and mood swings, long-term risks are worse for mental and emotional health and include:
- Depression
- Relationship problems
- Decrease in quality of life
- Dementia
- Inability to think clearly
- Alcohol dependence
- Low vitamin B, zinc and magnesium (which can affect mood as well as physical health)
- Increased risk of some cancers – particularly breast cancer

EMOTIONAL Healthy Living

Wellbeing
Lifestyle and living well requires more than a healthy diet and some exercise. Your involvement in the following areas is important also:
- Intellectual stimulation
- Psychological balance
- Relationships with others
- Creative pursuits
- Community involvement
- Spiritual involvement

Natural Remedies

Natural remedies and how to utilize raw healing plants

"An apple a day keeps the doctor away."
Spanish Proverb

Introduction

Natural medicines can be as effective as modern medicine, but they will be much more accessible in a disaster. The following section will guide you on what natural medicines are effective against various illnesses.

Purpose	The aim of NATURAL REMEDIES is to provide a list of plants which can be used to help alleviate common ailments. It goes into detail and lists all the potential advantages it could have as well as any side-effects that may present from its use. There is also a section on using essential oils for aromatherapy, topical uses and ingestion uses.
Lost?	● If you're looking for modern medications, see the MEDICATION section. ● If you want to find out more about the ailment, see either the ILLNESS, INJURY or EMOTIONAL categories. ● For general medical information and the bodies systems, see the MEDICAL section. ● For nutrition information and recommended intakes, see the HEALTH section. ● For growing your own herbs, see the GARDENING section. ● For eating disorders, see the HEALTH > Nutrients section.

Contents

1 Essential Oils

These are the different ways essential oils can be applied to the body.

Topically	Able to penetrate the skin and pass into the blood stream and into different areas of the body for internal therapeutic benefits.
Aromatically	Absorbed into the bloodstream when inhaled. The large amount of blood vessels in the lungs absorb the oils and then circulate them throughout the body.
Ingestion	Can be used as a powerful form of medicine. Most essential oils are safe for internal use but a little bit goes a long way. Usually 1-3 drops is plenty mixed with water.

Health Benefits: Different oils can be blended together to enhance each's energy or can be blended with a base oil to be used for massage, shower gels or body lotions.

Insect Repellants	Lemongrass, Eucalyptus, Citronella, Peppermint, Clove.
Antibacterial	Basil, Cassia, Cinnamon, Clove, Cypress, Eucalyptus, Geranium, Lavender, Lemon, Marjoram, Melaleuca, Myrrh, Orange, Oregano, Peppermint, Rosemary, Tea Tree, Thyme.

Antiviral	Basil, Cassia, Cinnamon, Eucalyptus, Frankincense, Lemon, Lemongrass, Marjoram, Melaleuca, Myrrh, Oregano, Thyme.

Essential Oil Benefits

These are the benefits of essential oils.

Basil	● Soothes sore muscles and joints ● Assists with clear breathing ● Acts as a cooling agent for the skin ● Promotes mental alertness and lessens anxious feelings
Bergamot	● Calming and soothing aroma ● Promotes healthy, clear skin ● Frequently used in massage therapy for its calming benefits
Cardamom	● Eases indigestion and maintains an optimal gastrointestinal balance ● Promotes clear breathing and respiratory health ● Calms stomach upset and uplifts mood ● Flavourful spice for cooking and baking
Cedarwood	● Supports and maintains healthy respiratory function ● Helps skin recover quickly ● Promotes clear, healthy skin ● Relaxing and soothing aroma is perfect for massage
Chamomile	● Has a therapeutic, calming effect on the skin, mind, and body ● Soothes the systems of the body ● May help support healthy immune system function
Clove	● Anti-bacterial, anti-parasitic and antioxidant protection. ● Powerful antioxidant properties ● Promotes circulation ● Supports cardiovascular health ● Helps soothe teeth and gums ● Promotes oral health ● Supports a healthy immune system
Cypress	● Improves circulation, reduces varicose veins, lifts confidence and can help heal broken bones. ● Assists with clear breathing ● Promotes healthy respiratory function ● Soothes tight, tense muscles ● Supports localized blood flow ● Beneficial for oily skin conditions
Eucalyptus	● Improves respiratory issues like bronchitis, sinusitis and allergies. Also invigorating and purifies the body. ● Assists with clear breathing ● Supports overall respiratory health ● Soothes tired, sore muscles ● Purifying and cleansing properties
Fennel	● Relieves indigestion and digestive troubles ● Eases monthly menstrual cycles ● Supports a healthy lymphatic system ● Calms minor skin irritation
Frankincense	● Builds immunity, reduces inflammation, heals age spots, supports brain and may help fight cancer. Anti-inflammatory, heal bruising, reduce scars, boost immunity and emotional well-being. ● Promotes cellular health ● Reduces the appearance of scars and stretch marks ● Calming and soothing to the skin
Helichrysum	● Skin Antibiotic and Antifungal ● Sunburn Relief and Skin Cancer Protector ● Acne Treatment ● Anti-Inflammatory That Helps Boost Heart Health ● Natural Digestive and Diuretic ● Liver Stimulator and Detoxifier ● Natural Cancer Protector ● Antiviral That Increases Immunity ● Pain Reliever
Lavender	● Helps with relaxation, headaches, stress, improves mood and heals burns, cuts, rashes, eczema, stings, reduce anxiety and insomnia. ● Massage 2-3 drops to forehead. ● Antioxidant Protection ● Diabetes Natural Treatment ● Improves Mood ● Reduces Stress ● Supports Brain Function ● Heals Burns and Cuts ● Relieves Headaches ● Improves Sleep and Insomnia ● Relieves Pain
Lemon	● Great to use in homemade cleaning products, improves lymph drainage and cleanses the body. ● Cleanses and purifies the air and surfaces ● Naturally cleanses the body and aids in digestion ● Supports healthy respiratory function ● Promotes a positive mood and cognitive ability

Melaleuca (Tea Tree)	● Anti-bacterial, anti-fungal, can be used to prevent and reduce infection and clean air of pathogens and allergens. ● Renowned for its cleansing and rejuvenating effect on the skin ● Promotes healthy immune function ● Protects against environmental and seasonal threats
Myrrh	● Natural anti-septic and can prevent or reduce infections. Also, supports beautiful skin, reducing stretch marks and hormone balance. ● Powerful cleansing properties, especially for the mouth and throat ● Soothing to the skin; promotes a smooth, youthful-looking complexio ● Promotes emotional balance and well-being
Oregano	● Powerful anti-microbial properties, can kill fungus and help you kick a cold fast. ● Used as a powerful cleansing and purifying agent ● Provides immune-enhancing benefits ● Supports healthy digestion and respiratory function ● Excellent source of antioxidants ● Can help to soften skin
Patchouli	● Grounding, balancing effect on emotions ● Promotes a smooth, glowing complexion ● Reduces the appearance of wrinkles, scars, and stretch marks
Peppermint	● Supports digestion, improves focus, boosts energy, fever reducer, headache and muscle pain relief, reduce fevers, colds/flu, nausea, flatulence, clear sinuses, improve asthma, bronchitis and relieve headaches. ● Promotes healthy respiratory function and clear breathing ● Alleviates stomach upset ● Frequently used in toothpaste and chewing gum for oral health
Rose	● Incredible for reducing skin inflammation and great for creating glowing skin. Add a few drops to your facial moisturizer. ● Helps balance moisture levels in the skin ● Reduces the appearance of skin imperfections ● Promotes an even skin tone and healthy complexion ● Emotionally uplifting
Rosemary	● Can naturally thicken hair so it is great to add to homemade shampoos. Also, it improves brain function and memory so it's great to used when working, reading or studying. ● Supports healthy digestion ● Supports healthy respiratory function ● Helps reduce nervous tension and fatigue
Geranium	● Promotes clear, healthy skin ● Helps calm nerves and lessen stress ● Promotes healthy hair
Ginger	● Reduces inflammation, supports joints, improves digestion and relieves nausea. ● Helps ease indigestion and nausea ● Promotes digestion ● Supports overall digestive health ● Warming to the body
Grapefruit	● Supports metabolism and cellulite reduction. Mix with coconut oil and rub on areas of cellulite or take a few drops internally with water. ● Cleanses and purifies ● Beneficial for oily skin issues Supports healthy metabolism ● Helps reduce mental and physical fatigue
Sandalwood	● Natural aphrodisiac that improves libido and can also improve energy. ● Promotes healthy, smooth skin ● Reduces the appearance of scars and blemishes ● Enhances mood ● Frequently used in meditation for its grounding and uplifting properties
Spearmint	● Diffuse to uplift mood ● Apply to toothbrush before brushing teeth for fresh breath ● Add a drop or two to any dessert, drink, salad, or entrée for flavouring and to promote digestion* ● For occasional stomach upset, add 1–2 drops to water and drink*
Valerian	● Treats Sleep Disorders ● Lowers Anxiety & Depression ● Improves Stomach Health ● Prevents Heart Palpitations ● Regulates Blood Pressure ● Improves Cognitive Abilities

Essential Oil Expiry

In general, shelf life is determined by the chemical composition of the essential oils, some of which oxidize or evaporate more quickly than others. Essential oils which contain a lot of monoterpenes or oxides have the shortest shelf life, of approximately 1-2 years. Essential oils which contain a lot of phenols may last up to 3 years. Essential oils which contain ketones, monoterpenols, and/or esters have a shelf life of 4-5 years. The potentially longest-lasting essential oils contain lots of sesquiterpenes and sesquiterpenols which can last up to 6 years. Store oils in a cool, dark and dry place. Keep the lids tightly closed. Store in the fridge if possible.

The following items cause essential oils to go bad.

Oxygen	Oxygen that gets into your bottle and reacts with some of the constituents is called oxidation. This oxidation can affect the therapeutic properties of the essential oil, as well as render it more hazardous (source). The biggest hazard is increased risk for sensitization.
Heat	Heat causes the more volatile constituents to evaporate more quickly. CO2 extracts are more prone to damage from heat than steam-distilled essential oils.

Light	Ultraviolet light promotes free radicals. Amber coloured bottles are best at keeping UV light out. Cobalt (blue being the opposite colour of brown) bottles do not do a very good job of keeping UV light out, but they allow the light to pass through the glass more readily, and therefore into the product.

Shelf Life

The following are estimates of the shelf life of essential oils. They should not be used topically after this point but may still be used aromatically for a while longer.	● Basil - 3y ● Bergamot - 3y ● Blue Tansy - 3y ● Cardamom - 4y ● Cedarwood - 6+y ● Chamomile - 4y ● Cinnamon Bark - 4y ● Clary Sage - 4y ● Clove - 3y ● Copaiba - 6y ● Cypress -2y	● Elemi - 3y ● Eucalyptus - 2y ● Fennel - 3y ● Frankincense - 2y ● Geranium - 4y ● Ginger - 6y ● Helichrysum - 4y ● Juniper Berry - 3y ● Lavender - 4y ● Lemon Citrus - 1y	● Lime Citrus - 2y ● Mandarin Citrus - 1y ● Melissa - 3y ● Myrrh - 6y ● Neroli - 3y ● Orange - 1y ● Oregano - 3y ● Patchouli - 10+y ● Pepper - 6y ● Peppermint - 4y	● Rosalina - 3y ● Rose - 6y ● Rosemary - 3y ● Sandalwood - 6+y ● Spearmint - 4y ● Tea Tree - 2y ● Valerian - 5y ● Vetiver - 6+y ● Wintergreen - 6y ● Ylang Ylang - 4y

Aroma	If you make yourself familiar with the aroma of the essential oil when it is fresh, you will begin to notice it smells "off" once it has oxidized. A change in smell can alert you that it may not be safe for topical applications.
Adverse Reactions	Once oxidized, the potential for the essential oil to cause redness, irritation, itching, etc., increases even when diluted. If this starts happening to you, stop using the essential oil topically. Continuing to use the oxidized essential oil in this way will greatly increase your risk for sensitization.

Oxidized Oils

Confirm Oxidization
Many companies do not provide a distillation date, which can be used to determine shelf life. If you are unsure when it was distilled, or bottled, you can keep track of when you purchase it. Keep in mind there could be several months or longer between when the essential oil was distilled or bottled, and when you make your purchase. If you are left in the dark, there are two ways to tell if your essential oil has been oxidized: aroma, and adverse reactions. Oxidized essential oils are not recommended for use on the skin, but they can be used for cleaning. It is not recommended they are diffused, either, in cause of mucous membrane irritation. Be sure you wear gloves when you use the essential oils in your cleaning recipes. If you want your essential oils to last longer, keep them closed tightly when not in use, keep them away from light, and store them in a cool place. The best place for essential oils is in the refrigerator.

These are some of the essential oils which should be avoided if oxidized. These are also the essential oils to prioritize for refrigerator space.

● Angelica Seed Angelica archangelica
● Anise (Star) Illicium verum
● Bergamot Citrus bergamia, Citrus aurantium
● Camphor (Borneo) Dryobalanops aromatica, Dryobalanops camphora
● Caraway Carum carvi
● Celery leaf, Celery seed Apium graveolens
● Clementine Citrus clementina
● Cypress Cupressus sempervirens
● Dill seed (European) Anethum graveolens
● Elemi Canarium luzonicum, Canarium vulgare
● Fennel (bitter, sweet) Foeniculum vulgare

● Fir Needle (Canadian) Abies balsamea
● Fir Needle (Himalayan) Abies spectabilis, Abies webbiana
● Fir Needle (Japanese) Abies sachalinensis
● Fir Needle (Siberian) Abies sibirica
● Fir Needle (Silver) Abies alba
● Fragonia Agonis fragrans
● Frankincense Boswellia frereana, Boswellia papyrifera, Boswellia sacra (Boswellia carteri), Boswellia serrata, Boswellia neglecta, Boswellia rivae
● Gingergrass Cymbopogon martinii var. sofia, Andropogon martinii var. sofia
● Grapefruit Citrus x paradisi

● Spruce (white) Picea glauca, Picea alba, Picea canadensis
● Tangerine Citrus reticulata, Citrus nobilis, Citrus tangerine
● Tea Tree Melaleuca alternifolia
● Thyme (limonene chemotype) Thymus vulgaris, Thymus serphyllum
● Verbena (white) Lippia alba, Lippia gerinata

● Juniper Berry Juniperus communis
● Lemon Citrus x limon, Citrus limonum
● Lemon Balm Eucalyptus staigeriana
● Lime Citrus x aurantifolia, Citrus x latifolia
● Mandarin Citrus reticulata, Citrus nobilis
● Orange (bitter) Citrus x aurantium
● Orange (sweet) Citrus sinensis, Citrus aurantium var. sinensis
● Palo Santo Bursera graveolens
● Pepper (black, white) Piper nigrum
● Pine (black) Pinus nigra
● Pine (dwarf) Pinus mugo

● Pine (grey) Pinus divaricata, Pinus banksiana
● Pine (red) Pinus resinosa
● Pine (Scots) Pinus sylvestris
● Pine (white) Pinus strobus
● Sage (blue mountain) Salvia stenophylla
● Spruce (black) Picea mariana, Picea nigra
● Spruce (hemlock) Tsuga canadensis, Pinus canadensis, Picea canadensis
● Spruce (Norway) Picea abies, Picea excelsa
● Spruce (red) Picea rubens

2 Natural Medication

Antibiotics

Garlic	Garlic is probably one of the very best natural antibiotics you can take because it kills pathogens as well as bacteria and viruses without doing any damage to the beneficial gut flora in your body. Garlic contains many vitamins, nutrients, and minerals and also contains phytochemical allicin which is effective against MRSA. It's even possible to infuse olive oil with garlic as a method for treating external infections such as ear infections. Best of all, unlike penicillin, garlic is simple and easy to grow. In fact, in a SHTF scenario, you can grow garlic using hydroponics or aquaponics.
Honey	Use of honey as an antibiotic dates back to ancient times. Honey contains both hydrogen peroxide and sugar which can help stop the growth of some bacteria. Raw or Manuka honey are the two forms that offer humans the most health benefits. You can't really "grow" your own honey, but you can raise bees and harvest honey from their hive. You can also opt to plant a few bee-friendly flowers in your survival garden to help support local hives. Many people recommend mixing honey with apple cider vinegar (another natural antibiotic) and water.

Ginger	Fresh ginger is particularly useful for preppers because it has been proven to have an antibiotic effect on food borne pathogens like salmonella. If food is scarce, you may have to resort to eating items that are a little risky and eating some ginger as well can help protect you from food borne illness.

Antibacterials

3 Herbs

This section contains a list of herbs and their benefits.

Subheadings

1. Acai	2. Atlantic Kelp	3. Alfalfa	4. Amla
5. Ashwaganda	6. Andrographis	7. Annatto	8. Bilberry
9. Baobab	10. Bacopa	11. Black Walnut	12. Bay Leaf
13. Blue Cohosh	14. Blue Flag	15. Black Cohosh	16. Bladderwrack
17. Brindle Berry Extract	18. Comfrey	19. Calendula	20. Chaste Tree Berry
21. Cat's Claw	22. Cordyceps	23. Cardamom	24. Cocoa
25. Coleus	26. Club Moss	27. Cassia Cinnamon	28. Chlorella
29. Camu Camu	30. Chickweed	31. Comfrey	32. Catnip
33. Chaga	34. Cascara Sagrada	35. Diatomaceous Earth	36. Devil's Claw
37. Dandelion	38. Damiana	39. Dong Quai	40. Euphorbia
41. Horny Goat Weed	42. Evodia	43. Goat's Rue	44. Ginko
45. Gotu Kola	46. Guarana	47. Graviola	48. American Ginseng
49. Bitter Melon	50. Horehound	51. Hops	52. Hydrangea
53. Horsetail	54. Horseradish	55. He Shou Wu (Fo-Ti)	56. Hypericum
57. Hawthorn	58. Jiaogulan	59. Kudzu	60. Myrtle
61. Alpine Lady's Mantle	62. Lotus	63. Milk Thistle	64. Moringa
65. Maitake Mushroom	66. Mugwort	67. Neem	68. Nigella Seed
69. Nettle Leaf	70. Sweet Orange	71. Oats	72. Paw Paw
73. Psyllium Husk	74. Panax Notoginseng	75. Muira Puama	76. Sage
77. Rehmannia	78. Raspberry Leaf	79. Reishi Mushroom	80. Rhubarb
81. Ruscus	82. Red Clover	83. Saw Palmetto	84. Senna
85. Slippery Elm	86. Shiitake Mushroom	87. Spirulina	88. Schisandra
89. Sorrel	90. Tribulus	91. Holy Basil (Tulsi)	92. Wild Yam
93. Witch Hazel	94. Willow Bark	95. Wheatgrass	96. Yarrow

1 Acai

Acai, pronounced AH-sigh-EE, is a palm tree that is widely distributed in the northern area of South America. Its berries are used to make medicine. Acai is most commonly used for arthritis, high cholesterol, erectile dysfunction (ED), weight loss and obesity, "detoxification," aging skin, metabolic syndrome, and for improving general health. But there is limited scientific evidence to support these uses. As a food, the acai berry is eaten raw and as a juice. The juice is also used commercially as a beverage and in ice cream, jelly, and liqueurs. In manufacturing, acai berry is used as a natural purple food colorant. Acai contains chemicals that are antioxidants. Antioxidants are thought to protect body cells from the damaging effects of chemical reactions with oxygen (oxidation). According to some research, acai has more antioxidant content than cranberry, raspberry, blackberry, strawberry, or blueberry. Chemicals in acai might also reduce swelling, lower blood sugar levels, and stimulate the immune system.

Uses

Insufficient Evidence

Metabolic Syndrome	Early research shows that eating 100 mg of acai pulp two times per day for one month reduces fasting blood sugar and total cholesterol in overweight people. But acai pulp doesn't appear to lower triglycerides or "bad" low-density lipoprotein (LDL) cholesterol, increase "good" high-density lipoprotein (HDL) cholesterol, or improve blood pressure and markers of swelling.

Arthritis, High cholesterol, Erectile dysfunction, Weight loss, Aging skin, Improving general health.

Dosing

The appropriate dose of acai depends on several factors such as the user's age, health, and several other conditions. At this time, there is not enough scientific information to determine an appropriate range of doses for acai. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

NATURAL REMEDIES

Herbs

2 Atlantic Kelp (Sea Kelp)

Sea kelp is a natural source of vitamins A, B1, B2, C, D and E, as well as minerals including zinc, iodine, magnesium, iron, potassium, copper and calcium. In fact it contains the highest natural concentration of calcium of any food - 10 times more than milk. Weight loss: Iodine is a trace mineral vital for the operation of the thyroid gland which plays an important part in body development and metabolism. It combines with tyrosine - an amino acid - to create T3 and T4, thyroid hormones that regulate metabolism and other physiological functions throughout the body. As sea kelp is the richest natural source of iodine it can help to regulate metabolism and in turn affect weight loss and gain. Anti-ageing: The iodine content of kelp also appears to have other benefits. A 2008 study showed that the form of iodine in kelp effectively removed free radicals - chemicals that accelerate ageing - from human blood cells.Try Montagne Jeunesse Dead Sea Mud Spa clay mask: therapeutic Dead Sea minerals and Dead Sea mud, nutrient-rich seaweed, and mineral-packed kelp to keep your skin nourished and moisturised. Hair growth - There's plenty of anecdotal evidence suggesting taking sea kelp supplements can boost hair growth. Whether or not it actually boosts growth, it contains nutrients involved in hair health and strength, so it may help reduce split ends and breakages.

Risks	As sea kelp contains so many minerals and nutrients in such high quantities it may pose health problems if consumed in an incorrect dosage or by those with particular health issues. Iodine: Sea kelp is rich in iodine as it rapidly absorbs the high iodine content of the sea, and you might find anecdotal advice to take it for iodine deficiency. In the developed world though this condition is rare, and even if you are a sufferer it's unlikely iodine supplements would be the recommended course of action. In fact, you'll probably already get between 160mcg and 600mcg of iodine from salt, and taking excess iodine can cause many health problems including hyperthyroidism, Grave's disease and thyroid cancers. Different forms of kelp can vary greatly in iodine content too; another reason to be cautious. For example, the iodine content of different products containing bladderwrack (or seawrack) - a type of kelp - may vary greatly. Heavy metals: Sea kelp grown in polluted waters may well absorb toxic heavy metals which if ingested can cause major health problems. The potential for this means it isn't recommended to be taken if pregnant or breastfeeding, or by children or people with health issues, especially liver or kidney problems. It should be possible however to make sure a particular supplement comes from kelp grown in clean waters. Unpredictability: There are a large number of sea kelp supplements available containing a variety of different types of algae that all come under the name 'kelp', which may affect your body in different ways.

3 Alfalfa

Alfalfa is a herb. People use the leaves, sprouts, and seeds to make medicine. Alfalfa is used for kidney conditions, bladder and prostate conditions, and to increase urine flow. It is also used for high cholesterol, asthma, osteoarthritis, rheumatoid arthritis, diabetes, upset stomach, and a bleeding disorder called thrombocytopenic purpura. People also take alfalfa as a source of vitamins A, C, E, and K4; and minerals calcium, potassium, phosphorous, and iron. Alfalfa seems to prevent cholesterol absorption in the gut.

Uses

Insufficient Evidence

High cholesterol	Taking alfalfa seeds seems to lower total cholesterol and “bad” low-density lipoprotein (LDL) cholesterol in people with high cholesterol levels.

Dosing

BY MOUTH
For high cholesterol: a typical dose is 5-10 grams of the herb, or as a steeped strained tea, three times a day. 5-10 mL of a liquid extract (1:1 in 25% alcohol) three times a day has also been used.

4 Amla (Indian Gooseberry)

Indian gooseberry is a tree that grows in India, the Middle East, and some southeast Asian countries. Indian gooseberry has been used in Ayurvedic medicine for thousands of years. Today people still use the fruit of the tree to make medicine. Indian gooseberry is taken by mouth for high cholesterol, "hardening of the arteries" (atherosclerosis), diabetes, pain and swelling of the pancreas (pancreatitis), cancer, upset stomach, eye problems, joint pain, diarrhea, bloody diarrhea (dysentery), osteoarthritis, obesity, "organ restoration", and for a skin disorder that causes unpigmented skin (vitiligo). It is also used to kill germs and reduce pain and swelling caused by the body's reaction to injury or illness (inflammation).

Uses

Insufficient Evidence

High cholesterol	Some early research shows that taking Indian gooseberry for 4 weeks decreases low-density lipoprotein (LDL, or "bad") cholesterol in people with high cholesterol. Other early research shows that taking Indian gooseberry extract for 12 weeks decreases LDL cholesterol in obese people.
Osteoarthritis	Research shows that taking two capsules of an Ayurvedic formula containing Indian gooseberry and several other ingredients three times daily for 24 weeks is as beneficial as taking glucosamine sulfate or the drug celecoxib for reducing pain in people with knee osteoarthritis. Skin disorder that causes unpigmented skin (vitiligo). Early research suggests that taking one tablet containing Indian gooseberry and other ingredients three times daily for 6 months along with standard treatment can increase skin repigmentation and reduce signs of inflammation better than standard treatment alone.
Skin disorder that causes unpigmented skin (vitiligo)	Early research suggests that taking one tablet containing Indian gooseberry and other ingredients three times daily for 6 months along with standard treatment can increase skin repigmentation and reduce signs of inflammation better than standard treatment alone.

Dosing

The appropriate dose of Indian gooseberry depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for Indian gooseberry. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

5 Ashwaganda

Ashwagandha is a plant. The root and berry are used to make medicine. Ashwagandha has a lot of uses. But so far, there isn't enough information to judge whether it is effective for any of them. Ashwagandha is used for arthritis, anxiety, bipolar disorder, attention deficit hyperactivity disorder (ADHD), balance, obsessive-compulsive dirorder (OCD), trouble sleeping (insomnia), tumors, tuberculosis, asthma, a skin condition marked by white patchiness (leukoderma), bronchitis, backache, fibromyalgia, menstrual problems, hiccups, Parkinson's disease, and chronic liver disease. It is also used to reduce side effects of medications used to treat cancer and schizophrenia. Ashwagandha is used to reduce levels of fat and sugar in the blood. Ashwagandha is also used as an "adaptogen" to help the body cope with daily stress, and as a general tonic. Some people also use ashwagandha for improving thinking ability, decreasing pain and swelling (inflammation), and preventing the effects of aging. It is also used for fertility problems in men and women and also to increase sexual desire.

Ashwagandha is applied to the skin for treating wounds, backache, and one-sided paralysis (hemiplegia). The name Ashwagandha is from the Sanskrit language and is a combination of the word ashva, meaning horse, and gandha, meaning smell. The root has a strong aroma that is described as "horse-like." In Ayurvedic, Indian, and Unani medicine, ashwagandha is described as "Indian ginseng." Ashwagandha is also used in traditional African medicine for a variety of ailments. Don't confuse ashwagandha with Physalis alkekengi. Both are known as winter cherry. Ashwagandha contains chemicals that might help calm the brain, reduce swelling (inflammation), lower blood pressure, and alter the immune system.

Uses

Possibly Effective

Stress	Taking a specific ashwagandha root extract (KSM66, Ixoreal Biomed) 300 mg twice daily after food for 60 days appears to improve symptoms of stress.

Insufficient Evidence

Reducing side effects associated with medications called antipsychotics.	Antipsychotics are used to treat schizophrenia but they can cause levels of fat and sugar in the blood to increase. Taking a specific ashwagandha extract (Cap Strelaxin, M/s Pharmanza Herbal Pvt. Ltd., Gujarat, India) 400 mg three times daily for one month might reduce levels of fat and sugar in the blood in people using these medications.
Anxiety	Some clinical research shows that taking ashwagandha can reduce some symptoms of anxiety or anxious mood.
Attention deficit-hyperactivity disorder (ADHD)	Some clinical research shows that a combination herbal product containing ashwagandha may improve attention and impulse control in children with ADHD. The effect of ashwagandha alone is unclear.
Bipolar disorder	Taking a specific ashwagandha extract (Sensoril, Natreon, Inc., New Bruswick, New Jersey) for 8 weeks might improve brain function in people being treated for bipolar disorder.
A brain condition called cerebellar ataxia.	Preliminary research shows that ashwagandha in combination with an alternative form of medicine known as Ayurvedic therapy might improve balance in people with cerebellar ataxia.
Fatigue in people treated for cancer (chemotherapy)	Early research suggests taking a specific ashwagandha extract 2,000 mg (Himalaya Drug Co, New Delhi, India) during chemotherapy treatment might reduce feelings of tiredness.
Diabetes	There is some evidence that ashwagandha might reduce blood sugar levels in people with diabetes.
High cholesterol	There is some evidence that ashwagandha might reduce cholesterol levels in patients with high cholesterol.
Male infertility	Some preliminary clinical evidence suggests that ashwagandha might improve sperm quality, but not sperm count, in infertile men. It is not known if taking ashwagandha can actually improve fertility.
Osteoarthritis	Early research shows that ashwagandha taken along with a zinc complex, guggul, and turmeric might improve arthritis symptoms. The impact of ashwagandha alone is unclear.
Obsessive-compulsive disorder (OCD)	Early research shows that ashwagandha root extract might reduce symptoms of OCD when taken with prescribed medications for 6 weeks better than taking the prescribed medication alone.
Parkinson's disease	Preliminary research suggests that a combination of herbs including ashwagandha improves Parkinson's symptoms. The effect of ashwagandha alone in Parkinson's is unknown.
Rheumatoid arthritis	Early research shows that ashwagandha powder taken for 3 weeks followed by 4 weeks of sidh makardhwaj (a mixture of gold, mercury, and sulfur) slightly improves symptoms in some people with RA. The impact of ashwagandha alone in RA is unclear.

Dosing

The appropriate dose of ashwagandha depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for ashwagandha. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

6 Andrographis

Andrographis is a plant that is native to South Asian countries such as India and Sri Lanka. The leaf and underground stem are used to make medicine. Andrographis is frequently used for preventing and treating the common cold and flu (influenza). Some people claim andrographis stopped the 1919 flu epidemic in India, although this has not been proven. Andrographis is also used for a wide assortment of other conditions. It is used for digestive complaints including diarrhea, constipation, intestinal gas, colic, and stomach pain; for liver conditions including an enlarged liver, jaundice, and liver damage due to medications; for infections including leprosy, pneumonia, tuberculosis, gonorrhea, syphilis, malaria, cholera, leptospirosis, rabies, sinusitis, and HIV/AIDS; and for skin conditions including wounds, ulcers and itchiness. Some people use andrographis for sore throat, coughs, swollen tonsils, bronchitis, and allergies. It is also used for "hardening of the arteries" (atherosclerosis), and prevention of heart disease and diabetes. Other uses include treatment of snake and insect bites, loss of appetite, kidney problems (pyelonephritis), hemorrhoids, and an inherited condition called familial Mediterranean fever. Andrographis is also used as an astringent, bacteria killing agent, painkiller, fever reducer, and treatment for worms. Some Internet vendors offer andrographis products that contain extra amounts of an active ingredient called andrographolide. Some of these products are almost 30% andrographolide. However, be careful; the safety and effectiveness of andrographis preparations with high andrographolide content are unknown. Andrographis might stimulate the immune system. It may improve the blood cell counts in people with HIV, and help with allergies.

Uses

Possibly Effective

NATURAL REMEDIES | Herbs | Andrographis | Uses

Common cold	Some research shows that taking a specific andrographis extract in combination with Siberian ginseng (Kan Jang, Swedish Herbal Institute) by mouth improves symptoms of the common cold when started within 72 hours of feeling sick. Some symptoms can improve after 2 days of treatment, but it usually takes 4-5 days of treatment before most symptoms go away. Some research suggests this combination of andrographis and Siberian ginseng relieves cold symptoms in children better than echinacea. Also, early research suggests that taking a specific andrographis extract (KalmCold) might help treat colds, while other research suggests that taking a specific andrographis product (Kan Jang, Swedish Herbal Institute) might help prevent colds.
Reducing the fever and sore throat due to tonsillitis	Some research shows that high dose andrographis (6 grams daily) works about as well as acetaminophen (Tylenol) after 3 to 7 days of treatment.
Inflammatory bowel disease (ulcerative colitis)	Early research suggests that taking andrographis extract daily for 8 weeks reduces symptoms of inflammatory bowel disease about as well as the drug mesalamine.

Insufficient Evidence

Familial Mediterranean Fever	Developing research suggests that a combination of andrographis, Siberian ginseng, schisandra, and licorice (ImmunoGuard, Inspired Nutritionals) reduces the length, number, and severity of attacks of familial Mediterranean fever in children.
Treating flu (Influenza)	There is some evidence that patients with flu who take a specific Andrographis extract in combination with Siberian ginseng (Kan Jang, Swedish Herbal Institute) feel better more quickly than patients taking amantadine, a drug approved by the federal Food and Drug Administration (FDA) to prevent Asian flu and treat Influenza A. Patients who take this herbal combination also seem to have fewer complications such as sinus pain, as well as breathing problems and coughing (bronchitis), after the flu.
Rheumatoid arthritis	Early research suggests that taking andrographis for 14 weeks reduces symptoms of rheumatoid arthritis when compared with pretreatment, but not when compared to another group of people taking just a sugar pill.

Dosing

BY MOUTH
For treating the common cold: a combination of a specific andrographis extract, standardized to contain 4-5.6 mg andrographolide, plus 400 mg Siberian ginseng (Kan Jang, Swedish Herbal Institute) three times daily.

For relieving fever and sore throat in tonsillitis: 3-6 grams daily.

7 Annatto

Annatto is a plant. The seed and leaf are used to make medicine. People take annatto for diabetes, diarrhea, fevers, fluid retention, heartburn, malaria, and hepatitis. They also use it as an antioxidant and bowel cleanser. Annatto is sometimes put directly on the affected area to treat burns and vaginal infections and to repel insects. In foods, annatto is used as a coloring agent.

Uses

Insufficient Evidence

Enlarged prostate (benign prostatic hyperplasia; BPH).	Early research suggests that taking annatto 250 mg three times daily for 12 months does not improve symptoms of BPH.

Dosing

The appropriate dose of annatto depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for annatto. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

8 Bilberry

Bilberry is a plant. The dried, ripe fruit and leaves are used to make medicine. Bilberry is used for improving eyesight, including night vision. In fact, during World War II, British pilots in the Royal Air Force ate bilberry jam to improve their night vision, but later research showed it probably didn't help. Bilberry is also used for treating eye conditions such as cataracts and disorders of the retina. There is some evidence that bilberry may help retinal disorders. Some people use bilberry for conditions of the heart and blood vessels including hardening of the arteries (atherosclerosis), varicose veins, decreased blood flow in the veins, and chest pain. Bilberry is also used for chronic fatigue syndrome (CFS), hemorrhoids, diabetes, osteoarthritis, gout, skin infections, gastrointestinal (GI) disorders, kidney disease, and urinary tract infections (UTIs). It is sometimes applied directly to the inside of the mouth for mild mouth and throat soreness. Bilberry contains chemicals called tannins that can help improve diarrhea, as well as mouth and throat irritation, by reducing swelling (inflammation). There is some evidence that the chemicals found in bilberry leaves can help lower blood sugar and cholesterol levels. Some researchers think that chemicals called flavonoids in bilberry leaf might also improve circulation in people with diabetes. Circulation problems can harm the retina of the eye.

Uses

Possibly Effective

Poor circulation that can cause the legs to swell (chronic venous insufficiency or CVI)	Some research suggests that taking bilberry extract by mouth can improve symptoms of swelling, pain, bruising, and burning in people with a circulation problem called chronic venous insufficiency (CVI).

Possibly Ineffective

Ability to see in low-light conditions	Most evidence suggests that bilberry is not effective for improving night vision.

Insufficient Evidence

Diabetes	Early research suggests that bilberry can lower blood sugar levels.
Vision problems in people with diabetes (diabetic retinopathy)	Eating bilberry fruit containing a high amount of a certain chemical, called anthocyanoside, seems to improve retina problems associated with diabetes.

Menstrual cramps (dysmenorrhea)	Early research suggests that taking bilberry twice daily 3 days before the beginning of the period and continuing for 8 days for a least two consecutive menstrual cycles reduces pain, nausea, vomiting and headache in women with painful menstruation.
Muscle soreness caused by exercise	Early research suggests that drinking bilberry juice might make muscle soreness worse in athletes after running a marathon.
A group of eye disorders that can lead to vision loss (glaucoma)	Early research suggests that taking 60 mg of a bilberry chemical, called anthocyanin, twice daily for at least 12 months improves vision in people with glaucoma.
Vision problems in people with high blood pressure (hypertensive retinopathy)	Eating bilberry fruit containing a high amount of a certain chemical, called anthocyanoside, seems to improve retina problems associated with high blood pressure.
A grouping of symptoms that increase the risk of diabetes, heart disease, and stroke (metabolic syndrome)	Some evidence suggests that eating 400 grams of fresh bilberries daily does not affect body weight, blood sugar, or cholesterol in people with metabolic syndrome.
Nearsightedness	Some early research suggests that eating fermented bilberry seems to improve the ability to focus and see objects that are far away.
A type of inflammatory bowel disease (ulcerative colitis)	Some early research shows that consuming 160 grams of bilberry daily for 6 weeks can lead to remission in some people with ulcerative colitis.
Obesity	Early research suggests that eating 100 grams of frozen, whole bilberries daily for about a month decreases weight and waist circumference in overweight and obese women.

Dosing

The typical dose of the dried, ripe berries: 20-60 grams daily. People also drink a type of tea made from 5-10 grams (1-2 teaspoons) of the mashed berries. A dose of 160 mg of bilberry extract taken twice daily has been used in people with diseased retinas. Bilberry leaf is commonly used as a tea. The tea is prepared by steeping 1 gram, 1-2 teaspoons, finely chopped dried leaf in 150 mL boiling water for 5-10 minutes, and then straining. Don't use bilberry leaf long-term.

9 Baobab

Baobab is a tree native to Africa, Madagascar, Australia, and Arabia. The tree is used as a source of water and food for indigenous people. Fruit and leaves of the tree are used medicinally for asthma, mosquito repellent, and for allergic skin conditions. Some people are calling the baobab fruit the next "super food" because of its exotic nature and rich nutrient profile. There is not enough scientific information to know how baobab might work for any medical condition. The fruit and leaves contain several nutrients and have some antioxidant properties.

Uses

Insufficient Evidence

Dosing

The appropriate dose of baobab depends on several factors such as the user's age, health, and several other conditions. At this time, there is not enough scientific information to determine an appropriate range of doses for baobab. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

10 Bacopa

Bacopa, also known as brahmi, is a plant that has been used in traditional Indian medicine (Ayurveda). Be careful not to confuse brahmi (Bacopa monnieri) with gotu kola and other natural medicines that are also sometimes called brahmi. Bacopa is commonly used for Alzheimer's disease, improving memory, anxiety, and attention deficit-hyperactivity disorder (ADHD) among many other uses. But there is limited scientific research to support these uses. Bacopa might increase certain brain chemicals that are involved in thinking, learning, and memory. Some research suggests that it might also protect brain cells from chemicals involved in Alzheimer's disease.

Uses

Possibly Ineffective

Irritable bowel syndrome (IBS)	Bacopa does not seem to help keep IBS symptoms from returning after they have gone away for a while.

Insufficient Evidence

Anxiety	Taking bacopa syrup daily for 4 weeks seems to reduce symptoms of anxiety, including nervousness, racing heart, trouble sleeping, headaches, tiredness, difficulty concentrating, and stomach discomfort in some people with anxiety.
Attention deficit-hyperactivity disorder (ADHD).	Taking bacopa for 6 months seems to improve ADHD symptoms such as restlessness and learning problems by 20% or more in some children with ADHD.
Improving memory	There is mixed evidence about bacopa for improving memory. Some research shows that bacopa extract taken for 12 weeks does not improve memory and attention. However, other research shows that taking bacopa improves some measure of memory in otherwise healthy older adults. Also, taking bacopa extract seems to improve some measures of memory and hand-eye coordination in children aged 6-8 years. It seems that some bacopa extracts can benefit memory while others do not.

Epilepsy (seizures)	Taking bacopa extract for 5 months might prevent seizures in some people with epilepsy.

Dosing

The appropriate dose of bacopa depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for bacopa. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

11 Black Walnut

Black walnut is a tree. People use the outer covering of the nut (the hull) to make medicine. Black walnut is used to treat parasitic worm infections and certain other infections including diphtheria and syphilis. It is also used for leukemia. Some people use black walnut as a gargle, apply it to the scalp as hair dye, or put it on the skin to treat wounds. Black walnut contains high concentrations of chemicals called tannins, which can reduce pain and swelling and dry up body fluids such as mucous.

Uses

Insufficient Evidence

Dosing

The appropriate dose of black walnut depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for black walnut. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

12 Bay Leaf

Sweet bay is an herb. The Greeks made it famous by crowning their heroes with wreathes made out of sweet bay leaves. In addition to decorative use, the leaves and oil are used to make medicine. Sweet bay is used to treat cancer and gas; stimulate bile flow; and cause sweating. Some people apply sweet bay to the scalp for dandruff. It is also put on the skin for pain, especially muscle and joint pain (rheumatism). The fruit and fatty oils of sweet bay are used on the skin to treat boils (furuncles) caused by infected hair follicles. Veterinarians use sweet bay as an udder ointment. In food, sweet bay is used as a seasoning in cooking and in processed foods. In manufacturing, the oil is used in cosmetics, soaps, and detergents. Sweet bay contains ingredients that might cause sleepiness and might act against some bacteria and fungi.

Uses

Insufficient Evidence

Diabetes	Early research suggests that taking ground bay leaf twice daily along with medication for diabetes can lower pre-meal blood sugar levels, as well as levels of cholesterol, “bad” low-density lipoprotein (LDL) cholesterol, and blood fats called triglycerides in people with diabetes. Also, taking ground bay leaf seems to increase “good” high-density lipoprotein (HDL) cholesterol levels in these people.

Dosing

The appropriate dose of sweet bay depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for sweet bay. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

13 Blue Cohosh

Blue cohosh is a plant. "Cohosh" is from the Algonquin Indian word meaning "rough," and it refers to the appearance of the roots. The root is used to make medicine. Blue cohosh is not a safe plant. However, it still is available as a supplement. Sometimes the supplements do not include warnings. Blue cohosh is used for stimulating the uterus and starting labor; starting menstruation; stopping muscle spasms; as a laxative; and for treating colic, sore throat, cramps, hiccups, epilepsy, hysterics, inflammation of the uterus, infection of the female organs (pelvic inflammatory disease), over-growth of uterine tissue (endometriosis), and joint conditions. In foods, the roasted seeds of blue cohosh are used as a coffee substitute. It is thought that blue cohosh might have effects similar to the hormone estrogen. It also may narrow the vessels that carry blood to the heart that can decrease oxygen in the heart.

Uses

Insufficient Evidence

Dosing

The appropriate dose of blue cohosh depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for blue cohosh. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

14 Blue Flag

Blue flag is a plant. People use the underground stem (rhizome) of blue flag to make medicine. Despite serious safety concerns, blue flag is used as a laxative and to relieve fluid retention and bloating. It is also used to treat swelling (inflammation) and skin conditions; and to prevent vomiting. Some people use it for liver problems and to increase bile production. There isn't enough information to know how blue flag works.

Uses

Insufficient Evidence

Dosing

The appropriate dose of blue flag depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for blue flag. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

15 Black Cohosh

Black cohosh is an herb. The root of this herb is used for medicinal purposes. Black cohosh was first used for medicinal purposes by Native American Indians, who introduced it to European colonists. Black cohosh became a popular treatment for women's health issues in Europe in the mid-1950s. Since that time, black cohosh has commonly been used to treat symptoms of menopause, premenstrual syndrome (PMS), painful menstruation, acne, weakened bones (osteoporosis), and for starting labor in pregnant women. Black cohosh has also been tried for a lot of additional uses, such as anxiety, rheumatism, fever, sore throat, and cough, but it is not often used for these purposes these days. Some people also apply black cohosh directly on the skin. This is because there was some thought that black cohosh would improve the skin's appearance. Similarly, people used black cohosh for other skin conditions such as acne, wart removal, and even the removal of moles, but this is seldom done anymore. Black cohosh also goes by the name "bugbane" because it was once used as an insect repellent. It is no longer used for this purpose. Frontiersmen had said that black cohosh was useful for rattlesnake bites, but no modern researchers have tested this. Do not confuse black cohosh with blue cohosh or white cohosh. These are unrelated plants. The blue and white cohosh plants do not have the same effects as black cohosh, and may not be safe.

The root of black cohosh is used for medicinal purposes. Black cohosh root contains several chemicals that might have effects in the body. Some of these chemicals work on the immune system and might affect the body's defenses against diseases. Some might help the body to reduce inflammation. Other chemicals in black cohosh root might work in nerves and in the brain. These chemicals might work similar to another chemical in the brain called serotonin. Scientists call this type of chemical a neurotransmitter because it helps the brain send messages to other parts of the body. Black cohosh root also seems to have some effects similar to the female hormone, estrogen. In some parts of the body, black cohosh might increase the effects of estrogen. In other parts of the body, black cohosh might decrease the effects of estrogen. Estrogen itself has various effects in different parts of the body. Estrogen also has different effects in people at different stages of life. Black cohosh should not be thought of as an "herbal estrogen" or a substitute for estrogen. It is more accurate to think of it as an herb that acts similar to estrogen in some people.

Uses

Possibly Effective

Menopausal symptoms	Research shows that taking some black cohosh products can reduce some symptoms of menopause. However, the benefits are only modest. Black cohosh might lessen the frequency of hot flashes. Most of this research is for a specific commercial black cohosh product, Remifemin. The benefits may not occur with all products that contain black cohosh. Research using black cohosh products other than Remifemin have not always shown benefits for menopausal symptoms. Some of these studies show that these other black cohosh products do not reduce hot flashes or menopausal symptoms any better than a sugar pill ("placebo"). Some women take black cohosh for hot flashes related to breast cancer treatment. Women with breast cancer should not use black cohosh without talking to their cancer specialist or other health provider. Some early research suggested that black cohosh might reduce hot flashes in breast cancer patients, but more recent and higher quality research shows that black cohosh does not reduce hot flashes in women with breast cancer. Also, there is some question as to whether black cohosh is safe for women with breast cancer. It is important for a woman with breastcancer to discuss any use of black cohosh with her health provider before using it.

Insufficient Evidence

Breast cancer	One study suggests that taking black cohosh supplements is linked to a deceased risk of breast cancer. However, other research has found no link. One study found that taking black cohosh might increase survival in women already diagnosed with breast cancer.
Heart disease	Early research shows that taking 40 mg of a specific black cohosh extract (CR BNO 1055) daily does not lower the risk of heart disease in postmenopausal women.
Mental function	Early research suggests that taking 128 mg of black cohosh daily for 12 months does not improve memory or attention in postmenopausal women.
Infertility	Some early research suggests that taking black cohosh plus clomiphene citrate can increase pregnancy rates in infertile women compared to clomiphene citrate alone. Other research shows that taking black cohosh with clomiphene results in pregnancy rates that are similar to those found when clomiphene is taken with another fertility drug.
Induction of labor	Some people report that black cohosh can help start labor. As many as 45% of nurse-midwives use black cohosh to start labor in pregnant women at term. Despite its common use, there is no reliable scientific evidence that black cohosh works for this purpose.
Migraine headache	Early research shows that taking 50 mg of black cohosh plus soy isoflavones and dong quai daily for 24 weeks can reduce the occurrence of menstrual migraines.
Osteoarthritis	Early research suggests that taking a specific product containing black cohosh (Reumalex) twice daily for 2 months improves pain, but not joint function, in people with osteoarthritis.
Weak bones (Osteoporosis)	Evidence regarding the benefit of black cohosh for treating or preventing osteoporosis is unclear. Some early research shows that taking a specific black cohosh product (CR BNO 1055, Klimadynon/Menofem, Bionorica AG) daily for 12 weeks increases markers of bone formation in postmenopausal women. However, other research shows that taking the same black cohosh extract does not improve bone mineral density. It is not known if these black cohosh products can reduce the risk of bone fractures.
Rheumatoid arthritis	Early evidence suggests that taking a specific product containing black cohosh (Reumalex) twice daily for 2 months improves pain, but not joint function, in people with rheumatoid arthritis.

Dosing

BY MOUTH
Menopausal symptoms: 20-80 mg once or twice daily.
Weak bones (Osteoporosis): 40 mg daily.

16 Bladderwrack

Bladderwrack is a type of seaweed. People use the whole plant to make medicine. Bladderwrack is used for many conditions, but, so far, there isn't enough scientific evidence to determine whether or not it is effective for any of them. It's also important to note that it's not safe to take bladderwrack by mouth. Bladderwrack is used for thyroid disorders including underactive thyroid (myxedema), over-sized thyroid gland (goiter), and iodine deficiency. It is also used for obesity, arthritis, joint pain, "hardening of the arteries" (arteriosclerosis), digestive disorders, heartburn, "blood cleansing," constipation, bronchitis, emphysema, urinary tract disorders, and anxiety. Other uses include boosting the immune system and increasing energy. Some people also apply bladderwrack to the skin for skin diseases, burns, aging skin, and insect bites. Don't confuse bladderwrack with bladderwort. Bladderwrack, like many sea plants, contains varying amounts of iodine, which is used to prevent or treat some thyroid disorders. Bladderwrack products may contain varying amounts of iodine, which makes it an inconsistent source of iodine. Bladderwrack also contains algin, which can act as a laxative to help the stool pass through the bowels.

Uses

Insufficient Evidence

Obesity	Early research suggests that bladderwrack, used along with lecithin and vitamins, doesn't help people lose weight and keep it off.

Dosing

The appropriate dose of bladderwrack depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for bladderwrack. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

17 Brindle Berry Extract (Garcinia)

Garcinia is a small to medium-sized tree that grows in India and Southeast Asia. The fruit rind contains the chemical hydroxycitric acid (HCA) and is used to make medicine. Don't confuse garcinia with Garcinia hanburyi (gamboge resin). People try garcinia for weight loss and exercise performance, but there is no strong evidence to support these uses and using it can be unsafe. Garcinia contains the chemical hydroxycitric acid (HCA). Some laboratory research suggests that HCA might prevent fat storage, control appetite, and increase exercise endurance, but whether these effects occur in humans is unclear.

Uses

Insufficient Evidence

Exercise performance	Garcinia contains a chemical called hydroxycitric acid (HCA). Taking HCA might increase how long untrained women are able to exercise. But it does not seem benefit men in the same way.
Weight loss	It's unclear if garcinia helps people lose weight. Some research shows that it has a small benefit. Other research shows it doesn't help.

Dosing

The appropriate dose of garcinia depends on several factors such as the user's age, health, and several other conditions. At this time, there is not enough scientific information to determine an appropriate range of doses for garcinia. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

18 Comfrey

Comfrey is a plant. Even though this plant contains poisonous chemicals called pyrrolizidine alkaloids (PAs), the leaf, root, and root-like stem (rhizome) are used to make medicine. The amount of PAs found in comfrey changes according to the time of harvesting and the age of the plant. The roots have 10 times higher amounts of PAs than the leaves. Some products labeled "common comfrey" or Symphytum officinale actually contain the more poisonous "prickly comfrey" (Symphytum asperum) or "Russian comfrey" (Symphytum x uplandicum) species. Comfrey is used as a tea for upset stomach, ulcers, heavy menstrual periods, diarrhea, bloody urine, persistent cough, painful breathing (pleuritis), bronchitis, cancer, and chest pain (angina). It is also used as a gargle for gum disease and sore throat. Comfrey is applied to the skin for ulcers, wounds, joint inflammation, bruises, rheumatoid arthritis, swollen veins (phlebitis), gout, and fractures. The chemicals in comfrey might have a healing effect and reduce inflammation when applied to the skin. However, comfrey contains toxic chemicals that can be absorbed through the skin.

Uses

Possibly Effective

Back pain	Applying a comfrey extract ointment to the affected area for 5 days seems to decrease lower or upper back pain. Also applying a cream containing comfrey extract plus methyl nicotinate to the affected area for 5 days seems to decrease back pain when resting or moving.
Osteoarthritis	Applying a comfrey extract ointment to the affected area for 3 weeks or applying a specific cream containing comfrey extract, tannic acid, Aloe vera gel, eucalyptus oil, and frankincense oil to the affected are for 6-12 weeks seems to decrease pain in people with knee osteoarthritis.
Sprains	Early research shows that applying comfrey ointment to the affected area for up to 2 weeks improves mobility, decreases pain, and reduces tenderness and swelling of sprains. The effect of comfrey ointment in relieving pain and reducing swelling seems to be comparable to the effects of diclofenac gel.

Insufficient Evidence

Bruises	Early research shows that applying comfrey directly to the skin for 2 weeks might decrease pain and tenderness of bruises.

Dosing

APPLIED TO THE SKIN
For back pain: About 4 grams of a specific ointment containing 35% comfrey root extract has been applied three times daily for 5 days. About 4 grams of another cream containing 35% comfrey plus 1.2% methyl nicotinate has also been applied three times daily for 5 days. For osteoarthritis: About 2 grams of a specific ointment containing 35% comfrey root extract has been applied to the knee three times daily for 3 weeks. Also, about 3.5 grams of a specific cream containing comfrey extract, tannic acid, aloe vera gel, eucalyptus oil, and frankincense oil has been applied to the knee three times daily for 6-12 weeks. For sprains: About 2 grams of a specific ointment containing 35% comfrey extract has been applied to ankle sprains four times daily for 8 days.

19 Calendula

Calendula is a plant. The flower is used to make medicine. Calendula flower is used to prevent muscle spasms, start menstrual periods, and reduce fever. It is also used for treating sore throat and mouth, menstrual cramps, cancer, and stomach and duodenal ulcers. Calendula has also been used for measles, smallpox, and jaundice. Calendula is applied to the skin to reduce pain and swelling (inflammation) and to treat poorly healing wounds and leg ulcers. It is also applied to the skin (used topically) for nosebleeds, varicose veins, hemorrhoids, inflammation of the rectum (proctitis), ear infection, gum disease, peeling lips (exfoliative cheilitis), diaper rash, vaginal yeast infection, and inflammation of the lining of the eyelid (conjunctivitis). Essential oil of calendula has been used as an insect repellant. Don't confuse calendula with ornamental marigolds of the Tagets genus, which are commonly grown in vegetable gardens. It is thought that the chemicals in calendula help new tissue grow in wounds and decrease swelling in the mouth and throat.

Uses

Insufficient Evidence

Anal tears (anal fissures)	Early research suggests that that applying calendula to the affected area may reduce pain in people with anal tears who do not respond to treatment with sitz baths and the medication nifedipine.
Diabetic foot ulcers	Early research shows that using a calendula spray in addition to standard care and hygiene might prevent infection and decrease odor in people with long-term foot ulcer from diabetes.
Diaper Rash	Some early research suggests that applying a calendula ointment to the skin for 10 days improves diaper rash compared to aloe gel. But other early research shows that applying calendula cream does not improve diaper rash as effectively as bentonite solution.
Peeling Lips (Exfoliative Cheilitis	Early research shows that using calendula ointment for 15 days might help stop peeling lips.
Gum inflammation	Early research shows that rinsing the mouth with a specific calendula tincture for 6 months might decrease plaque, gum inflammation, and bleeding by 10% to 18% compared to using water to rinse. Other early research shows that rinsing the mouth with a combination mouthwash containing calendula, rosemary, and ginger for 2 weeks decreases plaque, gum inflammation, and bleeding compared to placebo mouthwash. In fact, it the combination mouthwash seems to work as effectively as chlorhexidine mouthwash.
Insect repellant	Applying calendula essential oil to the skin does not seem to repel mosquitoes as effectively as applying DEET.
Ear infections (otitis media)	Early research shows that applying a specific product that contains mullein, garlic, calendula, and St. John's wort to the ear for 3 days reduces ear pain in children and teenagers with ear infections.
Pressure ulcers	Early research shows that using a specific calendula product might improve the healing of long-term pressure ulcers.
Skin inflammation due to radiation therapy (radiation dermatitis)	Early research suggests that applying calendula ointment on the skin might reduce radiation dermatitis in people receiving radiation therapy for breast cancer. However, other early research shows that using a calendula cream is no different than petroleum jelly for reducing radiation dermatitis.
Thinning of the wall of the vagina (vaginal atrophy)	Early research suggests that applying a gel containing calendula, Lactobacillus sporogenes, isoflavones, and lactic acid to the vagina for 4 weeks reduces symptoms of vaginal atrophy such as vaginal itching, burning, dryness, and pain during intercourse.
Vaginal yeast infection	Early research shows that applying calendula cream inside the vagina for 7 days does not treat yeast infections as effectively as using clotrimazole cream.
Leg ulcers	Early research shows that applying a calendula ointment to the skin speeds up the healing of leg ulcers caused by poor blood circulation.
Wound healing	Early research shows that applying calendula ointment along with routine care does not improve the healing of surgical cut of the vagina made during childbirth.

Dosing

The appropriate dose of calendula depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for calendula. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

20 Chaste Tree Berry (Vitex Agnus-Castus)

Vitex agnus-castus tree is a shrub that is native to the Mediterranean and Central Asia. The shrub has long, finger-shaped leaves, blue-violet flowers, and dark purple berries. The fruit and seed are used to make medicine. Vitex agnus-castus is commonly taken by mouth for conditions related to the menstrual cycle such as premenstrual syndrome and a more severe form called premenstrual dysphoric disorder. It is also used for "lumpy" breasts and and many other conditions. Vitex agnus-castus seems to affect many hormones that are involved in women's reproductive cycle.

Uses

Possibly Effective

Premenstrual dysphoric disorder	Some research shows that vitex agnus-castus might work about as well as the prescription drug fluoxetine (Prozac) for relieving symptoms of this condition. Vitex agnus-castus seems to be better for physical symptoms like breast tenderness, swelling, and cramps. Fluoxetine seems to be better for depressed mood, feeling nervous and feeling out of control.

NATURAL REMEDIES | Herbs | Vitex Agnus-Castus | Uses

Premenstrual syndrome	Some research shows that taking vitex agnus-castus decreases some symptoms, especially breast pain or tenderness, depressed mood or moodiness, anger, and headache. But it does not seem to help for bloating.

Possibly Ineffective

Bone fractures	Taking vitex agnus-castus extract does not seem to improve the healing of broken bones.

Insufficient Evidence

Bleeding caused by an intrauterine device	Early research shows that taking vitex agnus-castus three times daily might reduce bleeding caused by an intrauterine device.
Infertility	The effects of vitex agnus-castus on fertility is not clear. Some early research shows that it does not improve the chance of becoming pregnant in women with infrequent menstrual bleeding, but it might help those who do not produce enough progesterone.
Repelling insects	Early research shows that vitex agnus-castus seed extract repels ticks and fleas for 6 hours, mosquitoes for 3 to 8 hours, and biting flies for 3 hours, when applied to the skin.
Breast pain	Early research shows that vitex agnus-castus) might relieve breast pain.

Dosing

BY MOUTH
For premenstrual dysphoric disorder (PMDD): 20-40 mg of vitex agnus-castus extract taken daily for 8 weeks has been used.

For premenstrual syndrome (PMS): A specific extract known as BNO 1095 (Agnucaston/Cyclodynon, Bionorica AG), which contains 4 mg of vitex agnus-castus extract has been taken daily for three menstrual cycles. Another specific extract known as Ze 440 (Prefemin, Max Zeller Sohne AG, Romanshorn, Switzerland) which contains 20 mg of vitex agnus-castus extract has been taken daily for three menstrual cycles. Another specific product (Femicur, Schaper & Brummer GmbH & Co. KG, Salzgitter, Germany) containing 6.4-12 mg of vitex agnus-castus extract has been taken daily in two divided doses for three menstrual cycles. Specific capsules (Agnolyt, Madaus AG, Cologne, Germany) containing 3.5-4.2 mg of vitex agnus-castus extract has been taken daily on days 16-35 over three menstrual cycles. Vitex agnus-castus extract, 40 drops added to one glass of fruit juice once daily before breakfast starting 6 days prior to menstrual bleeding and lasting until menstrual bleeding occurs, has been used for six cycles.

21 Cat's Claw

Cat's claw is a plant. Two species of cat's claw, Uncaria tomentosa and Uncaria guianensis, are of primary interest for use as medicine. Uncaria tomentosa is most commonly used in the U.S., and Uncaria guianensis is typically used in Europe. Medicine is made from the root and bark. Be careful not to confuse cat's claw with cat's foot. Cat's claw is most commonly used for improving symptoms of both osteoarthritis and rheumatoid arthritis. It is also used for various digestive system disorders including swelling and pain (inflammation) of the large intestine (diverticulitis), inflammation of the lower bowel (colitis), inflammation of the lining of the stomach (gastritis), stomach ulcers, hemorrhoids, and leaky bowel syndrome. Some people use cat's claw for viral infections including shingles (caused by herpeszoster), cold sores (caused by herpes simplex), and AIDS (caused by human immunodeficiency virus (HIV)). Cat's claw is also used for chronic fatigue syndrome (CFS), wound healing, parasites, Alzheimer's disease, asthma, hay fever, cancer (especially urinary tract cancer), a particular type of brain cancer called glioblastoma, gonorrhea, dysentery, birth control, bone pains, and "cleansing" the kidneys. Cat's claw contains chemicals that might stimulate the immune system, kill cancer cells, and fight viruses.

Uses

Possibly Effective

Reducing pain from osteoarthritis	Taking a specific freeze-dried cat's claw extract (Uncaria guianensis) by mouth appears to relieve knee pain related to physical activity within one week of treatment, but it does not decrease pain at rest or decrease knee swelling. Taking a specific combination supplement (Reparagen) containing cat's claw (Vincaria) and maca (RNI 249) for 8 weeks seems to reduce pain and stiffness, improve function, and reduce the need to use rescue medication as well as taking glucosamine sulfate. Improving symptoms of a kind of arthritis called rheumatoid arthritis (RA) when used with regular rheumatoid arthritis medications. Taking a specific cat's claw extract (Uncaria tomentosa) that contains chemicals called pentacyclic oxindole alkaloids but is free of other chemicals called tetracyclic oxindole alkaloids appears to improve symptoms of RA somewhat. Taken by mouth in combination with sulfasalazine or hydroxychloroquine for 24 weeks, cat's claw seems to reduce the number of painful and swollen joints.

Insufficient Evidence

Human papilloma virus (HPV)	Early research suggests that taking a specific supplement containing echinacea, andrographis, grapefruit, papaya, pau d'arco, and cat's claw three times daily for one month can reduce the recurrence of anal warts after surgical removal in people with HPV.

Dosing

BY MOUTH
For osteoarthritis of the knee: 100 mg daily of a specific freeze-dried cat's claw extract.

For rheumatoid arthritis: 60 mg daily in three divided doses of a specific cat's claw extract that contains no chemicals called tetracyclic oxindole alkaloids. These chemicals, while found naturally in some cat's claw, work against other chemicals in cat's claw that seem to help rheumatoid arthritis.

22 Cordyceps

Cordyceps is a fungus that lives on certain caterpillars in the high mountain regions of China. Natural cordyceps is hard to get and may be expensive. Most supplements are made with cordyceps grown in a laboratory. Cordyceps is most commonly used for kidney disorders and male sexual problems. It is also used after a kidney transplant. It is also used for liver problems, improving athletic performance, and many other conditions but there is no good scientific evidence to support these uses. Cordyceps might improve immunity by stimulating cells and specific chemicals in the immune system. It may also have activity against cancer cells and may shrink tumor size, particularly with lung or skin cancers.

Uses

Possibly Ineffective

Athletic performance	Several studies have shown that taking cordyceps or a combination of cordyceps and roseroot does not improve endurance in trained male cyclists.

Insufficient Evidence

Kidney damage caused by the drug amikracin	Early research shows that using cordyceps with the drug amikracin might reduce kidney damage caused by the drug in older people.
Asthma	Early research suggests that taking cordyceps alone can reduce asthma symptoms in adults. However, other early research suggests that taking cordyceps along with other herbs for 6 months does not reduce the need for medication or improve asthma symptoms in children.
Chemotherapy	Early evidence shows that taking cordyceps by mouth during or after chemotherapy might improve quality of life and improve tolerance to the treatments.
Chronic kidney disease (CKD)	Early research suggests that taking cordyceps along with standard therapy for chronic kidney disease may improve kidney function. However, most of these studies are low quality and were conducted for only 6 months or less.
Kidney damage caused by contrast dyes (Contrast induced nephropathy	Some early research shows that taking cordyceps while undergoing an exam using contrast dye reduces the chance of kidney damage caused by the dye. But other early research shows no benefit.
Kidney damage caused by the drug cyclosporine	There is early evidence that taking cordyceps with cyclosporine can reduce kidney damage caused by cyclosporine in people with kidney transplants.
Hepatitis B	Early evidence shows that taking cordyceps by mouth might improve liver function in people with hepatitis B. However, cordyceps seems to be less effective than the supplements astragalus and polygonum (fo-ti).
Sexual desire	Early research suggests that taking a specific cordyceps product (CordyMax Cs-4) daily for 40 days can improve sex drive in people with low sex drive.
Kidney transplant	Early research shows that taking cordyceps with low-dose cyclosporine can improve 1-year survival, prevent transplant rejection, and reduce the risk of infection similar to taking standard dose cyclosporine in people who received a kidney transplant. Also cordyceps seems to improve kidney transplant survival, kidney transplant rejection, and infection similar to azathioprine when taken with medications to prevent organ rejection. It might also reduce the risk of long-term impaired kidney function called chronic allograft nephropathy. This is the leading cause of kidney transplant failure.

Dosing

The appropriate dose of cordyceps depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for cordyceps. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

23 Cardamom

Cardamom is an herb. The seeds and oil from the seeds are used to make medicine. Cardamom is used for digestion problems including heartburn, intestinal spasms, irritable bowel syndrome (IBS), diarrhea, constipation, liver and gallbladder complaints, and loss of appetite. It is also used for common cold and other infections, cough, bronchitis, sore mouth and throat, urinary problems, epilepsy, headache, and high blood pressure. In foods, cardamom is used as a spice. It is also used in soaps, creams, and perfumes. Cardamom contains chemicals that might treat intestinal spasms, kill some bacteria, reduce swelling, and help the immune system.

Uses

Insufficient Evidence

High blood pressure	Early research shows that taking cardamom by mouth might help reduce blood pressure in people with newly-diagnosed, untreated high blood pressure.
Nausea and vomiting that can occur after surgery	Early research shows that applying a mixture of ginger, cardamom, and tarragon essential oils to the neck after anesthesia and surgery may help relieve nausea and prevent vomiting for up to 30 minutes in some people. However, the effect seems to vary depending on the number of vomit-causing drugs that were given during anesthesia or as pain relievers during and/or after surgery. In other research, breathing in a mixture of cardamom, ginger, spearmint, and peppermint from a gauze pad after minor surgery reduces nausea and the amount of medicine needed to control it.

Dosing

The appropriate dose of cardamom for use as treatment depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for cardamom. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

24 Cocoa

Cocoa is the plant from which chocolate is made. Bitter chocolate is produced by pressing roasted cocoa kernels (seeds) between hot rollers. Cocoa powder is produced by squeezing the fat (cocoa butter) from bitter chocolate and powdering the remaining material. Sweet chocolate is produced by adding sugar and vanilla to bitter chocolate. White chocolate contains sugar, cocoa butter, and milk solids. Long regarded as a food treat, cocoa is now used by some people as medicine. Cocoa is commonly used by mouth for heart disease and high blood pressure. There is some scientific research that supports these uses. Some people apply cocoa butter to the skin to prevent wrinkles and stretch marks or take cocoa orally to treat many other conditions, including liver, bladder, and kidney disease and memory loss. But there is limited scientific research to support these other uses. Cocoa contains a variety of chemicals, including antioxidants called flavonoids. It is not clear how these might work in the body, but they appear to cause relaxation of veins. This could lead to lower blood pressure. These compounds might also reduce the activity of chemicals in the body that promote inflammation or blockage of blood vessels.

Uses

Possibly Effective

Heart disease	Some research shows that eating cocoa lowers the chance of heart disease and death, possibly by lowering blood pressure and improving the function of blood vessels.
High blood pressure	Most research shows that eating dark chocolate or cocoa products for 2-18 weeks can lower the top number in a blood pressure reading (systolic blood pressure) by 2.8-4.7 mmHg and the lower number (diastolic blood pressure) by 1.9-2.8 mmHg in people with normal blood pressure or high blood pressure.

Possibly Ineffective

High cholesterol	Cocoa products do not seem to improve cholesterol levels in people with high cholesterol.

Insufficient Evidence

Aging skin	Some research suggests that taking cocoa extract alone or in combination with other ingredients might improve skin wrinkles, elasticity, and roughness.
Chronic fatigue syndrome	Early research suggests that consuming a large amount of cocoa daily can reduce fatigue, anxiety, and depression and increase the overall ability to function in people with chronic fatigue syndrome.
Cirrhosis	Research suggests that consuming a liquid meal plus dark chocolate can improve liver health in people with cirrhosis.
Mental function	Evidence on the effects of cocoa for improving mental function is mixed. Some research shows that cocoa might improve some aspects of mental function. Other research show no benefit.
Constipation	Early research suggests that taking cocoa daily might soften stools in children with constipation.
Diabetes	Early research suggests that cocoa might reduce insulin resistance and improve sensitivity. However, cocoa does not appear to affect blood sugar levels.
Insect repellant	Early research suggests that applying cocoa oil to the skin reduces black fly insect bites.
High blood pressure in which only the first number (systolic pressure) is too high (isolated systolic hypertension)	Early research suggests that eating 100 grams of dark chocolate that is rich in cocoa flavonoids daily might slightly reduce systolic and diastolic blood pressure in elderly people with isolated systolic hypertension.
Parkinson's disease	Early research suggests that eating 200 mg of dark chocolate does not improve movement in people with Parkinson's disease.
Weight loss	Early research suggests that following a reduced-calorie diet, eating two squares of dark chocolate, and drinking a sugar-free cocoa beverage daily for 18 weeks does not increase weight loss.

Dosing

BY MOUTH
For heart disease: Cocoa 19-54 grams daily, dark chocolate 46-100 grams daily, or cocoa products containing 16.6-1080 mg of cocoa polyphenols daily.

For high blood pressure: Chocolate or cocoa providing 25-1,080 mg of cocoa polyphenols daily.

25 Coleus

Forskolin is a chemical found in the roots of the plant Plectranthus barbatus (Coleus forskohlii). This plant has been used since ancient times to treat heart disorders such as high blood pressure and chest pain (angina), as well as respiratory disorders such as asthma. When taken by mouth, forskolin is also used to treat allergies, skin conditions such as eczema and psoriasis, obesity, painful menstrual periods, irritable bowel syndrome (IBS), urinary tract infections (UTI), bladder infections, advanced cancer, blood clots, sexual problems in men, trouble sleeping (insomnia), and convulsions. Healthcare providers sometimes give forskolin intravenously (by IV) for heart failure. Some people breathe in (inhale) forskolin powder for asthma. Forskolin drops are used in the eyes to treat glaucoma. Herbal product manufacturers are now producing Coleus forskohlii extracts that contain high levels of forskolin. These preparations are being promoted for the same conditions for which forskolin has been traditionally used. However, currently there is no reliable scientific information that shows Coleus forskohlii extracts taken by mouth are effective. Forskolin works on muscles in the heart and in the walls of the blood vessels. It produces a more powerful heartbeat and widening of the blood vessels, which lowers blood pressure.

Uses

Possibly Effective

A heart condition called idiopathic congestive cardiomyopathy	Some research shows that giving coleus intravenously (by IV) may improve the function of the heart in people with congestive cardiomyopathy.
Asthma	Some research shows that inhaling a single dose of coleus can improve symptoms of asthma.

Insufficient Evidence

Erectile dysfunction (ED)	Early research suggests that injecting coleus into the base of the penis along with the drugs phentolamine, papaverine, and prostaglandin E1 improves sexual function in men with ED.
Increased pressure in the eyes	Some early research suggests that using coleus eye drops can significantly decrease eye pressure in healthy people without eye disease. Coleus has not yet been tested in patients with glaucoma.

Dosing

INTRAVENOUS
Healthcare providers give forskolin intravenously (by IV) for a heart condition called idiopathic congestive cardiopathy.

INHALATION
Under medical supervision, people with asthma breathe in forskolin powder using a Spinhaler inhalator.

26 Club Moss

NATURAL REMEDIES | Herbs | Club Moss

Club moss is an herb. People use the whole plant to make medicine. Despite safety concerns, people use club moss for bladder and kidney disorders, and as a diuretic to increase urine. Don't confuse club moss with Chinese club moss. Only Chinese club moss contains huperzine A, a chemical which is thought to be helpful in dementia, memory loss, and myasthenia gravis. There isn't enough information available to know how club moss works.

Uses

Insufficient Evidence

Dosing

The appropriate dose of club moss depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for club moss. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

27 Cassia Cinnamon

Cassia cinnamon is a type of cinnamon. It is prepared from the dried inner bark of a certain evergreen tree. In addition to cassia cinnamon, Cinnamomum verum (Ceylon cinnamon) is commonly used. The cinnamon spice found in food stores might contain both of these types of cinnamon. But, the most common cinnamon sold in North America is cassia cinnamon. People take Cassia cinnamon by mouth for diabetes and prediabetes, gas (flatulence), muscle and stomach spasms, preventing nausea and vomiting, diarrhea, infections, the common cold, and loss of appetite. Some people use it for erectile dysfunction (ED), hernia, bed-wetting, joint pain, menopausal symptoms, menstrual problems, and to cause abortions. Cassia cinnamon is also used for chest pain, kidney disorders, high blood pressure, cramps, and cancer. People apply cassia cinnamon to the skin to repel mosquitos. In food and beverages, cassia cinnamon is used as a flavoring agent. Cassia cinnamon contains hydroxychalcone and similar chemicals. These chemicals seem to improve insulin sensitivity. Cassia cinnamon also contains chemicals that may activate blood proteins that increase blood sugar uptake. These effects may improve blood sugar control in patients with diabetes. Cassia cinnamon also contains cinnamaldehyde. This chemical might have activity against bacteria and fungi. It also seems to stop the growth of some types of solid tumor cells.

Uses

Insufficient Evidence

Prediabetes	One small study shows that taking cassia cinnamon for 3 months does not help to control blood sugar or lower cholesterol in people with prediabetes.
Mosquito repellent	Early research suggests that applying cassia cinnamon oil cream to the skin can protect against mosquito bites. But, it seems to decrease in effectiveness faster than creams containing citronella and geranium oils or DEET.

Dosing

The appropriate dose of cassia cinnamon depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for cassia cinnamon. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

28 Chlorella

Chlorella is a type of algae that grows in fresh water. The whole plant is used to make nutritional supplements and medicine. Most of the chlorella that is available in the U.S. is grown in Japan or Taiwan. It is processed and made into tablets and liquid extracts. These extracts contain "chlorella growth factor," which is described as a water-soluble extract of chlorella containing chemicals including amino acids, peptides, proteins, vitamins, sugars, and nucleic acids. Be aware that chlorella products can vary significantly depending on the way "the crop" used to make them was cultivated, harvested, and processed. Investigators have found that dried preparation of chlorella can contain from 7% to 88% protein, 6% to 38% carbohydrate, and 7% to 75% fat. Chlorella is a good source of protein, fats, carbohydrates, fiber, chlorophyll, vitamins, and minerals. It may act as an antioxidant and help to decrease cholesterol, but more research is still needed.

Uses

Possibly Effective

Iron deficiency during pregnancy	Early research shows that taking chlorella might reduce the risk of anemia caused by too little iron in the body when taken by women who are pregnant.

Possibly Ineffective

Pregnancy-induced high blood pressure	Early research shows that taking chlorella during pregnancy does not reduce the risk of high blood pressure (gestational hypertension).

Insufficient Evidence

Depression	Early research shows that taking chlorella extract tablets for 6 weeks, in addition to already prescribed antidepressant medications, may improve some symptoms of depression and anxiety in patients with major depression disorder.
Fibromyalgia	Some people with fibromyalgia say they feel better when they take chlorella tablets plus a liquid extract containing malic acid daily for 2 months.
Brain tumor (gilioma)	Early research shows that taking chlorella tablets plus chlorella liquid extract might help people with a type of brain cancer called glioma better tolerate chemotherapy and radiation treatments. However, chlorella does not seem to slow the progression of the cancer or improve survival.
Hepatitis C	Early research shows that taking chlorella for 12 weeks improves liver inflammation but does not decrease levels of the hepatitis C virus in the blood.
High cholesterol	Early research shows that taking chlorella for 4 weeks decreases total cholesterol and triglycerides but does not decrease LDL "bad" cholesterol or increase HDL "good" cholesterol.
High blood pressure	Early research shows that taking chlorella daily for 1-2 months does not reduce blood pressure in people with high blood pressure.

Metabolic syndrome	Early research shows that taking a product containing a combination of red yeast rice, bitter melon, chlorella, licorice, and soy protein for 12 weeks decreases total cholesterol, LDL "bad" cholesterol, and triglyceride levels, but does not improve waist circumference, HDL "good" cholesterol, or blood sugar levels.

Dosing

ADULTS
BY MOUTH
For iron deficiency during pregnancy: Chlorella (Sun Chlorella A by Sun Chlorella Corp.) 2 grams three times daily has been taken from the 12-18th week of gestation, until delivery.

29 Camu Camu

Camu camu is a shrub that grows in swampy or flooded areas of the Amazon rain forests of Peru, Brazil, Venezuela, and Colombia. The fruit and leaves are used as a medicine. Camu camu is used for viral infections including herpes, cold sores, shingles, and the common cold. It is also used for eye conditions including cataracts and glaucoma. Other uses include treatment of asthma, "hardening of the arteries" (atherosclerosis), chronic fatigue syndrome, depression, gum disease (gingivitis), headaches, and osteoarthritis. Some people use camu camu to increase energy and maintain healthy gums, eyes, and skin; and as an antioxidant and immune system stimulant. People eat the fruit as food. Camu camu fruit contains many nutrients including vitamin C, beta-carotene, fatty acids, protein, and others. It also contains other chemicals that might have an effect on the body. However, there is not enough information to know how camu camu might work for treating or preventing any medical condition.

Uses

Insufficient Evidence

Dosing

The appropriate dose of camu camu depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for camu camu. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

30 Chickweed

Chickweed is a plant. The leaf is used to make medicine. People take chickweed for constipation, stomach and bowel problems, blood disorders, asthma and other lung diseases, obesity, a vitamin C deficiency disease called scurvy, a skin condition called psoriasis, rabies, itching, and muscle and joint pain. Chickweed is sometimes applied directly to the skin for skin problems including boils, abscesses, and ulcers. In foods, chickweed is eaten in salads or served as cooked greens. There isn't enough information to know how chickweed might work. While some people try chickweed for a vitamin C deficiency disease called scurvy, the amount of vitamin C in chickweed is too small to be effective.

Uses

Insufficient Evidence

Dosing

The appropriate dose of chickweed depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for chickweed. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

31 Comfrey

Comfrey is a plant. Even though this plant contains poisonous chemicals called pyrrolizidine alkaloids (PAs), the leaf, root, and root-like stem (rhizome) are used to make medicine. The amount of PAs found in comfrey changes according to the time of harvesting and the age of the plant. The roots have 10 times higher amounts of PAs than the leaves. Some products labeled "common comfrey" or Symphytum officinale actually contain the more poisonous "prickly comfrey" (Symphytum asperum) or "Russian comfrey" (Symphytum x uplandicum) species. Comfrey is used as a tea for upset stomach, ulcers, heavy menstrual periods, diarrhea, bloody urine, persistent cough, painful breathing (pleuritis), bronchitis, cancer, and chest pain (angina). It is also used as a gargle for gum disease and sore throat. Comfrey is applied to the skin for ulcers, wounds, joint inflammation, bruises, rheumatoid arthritis, swollen veins (phlebitis), gout, and fractures. The chemicals in comfrey might have a healing effect and reduce inflammation when applied to the skin. However, comfrey contains toxic chemicals that can be absorbed through the skin.

Uses

Possibly Effective

Back pain	Applying a comfrey extract ointment to the affected area for 5 days seems to decrease lower or upper back pain. Also applying a cream containing comfrey extract plus methyl nicotinate to the affected area for 5 days seems to decrease back pain when resting or moving.
Osteoarthritis	Applying a comfrey extract ointment to the affected area for 3 weeks or applying a specific cream containing comfrey extract, tannic acid, Aloe vera gel, eucalyptus oil, and frankincense oil to the affected are for 6-12 weeks seems to decrease pain in people with knee osteoarthritis.
Sprains	Early research shows that applying comfrey ointment to the affected area for up to 2 weeks improves mobility, decreases pain, and reduces tenderness and swelling of sprains. The effect of comfrey ointment in relieving pain and reducing swelling seems to be comparable to the effects of diclofenac gel.

Insufficient Evidence

NATURAL REMEDIES | Herbs | Comfrey

Bruises	Early research shows that applying comfrey directly to the skin for 2 weeks might decrease pain and tenderness of bruises.

Dosing

APPLIED TO THE SKIN
For back pain: About 4 grams of a specific ointment containing 35% comfrey root extract has been applied three times daily for 5 days. About 4 grams of another cream containing 35% comfrey plus 1.2% methyl nicotinate has also been applied three times daily for 5 days.

For osteoarthritis: About 2 grams of a specific ointment containing 35% comfrey root extract has been applied to the knee three times daily for 3 weeks. Also, about 3.5 grams of a specific cream containing comfrey extract, tannic acid, aloe vera gel, eucalyptus oil, and frankincense oil has been applied to the knee three times daily for 6-12 weeks.

For sprains: About 2 grams of a specific ointment containing 35% comfrey extract has been applied to ankle sprains four times daily for 8 days.

32 Catnip

Catnip is a plant. The flowering tops are used to make medicine. Catnip is used for trouble sleeping (insomnia); anxiety; migraine and other headaches; cold and other upper respiratory infections; flu; swine flu; fever; hives; worms; and gastrointestinal (GI) upset, including indigestion, colic, cramping, and gas (flatulence). It is also used as a tonic, for increasing urination, and for starting menstrual periods in girls with delayed onset of menstruation. Some people apply catnip directly to the skin for arthritis, hemorrhoids, and as a compress to relieve swelling. Some people also smoke catnip medicinally for respiratory conditions and recreationally for a "high." In manufacturing, catnip is used as a pesticide and insecticide. It is thought that the chemicals in catnip have a calming effect.

Uses

Insufficient Evidence

Mosquito repellent	Early research suggests that applying catnip oil or certain catnip chemicals to the skin may help repel yellow fever mosquitos. However, the commercial insect repellents SS220 and DEET might work better.

Dosing

The appropriate dose of catnip depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for catnip. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

33 Chaga

Chaga is a fungus. It produces a woody growth, called a conk, which is used to make medicine. People take chaga by mouth for heart disease, diabetes, stomach and intestine cancer, liver disease, parasites, stomach pain, and tuberculosis. Chaga might stimulate the immune system. It contains some chemicals that have antioxidant effects. Chaga might lower blood sugar and cholesterol levels.

Uses

Insufficient Evidence

Dosing

The appropriate dose of chaga depends on several factors such is the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for chaga. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

34 Cascara Sagrada

Cascara sagrada is a shrub. The dried bark is used to make medicine. Cascara sagrada used to be approved by the U.S. Food and Drug Administration (FDA) as an over-the-counter (OTC) drug for constipation. However, over the years, concerns were raised about cascara sagrada's safety and effectiveness. The FDA gave manufacturers the chance to submit safety and effectiveness information to answer these concerns. But the companies decided the cost of conducting safety and effectiveness studies would likely be more than the profit they could expect from sales of cascara sagrada. So they didn't comply with the request. As a result, the FDA notified manufacturers to remove or reformulate all OTC laxative products containing cascara sagrada from the U.S. market by November 5, 2002. Today, you can buy cascara sagrada as a "dietary supplement," but not as a drug. "Dietary supplements" don't have to meet the standards that the FDA applies to OTC or prescription drugs. Cascara sagrada is commonly used by mouth as a laxative for constipation. In foods and beverages, a bitterless extract of cascara sagrada is sometimes used as a flavoring agent. In manufacturing, cascara sagrada is used in the processing of some sunscreens.

Uses

Possibly Effective

Constipation	Cascara sagrada has laxative effects and may help relieve constipation in some people.

Possibly Ineffective

Bowel preparation before colonoscopy	Most research shows that taking cascara sagradaalong with magnesium sulfate or milk of magnesia does not improve bowel cleansing in people who are undergoing a colonoscopy.

Dosing

The appropriate dose of cascara sagrada depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for cascara sagrada. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

NATURAL REMEDIES | Herbs

35 Diatomaceous Earth

Diatomaceous earth is a type of powder made from the sediment of fossilized algae found in bodies of water. Because the cells of these algae were high in a compound called silica, the dried sediment produced from these fossils are also very high in silica. These deposits are found all over the world. The ancient Greeks used diatomaceous earth to make building materials, like bricks and blocks. Later on it became popular in Europe for various industrial uses. When taken by mouth, diatomaceous earth is used as a source of silica, for treating high cholesterol levels, for treating constipation, and for improving the health of skin, nails, teeth, bones, and hair. When applied to the skin or teeth, diatomaceous earth is used to brush teeth or remove unwanted dead skin cells. Diatomaceous earth is also used in industry. It is used to remove unwanted material from drinking water. It is also used as a filler or to prevent formation of lumps in foods, medicine, paints and plastics, and pet litter. It is used to clean up spills or for insulation in industry, as well as to scrub things. Diatomaceous earth is used as part of various chemical tests. It is also used as an insecticide. Diatomaceous earth is a powder containing about 80%-90% silica. Diatomaceous earth is thought to kill insects by dehydrating them or drying them out. Also, the powder allows liquids to flow through while capturing unwanted material.

Uses

Insufficient Evidence

High cholesterol levels	Early research suggests taking diatomaceous earth might reduce levels of cholesterol in the blood patients with high cholesterol levels.

Dosing

The appropriate dose of diatomaceous earth depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for diatomaceous earth in children or adults. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

36 Devil's Claw

Devil's claw is an herb. The botanical name, Harpagophytum, means "hook plant" in Greek. This plant gets its name from the appearance of its fruit, which is covered with hooks meant to attach onto animals in order to spread the seeds. The roots and tubers of the plant are used to make medicine. Devil's claw is used for "hardening of the arteries" (atherosclerosis), arthritis, gout, muscle pain (myalgia), back pain, fibromyalgia, tendonitis, chest pain, gastrointestinal (GI) upset or heart burn, fever, and migraine headache. It is also used for difficulties in childbirth, menstrual problems, allergic reactions, loss of appetite, and kidney and bladder disease. Some people apply devil's claw to the skin for injuries and other skin conditions. Devil's claw contains chemicals that might decrease inflammation and swelling and resulting pain.

Uses

Possibly Effective

Back pain	Taking devil's claw by mouth seems to reduce low-back pain. Devil's claw seems to work about as well as some non-steroidal anti-inflammatory drugs (NSAIDs).
Osteoarthritis	Taking devil's claw alone or along with nonsteroidal anti-inflammatory drugs (NSAIDs) seems to help decrease osteoarthritis-related pain. Some evidence suggests that devil's claw works about as well as diacerhein (a slow-acting drug for osteoarthritis that is not available in the U.S.) for improving osteoarthritis pain in the hip and knee after 16 weeks of treatment. Some people taking devil's claw seem to be able to lower the dose of NSAIDs they need for pain relief.

Insufficient Evidence

Rheumatoid arthritis (RA)	Early research suggests that taking devil's claw extract by mouth might not improve RA.

Dosing

BY MOUTH
For osteoarthritis: 2-2.6 grams of devil's claw extract have been taken in up to three divided doses daily for up to 4 months. A specific combination product providing 600 mg of devil's claw, 400 mg of turmeric, and 300 mg of bromelain has been taken 2-3 three times daily for up to 2 months.

For back pain: 0.6-2.4 grams of devil's claw extract has been taken daily, usually in divided doses, for up to 1 year.

37 Dandelion

Dandelion is an herb. People use the above ground parts and root to make medicine. Dandelion is used for many conditions, but so far, there isn't enough scientific evidence to determine whether or not it is effective for any of them. Dandelion is used for loss of appetite, upset stomach, intestinal gas, gallstones, joint pain, muscle aches, eczema, and bruises. Dandelion is also used to increase urine production and as a laxative to increase bowel movements. It is also used as skin toner, blood tonic, and digestive tonic. Some people use dandelion to treat infection, especially viral infections, and cancer. In foods, dandelion is used as salad greens, and in soups, wine, and teas. The roasted root is used as a coffee substitute. Dandelion contains chemicals that may increase urine production and decrease swelling (inflammation).

Uses

Insufficient Evidence

Inflammation of the tonsils (Tonsillitis)	An early study found that people who had their tonsils removed recovered faster if they ate soup containing dandelion compared to those who ate soup without dandelion.
Preventing urinary tract infections (UTIs)	A specific combination of dandelion root and leaf extracts of another herb called uva ursi taken by mouth seems to help reduce the number of UTIs in women. In this combination, uva ursi is used because it seems to kill bacteria, and dandelion is used to increase urine flow. However, this combination should not be used long-term because it is not known if uva ursi is safe for extended use.

Dosing

The appropriate dose of dandelion depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for dandelion. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

38 Damiana

Damiana is a wild shrub that grows in Mexico, Central America, and the West Indies. The leaf and stem are used to make medicine. Historically, it was used mostly to increase sexual desire (as an aphrodisiac). Damiana is commonly used by mouth as an aphrodisiac and to treat sexual problems. It is also used to treat stomach complains such as dyspepsia, diarrhea, and constipation and to improve symptoms of menopause and premenstrual syndrome (PMS). But there is little scientific evidence to support its use for any of these conditions. Some people inhale damiana for a slight "high." Damiana contains chemicals that may affect the brain and nervous system.

Uses

Insufficient Evidence

Sexual problems	Early research suggests that taking a specific combination product containing damiana, L-arginine, American ginseng, Panax ginseng, ginkgo, vitamins, and minerals might improve sexual satisfaction, increase orgasm frequency, and reduce vaginal dryness in women with sexual problems who are interested in improving their sex lives.
Weight loss	Early research suggests that taking a specific combination product containing damiana, guarana, and yerba mate might reduce body weight in people who are overweight.

Dosing

The appropriate dose of damiana depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for damiana. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

39 Dong Quai

Dong quai is a plant. The root is used to make medicine. Dong quai is commonly taken by mouth for menopausal symptoms, menstrual cycle conditions such as migraines and many other conditions. Dong quai root has been shown to affect estrogen and other hormones in animals. It is not known if these same effects happen in humans.

Uses

Possibly Effective

Menopausal symptoms	Various combination products that contain dong quai seem to reduce menopausal symptoms. Taking a specific product containing dong quai and chamomile (Climex) seems to reduce hot flushes in menopausal women. Taking a specific product containing American ginseng, black cohosh, dong quai, milk thistle, red clover, and vitex agnus-castus (Phyto-Female complex) seems to reduce hot flushes and night sweats and improve sleep quality in pre- and post-menopausal women. Taking a product containing burdock root, licorice root, motherwort, dong quai, and Mexican wild yam root seems to reduce menopausal symptoms as well. However, some evidence suggests that taking dong quai alone does to improve symptoms of menopause.
Premature ejaculation	When applied directly to the skin of the penis in combination with other herbs. The other herbs are Panax ginseng root, Cistanches deserticola, Zanthoxyl species, Torlidis seed, clove flower, Asiasari root, cinnamon bark, and toad venom (SS Cream).

Insufficient Evidence

Heart disease	Some early research shows that a natural medicine containing dong quai and other herbs given by injection might reduce chest pain, and improve heart function in people with heart disease.
High blood pressure in arteries carrying blood from the heart to the lungs (pulmonary hypertension)	Some early research shows that dong quai given by injection might reduce blood pressure and improve blood flow in people with chronic obstructive pulmonary disorder (COPD) and pulmonary hypertension.
Menopausal symptoms	Some early research shows that taking dong quai does not reduce hot flashes.
Stroke	Some rarly research shows that dong quai given by injection for 20 days does not improve brain function in people who had a stroke.

Dosing

BY MOUTH
For menopausal symptoms: 15 chewable tablets of a product containing dong quai and chamomile (Climex) have been taken daily for 12 weeks. A specific product containing American ginseng, black cohosh, dong quai, milk thistle, red clover, and vitex agnus-castus (Phyto-Female Complex) has been taken twice daily for 3 months. A specific product containing burdock root, licorice root, motherwort, dong quai, and Mexican wild yam root has been taken three times daily for 3 months.

APPLIED TO THE SKIN
For early orgasm in men (premature ejaculation): A specific cream containing Panax ginseng root, dong quai, Cistanches deserticola, Zanthoxyl species, Torlidis seed, clove flower, Asiasari root, cinnamon bark, and toad venom (SS Cream) has been applied to the glans penis 1 hour before sex and washed off immediately before sex.

40 Euphorbia

Euphorbia is an herb. The parts of the plant that grow above the ground are used to make medicine. Euphorbia is used for breathing disorders including asthma, bronchitis, and chest congestion. It is also used for mucus in the nose and throat, throat spasms, hay fever, and tumors. Some people use it to cause vomiting. In India, it is also used for treating worms, severe diarrhea (dysentery), gonorrhea, and digestive problems. Some researchers have studied how euphorbia might work in animals, but there isn't enough information to know how euphorbia might work in people.

Uses

Insufficient Evidence

NATURAL REMEDIES
Herbs
Euphorbia

Dosing

The appropriate dose of euphorbia depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for euphorbia. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

41 Horny Goat Weed (Epimedium)

Horny goat weed is an herb. The leaves are used to make medicine. As many as 15 horny goat weed species are known as "yin yang huo" in Chinese medicine. Horny goat weed is commonly used by mouth for sexual performance problems, such as erectile dysfunction (ED) and low sexual desire. It is also used for weak back and knees, joint pain, arthritis, mental and physical fatigue, and memory loss along with many other conditions. But there is limited scientific research to support any of these uses. Horny goat weed contains chemicals which might help increase blood flow and improve sexual function. It also contains phytoestrogens, chemicals that act somewhat like the female hormone estrogen. This might reduce bone loss in postmenopausal women.

Uses

Insufficient Evidence

Osteoporosis	Taking a specific extract of horny goat weed for 24 months in combination with calcium supplements decreases bone loss of the spine and hip in women who have passed menopause better than taking calcium alone. Chemicals in the extract act somewhat like the hormone estrogen.
Postmenopausal conditions	Taking horny goat weed water extract for 6 months can decrease cholesterol and increase estrogen levels in postmenopausal women.

Dosing

The appropriate dose of horny goat weed depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for horny goat weed. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

42 Evodia

Evodia is a tree that is native to China and Korea. Evodia fruit, which has a strong bitter taste, is commonly used in Traditional Chinese Medicine. The fruit and root bark are also used as medicine in other herbal practice. Evodia is used for digestion problems including diarrhea, dysentery, nausea, vomiting, abdominal pain, gastroesophageal reflux disease (GERD), stomach ulcers, and lack of appetite. It is also used for obesity, headache, high blood pressure, congestive heart failure (CHF), infections caused by viruses, Alzheimer's disease, cancer, and fluid retention. Women use evodia to prevent pregnancy, start their periods, and treat bleeding after giving birth. Evodia root bark is used for infections caused by parasites such as tapeworm and pinworm. Chemicals contained in evodia might have several effects in the body. They might decrease pain and swelling (inflammation), decrease diarrhea, decrease blood pressure, stimulate the heart, and have many other effects. But these effects have only been shown in animals. There is not enough information to know if evodia has these effects in people.

Uses

Insufficient Evidence

Dosing

The appropriate dose of evodia depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for evodia. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

43 Goat's Rue

Goat's rue is a plant. The parts that grow above the ground are used to make medicine. Be careful not to confuse goat's rue (Galega officinalis) with rue (Ruta graveolens). Goat's rue is used along with conventional treatment for diabetes and as a diuretic. In combination with other herbs, goat's rue is used to stimulate the adrenal gland and pancreas; to protect the liver; for digestion problems; and to start the flow of breast milk. Some people use herbal combinations that include goat's rue as a tonic and for "blood purification." Goat's rue contains a chemical that may lower blood sugar in a test tube. But it is unclear if goat's rue has this effect when taken by people.

Uses

Insufficient Evidence

Dosing

The appropriate dose of goat's rue depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for goat's rue. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

44 Ginko

NATURAL REMEDIES Herbs Ginko

Ginkgo is a large tree with fan-shaped leaves. Although Ginkgo is a native plant to China, Japan, and Korea, it has been grown in Europe since around 1730 and in the United States since around 1784. The ginkgo tree is thought to be one of the oldest living trees, dating back to more than 200 million years. Ginkgo leaf is often taken by mouth for memory disorders including Alzheimer's disease. It is also used for conditions that seem to be due to reduced blood flow in the brain, especially in older people. These conditions include memory loss, dizziness, difficulty concentrating, and mood disturbances. Some people use it for leg pain when walking related to poor blood flow (claudication). The list of other uses of ginkgo is very long. This may be because this herb has been around for so long. Ginkgo biloba is one of the longest living tree species in the world. Ginkgo trees can live as long as a thousand years. Using ginkgo for asthma and bronchitis was described in 2600 BCE. In manufacturing, ginkgo leaf extract is used in cosmetics. In foods, roasted ginkgo seed, which has the pulp removed, is an edible delicacy in Japan and China. Ginkgo seems to improve blood circulation, which might help the brain, eyes, ears, and legs function better. It may act as an antioxidant to slow down Alzheimer's disease and interfere with changes in the brain that might cause problems with thinking. Ginkgo seeds contain substances that might kill the bacteria and fungi that cause infections in the body. The seeds also contain a toxin that can cause serious side effects like seizures and loss of consciousness.

Uses

Possibly Effective

Anxiety	Research shows that taking a ginkgo extract for 4 weeks can reduce symptoms of anxiety.
Dementia related to Alzheimer's disease	Some research shows that taking ginkgo for up to one year slightly improves some symptoms of Alzheimer's, vascular, or other dementias. Doses of 240 mg per day might work better than doses of 120 mg per day. However, there are concerns that findings from many of these studies may not be reliable. While most research shows that ginkgo helps for symptoms of Alzheimer's disease and other dementias, there are some conflicting findings. This makes it hard to determine which people might benefit. While ginkgo may help treat the symptoms of various types of dementia, ginkgo does not appear to help prevent dementia from developing. Also, it does not appear to prevent Alzheimer's related dementia from getting worse. Early research shows that taking a specific ginkgo leaf extract called EGb 761 (Dr. Willmar Schwabe Pharmaceuticals) daily for 22-24 weeks seems to be as effective as the drug donepezil (Aricept) for treating mild to moderate Alzheimer's disease. But, other research suggests that ginkgo leaf extract might be less effective than the conventional drugs donepezil (Aricept) and tacrine (Cognex). Taking ginkgo together with prescription medications like donepezil or rivastigmine does not appear to be better than taking the medication alone for the symptoms of Alzheimer's disease.
Vision problems in people with diabetes	There is some evidence that taking ginkgo leaf extract by mouth for 6 months can improve color vision in people with retinal damage caused by diabetes.
Vision loss related to glaucoma	Taking ginkgo leaf extract by mouth for up to 12.3 years seems to improve pre-existing damage to the visual field in some people with glaucoma. However, since conflicting research shows that ginkgo does not prevent glaucoma progression when taken for only 4 weeks, it may need to be taken for a longer time in order to see any improvement.
Leg pain when walking related to poor blood flow (peripheral vascular disease).	Some evidence shows that taking ginkgo leaf extract increases the distance people with poor blood circulation in their legs can walk without pain. Taking ginkgo might also reduce the chance of requiring surgery. However, people with this condition may need to take ginkgo for at least 24 weeks before they see improvement.
Premenstrual syndrome (PMS)	Taking ginkgo leaf extract by mouth seems to relieve breast tenderness and other symptoms associated with PMS when started during the 16th day of the menstrual cycle and continued until the 5th day of the following cycle.
Schizophrenia	Research shows that taking ginkgo daily in addition to conventional antipsychotic medications for 8-16 weeks can reduce symptoms of schizophrenia. It may also reduce some side effects like thirst and constipation and adverse effects associated with the antipsychotic medication, haloperidol.
A movement disorder called tardive dyskinesia. Tardive dyskinesia is a movement disorder that is caused by certain antipsychotic drugs.	Research shows that taking a specific ginkgo extract (EGb 761, Yi Kang Ning, Yang Zi Jiang Pharmaceuticals Ltd., Jiangsu, China) for 12 weeks can reduce the severity of tardive dyskinesia symptoms in people with schizophrenia who are taking antipsychotic drugs.
Dizziness (vertigo)	Taking ginkgo leaf extract by mouth seems to improve symptoms of dizziness and balance disorders.

Possibly Ineffective

Sexual dysfunction caused by antidepressant drugs	Although some early research suggests that taking ginkgo leaf extract by mouth might improve sexual problems caused by antidepressant drugs, more recent research suggests it is probably not effective.
Mental problems caused by chemotherapy.	Research shows that taking a specific ginkgo leaf extract called EGb 761 (Dr. Willmar Schwabe Pharmaceuticals) twice daily starting before the second cycle of chemotherapy and continuing until one month after chemotherapy treatment ends does not prevent mental problems caused by the chemotherapy in people being treated for breast cancer.
High blood pressure	Research shows that taking a specific ginkgo leaf extract (EGb 761) by mouth for up to 6 years does not reduce blood pressure in older people with high blood pressure.
Multiple sclerosis	Taking ginkgo leaf extract or ginkgolide B, a specific chemical found in ginkgo extract, does not improve mental function or disability in people with multiple sclerosis.
Seasonal depression (seasonal affective disorder)	Taking ginkgo leaf extract by mouth does not seem to prevent winter depression symptoms in people with seasonal depression.
Ringing in the ears (tinnitus)	Taking ginkgo leaf extract by mouth does not seem to improve ringing in the ears.

Likely Ineffective

Heart disease	Taking a specific ginkgo extract (EGb 761, Dr. Willmar Schwabe Pharmaceuticals) does not reduce the chance of having a heart attack, chest pain, or stroke in elderly people.

Insufficient Evidence

Age-related vison loss (age-related macular degeneration)	There is some early evidence that ginkgo leaf extract might improve symptoms and distance vision in people with age-related vision loss.
Hayfever (allergic rhinitis)	Early research shows that applying specific eye drops (Trium, SOOFT) that contain ginkgo extract and hylauronic acid three times daily for one month can reduce eye redness, swelling and discharge in people with swollen eyes due to seasonal allergies.

Altitude sickness	Research on the effects of ginkgo leaf extract on altitude sickness is inconsistent. Some research suggests that taking ginkgo leaf extract can reduce altitude sickness symptoms when taken 4 days before climbing. However, other research shows that using a specific ginkgo extract (GK501, Pharmaton Natural Health Products) for 1-2 days before climbing does not prevent altitude sickness.
Asthma	Research shows that taking two capsules of a specific product containing ginkgo extract, ginger, and Picrorhiza kurroa (AKL1, AKL International Ltd) twice daily for 12 weeks does not improve lung function or asthma symptoms in adults with asthma.
Attention deficit-hyperactivity disorder (ADHD)	The effect of ginkgo on symptoms related to ADHD is unclear. There is early evidence that a product containing ginkgo leaf extract and American ginseng might help improve ADHD symptoms such as anxiety, hyperactivity, and impulsiveness in children 3-17 years-old. But other research shows that taking ginkgo extract does not improve ADHD symptoms compared to methylphenidate, a drug used to treat ADHD, in children 6-14 years-old. Also, taking gingko extract along with methylphenidate does not seem to greatly improve parent or teacher reported ADHD symptoms compared to methylphenidate alone in children 6-12 years-old.
Autism	Research shows that taking a specific ginkgo extract (Ginko T.D. Tolidaru Pharmaceuticals) daily for 10 weeks along with conventional medication does not improve autism symptoms in children.
A lung disease called chronic obstructive pulmonary disease (COPD)	Research shows that taking a specific product that contains ginkgo extract, ginger, and Picrorhiza kurroa (AKL1, AKL International Ltd) twice daily for 8 weeks does not improve lung function in people with COPD.
Cocaine addiction	Research suggests that taking a ginkgo leaf extract called EGb 761 twice daily for 10 weeks does not help people with a cocaine addiction.
Mental function	The effect of gingko leaf extract on mental function and memory in healthy adults is not clear. Some research shows that ginkgo might improve memory, speed of thinking, and attention in healthy adults. But other research shows no benefit. More studies are needed to determine the effect of gingko on mental function in healthy adults.
Colorectal cancer	Early research suggests that using a specific ginkgo leaf extract (EGb 761, ONC) intravenously (by IV) together with anticancer drugs might benefit people with advanced colorectal cancer.
Dyslexia	Early research suggests that taking a specific ginkgo leaf extract (EGb 761) for about 30 days might reduce dyslexia in children aged 5-16 years.
Fibromyalgia	Early research suggests that taking specific ginkgo leaf extract tablets (Bio- Biloba, Pharma Nord) together with coenzyme Q-10 capsules (Bio Quinone Q10, Pharma Nord) by mouth for 84 days might increase feelings of wellness and perception of overall health and reduce pain in people with fibromyalgia.
Stomach cancer	Early research suggests that taking carbohydrates from the outer layer of the ginkgo fruit by mouth twice daily for 30 days might reduce tumor size in people with stomach cancer.
Hearing loss	There is some early evidence that taking ginkgo might help short-term hearing loss due to unknown causes. However, many of these people recover hearing on their own. It is hard to know if ginkgo has any effect.
Hemorrhoids	Early research suggests that taking a combination of ginkgo and certain conventional medications might decrease some symptoms of hemorrhoids, including bleeding and pain.
Headaches related to migraines	Early research shows that taking ginkgolide B, a chemical found in ginkgo leaf extract, might help prevent migraines in children and women.
Ovarian cancer	Evidence suggests that using ginkgo leaf extract for 6 months is associated with a decreased risk of developing ovarian cancer.
Pancreatic cancer	Early research suggests that taking a specific injectable form of ginkgo leaf extract (EGb 761) intravenously (by IV) together with anticancer drugs might slow the progression of pancreatic cancer in some people.
Quality of life	Early evidence suggests that taking ginkgo extract (LI 1370, Lichtwer Pharma) for 6 months might improve quality of life measures such as activities in daily living, mood, sleep, and alertness in older people.
Radiation exposure	Early research suggests that taking a specific ginkgo leaf extract (EGb 761, Tanakan Ipsen) might reduce some of the negative effects of radiation on the body.
Skin toxicity caused by radiation	Early research suggests that applying a specific cream product (Radioskin 2, Herbalab di Perazza Massimiliano Company) that contains ginkgo extract, Aloe vera, and metal esculetina along with another product (Radioskin 1, Herbalab di Perazza Massimiliano Company) might improve skin moisture and reduce skin adverse events in breast cancer patients receiving radiation treatments.
Blood vessel disorder (Raynaud's syndrome)	Some research suggests that taking ginkgo leaf extract for 10 weeks by mouth might decrease the number of painful attacks per week in people with a blood vessel disorder called Raynaud's syndrome. However, other research suggests that ginkgo is not beneficial or is less effective than drugs such as nifedipine.
Sexual dysfunction	Some research shows that taking ginkgo leaf extract daily for 8 weeks does not improve sexual function in women with sexual arousal disorder. However, taking a specific combination product containing ginkgo, ginseng, damiana, L-arginine, multivitamins, and minerals (ArginMax for Women) for 4 weeks appears to improve sexual satisfaction in women with sexual dysfunction.
Stroke	The effect of ginkgo on recovery in people who have had a stroke caused by blocked blood vessels is not clear. Some evidence suggests that people might improve more after a stroke when treated with ginkgo. However, higher quality research shows no benefit.
Skin discolorations (Vitiligo)	There is some early research that taking a specific ginkgo leaf extract (Ginkgo Plus, Seroyal) might decrease the size and spread of skin lesions.

Dosing

NATURAL REMEDIES | Herbs | Ginko | Dosing

BY MOUTH:

For anxiety: 80 mg or 160 mg of a ginkgo leaf extract called EGb 761 has been taken three times per day for 4 weeks.

For all uses, start at a lower dose of not more than 120 mg per day to avoid gastrointestinal (GI) side effects. Increase to higher doses indicated as needed. Dosing may vary depending on the specific formulation used. Most researchers used specific standardized Ginkgo biloba leaf extracts. Some people take 0.5 mL of a standard 1:5 tincture of the crude ginkgo leaf three times daily. You should avoid crude ginkgo plant parts. These can contain dangerous levels of the toxic chemicals found in the seed of the plant and elsewhere. These chemicals can cause severe allergic reactions.

For dementia	60-480 mg per day of ginkgo leaf extract ,divided in two or three doses, has been taken for up to one year. The most commonly studied dose is 120-240 mg per day with 240 mg possibly being more effective. Most of the clinical studies on the effectiveness of ginkgo leaf for dementia have used the standardized extracts EGb 761 (Dr. Willmar Schwabe Pharmaceuticals and Ipsen) and LI 1370 (Lichtwer Pharma).
For retinal damage caused by diabetes	120 mg of a ginkgo leaf extract called EGb 761 has been taken daily for 6 months.
For walking leg pain related to poor circulation (claudication, peripheral vascular disease)	120-240 mg per day of ginkgo leaf extract (EGb 761), divided into two or three doses, has been used for up to 6.1 years. The higher dose may be more effective.
For dizziness (vertigo)	160 mg of a ginkgo leaf extract called EGb 761 has been taken once daily or in two divided doses daily for 3 months.
For premenstrual syndrome (PMS)	80 mg of a ginkgo leaf extract called EGb 761 has been taken twice daily, starting on the sixteenth day of the menstrual cycle until the fifth day of the next cycle. Also 40 mg of a ginkgo leaf extract called Ginko T.D. has been taken three times daily starting on the sixteenth day of the menstrual cycle until the fifth day of the next cycle.
For vision loss related to glaucoma	120 to 160 mg of ginkgo leaf extract has been taken in two or three divided doses per day for up to 12.3 years.
For schizophrenia	120-360 mg of a ginkgo leaf extract called EGb 761 (Yi Kang Ning, Yang Zi Jiang Pharmaceuticals Ltd., Jiangsu, China) has been used daily for 8-16 weeks.
For the movement disorder called tardive dyskinesia	80 mg of a ginkgo leaf extract called EGb 761, three times daily for 12 weeks, has been used.

45 Gotu Kola

Gotu kola is an herb that is commonly used in Traditional Chinese and Ayurvedic medicine. The above-ground parts are used to make medicine. Gotu kola is used to treat bacterial, viral, or parastitic infections such as urinary tract infection (UTI), shingles, leprosy, cholera, dysentery, syphilis, the common cold, influenza, H1N1 (swine) flu, elephantiasis, tuberculosis, and schistosomiasis. Gotu kola is also used for fatigue, anxiety, depression, psychiatric disorders, Alzheimer's disease, and improving memory and intelligence. Other uses include wound healing, trauma, and circulation problems (venous insufficiency) including varicose veins, and blood clots in the legs. Some people use gotu kola for sunstroke, tonsillitis, fluid around the lungs (pleurisy), liver disease (hepatitis), jaundice, systemic lupus erythematosus (SLE), stomach pain, diarrhea, indigestion, stomach ulcers, epilepsy, asthma, "tired blood" (anemia), diabetes, and for helping them live longer. Some women use gotu kola for preventing pregnancy, absence of menstrual periods, and to arouse sexual desire. Gotu kola is sometimes applied to the skin for wound healing and reducing scars, includiung stretch marks caused by pregnancy. Gotu kola contains certain chemicals that seem to decrease inflammation and also decrease blood pressure in veins. Gotu kola also seems to increase collagen production, which is important for wound healing.

Uses

Possibly Effective

Decreased return of blood from the feet and legs back to the heart (venous insufficiency)	Taking gotu kola or a specific extract of gotu kola (Centellase) by mouth for 4-8 weeks seems to improve blood circulation and reduce swelling in people with poor blood circulation in the legs.

Insufficient Evidence

Hardening of the arteries (atherosclerosis)	People with atherosclerosis have fatty deposits called plagues along the lining of their blood vessels. There is some evidence that taking gotu kola for 12 months might help stabilize these plaques so they are less likely to break off and trigger clot formation, causing a heart attack or stroke.
Mental function	Early research suggests that taking a combination of gotu kola, ginkgo, and docosahexaenoic acid (DHA) for 4 months does not improve mental function in healthy elderly adults.
Preventing blood clots in the legs while flying	Gotu kola might help prevent blood clots related to long plane flights. Developing evidence suggests that gotu kola might decrease fluid and improve blood circulation in people traveling on airplanes for more than 3 hours. However, it is not known if this finding translates into fewer blood clots.
Increasing circulation in people with diabetes	Taking gotu kola for 6-12 months might help increase circulation and decrease fluid retention in people with diabetes whose small blood vessels have been damaged by their disease.
Poor brain function related to liver disease	Early research suggests that taking a specific product containing gotu kola, brahmi, ginkgo, cat's claw, and rosemary (CognoBlend) twice daily for 5 weeks, in addition to standard therapy, improves symptoms in people with poor brain function related to liver disease better than standard therapy.
Excess scar tissue (keloids)	There is some evidence that applying and extract of gotu kola known as madecassol to the skin might help reduce excess scar tissue.
Red, scaly skin (psoriasis)	Some evidence suggests that applying gotu kola on the skin might help reduce symptoms of psoriasis.
Scarring	Early research suggests that applying a specific gotu kola cream (Alpha centella, not available in the U.S.) to the skin twice daily for 6-8 weeks after the removal of stitches might help reduce scarring.
Schistosomiasis	There is some evidence that gotu kola injected by a healthcare provider might help bladder wounds caused by a parasitic infection called schistosomiasis.

Stretch marks associated with pregnancy	Early research suggests that applying a specific mixture of gotu kola, vitamin E, and a collagen compound in a cream (Trofolastin, not available in the U.S.) daily during the last 6 months of pregnancy might reduce stretch marks. There is also some evidence that another specific mixture of gotu kola, vitamin E, essential fatty acids, hyaluronic acid, elastin, and menthol in an ointment (Verum, not available in the U.S.) might help prevent stretch marks during pregnancy.
Wound healing	Some evidence suggests that applying gotu kola on the skin might help improve wound healing.

Dosing

BY MOUTH
For blood circulation problems in the legs (venous insufficiency): 60-180 mg daily of gotu kola extract.

46 Guarana

Guarana is a plant. It is named for the Guarani tribe in the Amazon, who used its seeds to brew a drink. Today, guarana seeds are still used as medicine. People take guarana for weight loss, athletic performance, mental performance, to increase energy, as an aphrodisiac, and for many other conditions, but there is no good scientific evidence to support these uses. Guarana can also be unsafe when taken long-term in large amounts. Guarana contains caffeine. Caffeine works by stimulating the central nervous system (CNS), heart, and muscles. Guarana also contains theophylline and theobromine, which are chemicals similar to caffeine.

Uses

Insufficient Evidence

Anxiety	Early research shows that taking a product containing hawthorn, black horehound, passionflower, valerian, cola nut, and guarana can reduce anxiety in some people. It is not clear if guarana alone is beneficial.
Lack of appetite in patients with cancer	Early research shows that taking guarana extract slightly improves appetite and prevents weight loss in people with cancer who have lost their appetite and are losing weight. But the benefit is very small.
Chemotherapy-related fatigue	Some research shows that taking guarana can reduce feelings of tiredness in some people undergoing chemotherapy. But conflicting results exist.
Mental performance	Early research in healthy people shows that taking a single dose of guarana extract can improve thinking speed and some aspects of memory. However, other research shows that taking guarana does not improve mental function in adults or older people.
Exercise tolerance	Research shows that taking a single dose of a product containing guarana, B vitamins, vitamin C, and minerals improves exercise tolerance in trained athletes by a very small amount. It is not clear if guarana alone is beneficial.
Weight loss	Taking guarana along with mate and damiana seems to increase weight loss. There is also developing evidence that taking a specific combination product containing guarana, ephedra, and 17 other vitamins, minerals, and supplements helps reduce weight by approximately 2.7 kg over 8 weeks when used with a low-fat diet and exercise. It is not clear if guarana alone is beneficial.
Feelings of well-being	Early research shows that taking guarana does not improve feelings of mood in healthy individuals.
Radiation sickness	Research shows that taking guarana does not improve symptoms of depression or tiredness in people undergoing radiation treatment.

Dosing

The appropriate dose of guarana depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for guarana. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

47 Graviola

Graviola is a small evergreen tree. The leaves, fruit, seeds, and stem are used to make medicine. Some people take graviola by mouth for infections caused by bacteria and parasites, cancer, diabetes, and to cause vomiting. Some people apply graviola directly to the skin for use as an insect repellent, but there is no good scientific evidence to support any of these uses. In foods, graviola is used in cooking and beverages. Graviola contains many chemicals that may be active against cancer, as well as disease-causing agents such as bacteria, viruses, and parasites.

Uses

Insufficient Evidence

Dosing

The appropriate dose of graviola depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for graviola. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

48 American Ginseng

American ginseng (Panax quinquefolis) is an herb that grows mainly in North America. Wild American ginseng is in such high demand that it has been declared a threatened or endangered species in some states in the United States. People take American ginseng by mouth for stress, to boost the immune system, and as a stimulant. American ginseng is often used to fight infections such as colds and flu. There is some evidence that it might help prevent colds and flu and make symptoms milder when infections do occur. American ginseng is used for other infections including HIV/AIDS, infections of the intestine (dysentery), and particular infections (Pseudomonas infections) that are common in people with cystic fibrosis. Some people use American ginseng to improve digestion and for loss of appetite, as well as for vomiting, inflammation of the colon (colitis), and inflammation of the lining of the stomach (gastritis).

American ginseng is also used for low iron in the blood (anemia), diabetes, insulin resistance related to HIV treatments, cancer-related fatigue, high blood pressure, trouble sleeping (insomnia), nerve pain, erectile dysfunction (ED), fever, hangover symptoms, attention deficit-hyperactivity disorder (ADHD), blood and bleeding disorders, breast cancer, dizziness, headaches, convulsions, fibromyalgia, "hardening of the arteries" (atherosclerosis), memory loss, rheumatoid arthritis, schizophrenia, improving athletic performance, improving mental performance, as an anti-aging aid, menopausal symptoms, complications during pregnancy or childbirth, and for nervous exhaustion (neurasthenia). You may also see American ginseng listed as an ingredient in some soft drinks. Oils and extracts made from American ginseng are used in soaps and cosmetics. Don't confuse American ginseng with Siberian ginseng (Eleutherococcus senticosus) or Asian ginseng (Panax ginseng). They have different medicinal effects. American ginseng contains chemicals called ginsenosides that seem to affect insulin levels in the body and lower blood sugar. Other chemicals, called polysaccharides, might affect the immune system.

Uses

Possibly Effective

Diabetes	Taking 3 grams of American ginseng by mouth, up to two hours before a meal, can lower blood sugar after a meal in patients with type 2 diabetes. However, larger doses do not seem to have a greater effect. Taking 100-200 mg of American ginseng by mouth for 8 weeks might also help lower pre-meal blood sugar levels in patients with type 2 diabetes. Different American ginseng products may have different effects. Researchers think that is because they contain different amounts of the active chemicals called ginsenosides.
Respiratory tract infections	Some research suggests that taking a specific American ginseng extract called CVT-E002 (Cold-FX, Afexa Life Sciences, Canada) 200 mg twice daily for 3-4 months during flu season might prevent cold or flu symptoms in adults between the ages of 18 and 65. People older than 65 seem to need a flu shot at month 2 along with this treatment in order to decrease their risk of getting the flu or colds. This extract also seems to help make symptoms milder and last a shorter length of time when infections do occur. Some evidence suggests that the extract might not reduce the chance of getting the first cold of a season, but it seems to reduce the risk of getting repeat colds in a season. However, it might not help prevent cold or flu-like symptoms in patients with weakened immune systems.

Possibly Ineffective

Athletic performance	Taking 1600 mg of American ginseng by mouth for 4 weeks does not seem to improve athletic performance. But it might decrease muscle damage during exercise.

Insufficient Evidence

Insulin resistance caused by HIV treatment	Early research shows that taking capsules containing 1 gram of American ginseng root three times daily for 14 days while receiving the drug indinavir, which is a type of HIV therapy, does not reduce insulin resistance caused by indinavir in healthy people.
Attention deficit-hyperactivity disorder (ADHD)	There is early evidence that a specific product (AD-fX, Afexa Life Sciences, Canada) containing American ginseng extract in combination with ginkgo leaf extract might help improve ADHD symptoms such as anxiety, hyperactivity, and impulsiveness in children aged 3-17 years.
Breast cancer	Some studies conducted in China suggest that breast cancer patients treated with any form of ginseng (American or Panax) do better and feel better. However, this may not be a result of taking the ginseng, because the patients in the study were also more likely to be treated with the prescription cancer drug tamoxifen. It is difficult to know how much of the benefit to attribute to ginseng.
Cancer-related fatigue	Research on the effects of American ginseng in people with fatigue related to cancer is not consistent. One study shows that taking 700-2000 mg of American ginseng daily for 8 weeks does not reduce fatigue in people with cancer. However, other research shows that taking 2000 mg of American ginseng in two doses daily for 8 weeks reduces fatigue by 51%. The conflicting results might be due to the different methods used to measure fatigue in the studies.
Mental performance	Some research suggests that taking one 100-400 mg dose of American ginseng (Cereboost, Naturex) 1-6 hours before mental tests improves short-term memory and reaction time in healthy people.
High blood pressure	Evidence on the effects of American ginseng in people with high blood pressure is not consistent. Some research shows that taking 1500 mg of American ginseng twice daily for 12 weeks does not reduce blood pressure. But other research shows that taking 1000 mg of American ginseng extract three times daily for 12 weeks lowers blood pressure in people with diabetes and high blood pressure. The differences in the research might be related to the amount of ginsenosides, the active chemical in American ginseng, that is contained in the products used.
Menopausal symptoms	Early research suggests that taking a product containing American ginseng, black cohosh, dong quai, milk thistle, red clover, and vitex agnus-castus (Phyto-Female Complex, SupHerb, Netanya, Israel) twice daily for 3 months reduces menopausal symptoms, including hot flashes, night sweats, and sleep quality. However, it is not clear if these effects are caused by American ginseng or the other ingredients in the product.
Schizophrenia	Early research shows that American ginseng might improve some mental symptoms associated with schizophrenia. Taking 100 mg of a specific American ginseng extract called HT1001 (Afexa Life Sciences, Canada) twice daily for 4 weeks improves the patient's ability to hold visual information in the mind short-term. This treatment might also reduce some physical side effects of antipsychotic drugs. However, it does not improve other mental symptoms.

Dosing

BY MOUTH
For reducing blood sugar in people with type 2 diabetes: 3 grams up to 2 hours before a meal. American ginseng should be taken within 2 hours of a meal. If it is taken too long before eating, the blood sugar might become too low.100-200 mg of American ginseng have been taken daily for up to 8 weeks.

For preventing upper respiratory tract infections such as the common cold or flu: a specific American ginseng extract called CVT-E002 (Cold-fX, Afexa Life Sciences, Canada) 200 mg twice daily for 3-4 months has been used.

49 Bitter Melon

NATURAL REMEDIES | Herbs | Bitter Melon

Bitter melon is a vegetable used in India and other Asian countries. The fruit and seeds are used to make medicine. People use bitter melon for diabetes, stomach and intestinal problems, to promote menstruation, and many other conditions, but there is no good scientific evidence to support these uses. Bitter melon contains a chemical that acts like insulin to help reduce blood sugar levels.

Uses

Insufficient Evidence

Diabetes	Research results so far are conflicting and inconclusive. Some research shows that taking bitter melon can reduce blood sugar levels and lower HbA1c (a measure of blood sugar control over time) in people with type 2 diabetes. But these studies have some flaws, and conflicting results exist. Higher quality studies are needed.

Dosing

The appropriate dose of bitter melon depends on several factors such as the user's age, health, and several other conditions. At this time, there is not enough scientific information to determine an appropriate range of doses for bitter melon. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

50 Horehound

White horehound is a plant. The parts that grow above the ground are used to make medicine. White horehound is used for digestion problems including diabetes, loss of appetite, indigestion, bloating, gas, diarrhea, constipation, and liver and gallbladder complaints. It is also used for lung and breathing problems including cough, whooping cough, asthma, tuberculosis, bronchitis, and swollen breathing passages. Women use white horehound for painful menstrual periods. People also use it for yellowed skin (jaundice), to kill parasitic worms, to cause sweating, and to increase urine production. White horehound is sometimes applied to the skin for skin damage, ulcers, and wounds. In manufacturing, the extracts of white horehound are used as flavoring in foods and beverages, and as expectorants in cough syrups and lozenges. Expectorants are ingredients that make it easier to cough up phlegm. The chemicals in white horehound can thin mucus secretions, reduce spasms in the stomach and intestines, and decrease swelling (inflammation).

Uses

Insufficient Evidence

Diabetes	Early research suggests that drinking tea prepared from white horehound before meals, in addition to taking medication for diabetes, for 3 weeks slightly slower blood sugar levels in people with type 2 diabetes. However, drinking tea prepared from guarumo for the same duration seems to have a greater blood sugar-lowering effect.

Dosing

The appropriate dose of white horehound depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for white horehound. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

51 Hops

Hops are the dried, flowering part of the hop plant. They are commonly used in brewing beer and as flavoring components in foods. Hops are also used to make medicine. Hops are commonly used orally for anxiety, sleep disorders such as the inability to sleep (insomnia) or disturbed sleep due to rotating or nighttime work hours (shift work disorder), restlessness, tension, excitability, attention deficit-hyperactivity disorder (ADHD), nervousness, irritability, and symptoms of menopause among other uses. But there is limited scientific evidence to support using hopes for any of these conditions. The chemicals in hops seem to have weak effects similar to the hormone estrogen. Some chemicals in hops also seem to reduce swelling, prevent infections, and cause sleepiness.

Uses

Insufficient Evidence

Body odor	Early research suggests that applying a deodorant that contains hops, zinc salt, aloe leaf juice, witch hazel, chamomile, vitamin C, lemon grass, and other ingredients to the underarm can reduce body odor.
Insomnia	Taking hops along with other herbs and supplements may improve some aspects of sleep in people with insomnia, but research is mixed. Additionally, there is no evidence that taking hops by itself helps with insomnia. Some research suggests that taking a combination of hops extract plus valerian extract at bedtime helps some people fall asleep faster. It appears to take 28 days of treatment to see these benefits. Also, taking a combination of valerian extract and hops extract seems to improve sleep quality similarly to bromazepam (Lexotanil) when taken for only 14 days. In addition, taking a specific combination product containing valerian extract, passionflower extract, and hops extract daily at bedtime for 2 weeks seems to increase total sleep time by 2.5 hours, decrease the number of nighttime awakenings by 50%, and reduce the amount of time it takes to fall asleep by about one hour compared in patients with mild insomnia. These improvements are similar to the effects of the sedative zolpidem. However, other research suggests that taking a combination of hops, soya oil, soya lecithin, and Cannabis sativa for one month does not improve sleep quality. Other early research suggests that taking a combination of hops and valerian doesn't improve the time it takes to fall asleep.
Menopausal symptoms	Early research suggests that taking a specific product containing hops extract daily does not improve menopausal symptoms such as hot flashes after 8-12 weeks of treatment.
Sleep disorder due to rotating or night shifts (shift work disorder)	Early research suggests that drinking non-alcoholic beer containing hops at dinner for two weeks can reduce the amount of time it takes to fall asleep by about 8 minutes in nurses working rotating or night shifts. It also seems to decrease total activity during the night and anxiety. However, it doesn't appear to increase the total amount of time slept.
Leg ulcers	Early research suggests that applying a cream containing bladderwrack, English ivy, horse chestnut, gotu kola, butcher's broom, horsetail, and hops, together with compression therapy, might help decrease pain and inflammation in people with leg ulcers and poor blood circulation in the legs.

Dosing

The appropriate dose of hops depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for hops. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

52 Hydrangea

Hydrangea is a plant. The root and rhizome (underground stem) are used to make medicine. Hydrangea is used for urinary tract problems such as infections of the bladder, urethra and prostate; enlarged prostate; and kidney stones. It is also used for hay fever. The chemicals in hydrangea may cause increased urine output, which could help some urinary tract problems.

Uses

Insufficient Evidence

Dosing

The appropriate dose of hydrangea depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for hydrangea. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

53 Horsetail

Horsetail is a plant. The above ground parts are used to make medicine. Horsetail is used for "fluid retention" (edema), kidney and bladder stones, urinary tract infections, the inability to control urination (incontinence), and general disturbances of the kidney and bladder. It is also used for balding; tuberculosis; jaundice; hepatitis; brittle fingernails; joint diseases; gout; osteoarthritis; weak bones (osteoporosis); high cholesterol levels; frostbite; weight loss; heavy menstrual periods; and uncontrolled bleeding (hemorrhage) of the nose, lung, or stomach. Horsetail is applied directly to the skin to treat wounds and burns. Horsetail is sometimes used in cosmetics and shampoos. The chemicals in horsetail may have antioxidant and anti-inflammatory effects. Horsetail contains chemicals that work like "water pills" (diuretics) and increase urine output.

Uses

Insufficient Evidence

Weak bones (osteoporosis)	Early research suggests that taking dry horsetail extract or a specific product containing horsetail extract and calcium can increase bone density in postmenopausal women with osteoporosis.

Dosing

The appropriate dose of horsetail depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for horsetail. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

54 Horseradish

Horseradish is a plant. It is frequently prepared as a condiment, but the roots are also used as medicine. Horseradish is used for urinary tract infections, kidney stones, fluid retention, cough, bronchitis, achy joints (rheumatism), gallbladder disorders, sciatic nerve pain, gout, colic, and intestinal worms in children. Some people apply horseradish directly to the skin for painful and swollen joints or tissues and for minor muscle aches. Horseradish might help fight bacteria and stop spasms.

Uses

Insufficient Evidence

Bronchitis	Early research shows that taking a specific product (Angocin Anti-Infekt N) containing horseradish root and nasturtium by mouth for about 7-14 days reduces symptoms of acute bronchitis as effectively as antibiotics.
Nasal swelling (sinusitis)	Early research shows that taking a specific product (Angocin Anti-Infekt N) containing horseradish root and nasturtium by mouth for about 7-14 days reduces symptoms of acute sinusitis as effectively as antibiotics.
Urinary tract infections (UTIs)	Early research shows that taking a specific product (Angocin Anti-Infekt N) containing horseradish root and nasturtium by mouth for about 7-14 days is less effective than antibiotics for reducing symptoms of UTIs.

Dosing

The appropriate dose of horseradish depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for horseradish. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

55 He Shou Wu (Fo-Ti)

Fo-ti is an herb. The processed (cured) root of the plant is used to make medicine. Fo-ti is commonly used by mouth to help treat or prevent conditions related to aging, including cancer, heart disease, and memory problems. Fo-ti is also applied directly to the skin for sores, carbuncles, skin eruptions, and itching. But there is limited scientific evidence to support these uses. In manufacturing, fo-ti extract is used as an ingredient in hair and skin care products. Don't confuse fo-ti with the commercial product Fo-ti-Teng that contains no fo-ti. Fo-ti cured root might affect the levels of various chemicals in the body which have been suggested to have anti-aging effects.

Uses

Insufficient Evidence

Age-related memory problems	Early research suggests taking fo-ti root along with Panax ginseng might improve memory in older people.

Dosing

The appropriate dose of fo-ti depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for fo-ti. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

56 Hypericum (St. John's Wort)

St. John's wort is a plant with yellow, star-shaped flowers and five petals that grows in Europe, North and South America, Australia, New Zealand, and Eastern Asia. The plant grows in sunny, well-drained areas. It grows to be 50-100 cm tall. St. John's wort might cause serious interactions with some medications. Because of this, France has banned the use of St. John's wort in products. In other countries St. John's wort is only available with a prescription. St. John's wort is most commonly used for "the blues" or depression and symptoms that sometimes go along with mood such as nervousness, tiredness, poor appetite, and trouble sleeping. There is some strong scientific evidence that it is effective for mild to moderate depression. St. John's wort is also used for symptoms of menopause such as hot flashes and mood changes. An oil can be made from St. John's wort. Some people apply this oil to their skin to treat wounds. Applying St. John's wort directly to the skin is risky. It can cause serious sensitivity to sunlight. For a long time, scientists thought a chemical in St. John's wort called hypericin was responsible for its effects on improving mood. More recent information suggests other chemicals like hyperforin may play a larger role. These chemicals act on messengers in the nervous system that regulate mood.

Uses

Likely Effective

Depression	Taking St. John's wort extracts by mouth improves mood and decreases nervousness and tiredness related to depression. It seems to be about as effective as many prescription drugs. The American College of Physicians-American Society of Internal Medicine guidelines suggest that St. John's wort can be considered an option along with prescription medications for short-term treatment of mild depression. However, since St. John's wort causes many drug interactions, the guidelines suggest it might not be a good choice for many people. St. John's wort might not be as effective for more severe cases of depression.

Possibly Effective

Symptoms related to menopause	Most research shows that taking St. John's wort by mouth can help reduce hot flashes and other symptoms of menopause. Some evidence suggests that specific combinations of St. John's wort plus black cohosh (Remifemin; Remifemin Plus; Gynoplus) can also improve some symptoms of menopause such as hot flashes and mood changes. But not all St. John's wort combination products seem to be beneficial.
The condition of mental feelings causing bodily symptoms (somatization disorder)	Treatment with a specific St. John's wort product (LI 160, Lichtwer Pharma) daily for 6 weeks seems to reduce symptoms of somatization disorder.
Wound healing	Applying an ointment containing St. John's wort three times daily for 16 days seems to improve wound healing and reduce scar formation after a Cesarean section (C-section).

Possibly Ineffective

Pain in the mouth (burning mouth syndrome)	Taking St. John's wort three times daily for 12 weeks does not reduce pain from burning mouth syndrome.
Hepatitis C infection	Taking St. John's wort by mouth does not seem to be effective for treating adults with hepatitis C infection.
HIV/AIDS	Taking St. John's work by mouth does not seem to be effective for treating HIV-infected adults.
Irritable bowel syndrome (IBS)	Early research shows that taking a specific St. John's wort extract (St. John's Wort Extract Extra Strength, Enzymatic Therapy) twice daily is not effective for reducing symptoms of IBS.
Nerve pain	Taking St. John's wort by mouth does not seem to relieve nerve pain in diabetic or non-diabetic people.
Social nervousness	Taking St. John's wort daily does not seem to improve social nervousness.

Insufficient Evidence

A procedure to widen blocked arteries (angioplasty).	Early research shows that in people who do not respond to a prescription blood thinner medication called clopidogrel or Plavix and aspirin, taking St. John's wort three times daily for 2 weeks after a procedure to clear blocked arteries might improve outcomes of the procedure. It is thought that St. John's wort might help the blood thinning medications work better in some people.
Anxiety	Some reports suggest that taking St. John's wort alone or together with valerian might improve nervousness. Taking one capsule of a specific product that contains St. John's wort and valerian root (Sedariston Concentrate, Aristo Pharma GmbH) by mouth daily for one week, then one or two capsules twice daily for another week, reduces nervousness more than the prescription medication diazepam.
The condition of difficulty paying attention and controlling behaviors (attention deficit-hyperactivity disorder or ADHD)	A report of 3 males aged 14-16 with ADHD showed that taking St. John's wort daily for 4 weeks might improve attention and activity. But other research shows that taking a St. John's wort extract for 8 weeks does not improve ADHD symptoms in children ages 6-17 years.
A genetic condition of that causes bilirubin to build up in the body	A case report shows that taking St. John's wort by mouth three times daily for two 8-week periods might decrease bilirubin levels, reduce jaundice, and improve fatigue in people with this condition.
Brain tumor	Early research shows that taking hypericin, a chemical in St. John's wort, by mouth for up to 3 months might reduce tumor size and improve the survival rate in people with brain tumors.

Herpes	Early research suggests that using a specific combination of St. John's wort and copper sulfate pentahydrate might help reduce symptoms, including stinging, burning and pain, in people with cold sores or genital herpes.
Migraine headache	Early research suggests that taking a specific St. John's wort product three times daily improves migraine pain but does not reduce how often migraines occur.
The condition of difficult to control thoughts and behaviors that are repeated (obsessive-compulsive disorder or OCD)	The evidence about the effectiveness of St. John's wort for OCD is not clear. Study results have been mixed.
Skin redness and irritation (plaque psoriasis)	Early research suggests that applying St. John's wort liquid or ointment to the skin decreases the severity and the size of psoriasis patches.
Premenstrual syndrome (PMS)	The evidence about the use of St. John's wort for treating PMS is not clear. Some early research suggests that St. John's wort might help reduce PMS symptoms, including sleeping problems, confusion, crying, headache, tiredness, food cravings and swelling, by as much as 50% in some women. However, other research shows that taking St. John's wort does not reduce nervousness or other PMS symptoms.
Mood condition related to changes in the season (seasonal affective disorder)	Early studies suggest that St. John's wort might help improve symptoms of nervousness, decreased sex drive, and sleep problems in people with seasonal mood changes. It is useful alone or in combination with light therapy.
Smoking cessation	Early research suggests that taking a St. John's wort extract once or twice daily starting one week before and continuing for 3 months after quitting smoking does not improve long-term quit rates.
Tooth pulling	Early research suggests that applying a homeopathic St. John's wort preparation does not improve dental pain after a tooth is pulled or after dental surgery.

Dosing

ADULTS
BY MOUTH
For mild to moderate low mood or depression:
- In most studies, St. John's wort extract was standardized to 0.3% hypericin content and used at doses of 300 mg 3 times daily.
- Some studies have used St. John's wort extract standardized to 0.2% hypericin at doses of 250 mg twice daily.
- St. John's wort extract standardized to 5% hyperforin has been used at doses of 300 mg 3 times daily.

Do not suddenly stop taking St. John's wort. This might cause unpleasant side effects. If you decide to stop taking St. John's wort, reduce the dose slowly over time.

For symptoms of menopause	• St. John's wort extract (Hypiran, Poursina Pharmaceutical Mfg. Co., Tehran, Iran) containing 0.2 mg/mL hypericin, taken in doses of 20 drops 3 times daily for 2 months has been used. • St. John's wort 300mg 3 times daily for 3-4 months has been used.
For the condition of mental feelings causing bodily symptoms (somatization disorder)	A specific extract (LI 160, Lichtwer Pharma) 600 mg/day has been used.
APPLIED TO THE SKIN For wound healing	An ointment containing a 5% St. John's wort extract applied three times daily beginning 24 hours after a C-section and continued for 16 days has been used.
CHILDREN BY MOUTH	For mild to moderate depression: 150-300 mg of St. John's wort three times daily for 8 weeks in children 6-17 years-old has been used. A specific St. John's wort extract (LI 160, Lichtwer, Pharma) 300-1800 mg in three divided doses daily for up to 6 weeks has been used.

57 Hawthorn

Hawthorn is a plant. The leaves, berries, and flowers of hawthorn are used to make medicine. Hawthorn is used for diseases of the heart and blood vessels such as congestive heart failure (CHF), chest pain, and irregular heartbeat. It is also used to treat both low blood pressure and high blood pressure, "hardening of the arteries" (atherosclerosis), and high cholesterol. So far, research suggests that hawthorn might be effective in treating congestive heart failure, but there hasn't been enough research on other heart-related uses to know if it is effective for them. Some people use hawthorn for digestive system complaints such as indigestion, diarrhea, and stomach pain. It is also used to reduce anxiety, as a sedative, to increase urine output, and for menstrual problems. Hawthorn is also used to treat tapeworm and other intestinal infections. Some people apply hawthorn to the skin for boils, sores, and ulcers. Hawthorn preparations are used as a wash for sores, itching, and frostbite. You will find hawthorn among the ingredients in candied fruit slices, jam, jelly, and wine.

Before taking hawthorn, talk with your healthcare professional if you take any medications. It has major interactions with several prescription medications. Hawthorn can help improve the amount of blood pumped out of the heart during contractions, widen the blood vessels, and increase the transmission of nerve signals. Hawthorn also seems to have blood pressure-lowering activity, according to early research. It seems to cause relaxing of the blood vessels farther from the heart. It seems that this effect is due to a component in hawthorn called proanthocyanidin. Research suggests that hawthorn can lower cholesterol, low density lipoprotein (LDL, or "bad cholesterol"), and triglycerides (fats in the blood). It seems to lower accumulation of fats in the liver and the aorta (the largest artery in the body, located near the heart). Hawthorn fruit extract may lower cholesterol by increasing the excretion of bile, reducing the formation of cholesterol, and enhancing the receptors for LDLs. It also seems to have antioxidant activity.

Uses

Possibly Effective

Heart failure	Some specific hawthorn products (Faros 300 by Lichtwer Pharma, Crataegutt forte by Wilmer Schwabe Pharmaceuticals, or HeartCare, Nature's Way) seem to improve some heart failure symptoms in some people with mild to moderate heart failure. However, other research shows that these products may actually worsen heart failure and increase the risk of death or hospitalization.

Insufficient Evidence

Anxiety	There is some evidence that hawthorn, combined with magnesium and California poppy (a product called Sympathyl, which is not available in the U.S.), might be useful in treating mild to moderate anxiety disorders.
Chest pain ("angina")	Some research suggests that taking hawthorn might reduce chest pain.

High blood pressure	Some research shows that hawthorn might reduce blood pressure, but other research shows no benefit.

Dosing

BY MOUTH
For heart failure, some specific hawthorn products (Faros 300 by Lichtwer Pharma, Crataegutt forte by Wilmer Schwabe Pharmaceuticals, or HeartCare, Nature's Way) have been used in doses of 160 mg to 1800 mg divided and taken in 2-3 doses daily. These doses have been shown to improve symptoms of heart failure in some people, but they have also been shown to increase the risk of death or being hospitalized due to heart failure.

58 Jiaogulan

Jiaogulan is a plant that grows wild in parts of Asia. The leaf is used to make medicine. Jiaogulan is sometimes referred to as "Southern Ginseng" because it grows primarily in south central China and is used in similar ways as ginseng. People commonly use jiaogulan by mouth for high cholesterol, diabetes, liver disease, obesity, and many other conditions, but there is no good scientific evidence supporting most of these uses. Jiaogulan contains substances that might help reduce cholesterol levels.

Uses

Possibly Effective

Diabetes	Drinking jiaogulan tea seems to reduce fasting blood sugar levels and improve how sensitive the body is to the effects of insulin in people with diabetes.
High cholesterol	Taking jiaogulan can decrease total cholesterol and increase the "good" high-density lipoprotein (HDL)/total cholesterol ratio in people with high cholesterol levels.

Insufficient Evidence

Liver disease (nonalcoholic fatty liver disease)	Taking jiaogulan by mouth does not seem to improve liver function, body mass index, cholesterol levels, kidney function, or blood sugar in people with a type of liver disease called nonalcoholic fatty liver disease.
Obesity	Taking jiaogulan by mouth seems to slightly decrease body weight in people who are obese.

Dosing

ADULTS
BY MOUTH
For diabetes: 3 grams of jiaogulan tea in 60 mL of water has been taken twice daily for up to 12 weeks.

For high cholesterol: 10 mg of jiaogulan extract has been taken three times daily.

59 Kudzu

Kudzu is a vine. Under the right growing conditions, it spreads easily, covering virtually everything that doesn't move out of its path. Kudzu was introduced in North America in 1876 in the southeastern U.S. to prevent soil erosion. But kudzu spread quickly and overtook farms and buildings, leading some to call to kudzu "the vine that ate the South." Kudzu's root, flower, and leaf are used to make medicine. People use kudzu to treat alcoholism and to reduce symptoms of alcohol hangover, including headache, upset stomach, dizziness, and vomiting. Kudzu is also used for heart and circulatory problems, including high blood pressure, irregular heartbeat, heart failure, and chest pain; for upper respiratory problems including sinus infections, the common cold, hay fever, flu, and swine flu; and for skin problems, including allergic skin rash, itchiness, and psoriasis. Some people use kudzu for menopause symptoms, weight loss, exercise performance, muscle pain, measles, dysentery, stomach pain (gastritis), fever, diarrhea, thirst, neck stiffness, and to promote sweating. Other oral uses include treatment of polio myelitis, encephalitis, migraine, deafness, diabetes, nerve pain and vision loss associated with diabetes, and traumatic injuries. Health providers in China sometimes give puerarin, a chemical in kudzu, intravenously (by IV) to treat stroke due to a blood clot, as well as for back pain, heart attacks, and to reduce cholesterol levels in people with heart disease. There is information that suggests kudzu contains ingredients that counteract alcohol. It might also have effects like estrogen. Chemicals in kudzu might also increase blood circulation in the heart and brain.

Uses

Possibly Effective

Alcoholism	Research suggests that heavy drinkers or binge drinkers who take kudzu consume less beer when given a chance to drink. But kudzu doesn't seem to decrease the craving for alcohol or improve sobriety in long-term alcoholics.

Insufficient Evidence

Chest pains	Some early research suggests that puerarin, a chemical in kudzu, might improve signs and symptoms of chest pain when taken by mouth or injected intravenously (by IV). Some evidence suggests that using IV puerarin along with usual treatment might be more effective than usual treatment alone. However, studies on puerarin are generally of poor quality and might not be reliable. Puerarin injection products are not available in North America.
Preventing chest pain during a procedure called percutaneous transluminal coronary angioplasty (PTCA)	Early research suggests that injecting 200 mL of puerarin, a chemical in kudzu, intravenously (by IV) one week before and immediately prior to PTCA might reduce episodes of chest pain. Puerarin injection products are not available in North America.
Coronary heart disease (CHD)	Early research suggests that injecting 500 mL of puerarin, a chemical in kudzu, intravenously (by IV) once daily for 3 weeks might reduce "bad" low-density lipoprotein (LDL) cholesterol, increase "good" high-density lipoprotein (HDL) cholesterol, and reduce pre-meal insulin levels in people with coronary heart disease. Puerarin injection products are not available in North America.
Diabetes	Early research suggests that taking puerarin, a chemical in kudzu, 750 mg daily by mouth along with the diabetes medication rosiglitazone (Avandia) reduces blood sugar in patients with type 2 diabetes. However, injecting puerarin intravenously (by IV) does not appear to reduce blood sugar. Puerarin injection products are not available in North America.
Kidney disease in people with diabetes (diabetic nephropathy)	Early research suggests that taking puerarin, a chemical in kudzu, 750 mg daily by mouth along with the diabetes medication rosiglitazone (Avandia) improves kidney function in people with diabetic nephropathy.

Problems with the retina of the eye in people with diabetes (diabetic retinopathy)	Some research suggests that injecting puerarin, a chemical in kudzu, intravenously (by IV) does not improve vision in people with diabetic retinopathy. Puerarin injection products are not available in North America.
Exercise performance	Early research suggests that taking a combination supplement containing kudzu isoflavones along with other ingredients might improve exercise performance in some people.
Heart failure	Early research suggests that taking puerarin, a chemical in kudzu, 400 mg/day by mouth for 10 days might improve heart function in people with heart failure.
High blood pressure	Early research shows that taking kudzu powder might decrease blood pressure in people with slightly high blood pressure.
Stroke	Some early research suggests that taking puerarin, a chemical in kudzu, alone or with aspirin, might improve brain function in some people after stroke. However, other research shows that injecting puerarin intravenously (by IV) does not reduce death or dependency after a stroke.
Low back pain	Early research suggests that injections of puerarin, a chemical in kudzu, might reduce pain in some people with low back pain. Puerarin injection products are not available in North America.
Symptoms of menopause	Research on kudzu for symptoms of menopause has been conflicting. Some research suggests that taking kudzu by mouth can reduce hot flashes and improve vaginal dryness in women going through menopause. Other research shows that taking kudzu does not affect sex hormone levels, blood fat levels, bone density, or other symptoms of menopause. However, it might have a positive effect on the mental abilities of postmenopausal women.
Heart attack (myocardial infarction)	Early research suggests that injecting puerarin, a chemical in kudzu, intravenously (by IV) along with usual treatment might help some people after a heart attack. Puerarin injection products are not available in North America.
Weight loss	Early research suggests that taking kudzu extract 300 mg by mouth for 12 weeks reduces body fat and body mass index (BMI) in people who are obese. However, taking kudzu extract 200 mg daily does not appear to have the same effects.

Dosing

BY MOUTH
For alcoholism: 1.5-3 grams of kudzu root extract has been taken in 3 divided doses per day for 1-4 weeks. A single dose of 2 gram of kudzu extract has also been taken before a drinking episode.

60 Myrtle

Myrtle is a plant. The leaves and branches are used to make medicine. People take myrtle for treating lung infections including bronchitis, whooping cough, and tuberculosis. They also take it for bladder conditions, diarrhea, and worms. Myrtle might help fight against fungus and bacteria.

Uses

Insufficient Evidence

Dosing

The appropriate dose of myrtle depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for myrtle. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

61 Alpine Lady's Mantle

Alpine lady's mantle is an herb. It is used to make medicine. People take alpine lady's mantle for fluid retention, spasms, heart conditions, and various "female complaints." Don't confuse alpine lady's mantle (Alchemilla alpina) with lady's mantle (Alchemilla xanthochlora). It is not known how alpine lady's mantle might work for medicinal uses.

Uses

Insufficient Evidence

Dosing

The appropriate dose of alpine lady's mantle depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for alpine lady's mantle. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

62 Lotus

Lotus is a plant. The flowers, seed, leaves, and parts of the underground stem (rhizome) are used to make medicine. Lotus flowers are used to stop bleeding. Lotus seeds are used for disorders of the digestive tract, including diarrhea. There is not enough information to know how lotus might work.

Uses

Insufficient Evidence

Dosing

The appropriate dose of lotus depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for lotus. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

63 Milk Thistle

Milk thistle is a plant that is native to Europe and was brought to North America by early colonists. Milk thistle is now found throughout the eastern United States, California, South America, Africa, Australia, and Asia. The plant grows up to 2 meters high and has large, bright purple flowers. Milk thistle gets its name from the milky sap that comes out of the leaves when they are broken. The leaves also have unique white markings that, according to legend, were the Virgin Mary's milk. The above ground parts and seeds are used to make medicine. The seeds are more commonly used. Milk thistle is taken by mouth most often for liver disorders, including liver damage caused by chemicals, alcohol, and chemotherapy, as well as liver damage caused by Amanita phalloides (death cap) mushroom poisoning, nonalcoholic fatty liver disease, chronic inflammatory liver disease, cirrhosis of the liver, and chronic hepatitis. Milk thistle is also taken by mouth for heartburn (dyspepsia), inflammatory bowel disease (ulcerative colitis), enlarged prostate (benign prostatic hyperplasia), a blood disorder called beta-thalassemia, and infertility.

Some people also take milk thistle by mouth for diabetes, kidney damage caused by diabetes or contrast media use, prostate cancer, to decrease the side effects of chemotherapy and radiation, uterine complaints, increasing breast milk flow, allergy symptoms, starting menstrual flow, obsessive-compulsive disorder (OCD), Alzheimer's disease, Parkinson's disease, multiple sclerosis (MS), high cholesterol, and menopausal symptoms. Some people apply milk thistle directly to the skin for skin toxicity caused by radiation. People use milk thistle intravenously (by IV) for Amanita phalloides (death cap) mushroom poisoning. In foods, milk thistle leaves and flowers are eaten as a vegetable for salads and a substitute for spinach. The seeds are roasted for use as a coffee substitute. Don't confuse milk thistle with blessed thistle (Cnicus benedictus). Milk thistle seed might protect liver cells from toxic chemicals and drugs. It also seems to have blood sugar-lowering, antioxidant, and anti-inflammatory effects.

Uses

Possibly Effective

Diabetes	Taking milk thistle extract along with antidiabetes drugs can decrease blood sugar levels before meals in people with diabetes. It also seems to decrease average blood sugar levels in these people. Taking a specific product containing milk thistle and tree turmeric (Berberol, PharmExtracta) also seems to lower blood sugar in people with diabetes that is not well controlled. But it might take more than 3 months for milk thistle products to show benefit.
Heartburn (dyspepsia)	When used daily for 4 weeks, a specific combination product (Iberogast by Medical Futures, Inc.) that contains milk thistle plus eight other ingredients seems to reduce the severity of acid reflux, stomach pain, cramping, nausea, and vomiting.

Insufficient Evidence

Liver disease caused by excessive use of alcohol	There is conflicting evidence about the effectiveness of milk thistle for treating alcohol-related liver disease. Early research shows that taking milk thistle by mouth might improve liver function and reduce risk of death. However, other research shows no benefit.
Seasonal allergies	Some research shows that taking milk thistle extract by mouth along with the allergy medication cetirizine (Zyrtec) reduces seasonal allergies more than taking cetirizine alone.
Alzheimer's disease	Early research shows that taking a combination supplement containing milk thistle extract improves mental function in people with Alzheimer' s disease.
Amanita mushroom poisoning	Early research shows that giving silibinin, a chemical found in milk thistle, intravenously (by IV) and then by mouth may lessen liver damage caused by Amanita phalloides mushroom (death cap) poisoning. However, it is hard to obtain silibinin in the US.
Enlarged prostate (benign prostatic hyperplasia)	Early research shows that taking a specific combination of milk thistle extract and selenium for 6 months might improve symptoms of enlarged prostate in men.
Blood disorder called beta-thalassemia	Early research in children with the blood disorder beta-thalassemia shows that taking a specific milk thistle extract for 6-9 months, along with conventional medicine, might decrease iron levels better than conventional medicine alone.
Hand-foot syndrome	Early research shows that applying a gel containing milk thistle extract to the hands and feet beginning on the first day of chemotherapy and continuing for 9 weeks decreases the severity of a complication of chemotherapy called hand-foot syndrome.
Chemotherapy toxicity	Early research shows that taking a specific milk thistle product containing the chemical silibinin beginning at the start of chemotherapy treatment does not significantly reduce liver toxicity caused by chemotherapy.
Kidney damage caused by the chemotherapy drug cisplatin	Early research shows that taking milk thistle extract beginning 24-48 hours before starting therapy with cisplatin, and continuing until the end of the treatment course, does not prevent or decrease the rates of kidney injury.
Liver scarring (cirrhosis)	Early research shows that milk thistle extract might reduce the risk of death and improve liver function in people with cirrhosis. However, milk thistle extract does not seem to benefit all patients with liver disease.
Kidney disease in people with diabetes	Early research shows that taking milk thistle extract together with conventional treatment might help treat kidney disease in people with diabetes.
Hepatitis	Research on the effects of milk thistle in people with hepatitis is not consistent. Some research shows that taking milk thistle extract by mouth for 4 weeks reduces hepatitis symptoms, such as dark urine and jaundice, but does not improve liver function tests. But taking product containing the milk thistle constituent silybin plus phosphatidylcholine by mouth for 2 weeks to 3 months might improve some liver function tests.
Hepatitis B	Research on the effects of milk thistle in people with hepatitis B is not consistent. Early research shows that taking milk thistle extract by mouth for up to one year, or taking a product containing the milk thistle constituent silybin plus phosphatidylcholine by mouth for 1 week, improves liver function tests. But other research shows no benefit.
Hepatitis C	Research on the effects of milk thistle in people with hepatitis C is inconsistent. Early research shows that taking milk thistle extract by mouth for up to one year, or taking a product containing the milk thistle constituent silybin plus phosphatidylcholine by mouth for 1 week, improves liver function tests. But other research shows no benefit.

High cholesterol	Taking milk thistle along with tree turmeric seems to prevent cholesterol levels from increasing in people with high cholesterol who are taking statins but who require their statin dose to be lowered. Taking this product also seems to help lower cholesterol when used alone or along with low-dose statins or ezetimibe in people with high cholesterol who can't tolerate high dose statin treatment. It's unclear if these benefits are due to milk thistle, tree turmeric, or the combination. There is also evidence that taking a similar product containing milk thistle, tree turmeric, and chemicals called monacolins also helps to lower cholesterol levels. Monacolins are chemicals similar to statin drugs. So, it's not clear if the cholesterol reduction is due to milk thistle or the statin-like chemicals.
High levels of fat particles (lipids) in the blood	Taking milk thistle doesn't seem to lower lipid levels in the blood in people with high levels due to liver disease.
Infertility	Early research shows that taking milk thistle extract along with fertility hormones might provide some benefits for women undergoing in vitro fertilization due to male infertility.
Low milk production	Early research shows that taking milk thistle extract for 4 weeks does not increase milk production in mothers of premature infants.
Menopausal symptoms	Research shows that taking a specific combination product containing milk thistle and other ingredients by mouth for 3 months reduces hot flashes by 73% and night sweats by 69% in people with menopausal symptoms. Sleep quality also improves. It' s not clear if these benefits are due to milk thistle or other ingredients.
Multiple sclerosis (MS)	Early research shows that taking a combination supplement containing milk thistle extract can improve mental function and increase disease stabilization in people with multiple sclerosis.
Liver disease not caused by alcohol (nonalcoholic fatty liver disease; NAFLD)	There is evidence that milk thistle extract improves markers of liver injury in people with NAFLD. But these markers aren't always linked with the NAFLD severity. Most experts recommend that people with NAFLD lose weight to reduce fat build-up in the liver and lower their cholesterol to reduce the risk of heart disease. Taking milk thistle does not seem to improve either of these outcomes. But there is some evidence that milk thistle might benefit people with a severe form of NAFLD called nonalcoholic steatohepatitis (NASH). While taking milk thistle doesn't seems to improve the overall severity of NASH, it does seem to reduce scarring of the liver.
Obsessive-compulsive disorder (OCD)	Early research shows that taking milk thistle leaf extract by mouth three times daily for 8 weeks has a limited effect on OCD symptoms. It does not appear to more beneficial than conventional medication.
Parkinson's disease	Early research shows that taking a combination supplement containing milk thistle extract improves mental function and increases disease stabilization in people with Parkinson's disease.
Prostate cancer	Prostate-specific antigen (PSA) is a protein in the blood that can be measured to diagnose and monitor prostate cancer. Early research shows that taking a supplement containing milk thistle extract, soy isoflavones, lycopene, vitamins, minerals and antioxidants by mouth daily can delay the rise in PSA levels in men with a history of prostate cancer. The effects of milk thistle alone are not clear.
Skin toxicity caused by radiation	Early research shows that applying a specific product containing the milk thistle extract reduces the effect of radiation on the skin in women being treated for breast cancer.
Inflammation and ulcers (mucositis) caused by radiation	Early research shows that taking milk thistle extract starting on the first day of radiation and continuing for 6 weeks thereafter decreases the severity of ulcers caused by radiation.
Liver damage caused by chemicals	The effect of milk thistle on liver damage caused by chemicals is inconsistent. Taking milk thistle by mouth helps the liver to function in people who have been exposed to the chemicals toluene or xylene or those taking drugs for tuberculosis. But taking milk thistle extract by mouth does not seem to prevent liver damage associated with the drug tacrine (Cognex) in people with Alzheimer's disease.
Inflammation of the digestive tract (ulcerative colitis)	Early research shows that taking milk thistle extract by mouth for 6 months, in addition to standard medications, decreases the symptoms of ulcerative colitis and helps maintain remission.

Dosing

ADULTS
BY MOUTH
For diabetes: 200 mg of milk thistle extract has been taken once daily or three times daily for 4 months to one year. A specific product (Berberol, PharmExtracta) containing 210 mg of milk thistle extract and 1176 mg of tree turmeric extract has been taken daily for 3-12 months.

For upset stomach (dyspepsia): 1 mL of a specific combination product (Iberogast by Medical Futures, Inc.) containing milk thistle and several other herbs has been used three times daily for 4 weeks.

64 Moringa

Moringa is a plant that is native to the sub-Himalayan areas of India, Pakistan, Bangladesh, and Afghanistan. It is also grown in the tropics. The leaves, bark, flowers, fruit, seeds, and root are used to make medicine. Moringa is used for "tired blood" (anemia); arthritis and other joint pain (rheumatism); asthma; cancer; constipation; diabetes; diarrhea; epilepsy; stomach pain; stomach and intestinal ulcers; intestinal spasms; headache; heart problems; high blood pressure; kidney stones; fluid retention; thyroid disorders; and bacterial, fungal, viral, and parasitic infections. Moringa is also used to reduce swelling, increase sex drive (as an aphrodisiac), prevent pregnancy, boost the immune system, and increase breast milk production. Some people use it as a nutritional supplement or tonic. Moringa is sometimes applied directly to the skin as a germ-killer or drying agent (astringent). It is also used topically for treating pockets of infection (abscesses), athlete's foot, dandruff, gum disease (gingivitis), snakebites, warts, and wounds. Oil from moringa seeds is used in foods, perfume, and hair care products, and as a machine lubricant. Moringa is an important food source in some parts of the world. Because it can be grown cheaply and easily, and the leaves retain lots of vitamins and minerals when dried, moringa is used in India and Africa in feeding programs to fight malnutrition. The immature green pods (drumsticks) are prepared similarly to green beans, while the seeds are removed from more mature pods and cooked like peas or roasted like nuts. The leaves are cooked and used like spinach, and they are also dried and powdered for use as a condiment. The seed cake remaining after oil extraction is used as a fertilizer and also to purify well water and to remove salt from seawater. Moringa contains proteins, vitamins, and minerals. As an antioxidant, it seems to help protect cells from damage.

Uses

Insufficient Evidence

Asthma	Early research shows that taking 3 grams of moringa twice daily for 3 weeks reduces the severity of asthma symptoms and improves lung function in adults with mild to moderate asthma.
Diabetes	The effect of moringa on diabetes control is unclear. Some early research shows that taking moringa tablets along with a type medicine called sulfonylureas does not improve blood sugar control as measured by hemoglobin A1C levels. But it does seem to reduce fasting and post-meal blood sugar levels compared to taking sulfonylureas alone in people with diabetes. Other research also shows that ttaking moringa drumstick leaves with meals might also reduce post-meal blood sugar levels in people with diabetes not taking medications for diabetes.

NATURAL REMEDIES | Herbs | Moringa

HIV/AIDS	Early research shows that taking moringa leaf powder with each meal for 6 months might increase body mass index (BMI) but does not appear to improve immune function.
High cholesterol	The effect of moringa on lowering cholesterol levels is not clear. Early research of poor quality shows mixed results. Additional research is needed.
Increasing breast milk production	Research regarding the effects of moringa for increasing breast milk production is conflicting. Some early research shows that moringa increases milk production, while other early research shows no benefit. An analysis of data from five clinical studies shows that moringa moderately increases milk product after one week of use when started on postpartum day 3. But it's not clear if moringa is beneficial when used for longer periods of time.
Malnutrition	Early research shows that adding moringa powder to food for 2 months helps improve weight in malnourished children.
Menopausal symptoms	Early research shows that adding fresh moringa leaves to food for 3 months improves menopausal symptoms such as hot flashes and sleeping problems in healthy, postmenopausal women.
Vitamin A deficiency	Early research shows that adding moringa powder to infant cereal doesn't improve vitamin A levels in infants with low levels of vitamin A.
Weight loss	Early research shows that taking a product containing moringa and other ingredients does not reduce weight. But it might improve body composition by reducing the amount of fat mass and increasing the amount of lean mass. The effect of moringa alone on weight loss is not known.

Dosing

The appropriate dose of moringa depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for moringa. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

65 Maitake Mushroom

Maitake is a type of mushroom. People use it to make medicine. Some people take maitake mushroom by mouth for infertility due to a condition called polycystic ovary syndrome (PCOS). It is also used to treat cancer and to relieve some of the side effects of chemotherapy. There is limited scientific evidence to support these and other uses. Maitake mushroom contains chemicals which might help fight tumors, stimulate the immune system, and lower blood sugar levels.

Uses

Insufficient Evidence

Diabetes	Early research shows that taking maitake mushroom polysaccharides (MMP) by mouth may lower blood sugar in people with diabetes.
An ovary disorder known as polycystic ovary syndrome (PCOS)	Early research shows that taking a specific dietary supplement containing maitake mushroom extract can improve ovulation in women whose periods have stopped due to PCOS. Maitake mushroom does not appear to be as effective as the drug clomiphene for PCOS, but the combination of these two agents may be more effective than either one alone for improving ovulation.

Dosing

The appropriate dose of maitake mushroom depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for maitake mushroom. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

66 Mugwort

Mugwort is a plant that grows in Asia, North America, and Northern Europe. The plant parts that grow above the ground and the root are used to make medicine. People take mugwort root as a "tonic" and to boost energy. People take the rest of the plant for stomach and intestinal conditions including colic, diarrhea, constipation, cramps, weak digestion, worm infestations, and persistent vomiting. Mugwort is also used to stimulate gastric juice and bile secretion. It is also used as a liver tonic; to promote circulation; and as a sedative. Other uses include treatment of hysteria, epilepsy, and convulsions in children. Women take mugwort for irregular periods and other menstrual problems. In combination with other ingredients, mugwort root is used for mental problems (psychoneuroses), ongoing fatigue and depression (neurasthenia), depression, preoccupation with illness (hypochondria), general irritability, restlessness, trouble sleeping (insomnia), and anxiety. Some people apply mugwort lotion directly to the skin to relieve itchiness caused by burn scars. The chemicals in mugwort might stimulate the uterus.

Uses

Insufficient Evidence

Itching caused by scars, when applied to the affected skin	Developing research suggests that applying a lotion containing mugwort and menthol directly to the skin relieves itching in severe burn victims.

Dosing

The appropriate dose of mugwort depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for mugwort. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

67 Neem

NATURAL REMEDIES | Herbs | Neem

Neem is a tree. The bark, leaves, and seeds are used to make medicine. Less often, the root, flower, and fruit are also used. Neem leaf is used for leprosy, eye disorders, bloody nose, intestinal worms, stomach upset, loss of appetite, skin ulcers, diseases of the heart and blood vessels (cardiovascular disease), fever, diabetes, gum disease (gingivitis), and liver problems. The leaf is also used for birth control and to cause abortions. The bark is used for malaria, stomach and intestinal ulcers, skin diseases, pain, and fever. The flower is used for reducing bile, controlling phlegm, and treating intestinal worms. The fruit is used for hemorrhoids, intestinal worms, urinary tract disorders, bloody nose, phlegm, eye disorders, diabetes, wounds, and leprosy. Neem twigs are used for cough, asthma, hemorrhoids, intestinal worms, low sperm levels, urinary disorders, and diabetes. People in the tropics sometimes chew neem twigs instead of using toothbrushes, but this can cause illness; neem twigs are often contaminated with fungi within 2 weeks of harvest and should be avoided.

The seed and seed oil are used for leprosy and intestinal worms. They are also used for birth control and to cause abortions. The stem, root bark, and fruit are used as a tonic and astringent. Some people apply neem directly to the skin to treat head lice, skin diseases, wounds, and skin ulcers; as a mosquito repellent; and as a skin softener. Inside the vagina, neem is used for birth control. Neem is also used as an insecticide. Neem contains chemicals that might help reduce blood sugar levels, heal ulcers in the digestive tract, prevent pregnancy, kill bacteria, and prevent plaque formation in the mouth.

Uses

Insufficient Evidence

Dental plaque	Early research suggests that applying a gel containing neem leaf extract to the teeth and gums twice daily for 6 weeks might reduce the amount of plaque on the teeth. It also might reduce the number of bacteria in the mouth that can cause plaque. It's unclear if using a mouth rinse containing neem reduces plaque. Some research shows that using a neem mouth rinse is beneficial, but other research shows no benefit.
Insect repellant	Early research shows that applying extract of neem root or leaf to the skin helps repel black flies. Also, applying neem oil cream to the skin seems to protect against some types of mosquitos.
Ulcers	Early research suggests that taking neem bark extract by mouth for 10 weeks might help heal ulcers in the stomach and intestines.
Psoriasis	Early research suggests that taking neem extract by mouth for 12 weeks, along with daily sun exposure and the application of a coal tar and salicylic acid cream, might make the symptoms of psoriasis less severe.

Dosing

The appropriate dose of neem depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for neem. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

68 Nigella Seed (Black Seed)

Black seed is a plant. People have used the seed to make medicine for over 2000 years. It was even discovered in the tomb of King Tut. Historically, black seed has been used for headache, toothache, nasal congestion, asthma, arthritis, and intestinal worms. It has also been used for "pink eye" (conjunctivitis), pockets of infection (abscesses), and parasites. Today, black seed is most commonly used for asthma, diabetes, hypertension, weight loss, and many other conditions. There is some scientific evidence to suggest that black seed might help boost the immune system, fight cancer, prevent pregnancy, reduce swelling, and lessen allergic reactions by acting as an antihistamine, but there isn't enough information in humans yet.

Uses

Possibly Effective

Asthma	Research shows that taking black seed by mouth along with asthma medicines can improve coughing, wheezing, and lung function in some people with asthma. But it seems to work only in people with very low lung function before treatment. And it does not seem to work as well as the drugs theophylline or salbutamol.
Diabetes	Early research shows that taking black seed powder can improve blood sugar levels in people with diabetes. Black seed might also improve levels of cholesterol in people with diabetes. Doses of 2 grams daily seem to be needed for any benefit.
High blood pressure	Research shows that taking black seed by mouth might reduce blood pressure by a small amount.
To improve sperm function	Research shows that taking black seed oil increases the number of sperm and how quickly they move in men with infertility.
Breast pain (mastalgia)	Research shows that applying a gel containing black seed oil to the breasts during the menstrual cycle reduces pain in women with breast pain.

Insufficient Evidence

Hay fever (allergic rhinitis)	Early research suggests that taking black seed oil by mouth daily might improve allergy symptoms in people with hay fever.
Itchy and inflamed skin (eczema)	Early research suggests that taking black seed oil by mouth might improve symptoms in people with itchy and inflamed skin. But applying black seed oil ointment to the skin does not seem to help.
A disease that attacks the thyroid (autoimmune thyroiditis)	Taking black seed might improve some but not all measures of thyroid function in people with a disease called Hashimoto's thyroiditis.
Damage to the immune system during cancer treatment	Early research shows that taking black seed ass part of the diet while undergoing cancer drug treatment might prevent fever episodes due to low white blood cell counts (neutropenia) in children.
Mental performance	Early research shows that black seed helps with some but not all measures of memory and attention in boys and men. It's unknown if black seed improves memory and thinking skills in girls and women.
Dry nose	Early research shows that using a nasal spray containing black seed oil can reduce dryness, blockage, and crusting of the nostrils in elderly patients with nasal irritation.
Indigestion	Taking a product containing black seed oil, honey, and water seems to reduce symptoms of indigestion. It's unclear if this improvement is due to black seed or other ingredients.
Seizures (epilepsy)	Early research shows that taking black seed extract by mouth reduces the number of seizures in children with epilepsy. But taking black seed oil does not seem to work.

Stomach ulcers caused by Helicobacter pylori (H pylori infectoin)	Some research shows that taking black seed powder along with the drug omeprazole might help eliminate a certain bacterium (H. pylori) in the stomach that can cause stomach ulcers. But not all doses seem to work.
Hepatitis C	Early research shows that taking black seed oil daily for 3 months reduces viral load in people with hepatitis C. It also seems to reduce lower limb swelling. But it doesn't seem to improve liver function.
High cholesterol	Some early research shows that taking crushed black seed increases "good" high-density lipoprotein (HDL) cholesterol and reduces total cholesterol, "bad" low-density lipoprotein (LDL) cholesterol, and blood fats called triglycerides in people with borderline high cholesterol. Other research shows that taking both crushed black seed and garlic oil in addition to other products that lower cholesterol, such as simvastatin, can lead to larger improvements in blood cholesterol and triglyceride levels than simvastatin alone. However, not all research agrees.
Leukemia	Taking black seed while being treated for a type of leukemia called acute lymphoblastic leukemia might increase the chances of staying cancer-free once treatment ends. But it doesn't improve overall survival.
Metabolic syndrome	Early research suggests that taking a specific black seed oil product twice daily for 6 weeks might reduce total cholesterol, "bad" low-density lipoprotein (LDL) cholesterol, and blood sugar levels in people with metabolic syndrome.
Reducing harmful effects of a medicine called methotrexate	Early research shows that taking black seed might reduce liver damage caused by a certain drug used to treat cancer in children with a type of leukemia.
Obesity	Some research shows that taking black seed oil or powder might improve weight loss by a small amount in people who are obese or overweight. But other research shows no benefit. Studies are generally small and low-quality, so more research is needed.
Relieving symptoms related to opioid withdrawal	Early research shows that taking black seed extract by mouth three times daily for 12 days might reduce symptoms of opioid withdrawal.
Osteoarthritis	Early research shows that applying black seed oil to the knee for 3 weeks can help relieve knee pain caused by osteoarthritis.
Rheumatoid arthritis	Early research shows that taking black seed oil improves pain and stiffness in people with rheumatoid arthritis who are already taking methotrexate.
Sore throat and swollen tonsils (tonsillopharyngitis)	Early research suggests that taking a combination of chanca piedra and black seed by mouth for 7 days relieves pain in people with sore throat and swollen tonsils.

Dosing

BY MOUTH
For asthma: 2 grams of ground black seed has been used daily for 12 weeks. Also, 500 mg of black seed oil has been taken twice daily for 4 weeks. In addition, 15 mL/kg of black seed extract has been used daily for 3 months. A single dose of 50-100 mg/kg has also been used.

For diabetes	1 gram of black seed powder has been used twice daily for up to 12 months.
For high blood pressure	0.5-2 grams of black seed powder has been taken daily for up to 12 weeks. Also, 100-200 mg or 2.5 mL of black seed oil has been used twice daily for 8 weeks.
To improve sperm function	2.5 mL of black seed oil has been used twice daily for 2 months.
ON THE SKIN: For breast pain	A gel containing 30% black seed oil has been applied to breasts every day for two menstrual cycles.

69 Nettle Leaf

Stinging nettle is a plant. People use the root and above ground parts as medicine. Stinging nettle is used for many conditions, but so far, there isn't enough scientific evidence to determine whether or not it is effective for any of them. Stinging nettle root is used for urination problems related to an enlarged prostate (benign prostatic hyperplasia (BPH)). These problems include nighttime urination, too frequent urination, painful urination, inability to urinate, and irritable bladder. Stinging nettle root is also used for joint ailments, as a diuretic, and as an astringent. Stinging nettle above ground parts are used along with large amounts of fluids in so-called "irrigation therapy" for urinary tract infections (UTI), urinary tract inflammation, and kidney stones (nephrolithiasis). The above-ground parts are also used for allergies, hayfever, and osteoarthritis.

Some people use the above ground parts of stinging nettle for internal bleeding, including uterine bleeding, nosebleeds, and bowel bleeding. The above ground parts are also used for anemia, poor circulation, an enlarged spleen, diabetes and other endocrine disorders, stomach acid, diarrhea and dysentery, asthma, lung congestion, rash and eczema, cancer, preventing the signs of aging, "blood purification," wound healing, and as a general tonic. Stinging nettle above ground parts are applied to the skin for muscle aches and pains, oily scalp, oily hair, and hair loss (alopecia). In foods, young stinging nettle leaves are eaten as a cooked vegetable. In manufacturing, stinging nettle extract is used as an ingredient in hair and skin products. Stinging nettle leaf has a long history of use. It was used primarily as a diuretic and laxative in ancient Greek times. Don't confuse stinging nettle (Uritica dioica) with white dead nettle (Lamium album). Stinging nettle contains ingredients that might decrease inflammation and increase urine output.

Uses

Possibly Effective

Osteoarthritis	There is evidence that taking stinging nettle by mouth or applying it to the skin might reduce pain in people with osteoarthritis. Research suggests that using stinging nettle might reduce the need for pain medications.

Insufficient Evidence

Hay fever	Early evidence suggests that using stinging nettle at the first signs of hay fever symptoms seems to help provide relief.

NATURAL REMEDIES | Herbs | Stinging Nettle | Uses

Benign prostatic hyperplasia (BPH)	There is contradictory evidence about the effectiveness of stinging nettle, taken alone or together with other ingredients, for improving symptoms of BPH. Early evidence suggests that taking 360 mg of stinging nettle for 6-24 months improves urinary tract symptoms associated with BPH. Many studies have looked at the effects of a combination product that contains both stinging nettle and saw palmetto. One particular product (PRO 160/120, Willmar Schwabe GmbH, Germany) containing a specific extract of stinging nettle (WS 1031) 120 mg plus a specific extract of saw palmetto (WS 1473) 160 mg seems to significantly improve urinary tract symptoms in men with BPH when taken twice daily for 24-48 weeks. This combination seems to be comparable to the prescription medication finasteride for relieving symptoms of BPH, and may be better tolerated. However, it is not known if this benefit is due to stinging nettle, saw palmetto, or both ingredients. On the other hand, another combination product containing 80 mg of stinging nettle root extract, 106 mg of saw palmetto lipoidal extract, 160 mg of pumpkin seed oil extract, 33 mg of lemon bioflavonoid extract, and 190 IU of vitamin A (100% as beta-carotene) does not significantly improve symptoms of BPH when taken three times daily for 6 months.
Bleeding	Some early research suggests that applying a specific product (Ankaferd blood stopper) containing alpinia, licorice, thyme, stinging nettle, and common grape vine to the skin reduces bleeding in surgery, but does not reduce time in surgery. Other early research suggests the same product reduces bleeding after dental surgery.
Diabetes	Early research suggests that taking stinging nettle daily for 8 weeks does not affect the control of blood sugar levels in people with diabetes who are taking antidiabetes drugs.
Gingivitis	Early research suggests that using a mouthwash containing stinging nettle, juniper, and yarrow twice daily for 3 months does not reduce plaque or bleeding in people with gingivitis.

Dosing

The appropriate dose of stinging nettle depends on several factors such as the user's age, health, and several other conditions. At this time, there is not enough scientific information to determine an appropriate range of doses for stinging nettle. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

70 Sweet Orange

Sweet orange is a fruit. The peel and juice are used to make medicine. Sweet orange is most commonly used for high cholesterol, high blood pressure, and stroke prevention. Some people use it in aromatherapy to help with anxiety, depression, and sleep. Sweet orange contains large amounts of vitamin C. Some researchers believe sweet orange might help asthma because of the antioxidant activity of vitamin C. Sweet orange also contains large amounts of potassium. There is evidence that potassium may help prevent high blood pressure and stroke. Sweet orange fruit and sweet orange juice are used to prevent kidney stones because they contain large amounts of a chemical called citrate. Citrate tends to bind with calcium before it can form kidney stones.

Uses

Possibly Effective

High cholesterol	Drinking sweet orange juice seems to help improve cholesterol levels. In large amounts (750 mL, or about three 8-oz glasses, per day for four weeks), sweet orange juice seems to increase "good" high-density lipoprotein and reduce the ratio of "bad" low-density lipoprotein (LDL) to HDL cholesterol in people with high cholesterol.
High blood pressure	Drinking sweet orange juice seems to help lower the risk of high blood pressure. The U.S. Food and Drug Administration (FDA) allows makers of sweet orange products that provide at least 350 mg of potassium per serving and are low in sodium, saturated fat, and cholesterol to make label claims that their product might reduce the risk of developing high blood pressure.
Stroke	Drinking sweet orange juice seems to help lower the risk of stroke. The U.S. Food and Drug Administration (FDA) allows makers of sweet orange products that provide at least 350 mg of potassium per serving and are low in sodium, saturated fat, and cholesterol to make label claims that their product might reduce the risk of stroke.

Possibly Ineffective

Prostate cancer	Higher dietary intake of sweet orange juice is not linked with a decreased risk of prostate cancer.

Insufficient Evidence

Asthma	There is some evidence that sweet orange and other fruits that are rich in vitamin C might improve lung function in people with asthma. But not all studies agree.
Colds	Some research shows that drinking 180 mL (about 6 ounces) of sweet orange juice daily might help prevent symptoms of the common cold.
Depression	Early research suggests that using sweet orange on the skin during massage, or in the air as aromatherapy, reduces depression in older adults.
Kidney stones (nephrolithiasis)	Some research reports that drinking 400 mL of sweet orange juice (about 13 ounces) increases the amount of citrate in the urine. This might help to prevent kidney stones that are made of calcium.
Obesity	Early research shows that drinking red sweet orange juice does not reduce body weight in overweight adults. Other research shows that taking a specific product containing sweet orange, blood orange, and grapefruit extracts seems to decrease body weight and body fat in overweight people. But it is not clear if this is from the sweet orange or from the other ingredients.
Sleep quality	Early research shows that inhaling sweet orange as aromatherapy might help people who are going through hemodialysis to sleep better and feel less tired.
Stress	Early research shows that smelling sweet orange essential oil during a stressful task might reduce anxiety and tension.

Dosing

NATURAL REMEDIES | Herbs | Sweet Orange | Dosing

BY MOUTH
For high cholesterol: 750 mL sweet orange juice per day.

For high blood pressure: Sweet orange juice products that provide at least 350 mg of potassium per serving and are low in sodium, saturated fat, and cholesterol are permitted by the FDA to make labeling claims that they might reduce the risk of developing high blood pressure.

For stroke: Sweet orange juice products that provide at least 350 mg of potassium per serving and are low in sodium, saturated fat, and cholesterol are permitted by the FDA to make labeling claims that they might reduce the risk of stroke.

71 Oats

Oat is a plant. People use the seed (oat), leaves and stem (oat straw), and bran (the outer layer of whole oats) to make medicine. Oat bran and whole oats are used for high blood pressure; high cholesterol; diabetes; and digestion problems including irritable bowel syndrome (IBS), diverticulosis, inflammatory bowel disease (IBD), diarrhea, and constipation. They are also used for preventing heart disease, gallstones, colon cancer, and stomach cancer. Oats are most commonly used to lower cholesterol and reduce the risk of heart disease. Oats might help reduce cholesterol and blood sugar levels and control appetite by causing a feeling of fullness. Oat bran might work by blocking the absorption from the gut of substances that contribute to heart disease, high cholesterol, and diabetes. When applied to the skin, oats appear to reduce swelling.

Uses

Likely Effective

Heart disease	Oat bran contains high amounts of fiber. Foods high in fiber can be used as part of a diet low in fat and cholesterol to prevent heart disease. In fact, food products containing whole oats that provide 750 mg of soluble fiber per serving can be labeled with the health claim that the product may reduce the risk of heart disease when included as part of a diet low in saturated fat and cholesterol.
Lowering cholesterol	Eating oats, oat bran, and other soluble fibers can modestly reduce total and "bad" low-density lipoprotein (LDL) cholesterol when consumed as part of a diet low in saturated fat. For each gram of soluble fiber (beta-glucan) consumed, total cholesterol decreases by about 1.42 mg/dL and LDL by about 1.23 mg/dL. Eating 3-10 grams of soluble fiber can reduce total cholesterol by about 4-14 mg/dL. But there's a limit. Doses of soluble fiber greater than 10 grams per day don't seem to increase effectiveness. Eating three bowls of oatmeal (28 gram servings) daily can decrease total cholesterol by about 5 mg/dL. Oat bran products (oat bran muffins, oat bran flakes, oat bran Os, etc.) may vary in their ability to lower cholesterol, depending on the total soluble fiber content. Whole oat products might be more effective in lowering LDL and total cholesterol than foods containing oat bran plus beta-glucan soluble fiber. The FDA recommends that approximately 3 grams of soluble fiber be taken daily to lower blood cholesterol levels. However, this recommendation doesn't match research findings; according to controlled clinical studies, at least 3.6 grams of soluble fiber daily is needed to lower cholesterol.

Possibly Effective

Reducing blood sugar levels in people with diabetes when oat bran is used in the diet.	Eating oats and oat bran for 6 weeks significantly decreases before-meal blood sugar, 24-hour blood sugar, and insulin levels in people with type 2 diabetes. There is some evidence that consuming 50 grams of oat bran daily, containing 25 grams of soluble fiber, might be more effective than the moderate fiber diet of 24 grams daily recommended by the American Diabetes Association.
Stomach cancer	People who eat high-fiber foods, such as oats and oat bran, seem to have a lower risk of stomach cancer.

Possibly Ineffective

Colon cancer	People who eat oat bran or oats don't seem to have a lower risk of colon cancer. Also, eating oat bran fiber isn't linked with a lower risk of colon tumor recurrence.
High blood pressure	Eating oats as oatmeal or oat cereal doesn't reduce blood pressure in men with slightly high blood pressure.

Insufficient Evidence

Dry skin	Applying a lotion that contains oats (Aveeno Active Naturals Skin Relief 24Hr Moisturizing Lotion) seems to reduce symptoms of dry skin.
Preventing fat redistribution syndrome in people with HIV disease	Eating a high-fiber diet, including oats, with adequate energy and protein might prevent fat accumulation in people with HIV. A one-gram increase in total dietary fiber may decrease the risk of fat accumulation by 7%.
Ulcerative colitis	Early research shows that taking a specific oat-based product (Profermin) by mouth can reduce symptoms and prevent recurrence of ulcerative colitis.
Itchy skin in people with kidney disease	Early research shows that applying lotion containing oats reduces skin itching in people with this condition. The lotion seems to work as well as taking the antihistamine hydroxyzine 10 mg.

Dosing

BY MOUTH
For high cholesterol: 56-150 grams of whole oat products such as oat bran or oatmeal, containing 3.6-10 grams of beta-glucan (soluble fiber) daily as part of a low-fat diet. One-half cup (40 grams) of Quaker oatmeal contains 2 grams of beta-glucan; one cup (30 grams) of Cheerios contains one gram of beta-glucan.

For lowering blood sugar levels in patients with type 2 diabetes: High fiber foods such as whole oat products containing up to 25 grams of soluble fiber are used daily. 38 grams of oat bran or 75 grams of dry oatmeal contains about 3 grams of beta-glucan.

72 Paw Paw

American pawpaw is a plant. The bark, leaf, and seed are used to make medicine. In homeopathy, American pawpaw is used for treating fever, vomiting, and pain and swelling (inflammation) of the mouth and throat. Homeopathy is an alternative treatment method that uses extreme dilutions of medicines. American pawpaw has chemicals that might have activity against certain lung and breast cancers.

Uses

Insufficient Evidence

Head lice	Early research suggests that applying a shampoo that contains American pawpaw, thymol, and tea tree oil to the head up to three times over 16 days can eliminate lice in adults and children.

Dosing

The appropriate dose of American pawpaw depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for American pawpaw. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

73 Psyllium Husk

Black psyllium is a plant. People use the seed to make medicine. Be careful not to confuse black psyllium with other forms of psyllium including blond psyllium. Black psyllium is used for chronic constipation and for softening stools in conditions such as hemorrhoids, cracks in the skin around the anus (anal fissures), surgery on the rectum, and pregnancy. It is also used for diarrhea, dysentery, irritable bowel syndrome (IBS), cancer, high cholesterol, and reducing the risk of coronary heart disease. Black psyllium adds bulk to the stool which might help with constipation, diarrhea, and irritable bowel syndrome. It also controls how quickly sugars are absorbed from the gut, which might help control blood sugar levels in people with diabetes.

Uses

Effective

Constipation	Black psyllium is safe and effective for short-term, over-the-counter use for treating constipation.

Likely Effective

Coronary heart disease	Foods containing black psyllium can help reduce the risk of coronary heart disease. The daily intake of psyllium must be at least 7 grams and it must be combined with a diet low in saturated fat and cholesterol.

Insufficient Evidence

Diabetes	Early research suggests that taking black psyllium by mouth might help control blood sugar in people with type 2 diabetes by reducing how quickly sugars are absorbed from food.
Obesity	Early research shows that taking black psyllium by mouth can slightly decrease body weight and body mass index in people with non-alcoholic fatty liver disease (NAFLD) who are overweight. But it doesn't work better than standard care for NAFLD.

Dosing

BY MOUTH
For constipation: The typical dose of black psyllium is 10-30 grams per day in divided amounts. Take each dose with plenty of water. 'Otherwise, black psyllium might cause choking. The FDA labeling recommends at least 8 ounces (a full glass) of water or other fluid with each dose.

For coronary heart disease: Black psyllium is added to a diet low in saturated fat and cholesterol in a dose of at least 7 grams daily.

For diabetes: Black psyllium has been used in a dose of 15 grams daily.

Black psyllium should be taken 30-60 minutes after taking other drugs.

74 Panax Notoginseng

Panax notoginseng is a plant. The leaves, fruit, and flowers are used to make medicine. However, the root is used the most commonly. Be careful not to confuse Panax notoginseng with other forms of ginseng, such as Panax ginseng, Panax pseudoginseng, or American ginseng. Panax notoginseng is used to stop or slow down bleeding. It is sometimes taken by people who have nosebleeds, vomit up or cough up blood, or find blood in their urine or feces. Panax notoginseng is also used to relieve pain; and to reduce swelling and blood pressure. It is also used for chest pain (angina), strokes and bleeding in the brain, build up of fat in the blood vessels, heart attacks, and some kinds of liver disease. It is also used to improve energy and ability to exercise, to reduce muscle soreness following exercise, and for osteoarthritis and rheumatoid arthritis. Some people apply Panax notoginseng directly to the skin to stop bleeding, help with bruising or swelling, and to improve blood movement in the muscles. Panax notoginseng might relax blood vessels. This would improve blood flow and reduce blood pressure. Some of the chemicals in Panax notoginseng might reduce swelling and protect the heart. There isn't enough information to know how Panax notoginseng might work for other conditions.

Uses

Possibly Effective

Chest pain (angina)	Research shows that Panax notoginseng, taken by mouth or given as an injection, seems to reduce symptoms of chest pain when used along with conventional medications. It might also reduce how often chest pain attacks occur and how long the attacks last when they do occur. These products are given by a doctor in countries like China.
Bleeding in the brain (intracranial hemorrhage)	Research shows that Panax notoginseng injections might improve recovery and reduce the risk of death in people that have had bleeding in the brain, usually because of a stroke. These products are given by a doctor in countries like China.
Stroke	Research shows that giving Panax notoginseng injections might increase the chance of a person improving or recovering after a stroke. These products are given by a doctor in countries like China.

Possibly Ineffective

Heart attack (myocardial infarction; MI)	Panax notoginseng does not seem to prevent heart attacks in people with heart disease when used along with conventional therapy.

Insufficient Evidence

Sore muscles a few days after exercise	Taking Panax notoginseng might reduce muscle soreness a few days after a downhill run. But the improvement is small.
Exercise performance	Early research shows that taking Panax notoginseng for 30 days might help non-athletes exercise longer.
Osteoarthritis	Some research shows that taking a combination of Panax notoginseng, Siberian ginseng, and rehmannia daily might help patients with osteoarthritis move better. However, it does not seem to help reduce pain or stiffness.

NATURAL REMEDIES | Herbs | Panax Notoginseng | Dosing

Dosing

ADULTS
BY MOUTH
For chest pain (angina): 200-400 mg of Panax notoginseng extract has been taken 2-3 times daily for 4-6 weeks. Also, 1 gram of Panax notoginseng powder has been taken 3 times daily.

For stroke	A specific extract of Panax notoginseng root (sanchitongtshu) has been taken three times daily for 28 days.
WITH A NEEDLE: For chest pain (angina)	400-500 mg of Panax notoginseng extract has been injected into the vein or given as a shot daily for 2-4 weeks.
For bleeding in the brain (intracranial hemorrhage)	140-800 mg of Panax notoginseng extract has been injected into the vein daily, usually for 2-4 weeks.
For stroke	Injections containing 200-600 mg of Panax notoginseng have been given daily for 2-4 weeks.

75 Muira Puama

Muira puama is a plant. The wood and root are used to make medicine. Muira puama is used for preventing sexual disorders and to increase interest in sexual activity (as an aphrodisiac). It is also used for upset stomach, menstrual disorders, joint pain (rheumatism), and paralysis caused by poliomyelitis; and as a general tonic and an appetite stimulant. Some people apply muira puama directly to the skin as an aphrodisiac and for rheumatism and muscle paralysis. In combination with other herbs, muira puama is used as a remedy for male sexual performance problems (erectile dysfunction, ED). The chemicals in muira puama have no known effects on the body.

Uses

Insufficient Evidence

Sexual disorders	Early research suggests that taking 2-6 tablets of a specific product (Herbal vX) containing muira puama extract and ginkgo extract modestly improves sexual desire and the frequency of sexual intercourse in women with a low sex drive.

Dosing

The appropriate dose of muira puama depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for muira puama. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

76 Sage

Sage is an herb. The leaf is used to make medicine. Sage is used for digestive problems, including loss of appetite, gas (flatulence), stomach pain (gastritis), diarrhea, bloating, and heartburn. It is also used for reducing overproduction of perspiration and saliva; and for depression, memory loss, and Alzheimer's disease. Women use sage for painful menstrual periods, to correct excessive milk flow during nursing, and to reduce hot flashes during menopause. Sage is applied directly to the skin for cold sores; gum disease (gingivitis); sore mouth, throat or tongue; and swollen, painful nasal passages. Some people inhale sage for asthma. In foods, sage is used as a commonly used spice. In manufacturing, sage is used as a fragrance component in soaps and cosmetics.

Uses

Possibly Effective

Alzheimer's disease	Taking extracts of two different sage species (Salvia officinalis and Salvia lavandulaefolia) for 4 months seems to improve learning, memory and information processing in people with mild to moderate Alzheimer's disease.
Mental performance	Taking a single dose of common sage (Salvia officinalis) or Spanish sage (Salvia lavandulaefolia) by mouth seems to improve memory, alertness, and attention in healthy adults. When used as aromatherapy, these sage species seem to improve alertness, but not attention and memory.
Cold sores when applied as a cream containing sage and rhubarb.	Applying a cream containing common sage (Salvia officinalis) and rhubarb (Rheum officinale and Rheum palmatum) to cold sores may be about as effective as acyclovir (Zovirax) cream. Acyclovir cream heals the cold sores in about 6 days; it takes the sage and rhubarb cream about 7 days to heal them. Sage and rhubarb together work faster than sage alone.
High cholesterol	Taking common sage (Salvia officinalis) three times per day for 2 months seems to reduce "bad" low-density lipoprotein (LDL) cholesterol and blood fats called triglycerides, and increase "good" high-density lipoprotein (HDL) cholesterol, in people with high cholesterol.
Memory	Taking a single dose of common sage (Salvia officinalis) or Spanish sage (Salvia lavandulaefolia) by mouth seems to improve memory in healthy adults. However, these sage species do not seem to improve memory when used as aromatherapy.
Menopausal symptoms	Early research suggests that taking extract of common sage (Sage Menopause, Bioforce AG) for 8 weeks improves symptoms of menopause, especially hot flashes. Also, other developing research suggests that taking a combination of common sage (Salvia officinalis) and alfalfa extract for 3 months reduces hot flashes and night sweats.

Insufficient Evidence

Lung cancer	People who regularly use sage as a spice seem to have a 54% lower chance of developing lung cancer compared to those who don't use sage.
Sore throat	People who regularly use sage as a spice seem to have a 54% lower chance of developing lung cancer compared to those who don't use sage.
Sore throat	Using a specific spray containing 15% common sage extract (Valverde Salvia Rachenspray) seems to reduce throat pain in people with a sore throat. However, sprays containing higher (30%) and lower (5%) amounts of common sage extract do not seem to reduce throat pain. Other early research suggests that spraying the throat with a specific product containing common sage and echinacea for up to 5 days improves sore throat symptoms similarly to a commonly used drug spray.

Pain after surgery	Early research suggests that taking common sage (Salvia officinalis) along with the drugs ibuprofen or diclofenac is less effective for reducing pain after surgery compared to using the drug benzydamine hydrochloride. Also, using common sage seems to increase the risk of infections after surgery compared to benzydamine hydrochloride.
Sunburn	Applying 2% common sage (Salvia officinalis) extract to the skin after UV exposure seems to reduce the development of skin redness.
Swelling of the tonsils (tonsillitis)	Early research suggests that spraying the throat with a specific product containing common sage and echinacea for up to 5 days improves symptoms of tonsillitis similarly to a commonly used drug

Dosing

BY MOUTH
For treating Alzheimer's disease: 1 gram of sage per day. A dose of sage extract, gradually increased over time to 2.5 mg three times daily, has also been used.

APPLIED TO THE SKIN
For treatment of herpes labialis (cold sores): A cream containing 23 mg/gram each of sage extract and rhubarb extract has been applied every 2 to 4 hours while awake, with treatment starting within 1 day of the first symptoms and continuing for 10 to 14 days.

77 Rehmannia

Rehmannia is a plant. The root and parts that grow above the ground are used to make medicine. Rehmannia is commonly found in herbal combinations used in Traditional Chinese Medicine and Japanese Medicine. Rehmannia is used for diabetes, "tired blood" (anemia), fever, weakened bones (osteoporosis), and allergies; and as a general tonic. There is not enough information to know how rehmannia might work for any medical condition. However, some chemicals in rehmannia seem to affect the immune system and might reduce pain and swelling. Some chemicals in rehmannia also seem to lower blood sugar levels.

Uses

Insufficient Evidence

Anemia caused by bone marrow failure (aplastic anemia)	Early research suggests that taking rehmannia along with the steroidal drug stanozolol might help improve symptoms of aplastic anemia better than stanozolol alone.
Chronic lung disease (chronic obstructive pulmonary disease, COPD)	Early research suggests that taking a Chinese herbal decoction containing rehmannia root and angelica (tongfei mixture) by mouth along with oxygen treatment might improve oxygen levels during the night better than oxygen treatment alone in people with COPD and low oxygen levels.

Dosing

The appropriate dose of rehmannia depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for rehmannia. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

78 Raspberry Leaf

Red raspberry is a plant that is the source of a widely eaten, tasty, sweet berry. However, red raspberry fruit and leaf have also been used as medicine for centuries. The therapeutic use of raspberry leaf was first described in 1597 in a book called "The Herbal," or "A General History of Plants." Today, red raspberry leaf and fruit are still used as medicine. Some people take red raspberry leaf by mouth for gastrointestinal (GI) tract disorders including diarrhea; for respiratory system disorders including flu and swine flu; and for heart problems including heart failure, high blood pressure, fever, diabetes, and vitamin deficiency. Some women take raspberry leaf by mouth for painful periods, heavy periods, morning sickness associated with pregnancy, preventing miscarriage, and easing labor and delivery. Red raspberry leaf is applied directly to the skin for sore throat and skin rash. In foods, red raspberry fruit is eaten and processed into jams and other foods. Red raspberry leaf in small quantities is a source of natural flavoring in Europe. The chemicals in red raspberry might have antioxidant effects and help relax blood vessels. They might also cause muscles to contract or relax, depending on the dose and the muscle involved. This is the theory behind red raspberry's use in easing labor and delivery.

Uses

Possibly Ineffective

Making labor and delivery easier	Taking red raspberry leaf does not seem to reduce the length of labor or decrease the need for pain-relieving medication around the time of delivery.

Dosing

The appropriate dose of red raspberry depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for red raspberry. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

79 Reishi Mushroom

Reishi mushroom is a fungus that some people describe as "tough" and "woody" with a bitter taste. The fruiting body (above-ground part) and mycelium (filaments connecting a group of mushrooms) are used as medicine. Reishi mushroom is used for boosting the immune system; viral infections such as the flu (influenza), swine flu, and avian flu; lung conditions including asthma and bronchitis; heart disease and contributing conditions such as high blood pressure and high cholesterol; kidney disease; cancer; and liver disease. It is also used for HIV/AIDS, altitude sickness, chronic fatigue syndrome (CFS), trouble sleeping (insomnia), stomach ulcers, poisoning, and herpes pain. Other uses include reducing stress and preventing fatigue. In combination with other herbs, reishi mushroom is used to treat prostate cancer. Reishi mushroom contains chemicals that seem to have a variety of potentially beneficial effects, including activity against tumors (cancer) and beneficial effects on the immune system.

Uses

Insufficient Evidence

NATURAL REMEDIES | Herbs | Reishi Mushroom | Uses

Noncancerous tumors in the colon and rectum (colorectal adenomas)	Early research suggests that taking reishi mushroom extract daily for 12 months reduces the number of tumors in people with colorectal adenomas.
Clogged arteries	Early research suggests that taking a specific reishi mushroom product (Ganopoly) reduces symptoms of clogged arteries, including chest pain and shortness of breath.
Diabetes	Early research suggests that taking a specific reishi mushroom product (Ganopoly) daily for 12 weeks reduces hemoglobin but not blood sugar levels in people with type 2 diabetes.
Hepatitis B	Early research suggests that taking a specific reishi mushroom product (Ganopoly) for 12 weeks reduces how much of the hepatitis B virus is circulating in the body. This product also seems to improve liver function in people with this condition.
High cholesterol	Early research suggests that taking reishi mushroom extract daily for 12 weeks does not affect cholesterol levels in people with high blood pressure and/or high cholesterol.
High blood pressure	There is inconsistent evidence about the effects of reishi mushroom on high blood pressure. Early research suggests that taking reishi mushroom extract daily for 12 weeks does not lower blood pressure in people with slightly high blood pressure. However, other research suggests that taking reishi mushroom lowers blood pressure in people with more severe high blood pressure.
Lung cancer	Early research suggests that taking reishi mushroom does not shrink lung tumors. However, it does appear to improve immune function and quality of life in people with lung cancer.
Shingles-related pain	Some people report that hot water extracts of reishi mushroom decreases pain when conventional treatment does not work.

Dosing

The appropriate dose of reishi mushroom depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for reishi mushroom. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

80 Rhubarb

Rhubarb is a plant. The root and underground stem (rhizome) are used to make medicine. The stem of rhubarb is also consumed as food. Traditional Chinese medicine commonly uses rhubarb alone or in combination with other ingredients. Rhubarb is used primarily for digestive complaints including constipation, diarrhea, heartburn, stomach pain, gastrointestinal (GI) bleeding, and preparation for certain GI diagnostic procedures. Some people use rhubarb to decrease the strain during bowel movements. Rhubarb is also used for gonorrhea, high levels of cholesterol in the blood, high blood pressure associated with pregnancy, and weight loss. Rhubarb is also used to improve symptoms associated with menopause or menstruation. It is also used to reduce pain associated with pancreas swelling (inflammation) or to slow down kidney disease. Rhubarb is used to reduce symptoms of stroke, sepsis (blood infection), or pesticide poisoning. It is also used for some types of cancer and for patients with nonalcoholic fatty liver disease (NAFLD). A mouth rinse containing rhubarb is used for gingivitis. Rhubarb is sometimes applied to the skin to treat cold sores. In food, rhubarb stems are eaten in pie and other recipes. Rhubarb is also used as a flavoring agent. Rhubarb contains several chemicals which might help heal cold sores and improve movement of the intestines. Some chemicals in rhubarb might reduce swelling. Rhubarb contains fiber that might reduce cholesterol levels.

Uses

Possibly Effective

Cold sores	Applying a cream containing rhubarb and sage to herpes cold sores seems to improve healing. It might be as effective as acyclovir (Zovirax) cream.
Menopause	Clinical research shows that taking a rhubarb root extract by mouth improves many symptoms of menopause, including hot flushes, sweating, sleep, mood, quality of life, fatigue, and sexual problems.
Pancreas inflammation (pancreatitis)	Rhubarb powder given through a tube directly into the intestines might help to reduce pain and other symptoms of pancreatitis. It might also decrease the length of a hospital stay for pancreatitis.

Insufficient Evidence

Painful menstruation (dysmenorrhea)	Early research suggests that taking rhubarb powder might reduce pain during menstruation.
Bleeding from the stomach and bowels	There is some evidence that taking rhubarb powder might be useful for treating gastrointestinal (GI) bleeding.
High cholesterol	Early research shows that eating ground rhubarb stalk for 4 weeks can lower total cholesterol and low-density lipoprotein (LDL or "bad") cholesterol in people with high cholesterol.
Kidney disease	There is not enough reliable information to know if rhubarb helps people with kidney disease. Most studies have measured the effects of rhubarb on markers of kidney disease and the progression of kidney disease to kidney failure. Results are conflicting. Nearly all of the studies are low quality and at high risk of bias.
Cancer affecting the area behind the nose (nasopharyngeal cancer)	Early research suggests that taking a specific Chinese herbal product (Shenlong) containing rhubarb and other herbs along with radiation therapy does not improve healing in people with nasopharyngeal cancer.
Nonalcoholic fatty liver disease (NAFLD)	Early research suggests that taking a specific Chinese herbal medicine (Danning Pian) containing rhubarb, giant knotweed, dried green orange peel, and dried old orange peel might improve liver function in people with non-alcoholic fatty liver disease. It's unknown if rhubarb helps if taken by itself.
Obesity	Some early research suggests that taking rhubarb extract 1-3 times daily for up to 3 months might reduce body weight in obese people. However, other research shows that taking rhubarb with other herbs does not reduce weight.
Poisoning	Exposure to large amounts of pesticides can result in poisoning. In people with pesticide poisoning, early research suggests that taking rhubarb or having rhubarb placed in the rectum as an enema, while also using regular treatments for poisoning, might reduce symptoms and maintain the function of the body.
Life-threatening infection (sepsis)	Early research suggests that using rhubarb along with standard treatments might help reduce the risk for certain complications from a life-threatening infection called sepsis. But rhubarb doesn't appear to reduce death due to this type of infection.

Stroke	Low-quality research suggests that using traditional Chinese medicine that contains rhubarb root and rhizome, in combination with regular stroke treatments, improves function and reduces damage to the brain better than the regular treatments alone in patients who have had a stroke. Higher-quality research is needed to confirm.

Dosing

BY MOUTH
For menopause: A specific rhubarb root dry extract (ERr 731, Anderson Global Group)) 4 mg per day for up to 2 years.

For swelling of the pancreas (pancreatitis): Rhubarb powder 15 grams in 100 mL warm water given by a healthcare provider through a tube going directly into the small intestine for up to one week.

APPLIED TO THE SKIN:
For cold sores: Cream containing rhubarb extract 23 mg and sage extract 23 mg in every gram of cream, applied every 2 to 4 hours while awake. Treatment starts within one day after symptoms appear and continues for 10 to 14 days.

81 Ruscus (Butcher's Broom)

Butcher's broom is a plant. The root is used to make medicine. Butcher's broom is used for hemorrhoids, gallstones, "hardening of the arteries" (atherosclerosis), and for symptoms of poor blood circulation such as pain, heaviness, leg cramps, leg swelling, varicose veins, itching, and swelling. Butcher's broom is also used as a laxative, as a diuretic to increase urine output, to reduce swelling, and to speed the healing of fractures. In some cultures, the roots are eaten in much the same way as asparagus. The chemicals in butcher's broom might cause the blood vessels to narrow or constrict. Butcher's broom might improve blood circulation in the legs by preventing blood from "pooling" in the veins.

Uses

Possibly Effective

Circulatory problems (chronic venous insufficiency)	Some research shows that taking butcher's broom by mouth, alone or in combination with vitamin C and hesperidin, seems to relieve the symptoms of poor circulation in the legs, such as pain, heaviness, cramps, itching, and swelling.

Insufficient Evidence

Vision problems caused by diabetes (diabetic retinopathy)	Early research suggests that taking a specific product containing butcher's broom extract (Fagorutin-Ruscus, Fink GmbH) by mouth for 3 months does not improve vision in people with diabetic retinopathy.
Swelling of the arms (lymphedema)	Early research suggests that taking a specific product (Cyclo 3 Fort) containing butcher's broom root extract, hesperidin methyl chalcone, and vitamin C by mouth for 90 days reduces swelling in the upper arm and forearm, and improves mobility and heaviness in women with swelling of the arm after breast cancer treatment.
Low blood pressure when getting up (orthostatic hypotension)	Some research suggests that taking butcher's broom by mouth might relieve the syndrome of low blood pressure upon getting up.

Dosing

BY MOUTH
For relieving symptoms of poor circulation (chronic venous insufficiency): 150 mg of butcher's broom root extract, combined with 150 mg of hesperidin and 100 mg of ascorbic acid twice daily.

82 Red Clover

Red clover is a plant. The flower tops are used to make medicine. Red clover is used for many conditions, but so far, there isn't enough scientific evidence to determine whether it is effective for any of them. It doesn't seem to work, though, for lowering cholesterol or controlling hot flashes in women. Red clover is used for cancer prevention, indigestion, high cholesterol, whooping cough, cough, asthma, bronchitis, and sexually transmitted diseases (STDs). Some women use red clover for symptoms of menopause such as hot flashes; for breast pain or tenderness (mastalgia); and for premenstrual syndrome (PMS). Red clover is applied to the skin for skin cancer, skin sores, burns, and chronic skin diseases including eczema and psoriasis. In foods and beverages, the solid extract of red clover is used as a flavoring ingredient. Red clover contains hormone-like chemicals called isoflavones that seem to cause reproductive problems in certain animals. Experts think a diet high in isoflavones may have been responsible for reports of reproductive failure and liver disease in cheetahs living in zoos. In large quantities, red clover can cause sterility in livestock. Red clover contains "isoflavones" which are changed in the body to "phytoestrogens" that are similar to the hormone estrogen.

Uses

Possibly Ineffective

High cholesterol in women	Research shows that taking red clover extracts by mouth for 3 months to a year does not seem reduce low-density lipoprotein (LDL or "bad") cholesterol or increase high-density lipoprotein (HDL or "good") cholesterol in women who have moderately elevated cholesterol levels.
Weak bones (osteoporosis)	Some early research suggests that taking red clover daily for 6 months increased bone mineral density and healthy postmenopausal women. However, most evidence suggests that taking red clover does not improve osteoporosis.

Insufficient Evidence

Hair loss (alopecia)	Early research shows that applying a combination product containing red clover flower extract increases hair growth in people with hair loss.
Symptoms of an enlarged prostate gland (benign prostatic hyperplasia)	Research suggests that red clover supplements might improve some symptoms of benign prostatic hyperplasia (BPH). It seems to decrease nighttime urination and improve the quality of life in men with BPH. However, red clover does not seem to affect urine flow rate, prostatic-specific antigen (PSA) values, or prostate size.
Breast cancer	Early evidence shows that taking a specific red clover extract (Promensil) daily for one year does not increase breast tissue density, suggesting that it might not affect breast cancer risk.
Cancer of the lining of the uterus (endometrial cancer)	Early research suggests that taking red clover supplements does not help prevent endometrial cancer.
Cyclical breast pain	There is some early evidence that red clover might relieve cyclic breast pain and tenderness.

Menopause symptoms	There are contradictory research findings about the effects of red clover on symptoms of menopause. Most research shows that taking red clover by mouth for up to a year does not reduce menopause symptoms such as hot flashes or night sweats, although some research shows that a specific red clover product (Promensil, Novogen) might reduce severity but not the frequency of hot flashes. However, other research shows that a different form of red clover (MF11RCE, Melbrosin International) might improve symptoms of menopause-related anxiety and depression.
Postmenopausal conditions	Some early evidence suggests that red clover may improve some secondary conditions associated with postmenopause. These effects include reducing blood pressure and improving cholesterol levels in postmenopausal women. However, red clover does not seem to improve thinking skills.

Dosing

The appropriate dose of red clover depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for red clover. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

83 Saw Palmetto

Saw palmetto is a tree. Its ripe fruit is used to make medicine. Saw palmetto is most commonly used for decreasing symptoms of an enlarged prostate called benign prostatic hypertrophy (BPH), but some scientific evidence shows that it does not work. Saw palmetto is also used to prevent complications from prostate surgery and for treating certain types of prostate conditions. Saw palmetto doesn't shrink the overall size of the prostate, but it seems to shrink the inner lining that puts pressure on the tubes that carry urine. Saw palmetto also might prevent testosterone from being converted to a more potent form of testosterone called dihydrotestosterone (DHT). It is thought that some types of hair loss are caused by increased sensitivity of hair follicles to DHT. Reduced levels of DHT may help prevent these types of hair loss.

Uses

Possibly Effective

Prostate surgery (transurethral resection of the prostate; TURP)	Research shows that taking 320 mg of saw palmetto daily for 2 months before prostate surgery can reduce the time spent in surgery, blood loss, the development of problems during surgery, and the total time spent in the hospital. However, one small study found that taking 160 mg of saw palmetto per day for 5 weeks before surgery does not lower the risk of problems during surgery.

Possibly Ineffective

Enlarged prostate (benign prostatic hyperplasia; BPH)	The effect of saw palmetto on prostate symptoms is conflicting. However, higher quality and more reliable research seems to indicate that saw palmetto has little or no benefit for reducing symptoms such as going to the bathroom at night or painful urination in men with BPH. Any benefit is modest at best. Also, saw palmetto does not seem to work as quickly or enhance the effects of certain drugs used to treat BPH.

Insufficient Evidence

Male and female pattern baldness (androgenic alopecia)	The effects of saw palmetto in people with male and female pattern baldness are conflicting. Some research shows that taking saw palmetto and beta-sitosterol by mouth improves the amount and quality of hair in men with male pattern baldness. However, taking saw palmetto by mouth does not appear to improve hair growth as well as the drug finasteride. Early research suggests that applying saw palmetto to the scalp may increase hair density in men and women who are balding. However, higher quality research is needed to confirm these results.
Underactive bladder (hypotonic bladder)	Underactive bladder is a condition in which the bladder can hold unusually large amounts of urine but does not empty completely upon urination. Early research suggests that taking 90-120 drops of a combination of echinacea and saw palmetto for 77 days improves the amount of urine the bladder can hold and the amount left in the bladder after urination in women with underactive bladder.
Prostate cancer	Taking saw palmetto doesn't seem to be linked with a reduced risk of prostate cancer. Also, taking saw palmetto during radiation for early prostate cancer doesn't seem to improve lower urinary tract symptoms. These symptoms are common in men undergoing radiation for prostate cancer.
Prostate swelling and chronic pelvic pain syndrome	Some early research shows that saw palmetto can improve symptoms in men with prostate swelling not caused by an infection. Other early research suggests that taking saw palmetto along with the drug prulifloxacin reduces pain and urinary symptoms better than taking prulifloxacin alone in men with prostate swelling caused by an infection. However, taking the combination doesn't appear to treat the infection or improve sexual function. Taking saw palmetto doesn't seem to improve prostate swelling and long-term pelvic pain syndrome better than the drug finasteride in people with prostate swelling but no infection. Some studies have researched saw palmetto in combination with other ingredients. Early research suggests that taking saw palmetto, selenium, and lycopene can improve symptoms of prostate swelling and chronic pelvic pain syndrome. However, taking saw palmetto alone doesn't seem to work. Other research suggests that taking certain herbal combinations containing saw palmetto and other ingredients can enhance the effects of sparfloxacin or prulifloxacin in treating prostate swelling symptoms caused by infection. However, it's not clear if the effects of these combinations are due to saw palmetto or other ingredients.

Dosing

ADULTS
BY MOUTH
Prostate surgery (transurethral resection of the prostate, TURP): 320 mg of saw palmetto extract daily for 2 months before surgery.

84 Senna

Senna is an herb. The leaves and the fruit of the plant are used to make medicine. Senna is an FDA-approved over-the-counter (OTC) laxative. A prescription is not required to purchase senna. It is used to treat constipation and also to clear the bowel before diagnostic tests such as colonoscopy. Senna is also used for irritable bowel syndrome (IBS), anal or rectal surgery, tears in the lining of the anus (anal fissures), hemorrhoids, and weight loss. Senna fruit seems to be gentler than senna leaf. This has led the American Herbal Products Association (AHPA) to warn against long-term use of senna leaf, but not senna fruit. The AHPA recommends that senna leaf products be labeled, "Do not use this product if you have abdominal pain or diarrhea. Consult a healthcare provider prior to use if you are pregnant or nursing. Discontinue use in the event of diarrhea or watery stools. Do not exceed recommended dose. Not for long-term use." Senna contains many chemicals called sennosides. Sennosides irritate the lining of the bowel, which causes a laxative effect.

Uses

Likely Effective

NATURAL REMEDIES | Herbs | Senna

Uses	
Constipation	Taking senna by mouth is effective for short-term treatment of constipation. Senna is an FDA-approved nonprescription drug for adults and children ages 2 years and older. However, in children ages 3-15 years, mineral oil and a medication called lactulose might be more effective than taking senna. Senna also appears to be effective for treating constipation when used in combination with psyllium or docusate sodium. In elderly people, senna plus psyllium is more effective than lactulose for treating ongoing constipation. Senna plus docusate sodium is effective for treating constipation in the elderly and in people who have undergone anorectal surgery. Taking senna appears to be as effective as lactulose, psyllium, and docusate for relieving constipation in people taking opioids or loperamide.
Possibly Effective	
Bowel preparation before colonoscopy	Taking senna by mouth is as effective as castor oil and bisocodyl for bowel preparation. Some evidence suggests that senna is also at least as effective as polyethylene glycol for bowel preparation. However, conflicting evidence exists. It is unclear if taking senna with polyethylene glycol is more effective than taking polyethylene glycol alone. Senna appears to be less effective than sodium phosphate for bowel cleansing. However, taking a combination of senna, sodium picosulfate, and polyethylene glycol appears to be more effective than sodium phosphate for bowel preparation prior to colonoscopy.
Possibly Ineffective	
Diagnostic imaging	Taking senna by mouth does not appear to improve imaging of abdominal organs.

Dosing

ADULTS
BY MOUTH
For constipation: For general constipation, the usual dose is 17.2 mg daily. Don't take more than 34.4 mg twice daily. In elderly people, 17 mg daily has been used. For constipation following pregnancy, 28 mg in 2 divided doses has been used.

For bowel preparation: Doses of senna containing 75 mg or sennosides taken the day before colonoscopy, or 120-150 mg taken once or twice the day before colonoscopy, have been used.

CHILDREN
BY MOUTH:
In children age 12 and over, the usual dose is 2 tablets, with 8.6 mg sennosides per tablet, once daily. The maximum dose is 4 tablets (34.4 mg sennosides) twice daily. In children ages 6 to 11 years, the usual dose is 1 tablet (8.6 mg sennosides) daily. The maximum dose is 2 tablets (17.2 mg sennosides) twice daily. In children ages 2 to 5 years, the usual dose is 1/2 tablet (4.3 mg sennosides) daily. The maximum dose is 1 tablet (8.6 mg sennosides) twice daily.

85 Slippery Elm

Slippery elm is a tree. The inner bark (not the whole bark) is used as medicine. People take slippery elm for coughs, sore throat, colic, diarrhea, constipation, hemorrhoids, irritable bowel syndrome (IBS), bladder and urinary tract infections, syphilis, herpes, and for expelling tapeworms. It is also used for protecting against stomach and duodenal ulcers, for colitis, diverticulitis, GI inflammation, and too much stomach acid. Slippery elm is also taken by mouth to cause an abortion. Slippery elm is applied to the skin for wounds, burns, gout, rheumatism, cold sores, boils, abscesses, ulcers, toothaches, sore throat, and as a lubricant to ease labor. In manufacturing, slippery elm is used in some baby foods and adult nutritionals, and in some oral lozenges used for soothing throat pain. Slippery elm contains chemicals that can help soothe sore throats. It can also cause mucous secretion which might be helpful for stomach and intestinal problems.

Uses

Possibly Effective	
Sore throat when added to lozenges.	Commercial lozenges containing slippery elm are preferred to the native herb when used for cough and sore throat. The lozenges prolong the pain-killing effect.
Insufficient Evidence	
Cancer	Early research suggests that a specific product containing burdock root, Indian rhubarb, sheep sorrel, and slippery elm bark does not improve quality of life in breast cancer patients.
Irritable bowel syndrome (IBS)	An early study shows that taking a specific product containing slippery elm bark, lactulose, oat bran, and licorice root can increase bowel movements and reduce stomach pain and bloating in people with IBS that is characterized by constipation. A different combination product containing slippery elm bark, bilberry, cinnamon, and agrimony can reduce stomach pain, bloating, and gas in people with IBS that is characterized by diarrhea.

Dosing

The appropriate dose of slippery elm depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for slippery elm. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

86 Shiitake Mushroom

Shiitake mushroom is a fungus. An extract made from this mushroom is used as medicine. Shiitake mushroom is used for boosting the immune system, HIV/AIDS, lowering blood cholesterol levels, hardening of the arteries, diabetes, eczema, colds and flu, treating prostate or breast cancer, and as an anti-aging agent. It is also used for hepatitis B, herpes, high blood pressure, and stomach ache. Shiitake mushroom is used in a mouth rinse for dental plaque. Shiitake mushroom is also eaten as food. Shiitake mushroom contains chemicals that might help lower cholesterol levels. It also contains very small amounts of a chemical that seems to keep tumors from getting bigger. This chemical might also stimulate the immune system.

Uses

Possibly Ineffective	
Dental plaque	Rinsing with liquid containing shiitake mushroom does not seem to reduce plaque (94250).
Insufficient Evidence	

Prostate cancer	Early research suggests that shiitake mushroom does not prevent prostate cancer from becoming worse.

Dosing

The appropriate dose of shiitake mushroom depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for shiitake mushroom. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

87 Spirulina (Blue Green Algae)

"Blue-green algae" describes a large and diverse group of simple, plant-like organisms found in salt water and some large fresh water lakes. Blue-green algae products are used for many conditions, but so far, there isn't enough scientific evidence to determine whether or not they are effective for any of them. Blue-green algae are used as a source of dietary protein, B-vitamins, and iron. They are also used for weight loss, attention deficit-hyperactivity disorder (ADHD), hayfever, diabetes, stress, fatigue, anxiety, depression, and premenstrual syndrome (PMS) and other women's health issues.

Some people use blue-green algae for treating precancerous growths inside the mouth, boosting the immune system, improving memory, increasing energy and metabolism, lowering cholesterol, preventing heart disease, healing wounds, and improving digestion and bowel health. Blue-green algae are commonly found in tropical or subtropical waters that have a high-salt content, but some types grow in large fresh water lakes. The natural color of these algae can give bodies of water a dark-green appearance. The altitude, temperature, and sun exposure where the blue-green algae are grown dramatically influence the types and mix of blue-green algae in the water. Some blue-green algae products are grown under controlled conditions. Others are grown in a natural setting, where they are more likely to be contaminated by bacteria, liver poisons (microcystins) produced by certain bacteria, and heavy metals. Choose only products that have been tested and found free of these contaminants.

You may have been told that blue-green algae are an excellent source of protein. But, in reality, blue-green algae is no better than meat or milk as a protein source and costs about 30 times as much per gram. Blue-green algae have a high protein, iron, and other mineral content which is absorbed when taken orally. Blue-green algae are being researched for their potential effects on the immune system, swelling (inflammation), and viral infections.

Uses

Insufficient Evidence

Seasonal allergies (hayfever)	Early research shows that taking 2 grams per day of blue-green algae by mouth for 6 months might relieve some allergy symptoms in adults.
Insulin resistance due to HIV medication	Early research shows that taking 19 grams per day of blue-green algae by mouth for 2 months increases insulin sensitivity in people with insulin resistance due to HIV medication.
Arsenic poisoning	Early research shows that taking 250 mg of blue-green algae and 2 mg of zinc by mouth twice daily for 16 weeks reduces arsenic levels and the effects of arsenic on the skin in people living in areas with high arsenic levels in the drinking water.
Attention deficit-hyperactivity disorder (ADHD)	Early research shows that dissolving 3 mL of a product containing blue-green algae, peony, ashwagandha, gotu kola, bacopa, and lemon balm (Nurture and Clarity, Tree of Healing-LD, Israel) into 50-60 mL of water and drinking three times daily for 4 months improves ADHD in children aged 6 years to 12 years who haven't taken other treatments for ADHD.
Tics or twitching of the eyelids (blepharospasm or Meige syndrome)	Early research shows that taking a specific blue-green algae product (Super Blue-Green Algae, Cell Tech, Klamath Falls, OR) at a dose of 1500 mg daily for 6 months does not reduce eyelid spasms in people with blepharospasm.
Diabetes	An early study shows that people with type 2 diabetes who take 1 gram of a blue-green algae product (Multinal, New Ambadi Estate Pvt. Ltd., Madras, India) by mouth twice daily for 2 mouths have lower blood sugar levels.
Exercise performance	An early study shows that men who jog regularly are able to sprint for longer periods of time before becoming tired when they take 2 grams of blue-green algae three times daily for 4 weeks.
Hepatitis C	Research on the effects of blue-green algae in people with chronic hepatitis C has been inconsistent. One study shows that taking 500 mg of spirulina blue-green algae by mouth three times daily for 6 months results in greater improvements in liver function compared to milk thistle in adults with hepatitis C who were not yet treated or were unresponsive to other treatments. However, another study shows that taking blue-green algae for one month worsens liver function in people with hepatitis C or hepatitis B.
HIV/AIDS	Research on the effects of blue-green algae in people with HIV/AIDS has been inconsistent. Some early research shows that taking 5 grams of blue-green algae by mouth daily for 3 months reduces the incidences of infections, stomach and intestinal problems, feelings of tiredness, and breathing problems in patients with HIV/AIDS. However, taking blue-green algae does not appear to improve CD4 cell counts or reduce viral load in HIV patients.
High cholesterol	Early research shows that blue-green algae lowers cholesterol in people with normal or slightly elevated cholesterol levels. However, the research findings have been somewhat inconsistent. In some studies, blue-green algae only lower low-density lipoprotein (LDL or "bad") cholesterol. In other studies, blue-green algae lower total cholesterol and LDL cholesterol, and increase high-density lipoprotein (HDL or "good") cholesterol.
High blood pressure	Early research shows that taking 4.5 grams per day of blue-green algae by mouth for 6 weeks reduces blood pressure in some people with high blood pressure.
Long-term fatigue	Early research shows that taking 1 gram per day of blue-green algae by mouth three times daily for 4 weeks does not improve fatigue in adults with long-term complaints of fatigue.
Malnutrition	Early research on the use of blue-green algae in combination with other dietary treatments for malnutrition in infants and children shows conflicting results. Weight gain was seen in undernourished children who were given spirulina blue-green algae with a combination of millet, soy and peanut for 8 weeks. However, in another study, children up to 3 years-old who were given 5 grams of blue-green algae daily for 3 months did not gain weight more than those given general treatments to improve nutrition alone.
Menopausal symptoms	An early study shows that taking 1.6 grams per day of a blue-green algae product by mouth daily for 8 weeks lowers anxiety and depression in women going through menopause. However, it doesn't appear to reduce symptoms such as hot flashes.
Obesity	Research on the effects of blue-green algae in people who are overweight or obese has been inconsistent. One early study shows that taking a specific blue-green algae product (Multinal, New Ambadi Estate Pvt. Ltd.) at a dose of 1 gram taken two or four times per day by mouth for 3 months slightly improve weight loss in overweight adults. However, another early study shows that taking 2.8 grams of spirulina by mouth three times per day for 4 weeks does not improve weight loss in obese adults who are also following a reduced-calorie diet.

Precancerous mouth sores (oral leukoplakia)	Early research shows that taking 1 gram of spirulina blue-green algae daily by mouth for 12 months reduces oral leukoplakia in people who chew tobacco.
Gum disease (periodontitis)	Early research shows that injecting a gel containing blue-green algae into the gums of adults with gum disease improves gum health.

Dosing

The appropriate dose of blue-green algae depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for blue-green algae. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

88 Schisandra

Schisandra is a plant. The fruit is used as food and also to make medicine. Schisandra is used as an "adaptogen" for increasing resistance to disease and stress, increasing energy, and increasing physical performance and endurance. Schisandra is also used for preventing early aging and increasing lifespan, normalizing blood sugar and blood pressure, stimulating the immune system, and speeding recovery after surgery. It is also used for treating liver disease (hepatitis) and protecting the liver from poisons. The Chinese have developed a liver-protecting drug called DBD that is made from schizandrin, one of the chemicals in schisandra. Other uses for schisandra include treatment of high cholesterol, pneumonia, coughs, asthma, sleep problems (insomnia), tiredness and irritability associated with emotional disturbance (neurasthenia), premenstrual syndrome (PMS), chronic diarrhea, dysentery, night sweats, spontaneous sweating, involuntary discharge of semen, thirst, erectile dysfunction (ED), physical exhaustion, excessive urination, depression, irritability, and memory loss. It is also used in children to reduce the frequency and severity of attacks of fever associated with an inherited disease called familial Mediterranean fever. Some people use schisandra for improving vision ad muscular activity, protecting against radiation, preventing motion sickness, preventing infection, boosting energy at the cellular level, and improving the health of the adrenal glands. Schisandra fruit is eaten as a food. The chemicals in schisandra improve liver function by stimulating enzymes (proteins that speed up biochemical reactions) in the liver and promoting liver cell growth.

Uses

Possibly Effective

Mental performance	Taking schisandra fruit extract by mouth, alone or in combination with rhodiola and Siberian ginseng, seems to improve concentration, attention, and speed of thinking.
Hepatitis	Schisandra fruit extracts reduce blood levels of an enzyme called glutamic-pyruvic transaminase (SGPT) in people with hepatitis. SGPT level is a marker for liver damage. A higher SGPT level means more damage; a lower SGPT means less damage.

Insufficient Evidence

Exercise performance	Taking schisandra fruit extract by mouth seems to improve coordination and endurance.
Inherited fever disorder (Familial Mediterranean fever)	Early research suggests that taking a combination product (ImmunoGuara, Inspired Nutritionals) containing andrographis, Siberian ginseng, schisandra, and licorice reduces the severity and frequency of familial Mediterranean fever attacks.
Nearsightedness	Early research suggests that applying a solution of schisandra for 20-24 days can improve vision in children with nearsightedness. However, schisandra does not improve vision in children with progressive nearsightedness.
Pneumonia	Early research suggests that taking a combination of rhodiola, schisandra, and Siberian ginseng (Chisan) twice daily for 10-15 days reduces the need for antibiotics and improves quality of life in people with pneumonia when taken along with standard care.

Dosing

BY MOUTH
For hepatitis: Schisandra extract standardized to 20 mg lignan content (equivalent to 1.5 grams crude schisandra) given daily.

For improving mental and physical performance: 500 mg to 2 grams of schisandra extract daily or 1.5-6 grams of crude schisandra daily. 5-15 grams daily of a boiled tea made from crude schisandra has also been used. People have also taken 100 mg of schisandra extract twice daily. Appropriate dosing may vary depending on extract type and the lignan content.

89 Sorrel

Sorrel is a plant. People use the above ground parts for medicine. Be careful not to confuse sorrel (Rumex acetosa) with roselle (Hibiscus sabdariffa), which is known as Jamaican sorrel or Guinea sorrel. People commonly take sorrel by mouth for reducing swelling (inflammation) of the nasal passages (sinusitis). It is also used to treat swelling of the respiratory tract (bronchitis). But there is limited scientific research to support this use. Sorrel is also used as an ingredient in sauces and soups.

Uses

Possibly Effective

Sinusitis (inflamed nasal passages)	Some research suggests that taking a specific product that contains sorrel, gentian root, European elderflower, verbena, and cowslip flower by mouth daily for up to 14 days improves symptoms of sinusitis, such as congestion and headache.

Insufficient Evidence

Breast cancer	Early research suggests that taking a specific product containing sorrel, burdock root, Indian rhubarb, and slippery elm by mouth does not improve quality of life or mood in people with breast cancer.
Bronchitis	Early research shows that taking a specific combination product containing sorrel, gentian root, European elderflower, verbena, and cowslip flower by mouth for 10 days improves cough and other symptoms of bronchitis.

Dosing

BY MOUTH
Sinusitis (inflamed nasal passages): A specific combination product containing 36 mg of sorrel, 12 mg of gentian root, and 36 mg each of European elder flower, verbena, and cowslip flower has been taken three times daily for up to 14 days.

NATURAL REMEDIES Herbs Tribulus

90 Tribulus

Tribulus is a plant that produces fruit covered with spines. Rumor has it that tribulus is also known as puncture vine because the spines are so sharp they can flatten bicycle tires. People use the fruit, leaf, and root as medicine. People use tribulus for conditions such as chest pain, eczema, enlarged prostate, sexual disorders, infertility, and many others, but there is no good scientific evidence to support these uses. Tribulus has chemicals that might increase levels of some hormones. However, it doesn't appear to increase male hormones (testosterone) in humans.

Uses

Possibly Ineffective

Enhancing athletic performance	Taking tribulus by mouth, alone or with other herbs and supplements, doesn't seem to enhance body composition or exercise performance in athletes.

Insufficient Evidence

Chest pain (angina pectoris)	Early research shows that taking tribulus extract by mouth might reduce symptoms of angina.
Eczema (atopic dermatitis)	Taking tribulus by mouth in combination with 9 other herbs might reduce redness and skin outbreaks in adults and children with a certain type of eczema. However, some research shows no benefit.
Enlarged prostate (Benign prostatic hyperplasia; BPH)	Early research shows that taking a supplement containing tribulus and curry leaf (Murraya koenigii) for 12 weeks improves symptoms similar to the prescription drug tamsulosin in men with an enlarged prostate. Other early research shows that taking a supplement containing tribulus, brown algae, chitosan, and saw palmetto for 2 months improves symptoms and quality of life in men with lower urinary tract symptoms, with or without BPH.
Erectile dysfunction (ED)	Some early research shows that taking tribulus for 3 months improves erections in men with a condition called partial androgen deficiency. Men with this condition often have ED. Other early research shows that taking a supplement containing tribulus, brown algae, and chitosan for 3 months improves sexual satisfaction, desire, ability to ejaculate, and sexual quality of life in men with ED. However, other research shows that taking tribulus for 30 days does not improve erections in men with ED.
Infertility	Research on tribulus for infertility is conflicting. Some early research shows that taking tribulus for 60 days does not improve sperm count in men with low sperm count. However, other research shows that taking a specific tribulus product for 30 days improves ejaculate volume, sperm concentration, and sperm movement in men with low sperm count and defective sperm movement. Other research shows that taking the same tribulus product for 1-2 months may increase sexual desire and erections in some men with infertility due to low levels of testosterone.
Sexual problems in women	Early research shows that taking tribulus for 4 weeks improves sexual desire, arousal, satisfaction, orgasm, pain, and lubrication in women with low sexual desire. Other early research shows that taking tribulus for 90 days improves sexual desire, arousal, sensation, lubrication, ability to reach orgasm, and sexual comfort in postmenopausal women with sexual problems.

Dosing

91 Holy Basil (Tulsi)

Holy basil is a plant. It is originally from India but now grows in Australia, West Africa, and some Middle Eastern countries. It is used in Ayurvedic medicine as an “adaptogen” to counter life’s stresses. It is considered a sacred plant by the Hindus and is often planted around Hindu shrines. The Hindu name for holy basil, Tulsi, means "the incomparable one." Medicine is made from the leaves, stems, and seeds. Holy basil is commonly used to help with anxiety and stress. But there is limited scientific research to support these and other uses. In cooking, holy basil is often added to stir-fry dishes and spicy soups because of its peppery taste. Cookbooks sometimes call it "hot basil." Chemicals in holy basil are thought to decrease pain and swelling (inflammation). Other chemicals might lower blood sugar in people with diabetes. There is interest in using holy basil seed oil for cancer. Early research suggests that the oil can slow progression and improve survival rate in animals with certain types of cancer. Researchers think this benefit may be explained by the oil’s ability to act as an antioxidant.

Uses

Insufficient Evidence

Anxiety	Early research suggests that taking holy basil leaf extract twice daily after meals reduces anxiety and associated stress and depression in people with anxiety.
Dental plaque	Some research shows that using mouthwash containing 4% holy basil leaf extract twice daily reduces plaque and gingivitis better than saline solution and similar to mouthwash containing 0.12% chlorhexidine. Chlorhexidine is considered to be the “gold standard” for reducing plaque.
Diabetes	Some early research suggests that a holy basil leaf extract might decrease blood sugar in people with type 2 diabetes.
Stress	Early research shows that taking holy basil extract by mouth in the morning and at night decreases symptoms of stress, including forgetfulness, sexual problems, exhaustion, and sleep problems.

Dosing

The appropriate dose of holy basil depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for holy basil. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

92 Wild Yam

NATURAL REMEDIES | Herbs | Wild Yam

Wild yam is a plant. It contains a chemical called diosgenin. This chemical can be made in the laboratory into various steroids, such as estrogen and dehydroepiandrosterone (DHEA). The root and the bulb of the plant are used as a source of diosgenin, which is prepared as an "extract," a liquid that contains concentrated diosgenin. There are over 600 species of wild yam. Some species are grown specifically as a source of diosgenin for laboratories to use in making steroids. These species are generally not eaten due to a bitter flavor. Only about 12 of the 600 species are considered edible. Diosgenin or wild yam is often promoted as a "natural alterative" to estrogen therapy, so you will see it used for estrogen replacement therapy, vaginal dryness in older women, PMS (premenstrual syndrome), menstrual cramps, weak bones (osteoporosis), increasing energy and sexual drive in men and women, and breast enlargement. Wild yam does seem to have some estrogen-like activity, but it is not actually converted into estrogen in the body. It takes a laboratory to do that. Similarly, you will also see wild yam and diosgenin promoted as a "natural DHEA." This is because in the laboratory DHEA is made from diosgenin, but this chemical reaction is not believed to occur in the human body. So taking wild yam extract will not increase DHEA levels in people. Individuals who are interested in taking DHEA should avoid wild yam products labeled as "natural DHEA." Wild yam is also used for treating a disorder of the intestines called diverticulosis, gallbladder pain, rheumatoid arthritis, and for increasing energy. Some women apply wild yam creams to the skin to reduce menopausal symptoms such as hot flashes. Wild yam contains a chemical that can be made into various steroids, such as estrogen, in the laboratory. However, the body can't change wild yam to estrogen.

Uses

Possibly Ineffective

Menopausal symptoms	Applying wild yam cream to the skin for 3 months does not seem to relieve menopausal symptoms such as hot flashes and night sweats. It also does not seem to affect levels of hormones that play a role in menopause.

Dosing

The appropriate dose of wild yam depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for wild yam. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

93 Witch Hazel

Witch hazel is a plant. The leaf, bark, and twigs are used to make medicine. You may see a product called witch hazel water (Hamamelis water, distilled witch hazel extract). This is a liquid that is distilled from dried leaves, bark, and partially dormant twigs of witch hazel. Witch hazel is taken by mouth for diarrhea, mucus colitis, vomiting blood, coughing up blood, tuberculosis, colds, fevers, tumors, and cancer. Some people apply witch hazel directly to the skin for itching, pain and swelling (inflammation), eye inflammation, skin injury, mucous membrane inflammation, varicose veins, hemorrhoids, bruises, insect bites, minor burns, acne, sensitive scalp, and other skin irritations. In manufacturing, witch hazel leaf extract, bark extract, and witch hazel water are used as astringents to tighten the skin. They are also included in some medications to give those products the ability to slow down or stop bleeding. Those medications are used for treating insect bites, stings, teething, hemorrhoids, itching, irritations, and minor pain. Witch hazel contains chemicals called tannins. When applied directly to the skin, witch hazel might help reduce swelling, help repair broken skin, and fight bacteria.

Uses

Possibly Effective

Hemorrhoids	Applying witch hazel water to the skin may help to temporarily relieve itching, discomfort, irritation, and burning from hemorrhoids and other anal disorders.
Minor bleeding	Applying witch hazel bark, leaf, or water to the skin reduces minor bleeding.
Skin irritation	Applying witch hazel cream seems to relieve mild skin irritation, but not as well as hydrocortisone. Other research shows that applying a specific witch hazel ointment (Hametum) to the skin appears to improve symptoms of skin injury or irritated skin as effectively as a dexpanthenol ointment in children.

Possibly Ineffective

Itchy and inflamed skin (eczema)	Applying a cream containing witch hazel to the skin for 14 days does not seem to improve itchy and inflamed skin in people with moderate eczema. Applying hydrocortisone cream seems to be a more effective treatment option.

Dosing

ADULTS
APPLIED TO THE SKIN: For skin irritation: An after sun lotion containing 10% witch hazel water has been used.
APPLIED TO THE ANUS: For itching and discomfort associated with hemorrhoids and other anal disorders: Witch hazel water has been applied up to 6 times per day or after every bowel movement. Suppositories have been placed in the anus 1-3 times per day.

CHILDREN
APPLIED TO THE SKIN: For skin irritation: An ointment containing witch hazel has been applied several times per day in children aged 2-11 years.

94 Willow Bark

Willow bark is the bark from several varieties of the willow tree, including white willow or European willow, black willow or pussy willow, crack willow, purple willow, and others. The bark is used to make medicine. Willow bark acts a lot like aspirin, so it is used for pain, including headache, muscle pain, menstrual cramps, rheumatoid arthritis (RA), osteoarthritis, gout, and a disease of the spine called ankylosing spondylitis. Willow barks pain relieving potential has been recognized throughout history. Willow bark was commonly used during the time of Hippocrates, when people were advised to chew on the bark to relieve pain and fever. Willow bark is also used for fever, the common cold, flu, and weight loss. Salicin, the active ingredient in willow bark, seems to have contributed to the death of the composer, Ludwig von Beethoven. Apparently, Beethoven ingested large amounts of salicin before he died. His autopsy report is the first recorded case of a particular type of kidney damage that can be caused by salicin. Willow bark contains a chemical called salicin that is similar to aspirin.

Uses

Possibly Effective

Treating lower back pain	Willow bark seems to reduce lower back pain. Higher doses seem to be more effective than lower doses. It can take up to a week for significant improvement in symptoms.

Insufficient Evidence

Weight loss	Early research suggests that taking willow bark in combination with ephedra and cola nut might cause slight weight loss in overweight and obese people. However, it is not wise to use this combination because of safety concerns about ephedra. Ephedra has been banned in the United States due to severe harmful side effects.

Osteoarthritis	Research on willow bark extract for osteoarthritis has produced conflicting results. Some research suggests it can reduce osteoarthritis pain, while other research shows no effect.
Rheumatoid arthritis (RA)	Early research suggests that willow bark extract is not effective for rheumatoid arthritis.

Dosing

BY MOUTH
For back pain: Willow bark extract providing 120-240 mg salicin has been used. The higher 240 mg dose might be more effective.

95 Wheatgrass

Wheatgrass is a kind of grass. The above-ground parts, roots, and rhizome are used to make medicine. Wheatgrass is primarily used as a concentrated source of nutrients. It contains vitamin A, vitamin C, and vitamin E, iron, calcium, magnesium, and amino acids. Wheatgrass is taken by mouth to increase production of hemoglobin, the chemical in red blood cells that carries oxygen, in patients with a blood disorder called beta-thalassemia. It is also commonly used for a variety of conditions including inflammatory bowel syndrome, diabetes, high cholesterol, and many more, but there is no good scientific evidence to support these uses. Wheatgrass juice is a popular health drink. It is thought to benefit health only when fresh and taken on an empty stomach immediately after being mixed. But there is no research to date that supports this. In foods and beverages, wheatgrass extracts are used as a flavoring component. Wheatgrass contains chemicals that might have antioxidant and anti-inflammatory (anti-swelling) activity. This is why some people think it might be helpful for conditions such as inflammatory bowel disease. It also contains a chemical that might fight bacterial infections.

Uses

Insufficient Evidence

Blood disorder called beta-thalassemia	Research evaluating wheatgrass for treating a blood disorder called beta-thalassemia shows conflicting results. Some early research suggests that drinking 100 mL of wheatgrass juice daily for 18 months or taking tablets containing 1-4 grams of wheatgrass daily for 12 months can reduce the need for blood transfusions in children with beta-thalassemia. However, other early research suggests that taking tablets containing 100-200 mg/kg of wheatgrass daily for 12 months does not reduce the need for blood transfusions in children and adults with beta-thalassemia. Larger, higher quality studies are needed to resolve these conflicting results.
Heel pain	Early research suggests that applying a wheatgrass cream to the bottom of the feet twice daily for 6 weeks does not reduce heel pain.
High cholesterol	Early research suggests that taking wheatgrass powder in a capsule daily for 10 weeks reduces total cholesterol and triglyceridecholesterol levels by a small amount in women with elevated cholesterol levels.
Inflammatory bowel disease (ulcerative colitis)	There is some early research that freshly extracted wheatgrass juice might reduce overall disease activity and the severity of rectal bleeding in people with ulcerative colitis.

Dosing

The appropriate dose of wheatgrass depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for wheatgrass. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

96 Yarrow

Yarrow is a plant. The above ground parts are used to make medicine. Yarrow is commonly used orally for diarrhea, gas, and other stomach issues. But there is limited scientific research to support these and other uses. In manufacturing, yarrow is used as a cosmetic cleanser and in shampoos.

Uses

Insufficient Evidence

Gum inflammation (gingivitis)	Early research shows that using a mouthwash containing yarrow and other ingredients doesn't reduce plaque build-up or swelling of the gums.
Irritable bowel syndrome (IBS)	Early research shows that taking a capsule containing yarrow, ginger, and boswellia three times daily for 30 days seems to improve pain and bloating symptoms in people with mild to moderate IBS. However, it's not clear if this is due to yarrow or the other ingredients.
Wound healing	Some women must have an incision made to the vagina during child birth. Early research shows that applying an ointment containing yarrow over the stitches from this incision helps to reduce pain and improve healing.

Dosing

The appropriate dose of yarrow depends on several factors such as the user's age, health, and several other conditions. At this time there is not enough scientific information to determine an appropriate range of doses for yarrow. Keep in mind that natural products are not always necessarily safe and dosages can be important. Be sure to follow relevant directions on product labels and consult your pharmacist or physician or other healthcare professional before using.

Meteorology

Types of weather, clouds, planets and space phenomena

"Wherever you go, no matter what the weather, always bring your own sunshine."
Anthony J. D'Angelo

Introduction

The weather is constantly changing and often requires constant attention to be able to predict what weather is likely to follow. Weather prediction is important in a survival situation where you have no shelter to shield yourself from the elements and where extra time can be the factor for life or death. This section contains ways to interpret, measure and read the tell-tale signs of weather.

Purpose	The aim of METEOROLOGY is to help the reader understand the different cycles that the earth goes through such as the day, seasons and lunar cycles. It also provides information on the different atmospheric layers from the ground level to the clouds to outer space and beyond. It finishes with the beaufort scale and details on how you can predict the weather using basic equipment.
Lost?	● For information on what lies below the surface see NATURAL DISASTERS > Earthquakes > Earth Composition ● For specific information on storms and other extreme weather, see the NATURAL DISASTERS section. ● For information on heat and cold related illnesses, see either the SURVIVAL, ILLNESS or NATURAL DISASTERS sections. ● For information on the common weather patterns for each region of the globe, see the GEOGRAPHY section.

Contents

1 Cycles

Listed are the benefits of each type of weather phenomenon.

Subheadings

1 Day Cycle

Day

A day is approximately the period of time during which the Earth completes one rotation around its axis. A solar day is the length of time which elapses between the Sun reaching its highest point in the sky two consecutive times. Days on other planets are defined similarly and vary in length due to differing rotation periods, that of Mars being slightly longer and sometimes called a sol.

In 1960, the second was redefined in terms of the orbital motion of the Earth in the year 1900, and was designated the SI base unit of time. The unit of measurement "day", was redefined as 86,400 SI seconds and symbolized d. In 1967, the second and so the day were redefined by atomic electron transition. A civil day is usually 24 hours, plus or minus a possible leap second in Coordinated Universal Time (UTC), and occasionally plus or minus an hour in those locations that change from or to daylight saving time.

Day can be defined as each of the twenty-four-hour periods, reckoned from one midnight to the next, into which a week, month, or year is divided, and corresponding to a rotation of the earth on its axis. However, its use depends on its context; for example, when people say 'day and night', 'day' will have a different meaning: the interval of light between two successive nights, the time between sunrise and sunset; the time of light between one night and the next.

For clarity when meaning 'day' in that sense, the word "daytime" may be used instead, though context and phrasing often makes the meaning clear. The word day may also refer to a day of the week or to a calendar date, as in answer to the question, "On which day?" The life patterns (circadian rhythms) of humans and many other species are related to Earth's solar day and the day-night cycle.

Day Benefits
- **Solar Electricity:** You can generate electricity from the sun during the day.
- **SODIS Disinfection:** You can use the sun to disinfect water.
- **Cooking Food:** The sun can be used to cook food.
- **Heating Water:** The sun can be used to heat water.
- **Greater Line of Sight:** You can see much further during the day than at night.
- **Less Threats:** There is generally less threats during the day as most dangerous animals come out and hunt at night.

Night

Night or nighttime (also spelled night-time or night time) is the period of ambient darkness from sunset to sunrise during each 24-hour day, when the Sun is below the horizon. The exact time when night begins and ends (equally true with evening) depends on the location and varies throughout the year. When night is considered as a period that which follows evening, it is usually considered to start around 8 pm and to last to about 4 am. Night ends with coming of morning at sunrise. The word can be used in a different sense as the time between bedtime and morning. In common communication, the word night is used as a farewell ("good night") and sometimes shortened to "night", mainly when someone is going to sleep or leaving. For example: "It was nice to see you. Good night!" Unlike "good morning", "good afternoon", and "good evening", "good night" (or "goodnight") is not used as a greeting.

Complete darkness or astronomical night is the period between astronomical dusk and astronomical dawn when the Sun is between 18 and 90 degrees below the horizon and does not illuminate the sky. As seen from latitudes between 48.5607189° and 65.7273855...° north or south of the Equator, complete darkness does not occur around the summer solstice because, although the Sun sets, it is never more than 18° below the horizon at lower culmination.

The opposite of night is day (or "daytime", to distinguish it from "day" referring to a 24-hour period). The start and end points of time for a night vary, based on factors such as season and latitude. Twilight is the period of night after sunset or before sunrise when the Sun still illuminates the sky when it is below the horizon. At any given time, one side of Earth is bathed in sunlight (the daytime) while the other side is in the shadow caused by Earth blocking the sunlight. The central part of the shadow is called the umbra.

Night Benefits
- **Radio Waves Travel Further:** You can receive radio signals from much further away as there's less interference from electromagnetic waves.
- **Easier to Move Undetected:** You can move much more stealthily at night.
- **Star Navigation:** You can use the stars to navigate by and tell the date from.
- **Less Fatigue:** You should be less fatigued at night than doing the same activity under the sun.

2 Seasons

A season is a division of the year marked by changes in weather, ecology, and the amount of daylight. On Earth, seasons are the result of Earth's orbit around the Sun and Earth's axial tilt relative to the ecliptic plane. In temperate and polar regions, the seasons are marked by changes in the intensity of sunlight that reaches the Earth's surface, variations of which may cause animals to undergo hibernation or to migrate, and plants to be dormant. Various cultures define the number and nature of seasons based on regional variations.

During May, June, and July, the Northern Hemisphere is exposed to more direct sunlight because the hemisphere faces the Sun. The same is true of the Southern Hemisphere in November, December, and January. It is Earth's axial tilt that causes the Sun to be higher in the sky during the summer months, which increases the solar flux. However, due to seasonal lag, June, July, and August are the warmest months in the Northern Hemisphere while December, January, and February are the warmest months in the Southern Hemisphere.

In temperate and sub-polar regions, four seasons based on the Gregorian calendar are generally recognized: spring, summer, autumn or fall, and winter. The definition of seasons is also cultural. In India from the ancient times, six seasons or Ritu based on south Asian religious or cultural calendars are recognised and identified even today for the purposes such as agriculture and trade. Ecologists often use a six-season model for temperate climate regions which are not tied to any fixed calendar dates: prevernal, vernal, estival, serotinal, autumnal, and hibernal. Many tropical regions have two seasons: the rainy, wet, or monsoon season and the dry season. Some have a third cool, mild, or harmattan season. Seasons often held special significance for agrarian societies, whose lives revolved around planting and harvest times, and the change of seasons was often attended by ritual.

Summer

Summer is the hottest of the four temperate seasons, falling after spring and before autumn. At or around the summer solstice (about 3 days before Midsummer Day), the earliest sunrise and latest sunset occurs, the days are longest and the nights are shortest, with day length decreasing as the season progresses after the solstice. The date of the beginning of summer varies according to climate, tradition, and culture. When it is summer in the Northern Hemisphere, it is winter in the Southern Hemisphere, and vice versa.

Summer Benefits	● **Easier to Keep Dry:** Clothes dry quickly. ● **Dry Firewood:** The heat dries out firewood quicker. ● **Longer Days:** The days are longer in summer. ● **Easier to Keep Clean:** It's easier to have a bath in warm water than cold water. ● **Easier to Start Fires:** o ● **Easier to find dry tinder:** o ● **Leaves:** Deciduous trees have leaves which help keep you hidden.

Fall / Autumn

Autumn, also known as fall in North American English, is one of the four temperate seasons. Autumn marks the transition from summer to winter, in September (Northern Hemisphere) or March (Southern Hemisphere), when the duration of daylight becomes noticeably shorter and the temperature cools considerably. One of its main features in temperate climates is the shedding of leaves from deciduous trees. Meteorologists (and most of the temperate countries in the southern hemisphere) use a definition based on Gregorian calendar months, with autumn being September, October, and November in the northern hemisphere, and March, April, and May in the southern hemisphere. Persians celebrate the beginning of the autumn as Mehregan to honor Mithra (Mehr).

In North America, autumn traditionally starts with the September equinox (21 to 24 September) and ends with the winter solstice (21 or 22 December). Popular culture in the United States associates Labor Day, the first Monday in September, as the end of summer and the start of autumn; certain summer traditions, such as wearing white, are discouraged after that date. As daytime and nighttime temperatures decrease, trees change color and then shed their leaves.

In traditional East Asian solar term, autumn starts on or around 8 August and ends on or about 7 November. In Ireland, the autumn months according to the national meteorological service, Met Éireann, are September, October and November. However, according to the Irish Calendar, which is based on ancient Gaelic traditions, autumn lasts throughout the months of August, September and October, or possibly a few days later, depending on tradition. In the Irish language, September is known as Meán Fómhair ("middle of autumn") and October as Deireadh Fómhair ("end of autumn").

Fall / Autumn Benefits	● **Easy Shelter Building:** An ample amount of leaves and sticks make shelter building faster and easier. ● **Nice Temperatures:** Fair temperatures, getting colder as the season progresses. ● **Fallen Leaves:** Can be used for tinder.

Winter

Winter is the coldest season of the year in polar and temperate zones (winter does not occur in most of the tropical zone). It occurs after autumn and before spring in each year. Winter is caused by the axis of the Earth in that hemisphere being oriented away from the Sun. Different cultures define different dates as the start of winter, and some use a definition based on weather. When it is winter in the Northern Hemisphere, it is summer in the Southern Hemisphere, and vice versa. In many regions, winter is associated with snow and freezing temperatures. The moment of winter solstice is when the Sun's elevation with respect to the North or South Pole is at its most negative value (that is, the Sun is at its farthest below the horizon as measured from the pole). The day on which this occurs has the shortest day and the longest night, with day length increasing and night length decreasing as the season progresses after the solstice. The earliest sunset and latest sunrise dates outside the polar regions differ from the date of the winter solstice, however, and these depend on latitude, due to the variation in the solar day throughout the year caused by the Earth's elliptical orbit (see earliest and latest sunrise and sunset).

Winter Benefits (Snow)	● **Keeps Food Cold Easily:** Perishable food can be kept much longer. ● **Hibernating Animals:** Most dangerous animals and creatures hibernate during winter. ● **Easier Tracking in Snow:** Tracking people and animals is easier when they leave tracks. ● **Less/No Vegetation:** There's less vegetation so you're able to see more. ● **Less Ticks/Leeches/Bugs:** A lot less or no annoying creatures and bugs. ● **Sled for Transport:** Moving gear is easier over snow with a sled. ● **Use Snow for Water:** Snow is 10% water so melting it will provide you with water. ● **Solar Efficiency:** Solar works better at a cooler temperature than in the heat. ● **Easy to Stay Cool:** It's easier to warm up than to cool down. ● **Frozen Water Travel:** You can travel over frozen water to cut down on travel time. ● **Cold Burns Calories:** Shivering burns calories.
Winter Benefits (No Snow)	● **Keeps Food Cold Easily:** Perishable food can be kept much longer. ● **Less Ticks/Leeches/Bugs:** A lot less or no annoying creatures and bugs. ● **Solar Efficiency:** Solar works better at a cooler temperature than in the heat. ● **Easy to Stay Cool:** It's easier to warm up than to cool down.

Spring

Spring, also known as springtime, is one of the four temperate seasons, succeeding winter and preceding summer. There are various technical definitions of spring, but local usage of the term varies according to local climate, cultures and customs. When it is spring in the Northern Hemisphere, it is autumn in the Southern Hemisphere and vice versa. At the spring (or vernal) equinox, days and nights are approximately twelve hours long, with daytime length increasing and nighttime length decreasing as the season progresses.

Spring and "springtime" refer to the season, and also to ideas of rebirth, rejuvenation, renewal, resurrection and regrowth. Subtropical and tropical areas have climates better described in terms of other seasons, e.g. dry or wet, monsoonal or cyclonic. Cultures may have local names for seasons which have little equivalence to the terms originating in Europe.

Spring Benefits	● **More Plant Life:** Plants grow back quickly after winter. ● **More Animal Life:** Animals are generally born in spring. ● **Nice Temperatures:** Fair temperatures, getting warmer as the season progresses.

3 Lunar Cycle

The lunar phase or Moon phase is the shape of the directly sunlit portion of the Moon as viewed from Earth. The lunar phases gradually change over the period of a synodic month (about 29.53 days), as the orbital positions of the Moon around Earth and of Earth around the Sun shift.

The Moon's rotation is tidally locked by Earth's gravity; therefore, most of the same lunar side always faces Earth. This near side is variously sunlit, depending on the position of the Moon in its orbit. Thus, the sunlit portion of this face can vary from 0% (at new moon) to 100% (at full moon). The lunar terminator is the boundary between the illuminated and darkened hemispheres.

Each of the four "intermediate" lunar phases is around 7.4 days, but this varies slightly due to the elliptical shape of the Moon's orbit. Aside from some craters near the lunar poles, such as Shoemaker, all parts of the Moon see around 13.77 days of daylight, followed by 13.77 days of "night". (The side of the Moon facing away from Earth is sometimes called the "dark side of the Moon", although that is a misnomer).

There are four principal lunar phases: new moon, first quarter, full moon, and last quarter (also known as third or final quarter), when the Moon's ecliptic longitude is at an angle to the Sun (as viewed from Earth) of 0°, 90°, 180°, and 270°, respectively. Each of these phases appear at slightly different times at different locations on Earth. During the intervals between principal phases are intermediate phases, during which the Moon's apparent shape is either crescent or gibbous. The intermediate phases last one-quarter of a synodic month, or 7.38 days, on average. The descriptor waxing is used for an intermediate phase when the Moon's apparent shape is thickening, from new to full moon, and waning when the shape is thinning. The longest duration between full moon to new moon (or new moon to full moon) lasts about 15 days and 14.5 hours, while the shortest duration between full moon to new moon (or new moon to full moon) lasts only about 13 days and 22.5 hours.

- New Moon appears higher on summer solstice than on winter solstice.
- First Quarter Moon appears higher on spring equinox than on autumnal (fall) equinox.
- Full Moon appears higher on winter solstice than on summer solstice.
- Last Quarter Moon appears higher on autumnal (fall) equinox than on spring equinox.
- Waxing Crescent Moon appears higher on mid-spring (May 5 in the Northern Hemisphere or November 7 in the Southern Hemisphere) than on mid-autumn (November 7 in the Northern Hemisphere or May 5 in the Southern Hemisphere).
- Waxing Gibbous Moon appears higher on mid-winter (February 4 in the Northern Hemisphere or August 7 in the Southern Hemisphere) than on mid-summer (August 7 in the Northern Hemisphere or February 4 in the Southern Hemisphere).
- Waning Gibbous Moon appears higher on mid-autumn (November 7 in the Northern Hemisphere or May 5 in the Southern Hemisphere) than on mid-spring (May 5 in the Northern Hemisphere or November 7 in the Southern Hemisphere).
- Waning Crescent Moon appears higher on mid-summer (August 7 in the Northern Hemisphere or February 4 in the Southern Hemisphere) than on mid-winter (February 4 in the Northern Hemisphere or August 7 in the Southern Hemisphere).

Moon Phase	Northern Hemisphere	Southern Hemisphere	Visibility	Average Moonrise Time	Min-phase Standard Time	Average Moonset Time	Northern Hemisphere Image	Southern Hemisphere Image
New Moon	Disc completely in Sun's shadow (lit by earthshine only)		Invisible (too close to Sun)	6 am	Noon	6 pm		Waxing Crescent	Right side, 0.1%–49.9% lit disc	Left side, 0.1–49.9% lit disc	Late morning to post-dusk	9 am	3 pm	9 pm		First Quarter	Right side, 50% lit disc	Left side, 50% lit disc	Afternoon and early evening	Noon	6 pm	Midnight		Waxing Gibbous	Right side, 50.1%–99.9% lit disc	Left side, 50.1%–99.9% lit disc	Late afternoon and most of night 3	3 pm	9 pm	3 am		Full Moon	100% illuminated disc		Sunset to sunrise (all night)	6 pm	Midnight	6 am		Waning Gibbous	Left side, 99.9%–50.1% lit disc	Right side, 99.9%–50.1% lit dis	Most of night and early morning	9 pm	3 am	9 am		Last Quarter	Left side, 50% lit disc	Right side, 50% lit disc	Late night and morning	Midnight	6 am	Noon		Waning Crescent	Left side, 49.9%–0.1% lit disc	Right side, 49.9%–0.1% lit disc	Pre-dawn to early afternoon	3 am	9 am	3 pm		
4 Solar Cycle

The solar cycle or solar magnetic activity cycle is a nearly periodic 11-year change in the Sun's activity measured in terms of variations in the number of observed sunspots on the solar surface. Sunspots have been observed since the early 17th century and the sunspot time series is the longest continuously observed (recorded) time series of any natural phenomena. Accompanying the 11 year quasi-periodicity in sunspots, the large-scale dipolar (north-south) magnetic field component of the Sun also flips every 11 years, however, the peak in the dipolar field lags the peak in the sunspot number, with the former occurring at the minimum between two cycles.

Levels of solar radiation and ejection of solar material, the number and size of sunspots, solar flares, and coronal loops all exhibit a synchronized fluctuation, from active to quiet to active again, with a period of 11 years. This cycle has been observed for centuries by changes in the Sun's appearance and by terrestrial phenomena such as auroras. Solar activity, driven both by the sunspot cycle and transient aperiodic processes govern the environment of the Solar System planets by creating space weather and impact space- and ground-based technologies as well as the Earth's atmosphere and also possibly climate fluctuations on scales of centuries and longer.

5 Water Cycle

The water cycle, also known as the hydrologic cycle or the hydrological cycle, describes the continuous movement of water on, above and below the surface of the Earth. The mass of water on Earth remains fairly constant over time but the partitioning of the water into the major reservoirs of ice, fresh water, saline water and atmospheric water is variable depending on a wide range of climatic variables. The water moves from one reservoir to another, such as from river to ocean, or from the ocean to the atmosphere, by the physical processes of evaporation, condensation, precipitation, infiltration, surface runoff, and subsurface flow. In doing so, the water goes through different forms: liquid, solid (ice) and vapor.

The water cycle involves the exchange of energy, which leads to temperature changes. When water evaporates, it takes up energy from its surroundings and cools the environment. When it condenses, it releases energy and warms the environment. These heat exchanges influence climate.

The evaporative phase of the cycle purifies water which then replenishes the land with freshwater. The flow of liquid water and ice transports minerals across the globe. It is also involved in reshaping the geological features of the Earth, through processes including erosion and sedimentation. The water cycle is also essential for the maintenance of most life and ecosystems on the planet.

The sun, which drives the water cycle, heats water in oceans and seas. Water evaporates as water vapor into the air. Some ice and snow sublimates directly into water vapor. Evapotranspiration is water transpired from plants and evaporated from the soil. The water molecule H2O has smaller molecular mass than the major components of the atmosphere, nitrogen and oxygen, N2 and O2, hence is less dense. Due to the significant difference in density, buoyancy drives humid air higher. As altitude increases, air pressure decreases and the temperature drops (see Gas laws). The lower temperature causes water vapor to condense into tiny liquid water droplets which are heavier than the air, and fall unless supported by an updraft. A huge concentration of these droplets over a large space up in the atmosphere become visible as cloud. Some condensation is near ground level, and called fog.

Atmospheric circulation moves water vapor around the globe; cloud particles collide, grow, and fall out of the upper atmospheric layers as precipitation. Some precipitation falls as snow or hail, sleet, and can accumulate as ice caps and glaciers, which can store frozen water for thousands of years. Most water falls back into the oceans or onto land as rain, where the water flows over the ground as surface runoff.

A portion of runoff enters rivers in valleys in the landscape, with streamflow moving water towards the oceans. Runoff and water emerging from the ground (groundwater) may be stored as freshwater in lakes. Not all runoff flows into rivers; much of it soaks into the ground as infiltration. Some water infiltrates deep into the ground and replenishes aquifers, which can store freshwater for long periods of time.

Some infiltration stays close to the land surface and can seep back into surface-water bodies (and the ocean) as groundwater discharge. Some groundwater finds openings in the land surface and comes out as freshwater springs. In river valleys and floodplains, there is often continuous water exchange between surface water and ground water in the hyporheic zone. Over time, the water returns to the ocean, to continue the water cycle.

Processes

Precipitation	Condensed water vapor that falls to the Earth's surface. Most precipitation occurs as rain, but also includes snow, hail, fog drip, graupel, and sleet. Approximately 505,000 km3 (121,000 cu mi) of water falls as precipitation each year, 398,000 km3 (95,000 cu mi) of it over the oceans. The rain on land contains 107,000 km3 (26,000 cu mi) of water per year and a snowing only 1,000 km3 (240 cu mi). 78% of global precipitation occurs over the ocean.
Canopy Interception	The precipitation that is intercepted by plant foliage eventually evaporates back to the atmosphere rather than falling to the ground.
Snowmelt	The runoff produced by melting snow.
Runoff	The variety of ways by which water moves across the land. This includes both surface runoff and channel runoff. As it flows, the water may seep into the ground, evaporate into the air, become stored in lakes or reservoirs, or be extracted for agricultural or other human uses.
Infiltration	The flow of water from the ground surface into the ground. Once infiltrated, the water becomes soil moisture or groundwater. A recent global study using water stable isotopes, however, shows that not all soil moisture is equally available for groundwater recharge or for plant transpiration.
Subsurface Flow	The flow of water underground, in the vadose zone and aquifers. Subsurface water may return to the surface (e.g. as a spring or by being pumped) or eventually seep into the oceans. Water returns to the land surface at lower elevation than where it infiltrated, under the force of gravity or gravity induced pressures. Groundwater tends to move slowly and is replenished slowly, so it can remain in aquifers for thousands of years.
Evaporation	The transformation of water from liquid to gas phases as it moves from the ground or bodies of water into the overlying atmosphere. The source of energy for evaporation is primarily solar radiation. Evaporation often implicitly includes transpiration from plants, though together they are specifically referred to as evapotranspiration. Total annual evapotranspiration amounts to approximately 505,000 km3 (121,000 cu mi) of water, 434,000 km3 (104,000 cu mi) of which evaporates from the oceans. 86% of global evaporation occurs over the ocean.
Sublimation	The state change directly from solid water (snow or ice) to water vapor by passing the liquid state.
Deposition	This refers to changing of water vapor directly to ice.
Advection	The movement of water through the atmosphere. Without advection, water that evaporated over the oceans could not precipitate over land.
Condensation	The transformation of water vapor to liquid water droplets in the air, creating clouds and fog.
Transpiration	The release of water vapor from plants and soil into the air.
Percolation	Water flows vertically through the soil and rocks under the influence of gravity.
Plate Tectonics	Water enters the mantle via subduction of oceanic crust. Water returns to the surface via volcanism.

The water cycle involves many of these processes.

Effects on Climate
The water cycle is powered from solar energy. 86% of the global evaporation occurs from the oceans, reducing their temperature by evaporative cooling. Without the cooling, the effect of evaporation on the greenhouse effect would lead to a much higher surface temperature of 67 °C (153 °F), and a warmer planet. Aquifer drawdown or overdrafting and the pumping of fossil water increases the total amount of water in the hydrosphere, and has been postulated to be a contributor to sea-level rise.

6 Weather Types

The following shows the types of benefits for varying weather types.

Sunny	● **Solar Electricity:** Sun provides solar power. ● **Bacteria Killing Sunlight:** The UV content of sunlight kills bacteria. ● **SODIS Purification:** Purify water using sunlight. ● **Vitamin D:** Gain an essential vitamin for survival. ● **Longer Line of Sight:** The ability to see further when the weather is clear.
Cloudy	● **Cooler Temperatures:** A reprieve from direct sunlight in the form of clouds, but clouds may also hold in heat. ● **Soft Shadows:** Harder to detect people in sunlight when the shadows are soft.
Rainy	● **Fresh Water:** Rain can provide fresh water. ● **Stealth:** Stealthier movement due to lower LOS and dampened sound. ● **Easy to Clean:** o ● **Dynamo:** Electricity Generation From Rivers
Stormy	● **Fresh Water:** Rain can provide fresh water. ● **Stealth:** Much stealthier movement due to lower LOS and dampened sound. ● **Dynamo:** Electricity Generation From Wind and Rivers.
Windy	● **Electricity Generation:** Can generate electricity using the wind. ● **Dampened Sound:** You can move more stealthily.
Cyclone / Hurricane / Typhoon	● **Electricity Generation:** Can generate electricity using the wind. ● **Dampened Sound:** You can move more stealthily.
Dust / Sand Storm	● **Electricity Generation:** Can generate electricity using the wind. ● **Dampened Sound:** You can move more stealthily. ● **Less Visibility:** You can move more stealthily and remain hidden easier.
Snow Storm / Blizzard (Falling Snow)	● **Electricity Generation:** Can generate electricity using the wind. ● **Dampened Sound:** You can move more stealthily. ● **Less Visibility:** You can move more stealthily and remain hidden easier. ● **Water:** Melting hail can provide you with water.
Tornado	● **Electricity Generation:** Can generate electricity using the wind. ● **Dampened Sound:** You can move more stealthily.
Humid	● **Water:** Extractable moisture from the air.
Fog / Mist	● **Less Visibility:** You can move more stealthily and remain hidden easier. ● **Moisture:** Can extract moisture from the air
Snow / Sleet	● **Water:** Meltable Snow for Water ● **Stealth:** Stealthier movement due to lower LOS and dampened sound.
Thundersnow	● **Water:** Meltable Snow for Water ● **Stealth:** Stealthier movement due to lower LOS and dampened sound.
Hail	● **Water:** Melting hail can provide you with water. ● **Protection:** People generally won't be outside if the hail is large enough.
Drought	● **Few Mosquitos:** There will generally be a huge reduction in the mosquito population in a drought.
Wildfire	● **Clears Terrain:** Fires clear terrain of debris. ● **More Visibility:** You can see further with less vegetation around once the smoke clears.

2 Atmosphere

The atmosphere of Earth is the layer of gases, commonly known as air, that surrounds the planet Earth and is retained by Earth's gravity. The atmosphere of Earth protects life on Earth by creating pressure allowing for liquid water to exist on the Earth's surface, absorbing ultraviolet solar radiation, warming the surface through heat retention (greenhouse effect), and reducing temperature extremes between day and night (the diurnal temperature variation).

By volume, dry air contains 78.09% nitrogen, 20.95% oxygen, 0.93% argon, 0.04% carbon dioxide, and small amounts of other gases. Air also contains a variable amount of water vapour, on average around 1% at sea level, and 0.4% over the entire atmosphere. Air composition, temperature, and atmospheric pressure vary with altitude, and air suitable for use in photosynthesis by terrestrial plants and breathing of terrestrial animals is found only in Earth's troposphere and in artificial atmospheres.

The atmosphere has a mass of about 5.15×1018 kg, three quarters of which is within about 11 km (6.8 mi; 36,000 ft) of the surface. The atmosphere becomes thinner and thinner with increasing altitude, with no definite boundary between the atmosphere and outer space. The Kármán line, at 100 km (62 mi), or 1.57% of Earth's radius, is often used as the border between the atmosphere and outer space. Atmospheric effects become noticeable during atmospheric re-entry of spacecraft at an altitude of around 120 km (75 mi). Several layers can be distinguished in the atmosphere, based on characteristics such as temperature and composition.

The Atmosphere

Below the Surface
For information on what lies below the surface see NATURAL DISASTERS > Earthquakes > Earth Composition

Surface (Sea Level)

The total surface area of Earth is about 510 million km2 (197 million sq mi). Of this, 70.8%, or 361.13 million km2 (139.43 million sq mi), is below sea level and covered by ocean water. Below the ocean's surface are much of the continental shelf, mountains, volcanoes, oceanic trenches, submarine canyons, oceanic plateaus, abyssal plains, and a globe-spanning mid-ocean ridge system. The remaining 29.2%, or 148.94 million km2 (57.51 million sq mi), not covered by water has terrain that varies greatly from place to place and consists of mountains, deserts, plains, plateaus, and other landforms.

Tectonics and erosion, volcanic eruptions, flooding, weathering, glaciation, the growth of coral reefs, and meteorite impacts are among the processes that constantly reshape the Earth's surface over geological time. The elevation of the land surface varies from the low point of −418 m (−1,371 ft) at the Dead Sea, to a maximum altitude of 8,848 m (29,029 ft) at the top of Mount Everest. The mean height of land above sea level is about 797 m (2,615 ft).

Height 0 km	**Contains** ● Humanity	**Temperature** o			

Troposphere

The troposphere is the lowest layer of Earth's atmosphere. It extends from Earth's surface to an average height of about 12 km (7.5 mi; 39,000 ft), although this altitude varies from about 9 km (5.6 mi; 30,000 ft) at the geographic poles to 17 km (11 mi; 56,000 ft) at the Equator, with some variation due to weather. The troposphere is bounded above by the tropopause, a boundary marked in most places by a temperature inversion (i.e. a layer of relatively warm air above a colder one), and in others by a zone which is isothermal with height.

Although variations do occur, the temperature usually declines with increasing altitude in the troposphere because the troposphere is mostly heated through energy transfer from the surface. Thus, the lowest part of the troposphere (i.e. Earth's surface) is typically the warmest section of the troposphere. This promotes vertical mixing.

The troposphere contains roughly 80% of the mass of Earth's atmosphere. The troposphere is denser than all its overlying atmospheric layers because a larger atmospheric weight sits on top of the troposphere and causes it to be most severely compressed. Fifty percent of the total mass of the atmosphere is located in the lower 5.6 km (3.5 mi; 18,000 ft) of the troposphere. Nearly all atmospheric water vapour or moisture is found in the troposphere, so it is the layer where most of Earth's weather takes place.

It has basically all the weather-associated cloud genus types generated by active wind circulation, although very tall cumulonimbus thunder clouds can penetrate the tropopause from below and rise into the lower part of the stratosphere. Most conventional aviation activity takes place in the troposphere, and it is the only layer that can be accessed by propeller-driven aircraft.

Height 0 - 12 km (0 - 7.5 mi)	**Contains** ● Contrails ● Weather Balloons ● Cirrus Clouds ● Cumulonimbus Clouds ● Nacreous Clouds	**Temperature** 15 to -51°C (59 to -60°F)			

Tropopause

The tropopause is the boundary in the Earth's atmosphere between the troposphere and the stratosphere. It is a thermodynamic gradient stratification layer, marking the end of troposphere. It lies, on average, at 17 kilometres (11 mi) above equatorial regions, and above 9 kilometres (5.6 mi) over the polar regions. Most commercial aircraft are flown in the lower stratosphere, just above the tropopause, where clouds are usually absent, as are significant weather perturbations.

Height 12 km (7.5 mi)	**Contains** ●	**Temperature** -15 to -51°C (5°F to -60°F)			

Stratosphere

The stratosphere is the second-lowest layer of Earth's atmosphere. It lies above the troposphere and is separated from it by the tropopause. This layer extends from the top of the troposphere at roughly 12 km (7.5 mi; 39,000 ft) above Earth's surface to the stratopause at an altitude of about 50 to 55 km (31 to 34 mi; 164,000 to 180,000 ft). The atmospheric pressure at the top of the stratosphere is roughly 1/1000 the pressure at sea level. It contains the ozone layer, which is the part of Earth's atmosphere that contains relatively high concentrations of that gas. The stratosphere defines a layer in which temperatures rise with increasing altitude. This rise in temperature is caused by the absorption of ultraviolet radiation (UV) radiation from the Sun by the ozone layer, which restricts turbulence and mixing.

Although the temperature may be −60 °C (−76 °F; 210 K) at the tropopause, the top of the stratosphere is much warmer, and may be near 0 °C. The stratospheric temperature profile creates very stable atmospheric conditions, so the stratosphere lacks the weather-producing air turbulence that is so prevalent in the troposphere. Consequently, the stratosphere is almost completely free of clouds and other forms of weather. However, polar stratospheric or nacreous clouds are occasionally seen in the lower part of this layer of the atmosphere where the air is coldest. The stratosphere is the highest layer that can be accessed by jet-powered aircraft.

Height 12 - 50 km (7.5 - 31 mi)	**Contains** ● Commercial Aircraft ● Meteors	**Temperature** 0°C (32°F)			

Stratopause

Height 50 km (31 mi)	**Contains** ●	**Temperature** ○			

Mesosphere

The mesosphere is the third highest layer of Earth's atmosphere, occupying the region above the stratosphere and below the thermosphere. It extends from the stratopause at an altitude of about 50 km (31 mi; 160,000 ft) to the mesopause at 80–85 km (50–53 mi; 260,000–280,000 ft) above sea level. Temperatures drop with increasing altitude to the mesopause that marks the top of this middle layer of the atmosphere. It is the coldest place on Earth and has an average temperature around −85 °C (−120 °F; 190 K). Just below the mesopause, the air is so cold that even the very scarce water vapour at this altitude can be sublimated into polar-mesospheric noctilucent clouds. These are the highest clouds in the atmosphere and may be visible to the naked eye if sunlight reflects off them about an hour or two after sunset or a similar length of time before sunrise.

They are most readily visible when the Sun is around 4 to 16 degrees below the horizon. Lightning-induced discharges known as transient luminous events (TLEs) occasionally form in the mesosphere above tropospheric thunderclouds. The mesosphere is also the layer where most meteors burn up upon atmospheric entrance. It is too high above Earth to be accessible to jet-powered aircraft and balloons, and too low to permit orbital spacecraft. The mesosphere is mainly accessed by sounding rockets and rocket-powered aircraft.

Height 50 - 80 km (31 - 50 mi)	**Contains** ● Noctiluscent Cloud	**Temperature** -85°C (-121°F)			

Mesopause

Height 80 km (50 mi)	**Contains** ●	**Temperature** ○			

Thermosphere

The thermosphere is the second-highest layer of Earth's atmosphere. It extends from the mesopause (which separates it from the mesosphere) at an altitude of about 80 km (50 mi; 260,000 ft) up to the thermopause at an altitude range of 500–1000 km (310–620 mi; 1,600,000–3,300,000 ft). The height of the thermopause varies considerably due to changes in solar activity.

Because the thermopause lies at the lower boundary of the exosphere, it is also referred to as the exobase. The lower part of the thermosphere, from 80 to 550 kilometres (50 to 342 mi) above Earth's surface, contains the ionosphere. The temperature of the thermosphere gradually increases with height. Unlike the stratosphere beneath it, wherein a temperature inversion is due to the absorption of radiation by ozone, the inversion in the thermosphere occurs due to the extremely low density of its molecules.

The temperature of this layer can rise as high as 1,500 °C (2,700 °F), though the gas molecules are so far apart that its temperature in the usual sense is not very meaningful. The air is so rarefied that an individual molecule (of oxygen, for example) travels an average of 1 kilometre (0.62 mi; 3300 ft) between collisions with other molecules. Although the thermosphere has a high proportion of molecules with high energy, it would not feel hot to a human in direct contact, because its density is too low to conduct a significant amount of energy to or from the skin.

This layer is completely cloudless and free of water vapour. However, non-hydrometeorological phenomena such as the aurora borealis and aurora australis are occasionally seen in the thermosphere. The International Space Station orbits in this layer, between 350 and 420 km (220 and 260 mi).

Height 80 to (500-1,000) km (50 to (310-620) mi)	**Contains** ● International Space Station (330-410km) ● Auroras	**Temperature** 1,500 °C (2,700 °F)			

Thermopause (Exobase)

The thermopause is the atmospheric boundary of Earth's energy system, located at the top of the thermosphere. The temperature of the thermopause could range from nearly absolute zero to 987.548 °C (1,810 °F). Below this, the atmosphere is defined to be active on the insolation received, due to the increased presence of heavier gases such as monatomic oxygen. The solar constant is thus expressed at the thermopause. Beyond (above) this, the exosphere describes the thinnest remainder of atmospheric particles with large mean free path, mostly hydrogen and helium.

As a limit for the exosphere this boundary is also called exobase. The exact altitude varies by the energy inputs of location, time of day, solar flux, season, etc. and can be between 500 and 1,000 kilometres (310 and 620 mi) high at a given place and time because of these. A portion of the magnetosphere dips below this layer as well. Although these are all named layers of the atmosphere, the pressure is so negligible that the chiefly-used definitions of outer space are actually below this altitude. Orbiting satellites do not experience significant atmospheric heating, but their orbits do decay over time, depending on orbit altitude. Space missions such as the ISS, space shuttle, and Soyuz operate under this layer.

Height 500 - 1,000 km (310 - 620 mi)	**Contains** ●	**Temperature** -273 to 987 °C (-460 to 1,810 °F)			

Exosphere

The exosphere is the outermost layer of Earth's atmosphere (i.e. the upper limit of the atmosphere). It extends from the exobase, which is located at the top of the thermosphere at an altitude of about 700 km above sea level, to about 10,000 km (6,200 mi; 33,000,000 ft) where it merges into the solar wind. This layer is mainly composed of extremely low densities of hydrogen, helium and several heavier molecules including nitrogen, oxygen and carbon dioxide closer to the exobase. The atoms and molecules are so far apart that they can travel hundreds of kilometres without colliding with one another. Thus, the exosphere no longer behaves like a gas, and the particles constantly escape into space.

These free-moving particles follow ballistic trajectories and may migrate in and out of the magnetosphere or the solar wind. The exosphere is located too far above Earth for any meteorological phenomena to be possible. However, the aurora borealis and aurora australis sometimes occur in the lower part of the exosphere, where they overlap into the thermosphere. The exosphere contains most of the satellites orbiting Earth.

Height 700 - 10,000 km	**Contains** ● Satellites	**Temperature** - °C (- °F)			

The Solar System

The Sun

The Sun is the star at the centre of the Solar System. It is a nearly perfect sphere of hot plasma, with internal convective motion that generates a magnetic field via a dynamo process. It is by far the most important source of energy for life on Earth. Its diameter is about 1.39 million kilometres (864,000 miles), or 109 times that of Earth, and its mass is about 330,000 times that of Earth. It accounts for about 99.86% of the total mass of the Solar System. Roughly three quarters of the Sun's mass consists of hydrogen (~73%); the rest is mostly helium (~25%), with much smaller quantities of heavier elements, including oxygen, carbon, neon, and iron.

The Sun is roughly middle-aged. It currently fuses about 600 million tons of hydrogen into helium every second, converting 4 million tons of matter into energy every second as a result. This energy, which can take between 10,000 and 170,000 years to escape from its core, is the source of the Sun's light and heat.

The Sun								**Temperature** 5,778 °K 5,504 °C (9,940 °F)	**Diameter** 1,391,400 km (864,575.87 mi)

The Moon (Luna)

The Moon is an astronomical body that orbits planet Earth and is Earth's only permanent natural satellite. It is the fifth-largest satellite in the Solar System, and the largest among planetary satellites relative to the size of the planet that it orbits (its primary). The Moon is in synchronous rotation with Earth, and thus always shows the same side to Earth, the near side. The near side is marked by dark volcanic maria that fill the spaces between the bright ancient crustal highlands and the prominent impact craters. After the Sun, the Moon is the second-brightest regularly visible celestial object in Earth's sky.

Its surface is actually dark, although compared to the night sky it appears very bright, with a reflectance just slightly higher than that of worn asphalt. Its gravitational influence produces the ocean tides, body tides, and the slight lengthening of the day. The Moon's apparent size in the sky is almost the same as that of the Sun, since the star is about 400 times the lunar distance and diameter. Therefore, the Moon covers the Sun nearly precisely during a total solar eclipse. This matching of apparent visual size will not continue in the far future because the Moon's distance from Earth is gradually increasing.

The Moon								**Average Distance (Earth)** 384,400 km (238,900 mi) **Temperature** 127 °C (260 °F) With Sun -173 °C (-280 °F) No Sun	**Diameter** 2,474.2 km (1537.3 mi)

Mercury

Mercury is the closest planet to our Sun, at just 58 million km (36 million miles) or 0.39 Astronomical Unit (AU) out. Mercury is also the smallest planet in our Solar System, and is also smaller than its largest moon (Ganymede, which orbits Jupiter).

Mercury				**Distance to Sun** 58m Km (36m Mi)	**Avg Distance to Earth** 92m km	**Diameter** 4,879 km (3,032 mi)	**Mass** 3.3011 x 10^23 kg (0.055 Earths)	**Orbit Time** 87.97 Earth Days	**Day Length** 59 Earth Days	**Temperature Range** -173 - 427 °C (-279 - 801 °F)	**Moons** 0

Venus

Venus is the second closest planet to our Sun, orbiting at an average distance of 108 million km (67 million miles) or 0.72 AU. Venus is often called Earth's "sister planet," as it is just a little smaller than Earth. Venus is 81.5% as massive as Earth, and has 90% of its surface area and 86.6% of its volume. The surface gravity, which is 8.87 m/s², is equivalent to 0.904 g – roughly 90% of the Earth standard.

Venus				**Distance to Sun** 108m Km (67m Mi)	**Avg Distance to Earth** 42m km	**Diameter** 12,104 km (7,521 mi)	**Mass** 4.867 x 10^24 kg (0.815 Earth mass)	**Orbit Time** 225 Earth Days	**Day Length** 243 Earth Days	**Temperature Range** 462 °C (864 °F)	**Moons** 0

Earth

Earth is a terrestrial planet with an ever-changing surface, and 70 percent of the Earth's surface is covered in oceans.

Earth				**Distance to Sun** 150m Km (93m Mi)	**Avg Distance to Earth** 0 km	**Diameter** 12,760 km (7,926 mi)	**Mass** 5.97 x 10^24 kg	**Orbit Time** 365 Days	**Day Length** 24 hours (Precisely, 23h 56m 4s)	**Temperature Range** Average is 14°C, (57°F) -88 to 58°C (-126 to 136°F)	**Moons** 1

Mars

Mars is the fourth planet from the sun at a distance of about 228 million km (142 million miles) or 1.52 AU. It is also known as "the Red Planet" because of its reddish hue, which is due to the prevalence of iron oxide on its surface. In many ways, Mars is similar to Earth, which can be seen from its similar rotational period and tilt, which in turn produce seasonal cycles that are comparable to our own.

Mars				**Distance to Sun** 228m Km (142m Mi)	**Avg Distance to Earth** 78m km	**Diameter** 6,787 km (4,217 mi)	**Mass** 6.4171 x 10^23 kg (0.107 Earths)	**Orbit Time** 687 Earth Days	**Day Length** 24 Hours 37 Minutes	**Temperature Range** Avg -55 C (-67 F) -153 to 20 °C (-225 to +70 °F)	**Moons** 2

Jupiter

Jupiter is the fifth planet from the Sun, at a distance of about 778 million km (484 million miles) or 5.2 AU. Jupiter is also the most massive planet in our Solar System, being 317 times the mass of Earth, and two and half times larger than all the other planets combined. It is a gas giant, meaning that it is primarily composed of hydrogen and helium, with swirling clouds and other trace gases.

Jupiter				**Distance to Sun** 778m Km (484m Mi)	**Avg Distance to Earth** 628m km	**Diameter** 428,400 km (88,730 mi)	**Mass** 1.8986 × 10^27 kg (317.8 Earths)	**Orbit Time** 11.9 Earth Years	**Day Length** 9.8 Earth Hours	**Temperature Range** -148 °C (-234 °F)	**Moons** 67

Saturn

Saturn is the sixth planet from the Sun at a distance of about 1.4 billion km (886 million miles) or 9.5 AU. Like Jupiter, it is a gas giant, with layers of gaseous material surrounding a solid core. Saturn is most famous and most easily recognized for its spectacular ring system, which is made of seven rings with several gaps and divisions between them.

Saturn				**Distance to Sun** 1,400m Km (886m Mi)	**Avg Distance to Earth** 1,250m km	**Diameter** 120,500 km (74,900 mi)	**Mass** 5.6836 x 10^26 kg (95.159 Earths)	**Orbit Time** 29.5 Earth Years	**Day Length** 10.7 Earth Hours	**Temperature Range** -178 °C (-288 °F)	**Moons** 53

Uranus

Uranus is the seventh planet from the sun at a distance of about 2.9 billion km (1.8 billion miles) or 19.19 AU. Though it is classified as a "gas giant", it is often referred to as an "ice giant" as well, owing to the presence of ammonia, methane, water and hydrocarbons in ice form. The presence of methane ice is also what gives it its bluish appearance.

Uranus				**Distance to Sun** 2,900m Km (1,800m Mi)	**Avg Distance to Earth** 2,750	**Diameter** 51,120 km (31,763 mi)	**Mass** 8.681 × 10^25 kg (14.541 Earths)	**Orbit Time** 84 Earth Years	**Day Length** 18 Earth Hours	**Temperature Range** -216 °C (-357 °F)	**Moons** 27

Neptune

Neptune is the eighth and farthest planet from the Sun, at a distance of about 4.5 billion km (2.8 billion miles) or 30.07 AU. Like Jupiter, Saturn and Uranus, it is technically a gas giant, though it is more properly classified as an "ice giant" with Uranus.

Neptune				**Distance to Sun** 4,500m Km (2,800m Mi)	**Avg Distance to Earth** 4,350	**Diameter** 9,530 km (30,775 mi)	**Mass** 1.0243 x 10^26 kg (17 Earths)	**Orbit Time** 165 Earth Years	**Day Length** 16 Earth Hours	**Temperature Range** -214 °C (-353 °F)	**Moons** 14

Pluto

Milky Way

The Milky Way is the galaxy that contains our Solar System, with the name describing the galaxy's appearance from Earth: a hazy band of light seen in the night sky formed from stars that cannot be individually distinguished by the naked eye. The Milky Way is a barred spiral galaxy with a diameter between 150,000 and 200,000 light-years (ly). It is estimated to contain 100–400 billion stars and more than 100 billion planets. The Solar System is located at a radius of about 27,000 light-years from the Galactic Centre, on the inner edge of the Orion Arm, one of the spiral-shaped concentrations of gas and dust.

Outside the Galaxy

Our galaxy, the Milky Way, is only one out of a total of about 100 to 200 billion galaxies that astronomers estimate to be in the Universe. That's more than 10 times the total number of people on Earth. As well as stars, galaxies contain vast amounts of gas and dust. Galaxies come in a variety of shapes and sizes. The Milky Way is an average-sized spiral galaxy: it is 100 000 light years across and contains around 200 billion stars. Small galaxies may contain only a few million stars, while large galaxies can have several trillion stars. Our closest galaxy neighbour is called the Andromeda Galaxy. Andromeda is 2.5 million light years away from the Milky Way. If you wanted to travel to Andromeda and could travel as fast as light, it would still take you 2.5 million years to get there.

Cumulus Humilis

Cumuliform cloud with little vertical extent that is commonly referred to as "fair weather cumulus" and common in the summer. Though if they develop into cumulus mediocris cloud or the cumulus congestus cloud, thunderstorms could develop later in the day.

Forecast: If these clouds are present in the morning, it is a sign of an unstable atmosphere. Larger clouds and possibly thunderstorms could form throughout the day to cause bad or severe weather in the afternoon or evening. Cumulus humilis clouds aren't rain clouds but could show an impending storm in the future.

Cumulus Mediocris

It also may exhibit small protuberances from the top. It may or may not show the cauliflower form characteristic of cumulus clouds.

Forecast: These clouds don't generally produce precipitation of more than very light intensity. They can grow into larger clouds (Cumulus Congestus) which could bring rain, winds and in worse cases, thunder and lightning. If these clouds are present in the morning or early afternoon they show a significant instability in the atmosphere likely leading to storms later in the day.

Cumulus Congestus

Cumulus congestus clouds are characteristic of unstable areas of the atmosphere which are undergoing convection. They are often characterized by sharp outlines and great vertical development. Because they are produced by strong updrafts, they are typically taller than they are wide.

Forecast: Cumulus congestus will mature into cumulonimbus calvus under conditions of sufficient instability. This transformation can be seen by the presence of smooth, fibrous, or striated aspects assumed by the cloud's upper part. This cloud type produces precipitation, often in abundance.

Cumulonimbus

Cumulonimbus progress from overdeveloped cumulus congestus clouds and may further develop as part of a supercell. The cumulonimbus base may extend several miles across and occupy low to middle altitudes. Peaks typically reach to as much as 12,000m. Well-developed cumulonimbus clouds are characterized by a flat, anvil-like top (anvil dome), caused by wind shear or inversion near the tropopause.

Forecast: Dense, towering vertical cloud associated with thunderstorms and atmospheric instability. These clouds are capable of producing lightning and other dangerous severe weather, such as tornadoes.

Stratus

Low-level clouds. Stratus clouds look like featureless gray to white sheets of cloud.

Forecast: A stratus cloud can form from stratocumulus spreading out under an inversion, indicating a continuation of prolonged cloudy weather with drizzle for several hours and then an improvement as it breaks into stratocumulus. Stratus clouds can persist for days in anticyclone conditions.

Nimbostratus

Nimbostratus has a diffuse cloud base generally found anywhere from near surface in the low levels to about 3,000m in the middle level of the troposphere. Although usually dark at its base, it often appears illuminated from within to a surface observer.

Forecast: Nimbostratus is generally a sign of an approaching warm or occluded front producing steady moderate precipitation, as opposed to the shorter period of typically heavier precipitation released by a cold-frontal cumulonimbus cloud. Precipitation may last for several days, depending on the speed of the frontal system.

Altostratus

Middle altitude cloud genus belonging to the stratiform physical category characterized by a generally uniform gray to bluish-green and sheet or layer. It is lighter in colour than nimbostratus and darker than high cirrostratus. The sun can be seen through thin altostratus, but thicker layers can be quite opaque.

Forecast: Altostratus tends to form ahead of a warm or occluded front, the altostratus gradually thickening into rain bearing nimbostratus. However it can also occur together with cumulus congestus or cumulonimbus at a cold front.

Cirrostratus

Difficult to detect and is capable of forming halos when the cloud takes the form of thin cirrostratus nebulosus.

Forecast: Cirrostratus clouds sometimes signal the approach of a warm front if they form after cirrus and spread from one area across the sky, and thus may be signs that precipitation might follow in the next 12 to 24 hours or as soon as 6–8 hours if the front is fast moving.

Cirrus

Characterized by thin, wispy strands. This cloud can form at any altitude between 5.0 km and 14 km above sea level. The strands of cloud sometimes appear in tufts of a distinctive form referred to by the common name of "mares' tails".
Forms from tropical cyclones, and is seen fanning out from the eyewalls of hurricanes. Contrails are a manmade type of cirrus cloud from jet engines.

Forecast: Random, isolated cirrus do not have any particular significance. A large number of cirrus clouds can be a sign of an approaching frontal system or upper air disturbance. This signals a change in weather in the near future, which usually becomes stormier.

Stratocumulus

A stratocumulus cloud belongs to a genus-type of clouds characterized by large dark, rounded masses, usually in groups, lines, or waves, the individual elements being larger than those in altocumulus, and the whole being at a lower altitude.

Forecast: Most often, stratocumulus produce no precipitation, and when they do, it is generally only light rain or snow. However, these clouds are often seen at either the front or tail end of worse weather, so they may indicate storms to come, in the form of thunderheads or gusty winds.

Altocumulus

Middle-altitude cloud genus that belongs mainly to the stratocumuliform physical category characterized by globular masses or rolls in layers or patches, the individual elements being larger and darker than those of cirrocumulus and smaller than those of stratocumulus.

Forecast: Towering altocumulus frequently signals the development of thunderstorms later in the day, as it shows instability and convection in the middle levels of the troposphere (the lowest layer of the atmosphere), the area where towering cumulus clouds can turn into cumulonimbus. It is therefore one of three warning clouds often recorded by the aviation industry, the other two being towering cumulus and cumulonimbus.

Cirrocumulus

Cirrocumulus is a cloud of the stratocumuliform physical category that shows both stratiform and cumuliform characteristics and typically appears as white, patchy sheets with ripples or tufts without gray shading. Each cloudlet appears no larger than a finger held at arm's length. These often are organized in rows like other cumuliform and stratocumuliform clouds, but since they are so small, cirrocumulus patches take on a finer appearance.

Forecast: Cirrocumulus usually only forms in patches. If it forms in patches with cirrus or cirrostratus and the clouds spread across the sky, it usually means rain in 8–10 hours.

Noctilucent

Tenuous cloud-like phenomena in the upper atmosphere. They are made of ice crystals and are only visible in a deep twilight. They are most commonly observed in the summer months at latitudes between 50° and 70° north and south of the equator. These clouds can be observed only during local summer months and when the Sun is below the horizon for the observer, but while the clouds are still in sunlight.

Forecast: None

Polar Stratospheric

Clouds in the winter polar stratosphere at altitudes of 15,000–25,000 meters. They are best observed during civil twilight when the sun is between 1 and 6 degrees below the horizon as well as in winter and in more northerly latitudes.

Forecast: None

4 Weather Phenomenon

Atmospheric optics is "the study of the optical characteristics of the atmosphere or products of atmospheric processes .... (including) temporal and spatial resolutions beyond those discernible with the naked eye". Meteorological optics is "that part of atmospheric optics concerned with the study of patterns observable with the naked eye". Nevertheless, the two terms are sometimes used interchangeably. Meteorological optical phenomena, as described in this article, are concerned with how the optical properties of Earth's atmosphere cause a wide range of optical phenomena and visual perception phenomena.

Subheadings

1 Rainbow

A rainbow is a meteorological phenomenon that is caused by reflection, refraction and dispersion of light in water droplets resulting in a spectrum of light appearing in the sky. It takes the form of a multi-coloured circular arc. Rainbows caused by sunlight always appear in the section of sky directly opposite the sun. Rainbows can be full circles. However, the observer normally sees only an arc formed by illuminated droplets above the ground, and centred on a line from the sun to the observer's eye. In a primary rainbow, the arc shows red on the outer part and violet on the inner side. This rainbow is caused by light being refracted when entering a droplet of water, then reflected inside on the back of the droplet and refracted again when leaving it. In a double rainbow, a second arc is seen outside the primary arc, and has the order of its colours reversed, with red on the inner side of the arc. This is caused by the light being reflected twice on the inside of the droplet before leaving it.

A rainbow is not located at a specific distance from the observer, but comes from an optical illusion caused by any water droplets viewed from a certain angle relative to a light source. Thus, a rainbow is not an object and cannot be physically approached. Indeed, it is impossible for an observer to see a rainbow from water droplets at any angle other than the customary one of 42 degrees from the direction opposite the light source. Even if an observer sees another observer who seems "under" or "at the end of" a rainbow, the second observer will see a different rainbow—farther off—at the same angle as seen by the first observer. Rainbows span a continuous spectrum of colours. Any distinct bands perceived are an artefact of human colour vision, and no banding of any type is seen in a black-and-white photo of a rainbow, only a smooth gradation of intensity to a maximum, then fading towards the other side. For colours seen by the human eye, the most commonly cited and remembered sequence is Newton's sevenfold red, orange, yellow, green, blue, indigo and violet, remembered by the mnemonic Richard Of York Gave Battle In Vain (ROYGBIV). Rainbows can be caused by many forms of airborne water. These include not only rain, but also mist, spray, and airborne dew.

Visibility
Rainbows can be observed whenever there are water drops in the air and sunlight shining from behind the observer at a low altitude angle. Because of this, rainbows are usually seen in the western sky during the morning and in the eastern sky during the early evening. The most spectacular rainbow displays happen when half the sky is still dark with raining clouds and the observer is at a spot with clear sky in the direction of the sun. The result is a luminous rainbow that contrasts with the darkened background. During such good visibility conditions, the larger but fainter secondary rainbow is often visible. It appears about 10° outside of the primary rainbow, with inverse order of colours.

The rainbow effect is also commonly seen near waterfalls or fountains. In addition, the effect can be artificially created by dispersing water droplets into the air during a sunny day. Rarely, a moonbow, lunar rainbow or night-time rainbow, can be seen on strongly moonlit nights. As human visual perception for colour is poor in low light, moonbows are often perceived to be white. It is difficult to photograph the complete semicircle of a rainbow in one frame, as this would require an angle of view of 84°. For a 35 mm camera, a wide-angle lens with a focal length of 19 mm or less would be required.

From above the earth such as in an aeroplane, it is sometimes possible to see a rainbow as a full circle. This phenomenon can be confused with the glory phenomenon, but a glory is usually much smaller, covering only 5–20°. The sky inside a primary rainbow is brighter than the sky outside of the bow. This is because each raindrop is a sphere and it scatters light over an entire circular disc in the sky.

The radius of the disc depends on the wavelength of light, with red light being scattered over a larger angle than blue light. Over most of the disc, scattered light at all wavelengths overlaps, resulting in white light which brightens the sky. At the edge, the wavelength dependence of the scattering gives rise to the rainbow. Light of primary rainbow arc is 96% polarised tangential to the arch. Light of second arc is 90% polarised.

Colours
A spectrum obtained using a glass prism and a point source is a continuum of wavelengths without bands. The number of colours that the human eye is able to distinguish in a spectrum is in the order of 100. Accordingly, the Munsell colour system (a 20th-century system for numerically describing colours, based on equal steps for human visual perception) distinguishes 100 hues. The apparent discreteness of main colours is an artefact of human perception and the exact number of main colours is a somewhat arbitrary choice.

Colours
- Red
- Orange
- Yellow
- Green
- Blue
- Indigo
- Violet

Newton, who admitted his eyes were not very critical in distinguishing colours, originally (1672) divided the spectrum into five main colours: red, yellow, green, blue and violet. Later he included orange and indigo, giving seven main colours by analogy to the number of notes in a musical scale. Newton chose to divide the visible spectrum into seven colours out of a belief derived from the beliefs of the ancient Greek sophists, who thought there was a connection between the colours, the musical notes, the known objects in the Solar System, and the days of the week. Scholars have noted that what Newton regarded at the time as "blue" would today be regarded as cyan, and what Newton called "indigo" would today be considered blue.

Colours
- Red
- Orange
- Yellow
- Green
- Cyan
- Blue
- Violet

According to Isaac Asimov, "It is customary to list indigo as a colour lying between blue and violet, but it has never seemed to me that indigo is worth the dignity of being considered a separate colour. To my eyes it seems merely deep blue." The question of whether everyone sees seven colours in a rainbow is related to the idea of linguistic relativity. Suggestions have been made that there is universality in the way that a rainbow is perceived. However, more recent research suggests that the number of distinct colours observed and what these are called depend on the language that one uses with people whose language has fewer colour words seeing fewer discrete colour bands.

Explanation

When sunlight encounters a raindrop, part of the light is reflected and the rest enters the raindrop. The light is refracted at the surface of the raindrop. When this light hits the back of the raindrop, some of it is reflected off the back. When the internally reflected light reaches the surface again, once more some is internally reflected and some is refracted as it exits the drop. (The light that reflects off the drop, exits from the back, or continues to bounce around inside the drop after the second encounter with the surface, is not relevant to the formation of the primary rainbow.) The overall effect is that part of the incoming light is reflected back over the range of 0° to 42°, with the most intense light at 42°. This angle is independent of the size of the drop, but does depend on its refractive index. Seawater has a higher refractive index than rain water, so the radius of a "rainbow" in sea spray is smaller than a true rainbow. This is visible to the naked eye by a misalignment of these bows. The reason the returning light is most intense at about 42° is that this is a turning point – light hitting the outermost ring of the drop gets returned at less than 42°, as does the light hitting the drop nearer to its centre. There is a circular band of light that all gets returned right around 42°.

When sunlight encounters a raindrop, part of the light is reflected and the rest enters the raindrop. The light is refracted at the surface of the raindrop. When this light hits the back of the raindrop, some of it is reflected off the back. When the internally reflected light reaches the surface again, once more some is internally reflected and some is refracted as it exits the drop. (The light that reflects off the drop, exits from the back, or continues to bounce around inside the drop after the second encounter with the surface, is not relevant to the formation of the primary rainbow.) The overall effect is that part of the incoming light is reflected back over the range of 0° to 42°, with the most intense light at 42°. This angle is independent of the size of the drop, but does depend on its refractive index. Seawater has a higher refractive index than rain water, so the radius of a "rainbow" in sea spray is smaller than a true rainbow. This is visible to the naked eye by a misalignment of these bows. The reason the returning light is most intense at about 42° is that this is a turning point – light hitting the outermost ring of the drop gets returned at less than 42°, as does the light hitting the drop nearer to its centre. There is a circular band of light that all gets returned right around 42°.

The light at the back of the raindrop does not undergo total internal reflection, and some light does emerge from the back. However, light coming out the back of the raindrop does not create a rainbow between the observer and the sun because spectra emitted from the back of the raindrop do not have a maximum of intensity, as the other visible rainbows do, and thus the colours blend together rather than forming a rainbow. A rainbow does not exist at one particular location. Many rainbows exist; however, only one can be seen depending on the particular observer's viewpoint as droplets of light illuminated by the sun. All raindrops refract and reflect the sunlight in the same way, but only the light from some raindrops reaches the observer's eye. This light is what constitutes the rainbow for that observer. The whole system composed by the sun's rays, the observer's head, and the (spherical) water drops has an axial symmetry around the axis through the observer's head and parallel to the sun's rays. The rainbow is curved because the set of all the raindrops that have the right angle between the observer, the drop, and the sun, lie on a cone pointing at the sun with the observer at the tip. The base of the cone forms a circle at an angle of 40–42° to the line between the observer's head and their shadow but 50% or more of the circle is below the horizon, unless the observer is sufficiently far above the earth's surface to see it all, for example in an aeroplane (see above). Alternatively, an observer with the right vantage point may see the full circle in a fountain or waterfall spray

Variations

Double Rainbows	The term double rainbow is used when both the primary and secondary rainbows are visible. In theory, all rainbows are double rainbows, but since the secondary bow is always fainter than the primary, it may be too weak to spot in practice. Secondary rainbows are caused by a double reflection of sunlight inside the water droplets. Technically the secondary bow is centred on the sun itself, but since its angular size is more than 90° (about 127° for violet to 130° for red), it is seen on the same side of the sky as the primary rainbow, about 10° outside it at an apparent angle of 50–53°. As a result of the "inside" of the secondary bow being "up" to the observer, the colours appear reversed compared to those of the primary bow. The secondary rainbow is fainter than the primary because more light escapes from two reflections compared to one and because the rainbow itself is spread over a greater area of the sky. Each rainbow reflects white light inside its coloured bands, but that is "down" for the primary and "up" for the secondary. The dark area of unlit sky lying between the primary and secondary bows is called Alexander's band, after Alexander of Aphrodisias who first described it.
Twinned Rainbow	Unlike a double rainbow that consists of two separate and concentric rainbow arcs, the very rare twinned rainbow appears as two rainbow arcs that split from a single base. The colours in the second bow, rather than reversing as in a secondary rainbow, appear in the same order as the primary rainbow. A "normal" secondary rainbow may be present as well. Twinned rainbows can look similar to, but should not be confused with supernumerary bands. The two phenomena may be told apart by their difference in colour profile: supernumerary bands consist of subdued pastel hues (mainly pink, purple and green), while the twinned rainbow shows the same spectrum as a regular rainbow. The cause of a twinned rainbow is the combination of different sizes of water drops falling from the sky. Due to air resistance, raindrops flatten as they fall, and flattening is more prominent in larger water drops. When two rain showers with different-sized raindrops combine, they each produce slightly different rainbows which may combine and form a twinned rainbow. A numerical ray tracing study showed that a twinned rainbow on a photo could be explained by a mixture of 0.40 and 0.45 mm droplets. That small difference in droplet size resulted in a small difference in flattening of the droplet shape, and a large difference in flattening of the rainbow top. Meanwhile, the even rarer case of a rainbow split into three branches was observed and photographed in nature.
Full-Circle Rainbow	In theory, every rainbow is a circle, but from the ground, usually only its upper half can be seen. Since the rainbow's centre is diametrically opposed to the sun's position in the sky, more of the circle comes into view as the sun approaches the horizon, meaning that the largest section of the circle normally seen is about 50% during sunset or sunrise. Viewing the rainbow's lower half requires the presence of water droplets below the observer's horizon, as well as sunlight that is able to reach them. These requirements are not usually met when the viewer is at ground level, either because droplets are absent in the required position, or because the sunlight is obstructed by the landscape behind the observer. From a high viewpoint such as a high building or an aircraft, however, the requirements can be met and the full-circle rainbow can be seen. Like a partial rainbow, the circular rainbow can have a secondary bow or supernumerary bows as well. It is possible to produce the full circle when standing on the ground, for example by spraying a water mist from a garden hose while facing away from the sun. A circular rainbow should not be confused with the glory, which is much smaller in diameter and is created by different optical processes. In the right circumstances, a glory and a (circular) rainbow or fog bow can occur together. Another atmospheric phenomenon that may be mistaken for a "circular rainbow" is the 22° halo and is located around the sun (or moon), not opposite it.
Supernumerary Rainbows	In certain circumstances, one or several narrow, faintly coloured bands can be seen bordering the violet edge of a rainbow; i.e., inside the primary bow or, much more rarely, outside the secondary. These extra bands are called supernumerary rainbows or supernumerary bands; together with the rainbow itself the phenomenon is also known as a stacker rainbow. The supernumerary bows are slightly detached from the main bow, become successively fainter along with their distance from it, and have pastel colours (consisting mainly of pink, purple and green hues) rather than the usual spectrum pattern. The effect becomes apparent when water droplets are involved that have a diameter of about 1 mm or less; the smaller the droplets are, the broader the supernumerary bands become, and the less saturated their colours. Due to their origin in small droplets, supernumerary bands tend to be particularly prominent in fogbows. Supernumerary rainbows cannot be explained using classical geometric optics. The alternating faint bands are caused by interference between rays of light following slightly different paths with slightly varying lengths within the raindrops. Some rays are in phase, reinforcing each other through constructive interference, creating a bright band; others are out of phase by up to half a wavelength, cancelling each other out through destructive interference, and creating a gap. Supernumerary rainbows are clearest when raindrops are small and of uniform size.

Reflected Rainbow	When a rainbow appears above a body of water, two complementary mirror bows may be seen below and above the horizon, originating from different light paths. Their names are slightly different. A reflected rainbow may appear in the water surface below the horizon. The sunlight is first deflected by the raindrops, and then reflected off the body of water, before reaching the observer. The reflected rainbow is frequently visible, at least partially, even in small puddles. A reflection rainbow may be produced where sunlight reflects off a body of water before reaching the raindrops (see diagram and Reflection and reflected bows, Norway), if the water body is large, quiet over its entire surface, and close to the rain curtain. The reflection rainbow appears above the horizon. It intersects the normal rainbow at the horizon, and its arc reaches higher in the sky, with its centre as high above the horizon as the normal rainbow's centre is below it. Due to the combination of requirements, a reflection rainbow is rarely visible. Up to eight separate bows may be distinguished if the reflected and reflection rainbows happen to occur simultaneously: The normal (non-reflection) primary and secondary bows above the horizon (1, 2) with their reflected counterparts below it (3, 4), and the reflection primary and secondary bows above the horizon (5, 6) with their reflected counterparts below it (7, 8).
Monochrome Rainbow	Occasionally a shower may happen at sunrise or sunset, where the shorter wavelengths like blue and green have been scattered and essentially removed from the spectrum. Further scattering may occur due to the rain, and the result can be the rare and dramatic monochrome or red rainbow.
Higher-Order Rainbows	In addition to the common primary and secondary rainbows, it is also possible for rainbows of higher orders to form. The order of a rainbow is determined by the number of light reflections inside the water droplets that create it: One reflection results in the first-order or primary rainbow; two reflections create the second-order or secondary rainbow. More internal reflections cause bows of higher orders—theoretically unto infinity. As more and more light is lost with each internal reflection, however, each subsequent bow becomes progressively dimmer and therefore increasingly harder to spot. An additional challenge in observing the third-order (or tertiary) and fourth-order (quaternary) rainbows is their location in the direction of the sun (about 40° and 45° from the sun, respectively), causing them to become drowned in its glare. For these reasons, naturally occurring rainbows of an order higher than 2 are rarely visible to the naked eye. Nevertheless, sightings of the third-order bow in nature have been reported, and in 2011 it was photographed definitively for the first time. Shortly after, the fourth-order rainbow was photographed as well, and in 2014 the first ever pictures of the fifth-order (or quinary) rainbow, located in between the primary and secondary bows, were published. In a laboratory setting, it is possible to create bows of much higher orders.
Rainbows Under Moonlight	Like most atmospheric optical phenomena, rainbows can be caused by light from the Sun, but also from the Moon. In case of the latter, the rainbow is referred to as a lunar rainbow or moonbow. They are much dimmer and rarer than solar rainbows, requiring the Moon to be near-full in order for them to be seen. For the same reason, moonbows are often perceived as white and may be thought of as monochrome. The full spectrum is present, however, but the human eye is not normally sensitive enough to see the colours. Long exposure photographs will sometimes show the colour in this type of rainbow.
Fogbow	Fogbows form in the same way as rainbows, but they are formed by much smaller cloud and fog droplets that diffract light extensively. They are almost white with faint reds on the outside and blues inside; often one or more broad supernumerary bands can be discerned inside the inner edge. The colours are dim because the bow in each colour is very broad and the colours overlap. Fogbows are commonly seen over water when air in contact with the cooler water is chilled, but they can be found anywhere if the fog is thin enough for the sun to shine through and the sun is fairly bright. They are very large—almost as big as a rainbow and much broader. They sometimes appear with a glory at the bow's centre. Fog bows should not be confused with ice halos, which are very common around the world and visible much more often than rainbows (of any order), yet are unrelated to rainbows.
Circumhorizontal and Circumzenithal Arcs	The circumzenithal and circumhorizontal arcs are two related optical phenomena similar in appearance to a rainbow, but unlike the latter, their origin lies in light refraction through hexagonal ice crystals rather than liquid water droplets. This means that they are not rainbows, but members of the large family of halos. Both arcs are brightly coloured ring segments centred on the zenith, but in different positions in the sky: The circumzenithal arc is notably curved and located high above the Sun (or Moon) with its convex side pointing downwards (creating the impression of an "upside down rainbow"); the circumhorizontal arc runs much closer to the horizon, is more straight and located at a significant distance below the Sun (or Moon). Both arcs have their red side pointing towards the sun and their violet part away from it, meaning the circumzenithal arc is red on the bottom, while the circumhorizontal arc is red on top. The circumhorizontal arc is sometimes referred to by the misnomer "fire rainbow". In order to view it, the Sun or Moon must be at least 58° above the horizon, making it a rare occurrence at higher latitudes. The circumzenithal arc, visible only at a solar or lunar elevation of less than 32°, is much more common, but often missed since it occurs almost directly overhead.

2 Aurora

An aurora, sometimes referred to as polar lights, northern lights (aurora borealis), southern lights (aurora australis), is a natural light display in the Earth's sky, predominantly seen in the high-latitude regions (around the Arctic and Antarctic). Auroras are the result of disturbances in the magnetosphere caused by solar wind. These disturbances are regularly strong enough to alter the trajectories of charged particles in both solar wind and magnetospheric plasma. These particles, mainly electrons and protons, precipitate into the upper atmosphere (thermosphere/exosphere). The resulting ionization and excitation of atmospheric constituents emits light of varying colour and complexity. The form of the aurora, occurring within bands around both polar regions, is also dependent on the amount of acceleration imparted to the precipitating particles. Precipitating protons generally produce optical emissions as incident hydrogen atoms after gaining electrons from the atmosphere. Proton auroras are usually observed at lower latitudes. See LIGHT for information on the colours of auroras.

Occurrence
Most auroras occur in a band known as the "auroral zone", which is typically 3° to 6° wide in latitude and between 10° and 20° from the geomagnetic poles at all local times (or longitudes), most clearly seen at night against a dark sky. A region that currently displays an aurora is called the "auroral oval", a band displaced towards the night side of the Earth. Early evidence for a geomagnetic connection comes from the statistics of auroral observations. Elias Loomis (1860), and later Hermann Fritz (1881) and S. Tromholt (1882) in more detail, established that the aurora appeared mainly in the auroral zone. Day-to-day positions of the auroral ovals are posted on the Internet.

In northern latitudes, the effect is known as the aurora borealis or the northern lights. The former term was coined by Galileo in 1619, from the Roman goddess of the dawn and the Greek name for the north wind. The southern counterpart, the aurora australis or the southern lights, has features almost identical to the aurora borealis and changes simultaneously with changes in the northern auroral zone. The Aurora Australis is visible from high southern latitudes in Antarctica, Chile, Argentina, New Zealand, and Australia. A geomagnetic storm causes the auroral ovals (north and south) to expand, and bring the aurora to lower latitudes.

The instantaneous distribution of auroras is slightly different, being centred about 3–5° nightward of the magnetic pole, so that auroral arcs reach furthest toward the equator when the magnetic pole in question is in between the observer and the Sun. The aurora can be seen best at this time, which is called magnetic midnight. Auroras seen within the auroral oval may be directly overhead, but from farther away, they illuminate the poleward horizon as a greenish glow, or sometimes a faint red, as if the Sun were rising from an unusual direction. Auroras also occur poleward of the auroral zone as either diffuse patches or arcs, which can be subvisual.

Auroras are occasionally seen in latitudes below the auroral zone, when a geomagnetic storm temporarily enlarges the auroral oval. Large geomagnetic storms are most common during the peak of the 11-year sunspot cycle or during the three years after the peak. An aurora may appear overhead as a "corona" of rays, radiating from a distant and apparent central location, which results from perspective. An electron spirals (gyrates) about a field line at an angle that is determined by its velocity vectors, parallel and perpendicular, respectively, to the local geomagnetic field vector B. This angle is known as the "pitch angle" of the particle.

The distance, or radius, of the electron from the field line at any time is known as its Larmor radius. The pitch angle increases as the electron travels to a region of greater field strength nearer to the atmosphere. Thus, it is possible for some particles to return, or mirror, if the angle becomes 90° before entering the atmosphere to collide with the denser molecules there. Other particles that do not mirror enter the atmosphere and contribute to the auroral display over a range of altitudes.

Other types of auroras have been observed from space, e.g. "poleward arcs" stretching sunward across the polar cap, the related "theta aurora", and "dayside arcs" near noon. These are relatively infrequent and poorly understood. Other interesting effects occur such as flickering aurora, "black aurora" and subvisual red arcs. In addition to all these, a weak glow (often deep red) observed around the two polar cusps, the field lines separating the ones that close through the Earth from those that are swept into the tail and close remotely.

Causes
A full understanding of the physical processes which lead to different types of auroras is still incomplete, but the basic cause involves the interaction of the solar wind with the Earth's magnetosphere. The varying intensity of the solar wind produces effects of different magnitudes, but includes one or more of the following physical scenarios.

1. A quiescent solar wind flowing past the Earth's magnetosphere steadily interacts with it and can both inject solar wind particles directly onto the geomagnetic field lines that are 'open', as opposed to being 'closed' in the opposite hemisphere, and provide diffusion through the bow shock. It can also cause particles already trapped in the radiation belts to precipitate into the atmosphere. Once particles are lost to the atmosphere from the radiation belts, under quiet conditions, new ones replace them only slowly, and the loss-cone becomes depleted. In the magnetotail, however, particle trajectories seem constantly to reshuffle, probably when the particles cross the very weak magnetic field near the equator. As a result, the flow of electrons in that region is nearly the same in all directions ("isotropic"), and assures a steady supply of leaking electrons. The leakage of electrons does not leave the tail positively charged, because each leaked electron lost to the atmosphere is replaced by a low energy electron drawn upward from the ionosphere. Such replacement of "hot" electrons by "cold" ones is in complete accord with the 2nd law of thermodynamics. The complete process, which also generates an electric ring current around the Earth, is uncertain.

2. Geomagnetic disturbance from an enhanced solar wind causes distortions of the magnetotail ("magnetic substorms"). These 'substorms' tend to occur after prolonged spells(hours) during which the interplanetary magnetic field has had an appreciable southward component. This leads to a higher rate of interconnection between its field lines and those of Earth. As a result, the solar wind moves magnetic flux (tubes of magnetic field lines, 'locked' together with their resident plasma) from the day side of Earth to the magnetotail, widening the obstacle it presents to the solar wind flow and constricting the tail on the night-side. Ultimately some tail plasma can separate ("magnetic reconnection"); some blobs ("plasmoids") are squeezed downstream and are carried away with the solar wind; others are squeezed toward Earth where their motion feeds strong outbursts of auroras, mainly around midnight ("unloading process"). A geomagnetic storm resulting from greater interaction adds many more particles to the plasma trapped around Earth, also producing enhancement of the "ring current". Occasionally the resulting modification of the Earth's magnetic field can be so strong that it produces auroras visible at middle latitudes, on field lines much closer to the equator than those of the auroral zone.

3. Acceleration of auroral charged particles invariably accompanies a magnetospheric disturbance that causes an aurora. This mechanism, which is believed to predominantly arise from strong electric fields along the magnetic field or wave-particle interactions, raises the velocity of a particle in the direction of the guiding magnetic field. The pitch angle is thereby decreased, and increases the chance of it being precipitated into the atmosphere. Both electromagnetic and electrostatic waves, produced at the time of greater geomagnetic disturbances, make a significant contribution to the energising processes that sustain an aurora.

Particle acceleration provides a complex intermediate process for transferring energy from the solar wind indirectly into the atmosphere. The details of these phenomena are not fully understood. However it is clear that the prime source of auroral particles is the solar wind feeding the magnetosphere, the reservoir containing the radiation zones and temporarily magnetically-trapped particles confined by the geomagnetic field, coupled with particle acceleration processes.

Causes
Auroras result from emissions of photons in the Earth's upper atmosphere, above 80 km (50 mi), from ionized nitrogen atoms regaining an electron, and oxygen atoms and nitrogen based molecules returning from an excited state to ground state. They are ionized or excited by the collision of particles precipitated into the atmosphere. Both incoming electrons and protons may be involved. Excitation energy is lost within the atmosphere by the emission of a photon, or by collision with another atom or molecule:

Oxygen emissions
green or orange-red, depending on the amount of energy absorbed.

Nitrogen emissions
blue or red; blue if the atom regains an electron after it has been ionized, red if returning to ground state from an excited state.

Oxygen is unusual in terms of its return to ground state: it can take three quarters of a second to emit green light and up to two minutes to emit red. Collisions with other atoms or molecules absorb the excitation energy and prevent emission. Because the highest atmosphere has a higher percentage of oxygen and is sparsely distributed such collisions are rare enough to allow time for oxygen to emit red. Collisions become more frequent progressing down into the atmosphere, so that red emissions do not have time to happen, and eventually even green light emissions are prevented. This is why there is a colour differential with altitude; at high altitudes oxygen red dominates, then oxygen green and nitrogen blue/red, then finally nitrogen blue/red when collisions prevent oxygen from emitting anything. Green is the most common colour. Then comes pink, a mixture of light green and red, followed by pure red, then yellow (a mixture of red and green), and finally, pure blue.

3 Halo

Halo is the name for a family of optical phenomena produced by sunlight interacting with ice crystals suspended in the atmosphere. Halos can have many forms, ranging from coloured or white rings to arcs and spots in the sky. Many of these appear near the Sun or Moon, but others occur elsewhere or even in the opposite part of the sky. Among the best known halo types are the circular halo (properly called the 22° halo), light pillars, and sun dogs, but many others occur; some are fairly common while others are (extremely) rare. The ice crystals responsible for halos are typically suspended in cirrus or cirrostratus clouds in the upper troposphere (5–10 km (3.1–6.2 mi)), but in cold weather they can also float near the ground, in which case they are referred to as diamond dust. The particular shape and orientation of the crystals are responsible for the type of halo observed. Light is reflected and refracted by the ice crystals and may split into colours because of dispersion. The crystals behave like prisms and mirrors, refracting and reflecting light between their faces, sending shafts of light in particular directions. Atmospheric optical phenomena like halos were used as part of weather lore, which was an empirical means of weather forecasting before meteorology was developed. They often do indicate that rain will fall within the next 24 hours, since the cirrostratus clouds that cause them can signify an approaching frontal system. Other common types of optical phenomena involving water droplets rather than ice crystals include the glory and rainbow.

Light Pillar
A light pillar, or sun pillar, appears as a vertical pillar or column of light rising from the sun near sunset or sunrise, though it can appear below the sun, particularly if the observer is at a high elevation or altitude. Hexagonal plate- and column-shaped ice crystals cause the phenomenon. Plate crystals generally cause pillars only when the sun is within 6 degrees of the horizon; column crystals can cause a pillar when the sun is as high as 20 degrees above the horizon. The crystals tend to orient themselves near-horizontally as they fall or float through the air, and the width and visibility of a sun pillar depend on crystal alignment. Light pillars can also form around the moon, and around street lights or other bright lights. Pillars forming from ground-based light sources may appear much taller than those associated with the sun or moon. Since the observer is closer to the light source, crystal orientation matters less in the formation of these pillars.

METEOROLOGY Weather Phenomenon Halo

Circular Halo
Among the best-known halos is the 22° halo, often just called "halo", which appears as a large ring around the Sun or Moon with a radius of about 22° (roughly the width of an outstretched hand at arm's length). The ice crystals that cause the 22° halo are oriented semi-randomly in the atmosphere, in contrast to the horizontal orientation required for some other halos such as sun dogs and light pillars. As a result of the optical properties of the ice crystals involved, no light is reflected towards the inside of the ring, leaving the sky noticeably darker than the sky around it, and giving it the impression of a "hole in the sky". The 22° halo is not to be confused with the corona, which is a different optical phenomenon caused by water droplets rather than ice crystals, and which has the appearance of a multi-coloured disk rather than a ring. Other haloes can form at 46° to the sun, or at the horizon, or around the zenith, and can appear as full haloes or incomplete arcs.

Bottlinger's Ring
A Bottlinger's ring is a rare type of halo that is elliptical instead of circular. It has a small diameter, which makes it very difficult to see in the Sun's glare and more likely to be spotted around the dimmer Subsun, often seen from mountain tops or airplanes. Bottlinger's rings are not well understood yet. It is suggested that they are formed by very flat pyramidal ice crystals with faces at uncommonly low angles, suspended horizontally in the atmosphere. These precise and physically problematic requirements would explain why the halo is very rare.

4 Afterglow

METEOROLOGY Weather Phenomenon Afterglow

An afterglow is a broad arch of whitish or pinkish sunlight in the sky that is scattered by fine particulates like dust suspended in the atmosphere. An afterglow may appear above the highest clouds in the hour of fading twilight, or be reflected off high snowfields in mountain regions long after sunset. The particles produce a scattering effect upon the component parts of white light. True alpenglow, which occurs long after sunset or long before sunrise, is caused by the backscattering of red sunlight by aerosols and fine dust particles low in the atmosphere.

After sunset, alpenglow is an afterglow caused by the illumination of atmospheric particles by sunlight as it gets refracted and scattered through the Earth's atmosphere. The high-energy and high-frequency light is scattered out the most, while the remaining low-energy and -frequency light reaches the observer on the horizon at twilight. The backscattering of this light further turns it pinkish to reddish. This period of time is referred to as blue hour and is widely treasured by photographers and painters, as it offers breathtaking views.

The afterglow persists until the Earth's shadow (terminator line) overtakes the sky above the observer as night falls and the stars appear, with Venus (the second-brightest celestial object after the Moon in the night sky) visible above the horizon opposite of the Belt of Venus around the antisolar point. After the 1883 eruption of the volcano Krakatoa, a remarkable series of red sunsets appeared worldwide. An enormous amount of exceedingly fine dust were blown to a great height by the volcano's explosion, and then globally diffused by the high atmospheric winds. Edvard Munch's painting The Scream possibly depicts an afterglow during this period.

5 Corona

METEOROLOGY Weather Phenomenon Corona

In meteorology, a corona (plural coronae) is an optical phenomenon produced by the diffraction of sunlight or moonlight (or, occasionally, bright starlight or planetlight) by individual small water droplets and sometimes tiny ice crystals of a cloud or on a foggy glass surface. In its full form, a corona consists of several concentric, pastel-coloured rings around the celestial object and a central bright area called aureole. The aureole is often (especially in case of the Moon) the only visible part of the corona and has the appearance of a bluish-white disk which fades to reddish-brown towards the edge. The angular diameter of a corona depends on the sizes of the water droplets involved; smaller droplets produce larger coronae. For the same reason, the corona is the most pronounced when the size of the droplets is most uniform.

Coronae differ from halos in that the latter are formed by refraction (rather than diffraction) from comparatively large rather than small ice crystals. Pollen suspended in the air can also cause diffraction of sunlight that produces coronae. Because pollen grains are not always spherical, the resulting pollen coronae often have characteristic elliptic shape and brighter spots in them. They can be seen during blooming season where there is significant source of pollen like forests. They are more easily seen during sunset or sunrise as there is less sun glare and the light path through pollen laden atmosphere is longer.

6 Circumzenithal Arc

METEOROLOGY Weather Phenomenon Circumzenithal Arc

The circumzenithal arc, also called the circumzenith arc (CZA), upside-down rainbow, and the Bravais arc, is an optical phenomenon similar in appearance to a rainbow, but belonging to the family of halos arising from refraction of sunlight through ice crystals, generally in cirrus or cirrostratus clouds, rather than from raindrops. The arc is located at a considerable distance (approximately 46°) above the sun and at most forms a quarter of a circle centred on the zenith. It has been called "a smile in the sky", its first impression being that of an upside-down rainbow. The CZA is one of the brightest and most colourful members of the halo family. Its colours, ranging from violet on top to red at the bottom, are purer than those of a rainbow because there is much less overlap in their formation. The intensity distribution along the circumzenithal arc requires consideration of several effects: Fresnel's reflection and transmission amplitudes, atmospheric attenuation, chromatic dispersion (i.e. the width of the arc), azimuthal angular dispersion (ray bundling), and geometrical constraints. In effect, the CZA is brightest when the sun is at about 20°. Contrary to public awareness, the CZA is not a rare phenomenon, but it tends to be overlooked since it occurs so far overhead. It is worthwhile to look out for it when sun dogs are visible, since the same type of ice crystals that cause them (plate-shaped hexagonal prisms in horizontal orientation) are responsible for the CZA.

Formation
The light that forms the CZA enters an ice crystal through its flat top face, and exits through a side prism face. The refraction of almost parallel sunlight through what is essentially a 90-degree prism accounts for the wide colour separation and the purity of colour. The CZA can only form when the sun is at an altitude lower than 32.2°. The CZA is brightest when the sun is at 22° above the horizon, which causes sunlight to enter and exit the crystals at the minimum deviation angle; then it is also about 22° in radius, 3° in width. The CZA radius varies between 32.2° and 0° depending on the solar altitude. Towards either of the extremes it is vanishingly faint. When the sun is above 32.2°, light exits the crystals through the bottom face instead, to contribute to the almost colourless parhelic circle. Because the phenomenon also requires that the ice crystals have a common orientation, it occurs only in the absence of turbulence and when there is no significant up- or downdraft.

7 Circumhorizontal Arc

METEOROLOGY Weather Phenomenon Circumhorizontal

A circumhorizontal arc is an optical phenomenon that belongs to the family of ice halos formed by the refraction of sun- or moonlight in plate-shaped ice crystals suspended in the atmosphere, typically in cirrus or cirrostratus clouds. In its full form, the arc has the appearance of a large, brightly spectrum-coloured band (red being the topmost colour) running parallel to the horizon, located far below the Sun or Moon. The distance between the arc and the Sun or Moon is twice as far as the common 22-degree halo. Often, when the halo-forming cloud is small or patchy, only fragments of the arc are seen. As with all halos, it can be caused by the Sun as well as (but much more rarely) the Moon. Other currently accepted names for the circumhorizontal arc are circumhorizon arc or lower symmetric 46° plate arc. The misleading term "fire rainbow" is sometimes used to describe this phenomenon, although it is neither a rainbow, nor related in any way to fire. The term, apparently coined in 2006, may originate in the occasional appearance of the arc as "flames" in the sky, when it occurs in fragmentary cirrus clouds.

Formation
The halo is formed by sunlight entering horizontally-oriented, flat, hexagonal ice crystals through a vertical side face and leaving through the near horizontal bottom face (plate thickness does not affect the formation of the halo). In principle, Parry oriented column crystals may also produce the arc, although this is rare. The 90° inclination between the ray entrance and exit faces produce the well-separated spectral colours. The arc has a considerable angular extent and thus, rarely is complete. When only fragments of a cirrus cloud are in the appropriate sky and sun position, they may appear to shine with spectral colours.

Frequency
How often a circumhorizontal arc is seen, depends on the location and the latitude of the observer. In the United States it is a relatively common halo, seen several times each summer in any one place. In contrast, it is a rare phenomenon in northern Europe for several reasons. Apart from the presence of ice-containing clouds in the right position in the sky, the halo requires that the light source (Sun or Moon) be very high in the sky, at an elevation of 58° or greater. This means that the solar variety of the halo is impossible to see at locations north of 55°N or south of 55°S. A lunar circumhorizon arc might be visible at other latitudes, but is much rarer since it requires a nearly full Moon to produce enough light. At other latitudes the solar circumhorizontal arc is visible, for a greater or lesser time, around the summer solstice. Slots of visibility for different latitudes and locations may be looked up here. For example, in London, England the sun is only high enough for 140 hours between mid-May and late July, whereas Los Angeles has the sun higher than 58 degrees for 670 hours between late March and late September.

Artificial Circumhorizontal Arcs
A water glass experiment (known about since at least 1920) may be modified slightly to create an artificial circumhorizontal arc. Illuminating under a very steep angle from below the side face of a nearly completely water-filled cylindrical glass will refract the light into the water. The glass should be situated at the edge of a table. The second refraction at the top water-air interface will then project a hyperbola at a vertical wall behind it. The overall refraction is then equivalent to the refraction through an upright hexagonal plate crystal when the rotational averaging is taken into account. A colourful artificial circumhorizontal arc will then appear projected on the wall. Using a spherical projection screen instead will result in a closer analogy to the natural halo counterpart. Other artificial halos can be created by similar means.

Similar Optical Phenomena
Circumhorizontal arcs, especially when only fragments can be seen, are sometimes confused with cloud iridescence. This phenomenon also causes clouds to appear multi-coloured, but it originates from diffraction (typically by liquid water droplets or ice crystals) rather than refraction. The two phenomena can be distinguished by several features. Firstly, a circumhorizon arc always has a fixed location in the sky in relation to the Sun or Moon (namely below it at an angle of 46°), while iridescence can occur in different positions (often directly around the Sun or Moon). Secondly, the colour bands in a circumhorizon arc always run horizontally with the red on top, while in iridescence they are much more random in sequence and shape, which roughly follows the contours of the cloud that causes it. Finally, the colours of a circumhorizon arc are pure and spectral (more so than in a rainbow), while the colours in cloud iridescence have a more washed-out, "mother of pearl" appearance. Confusion with other members of the halo family, such as sun dogs or the circumzenithal arc, may also arise, but these are easily dismissed by their entirely different positions in relation to the Sun or Moon. More difficult is the distinction between the circumhorizontal arc and the infralateral arc, both of which almost entirely overlap when the Sun or Moon is at a high elevation. The difference is that the circumhorizontal arc always runs parallel to the horizon (although pictures typically show it as a curved line due to perspective distortion), whereas the infralateral arc curves upward at its ends.

8 Crepuscular Rays

Crepuscular rays (more commonly known as sunbeams, sun rays, splintered light, or god rays), in meteorological optics, are rays of sunlight that appear to radiate from the point in the sky where the Sun is located. Shining through openings in clouds (particularly stratocumulus) or between other objects such as mountains, these columns of sunlit scattering particles are separated by darker shadowed volumes. Despite seeming to converge toward the light source, the rays are essentially parallel shafts of sunlit and shadowed particles. Their apparent convergence is a visual illusion from linear perspective. This illusion is the same as railway lines' or long hallways' appearing to converge at a distant vanishing point. The scattering particles that make crepuscular rays visible can be air molecules or particulates.

Colour
Crepuscular rays usually appear orange because the path through the atmosphere at sunrise and sunset passes through up to 40 times as much air as rays from a high midday sun. Particles in the air scatter short wavelength light (blue and green) through Rayleigh scattering much more strongly than longer wavelength yellow and red light.

9 Anticrepuscular Rays

Anticrepuscular rays, or antisolar rays, are meteorological optical phenomena similar to crepuscular rays, but appear opposite of the Sun in the sky. Anticrepuscular rays are essentially parallel, but appear to converge toward the antisolar point, the vanishing point, due to a visual illusion from linear perspective. Anticrepuscular rays are most frequently visible around sunrise or sunset. This is because the atmospheric light scattering that makes them visible is larger for low angles to the horizon, backscattering, (see Mie theory) than at most other angles. Anticrepuscular rays are dimmer than crepuscular rays because backscattering is less than forward scattering. Anticrepuscular rays can be continuous with crepuscular rays, curving across the whole sky in great circles.

Mountain Shadow
A common example of a single anticrepuscular ray is provided by the shadow of a mountain at sunset, when viewed from the summit. It appears to be triangular, whatever the shape of the mountain, with the apex at the antisolar point.

Wagon-Wheel Spokes
Anticrepuscular rays are sometimes seen enclosed by a rainbow (see picture). In this case they can be called wagon-wheel spokes.

10 Sun Dog

A sun dog (or sundog) or mock sun, formally called a parhelion in meteorology, is an atmospheric optical phenomenon that consists of a bright spot to one or both sides of the Sun. Two sun dogs often flank the Sun within a 22° halo. The sun dog is a member of the family of halos, caused by the refraction of sunlight by ice crystals in the atmosphere. Sun dogs typically appear as a pair of subtly coloured patches of light, around 22° to the left and right of the Sun, and at the same altitude above the horizon as the Sun. They can be seen anywhere in the world during any season, but are not always obvious or bright. Sun dogs are best seen and most conspicuous when the Sun is near the horizon.

Formation
Sun dogs are commonly caused by the refraction and scattering of light from plate-shaped hexagonal ice crystals either suspended in high and cold cirrus or cirrostratus clouds, or drifting in freezing moist air at low levels as diamond dust. The crystals act as prisms, bending the light rays passing through them with a minimum deflection of 22°. As the crystals gently float downwards with their large hexagonal faces almost horizontal, sunlight is refracted horizontally, and sun dogs are seen to the left and right of the Sun. Larger plates wobble more, and thus produce taller sundogs. Sun dogs are red-coloured at the side nearest the Sun; farther out the colours grade through oranges to blue.

The colours overlap considerably and are muted, never pure or saturated. The colours of the sun dog finally merge into the white of the parhelic circle (if the latter is visible). The same plate-shaped ice crystals that cause sun dogs are also responsible for the colourful circumzenithal arc, meaning that these two types of halo tend to co-occur. The latter is often missed by viewers, since it is located more or less directly overhead. Another halo variety often seen together with sun dogs is the 22° halo, which forms a ring at roughly the same angular distance from the sun as the sun dogs, thus appearing to interconnect them.

As the Sun rises higher, the rays passing through the plate crystals are increasingly skewed from the horizontal plane, causing their angle of deviation to increase and the sun dogs to move farther from the 22° halo, while staying at the same elevation. It is possible to predict the forms of sun dogs as would be seen on other planets and moons. Mars might have sun dogs formed by both water-ice and CO2-ice. On the gas giant planets — Jupiter, Saturn, Uranus and Neptune—other crystals form clouds of ammonia, methane, and other substances that can produce halos with four or more sun dogs.

11 Mirage

A mirage is a naturally occurring optical phenomenon in which light rays bend to produce a displaced image of distant objects or the sky. The word comes to English via the French mirage, from the Latin mirari, meaning "to look at, to wonder at". This is the same root as for "mirror" and "to admire". Mirages can be categorized as "inferior" (meaning lower), "superior" (meaning higher) and "Fata Morgana", one kind of superior mirage consisting of a series of unusually elaborate, vertically stacked images, which form one rapidly changing mirage. In contrast to a hallucination, a mirage is a real optical phenomenon that can be captured on camera, since light rays are actually refracted to form the false image at the observer's location. What the image appears to represent, however, is determined by the interpretive faculties of the human mind. For example, inferior images on land are very easily mistaken for the reflections from a small body of watersurface.

Inferior Mirage
For exhausted travellers in the desert, an inferior mirage may appear to be a lake of water in the distance. An inferior mirage is called "inferior" because the mirage is located under the real object. The real object in an inferior mirage is the (blue) sky or any distant (therefore bluish) object in that same direction. The mirage causes the observer to see a bright and bluish patch on the ground in the distance which is also called oasis mirage. Light rays coming from a particular distant object all travel through nearly the same air layers and all are bent over about the same amount. Therefore, rays coming from the top of the object will arrive lower than those from the bottom. The image usually is upside down, enhancing the illusion that the sky image seen in the distance is really a water or oil puddle acting as a mirror. Inferior images are not stable. Hot air rises, and cooler air (being more dense) descends, so the layers will mix, giving rise to turbulence. The image will be distorted accordingly. It may be vibrating; it may be vertically extended (towering) or horizontally extended (stooping). If there are several temperature layers, several mirages may mix, perhaps causing double images. In any case, mirages are usually not larger than about half a degree high (same apparent size as the sun and moon) and from objects only a few kilometres away.

Heat Haze
Heat haze, also called heat shimmer, refers to the inferior mirage experienced when viewing objects through a layer of heated air; for example, viewing objects across hot asphalt or through the exhaust gases produced by jet engines. When appearing on roads due to the hot asphalt, it is often referred to as a highway mirage. Heat haze, also called heat shimmer, refers to the inferior mirage experienced when viewing objects through a layer of heated air; for example, viewing objects across hot asphalt or through the exhaust gases produced by jet engines. When appearing on roads due to the hot asphalt, it is often referred to as a highway mirage. Light from the sky at a shallow angle to the road is refracted by the index gradient, making it appear as if the sky is reflected by the road's surface. The mind interprets this as a pool of water on the road, since water also reflects the sky. The illusion fades as one gets closer. On tarmac roads it may look as if water, or even oil, has been spilled. These kinds of inferior mirages are often called "desert mirages" or "highway mirages". Both sand and tarmac can become very hot when exposed to the sun, easily being more than 10 °C hotter than the air one meter above, enough to create conditions suitable for the formation of the mirage. Heat haze is not related to the atmospheric phenomenon of haze.

Superior Mirage
A superior mirage occurs when the air below the line of sight is colder than the air above it. This unusual arrangement is called a temperature inversion, since warm air above cold air is the opposite of the normal temperature gradient of the atmosphere. Passing through the temperature inversion, the light rays are bent down, and so the image appears above the true object, hence the name superior. Superior mirages are in general less common than inferior mirages, but, when they do occur, they tend to be more stable, as cold air has no tendency to move up and warm air has no tendency to move down. Superior mirages are quite common in polar regions, especially over large sheets of ice that have a uniform low temperature. Superior mirages also occur at more moderate latitudes, although in those cases they are weaker and tend to be less smooth and stable. For example, a distant shoreline may appear to tower and look higher (and, thus, perhaps closer) than it really is. Because of the turbulence, there appear to be dancing spikes and towers. This type of mirage is also called the Fata Morgana or hafgerdingar in the Icelandic language. A superior mirage can be right-side up or upside down, depending on the distance of the true object and the temperature gradient. Often the image appears as a distorted mixture of up and down parts. Superior mirages can have a striking effect due to the Earth's curvature. Were the Earth flat, light rays that bend down would soon hit the ground and only nearby objects would be affected.

Since Earth is round, if their downward bending curve is about the same as the curvature of the Earth, light rays can travel large distances, perhaps from beyond the horizon. This was observed and documented for the first time in 1596, when a ship under the command of Willem Barentsz in search of the Northeast passage became stuck in the ice at Novaya Zemlya. The crew was forced to endure the polar winter there. They saw their midwinter night come to an end with the rise of a distorted Sun about two weeks earlier than expected. It was not until the 20th century that science could explain the reason: the real Sun had still been below the horizon, but its light rays followed the curvature of the Earth. This effect is often called a Novaya Zemlya mirage. For every 111.12 kilometres (69.05 mi) the light rays can travel parallel to the Earth's surface, the Sun will appear 1° higher on the horizon. The inversion layer must have just the right temperature gradient over the whole distance to make this possible. In the same way, ships that are in reality so far away that they should not be visible above the geometric horizon may appear on the horizon or even above the horizon as superior mirages. This may explain some stories about flying ships or coastal cities in the sky, as described by some polar explorers. These are examples of so-called Arctic mirages, or hillingar in Icelandic. If the vertical temperature gradient is +12.9 °C per 100 meters (where the positive sign means temperature gets hotter as one goes higher) then horizontal light rays will just follow the curvature of the Earth, and the horizon will appear flat. If the gradient is less (as it almost always is) the rays are not bent enough and get lost in space, which is the normal situation of a spherical, convex "horizon".

Fata Morgana
A Fata Morgana, the name of which comes from the Italian translation of Morgan le Fay, the fairy shapeshifting half-sister of King Arthur, is a very complex superior mirage. It appears with alternations of compressed and stretched areas, erect images, and inverted images. A Fata Morgana is also a fast-changing mirage. Fata Morgana mirages are most common in polar regions, especially over large sheets of ice with a uniform low temperature, but they can be observed almost anywhere. In polar regions, a Fata Morgana may be observed on cold days; in desert areas and over oceans and lakes, a Fata Morgana may be observed on hot days.

For a Fata Morgana, temperature inversion has to be strong enough that light rays' curvatures within the inversion are stronger than the curvature of the Earth. The rays will bend and create arcs. An observer needs to be within an atmospheric duct to be able to see a Fata Morgana. Fata Morgana mirages may be observed from any altitude within the Earth's atmosphere, including from mountaintops or airplanes. A Fata Morgana can go from superior to inferior mirage and back within a few seconds, depending on the constantly changing conditions of the atmosphere.

Sixteen frames of the mirage of the Farallon Islands, which cannot be seen from sea level at all under normal conditions because they are located below the horizon, were photographed on the same day. The first fourteen frames have elements of a Fata Morgana display—alternations of compressed and stretched zones. The last two frames were photographed a few hours later around sunset. The air was cooler while the ocean was probably a little bit warmer, which made temperature inversion lower. The mirage was still present, but it was not as complex as it had been a few hours before sunset, and it corresponded no longer to a Fata Morgana but rather to a superior mirage display.

Distortions of image and bending of light can produce spectacular effects. In his book Pursuit: The Chase and Sinking of the "Bismarck", the author Ludovic Kennedy describes an incident that allegedly took place below the Denmark Strait during 1941, following the sinking of the Hood. The Bismarck, while pursued by the British cruisers Norfolk and Suffolk, passed out of sight into a sea mist. Within a matter of seconds, the ship re-appeared steaming toward the British ships at high speed. In alarm the cruisers separated, anticipating an imminent attack, and observers from both ships watched in astonishment as the German battleship fluttered, grew indistinct and faded away. Radar watch during these events indicated that the Bismarck had in fact made no changes of course.

Night-Time Mirages
The conditions for producing a mirage can take place at night. Under most conditions, these are not observed. However, under some circumstances lights from moving vehicles, aircraft, ships, buildings, etc. can be observed at night, even though, as with a daytime mirage, they would not be observable. This includes the mirage of astronomical objects.

5 Weather Patterns

Weather generally follows set patterns, use this to your advantage by reading the signs.

El Niño

El Niño is the warm phase of the El Niño–Southern Oscillation (ENSO) and is associated with a band of warm ocean water that develops in the central and east-central equatorial Pacific (between approximately the International Date Line and 120°W), including the area off the Pacific coast of South America. The ENSO is the cycle of warm and cold sea surface temperature (SST) of the tropical central and eastern Pacific Ocean. El Niño is accompanied by high air pressure in the western Pacific and low air pressure in the eastern Pacific. El Niño phases are known to occur close to four years, however, records demonstrate that the cycles have lasted between two and seven years. During the development of El Niño, rainfall develops between September–November. The cool phase of ENSO is La Niña, with SSTs in the eastern Pacific below average, and air pressure high in the eastern Pacific and low in the western Pacific. The ENSO cycle, including both El Niño and La Niña, causes global changes in temperature and rainfall.

Developing countries that depend on their own agriculture and fishing, particularly those bordering the Pacific Ocean, are usually most affected. In American Spanish, the capitalized term El Niño means "the boy". In this phase of the Oscillation, the pool of warm water in the Pacific near South America is often at its warmest about Christmas. The original phase, El Niño de Navidad, arose centuries ago, when Peruvian fishermen named the weather phenomenon after the newborn Christ. La Niña, chosen as the "opposite" of El Niño, is American Spanish for "the girl".

La Niña

La Niña is a coupled ocean-atmosphere phenomenon that is the colder counterpart of El Niño, as part of the broader El Niño–Southern Oscillation climate pattern. The name La Niña originates from Spanish, meaning "the little girl", analogous to El Niño meaning "the little boy". It has also in the past been called anti-El Niño, and El Viejo (meaning "the old man"). During a period of La Niña, the sea surface temperature across the equatorial Eastern Central Pacific Ocean will be lower than normal by 3 to 5°C (5.4 to 9°F). An appearance of La Niña persists for at least five months. It has extensive effects on the weather across the globe, particularly in North America, even affecting the Atlantic and Pacific hurricane seasons, in which more tropical cyclones in the Atlantic basin due to low wind shear and warmer sea surface temperatures, while reducing tropical cyclogenesis in the Pacific Ocean during a La Niña.

La Niña is the positive and cold phase of the El Niño–Southern Oscillation, and is associated with cooler-than-average sea surface temperatures in the central and eastern tropical Pacific Ocean. However, each country and island nation has a different threshold for what constitutes a La Niña event, which is tailored to their specific interests. For example, the Australian Bureau of Meteorology looks at the trade winds, SOI, weather models and sea surface temperatures in the Niño 3 and 3.4 regions before declaring that a La Niña event has started. However, the Japan Meteorological Agency declares that a La Niña event has started when the average five-month sea surface temperature deviation for the NINO.3 region is more than 0.5 °C (0.90 °F) cooler for six consecutive months or longer.

6 Reading Weather

Beaufort Scale

The Beaufort scale is an empirical measure that relates wind speed to observed conditions at sea or on land. Its full name is the Beaufort wind force scale. For additional wind speed conversions such as those of a cyclone or hurricane, see the NATURAL DISASTERS > Cyclone / Hurricane section.

Rating	Term	Windspeed	Land Description	Sea Description
0	Calm	<2 km/h <1 mph <1 Knot	Smoke rises vertically.	Sea like a mirror.
1	Light Air	2-5 km/h 1-3 mph 1-3 Knots	Direction shown by smoke drift but not by wind vanes.	Ripples with appearance of scales are formed, without foam crests.
2	Light Breeze	6-11 km/h 4-7 mph 4-6 Knots	Wind felt on face; leaves rustle; wind vane moved by wind.	Small wavelets still short but more pronounced; crests have a glassy appearance but do not break.
3	Gentle Breeze	12-19 km/h 8-12 mph 7-10 Knots	Leaves and small twigs in constant motion; light flags extended.	Large wavelets; crests begin to break; foam of glassy appearance; perhaps scattered white horses.
4	Moderate Winds	20-29 km/h 13-18 mph 11-16 Knots	Raises dust and loose paper; small branches are moved.	Small waves - becoming longer; fairly frequent white horses.
5	Fresh Winds	30-39 km/h 19-24 mph 17-21 Knots	Small trees in leaf begin to sway; crested wavelets form on inland waters.	Moderate waves, taking a more pronounced long form; many white horses are formed - a chance of some spray.
6	Strong Winds	40-50 km/h 25-31 mph 22-27 Knots	Large branches in motion; whistling heard in telephone wires; umbrellas used with difficulty.	Large waves begin to form; the white foam crests are more extensive with probably some spray.
7	Near Gale	51-62 km/h 32-38 mph 28-33 Knots	Whole trees in motion; inconvenience felt when walking against wind.	Sea heaps up and white foam from breaking waves begins to be blown in streaks along direction of wind.

8	Gale	63-75 km/h 39-46 mph 34-40 Knots	Twigs break off trees; progress generally impeded.	Moderately high waves of greater length; edges of crests begin to break into spindrift; foam is blown in well-marked streaks along the direction of the wind.
9	Strong Gale	76-87 km/h 47-54 mph 41-47 Knots	Slight structural damage occurs - roofing dislodged; larger branches break off.	High waves; dense streaks of foam; crests of waves begin to topple, tumble and roll over; spray may affect visibility.
10	Storm, Whole Gale	88-102 km/h 55-63 mph 48-55 Knots	Seldom experienced inland; trees uprooted; considerable structural damage.	Very high waves with long overhanging crests; the resulting foam in great patches is blown in dense white streaks; the surface of the sea takes on a white appearance; the tumbling of the sea becomes heavy with visibility affected.
11	Violent Storm	103-1170 km/h 64-72 mph 56-63 Knots	Very rarely experienced - widespread damage.	Exceptionally high waves; small and medium sized ships occasionally lost from view behind waves; the sea is completely covered with long white patches of foam; the edges of wave crests are blown into froth.
12	Hurricane	118+ km/h 73+ mph >= 64 Knots	Devastation.	The air is filled with foam and spray. Sea completely white with driving spray; visibility very seriously affected.

7 Predicting Weather

How to use the signs around us to predict the weather.

Using Nature

Observing the Wind

1	Detect the direction of the wind. Wind is caused when air moves from a high-pressure area to a low-pressure area. Since weather moves in from the west, westerly winds indicate good weather because they suggest the bad weather is already to your east. Easterly winds suggest that the bad weather is coming toward you. ● You can use grass or flower petals to determine the direction of the wind. Throw your grass or flower petals into the wind and watch the way that it blows or falls. ● You can also detect the direction of the wind by wetting your finger and holding it out. The side of your finger that gets cool will tell you from which direction the wind is blowing.
2	Watch smoke from a fire. The air pressure determines what direction the smoke will go. In high pressure, the smoke will go directly up into the air. If the pressure is low, it will spiral back down around the fire. If you see the smoke spiralling back down, bad weather is likely on the way. ● When smoke spirals downwards, it means that bad weather is very close. The low-pressure system is already in place over your area.
3	Watch for calm conditions. Before a storm, the low-pressure system can push out the area's normal wind patterns. This creates a temporary calm before the storm begins. You'll notice a lack of wind, which creates a stillness over the area. If you're near water, it will be calm and still, as well. This calm indicates a coming storm. ● At this point, you should be able to observe other signs of a storm, such as dark clouds.
4	Take a deep breath. Close your eyes and smell the air. Smells become wet right before a storm, making them stronger. Before a storm, you should also notice a compost smell as plants release their waste. If you start to smell a compost scent, it likely means that a storm is coming. ● If you are near a swamp, you will likely smell swamp gases right before a storm. Swamp gas smells like rotten eggs because it comes from decaying vegetation.
5	Check for humidity. High humidity often precedes a storm, so watch for signs of high humidity, such as frizzy hair, curling leaves, and swollen wood. These signs can tell you that a storm is on the way. ● Pine cones can also tell you if it's humid because they will stay closed if the humidity is high but will open if the air is dry. ● If you live in an area that always has high humidity, rely on other observations to predict the weather.
6	Observe ocean swells. If you're near the ocean, look for ocean swells. These swells can be caused by winds that are blowing a storm system from out over the sea. This could mean that rain is on the way.

Observing Clouds

1	Look at the shape of the clouds. The types of clouds in the sky can tell you a lot about the weather. In general, clouds that are white and high indicate good weather, and clouds that are dark and low mean rain or storms are on the way. ● White, wispy clouds usually mean that the weather will be clear. ● Flat clouds mean that the air is stable, while fluffy clouds mean that it is unstable. ● Smaller puffy clouds may look calm, but they often build over the course of the day. If you see these clouds, it could mean a storm is brewing.
2	Observe the position of the clouds. Clouds that look high usually mean that they are farther away but could become a weather threat up to six hours later. Lower clouds mean that bad weather is closer. As the weather threat approaches, you will see the clouds move lower in the sky.
3	Check the colour of the clouds. Clouds can be various shades of white, gray, black, and brown, and each also means something different about the weather. ● Black clouds mean that there is a coming storm that does not have strong winds. ● Brown clouds mean that there is a coming storm that does have strong winds. ● White clouds usually mean good weather, though a storm could be on its way later in the day. ● Gray clouds usually mean a new or a light storm. However, gray skies mean that the storm is affecting a large area and may remain for awhile.
4	Watch the movement of the clouds. The direction that the clouds are travelling can tell you if weather is on the way. Additionally, you should watch if the clouds are coming together or moving apart. ● Lowering, gathering clouds are a sign of bad weather coming. ● Clouds that are rising and spreading out indicate that the weather is clearing.

Observing the Sky

METEOROLOGY Predicting Weather Using Nature Observing the Sky

1	Check for a red sky in the morning. Weather moves from west to east, while the sun rises in the east and sets in the west. If you see a red sky in the morning, then it means that there is clear weather in the east where the sun is rising, but bad weather in the west, making the sky look red. The bad weather from the west will be moving toward you, as that is how weather patterns work. ● The redness can appear as a bold orange to a deep red. ● If you see a red sky in the evening, you can rest easy. This means that there are clear skies in the west coming toward you, while the bad weather is to the east moving away from you. ● You can use the following rhyme: "Red sky at night is a shepherd's delight. Red sky in the morning is a shepherd's warning."
2	Look for a rainbow in the west. A rainbow in the west means that the sun's morning rays are striking moisture to your west, which is the direction from which the weather is moving. This means that a storm is moving your way, indicating bad weather later in the day. ● If you see a rainbow in the east, then it means that the weather has already passed over you, so clear skies are likely ahead. ● Remember the old saying, "Rainbow in the morning gives you fair warning."
3	Stare at the moon. Look to see how visible the moon is. If the moon is easy to see in a clear sky, then it could mean that the weather is cooling. It may also mean that a low-pressure system is moving into the area, which clears away dust. This means rain could be on the way. If the moon is visible, look for a wide halo that spreads out from the moon. A halo happens when the moon shines through cirrus clouds, which suggests coming rain. ● Remember the old saying, "Ring around the moon? Rain real soon." A ring around the moon means a warm front is coming, which usually brings rain. The ring is caused by ice crystals that are passing over the moon. ● A double halo around the moon could signal strong winds in the coming storm. ● Another old saying is, "Clear moon, frost soon." A clear sky means that there are no clouds to hold in the earth's heat. This means that the weather will be cooler that night and the next morning, even if it's not cold enough to frost.
4	Count the stars. If you suspect a storm is coming, look at the stars. More than ten stars means that any coming storms should be light, while fewer than ten visible stars means that the storm will be heavy. ● A lack of stars means that there is excessive cloud coverage from an oncoming weather system. If many stars are visible, then the sky is clear.

Observing Animals

METEOROLOGY Predicting Weather Using Nature Observing Animals

1	Look for high ant mounds. Before a storm, ants will build up their mounds and create steep sides. If you see raised ant beds, especially if they were lower before, then there may be a storm coming.
2	Watch for low-flying or roosting birds. When the air pressure falls before a storm, birds feel discomfort in their ears. This causes them to fly lower toward the ground or to perch on lower tree branches or power lines. You may also observe the birds eating ground insects. This behaviour suggests that a storm is coming. ● If the birds are flying high in the sky, then there will likely be fair weather. ● If you're near the sea, look for seagulls perched on the beach, which could indicate that a storm is coming. ● Watch for large groups of roosting birds. ● Birds also become quiet before a storm. Singing and chirping birds could indicate good weather.
3	Look for bird migrations. Birds can sense air pressure and will time their migrations to good weather. If you see flocks of birds migrating in the sky, then the weather will likely be good that day.
4	Notice if birds eat during a storm. If a storm is going to be short, birds will usually wait for the rain to end before looking for food. If you see birds eating during a storm, then it will likely last for a long time. Birds can sense the pressure patterns, allowing them to predict the weather.
5	Search for bees and butterflies. Bees and butterflies return to their homes before a storm for safety. In the case of bees, they also work to preserve the hive. If you don't see any bees and butterflies when you would expect to - such as in a field of flowers - then there may be a storm coming.
6	Check cow pastures to see if they are lying down together. Cows usually gather together and lie down in their pasture before a rainstorm. This is likely because it cools down before a storm, and cows like to be close to the ground when the weather cools. Cows lying on the ground is an indication that it may rain. ● This only applies to cows, not other livestock.
7	Look for snakes. Snakes will leave their nests before bad weather, even if it's in the middle of wintertime. Seeing snakes in unexpected places or at a time when the snake would normally be in its nest can be a sign of bad weather. ● Snakes can even predict earthquakes. If you see a snake out of its nest behaving erratically, there could be an earthquake coming. ● Snakes usually come out of their nests in sunny weather to warm themselves. They don't like the cold because they are cold-blooded. A snake out of its nest when it's not a warm, sunny day is an indication that bad weather is coming.
8	Watch tortoises if they are nearby. Tortoises will seek higher ground before a storm, so look for movement to higher locations. You may see them in the road one to two days before a rain.

Using Tools

Thermometer

METEOROLOGY Predicting Weather Using Tools Thermometer

The following directions apply to all types of thermometers, from classic mercury thermometers to new-age digital temperature sensors.

● Place the thermometer 1.5m (5ft) above the ground (+/- 1ft.). A thermometer too low will pick up excess heat from the ground and a thermometer too high will likely have too cool of a temperature due to natural cooling aloft.
● The thermometer must be placed in the shade. If you put your thermometer in full sunlight, direct radiation from the sun is going to result in a temperature higher than what it should be.
● Have good air flow for your thermometer. This keeps air circulating around the thermometer, maintaining a balance with the surrounding environment. Therefore, it is important to make sure there are no obstructions blocking your thermometer such as trees or buildings. The more open, the better.
● Place the thermometer over a grassy or dirt surface. Concrete and pavement attract much more heat than grass. That is why cities are often warmer compared to suburbs. It is recommended to keep the thermometer at least 30m (100ft) from any paved or concrete surfaces to prevent an erroneously high temperature measurement.

● Keep the thermometer covered. When precipitation falls, you do not want your thermometer to get wet as that could permanently damage it. A Stevenson screen is a great place to store thermometers and other instruments as they provide cover as well as adequate ventilation. If you can't get one, a simple solar radiation shield is adequate.

Thermometer Limits	**Digital Thermometer Limits** **Min:** -58°C (-72.4°F) **Max:** 572°C (1061°F)	**Mercury Thermometer Limits** **Min:** -38.83°C (-37.894°F) **Max:** 356.7°C (674.06°F)	**Coloured Ethanol Thermometer Limits** **Min:** -144°C (-227°F) **Max:** 78°C (172°F)

Barometer

A barometer is a scientific instrument used in meteorology to measure atmospheric pressure. Pressure tendency can forecast short term changes in the weather. Many measurements of air pressure are used within surface weather analysis to help find surface troughs, high pressure systems and frontal boundaries. Barometers and pressure altimeters (the most basic and common type of altimeter) are essentially the same instrument, but used for different purposes. An altimeter is intended to be transported from place to place matching the atmospheric pressure to the corresponding altitude, while a barometer is kept stationary and measures subtle pressure changes caused by weather. The main exception to this is ships at sea, which can use a barometer because their elevation does not change.

Barometer Reading
Find the difference of pressure over an hour to determine the weather. The bigger the difference the more wild the weather. Set the barometers pointer every hour to easily tell what the last reading was.

High Pressure
A sign of good weather.

Low Pressure
A sign of clouds, rain and storms.

Barometer Weather Prediction

Baro	Fluctuation	Wind Direction	Weather
1016-1022 (30-30.20)	Steady	Westerly	Fair, with slight changes in temp for one to two days
1016-1022 (30-30.20)	Rising Fast	Westerly	Fair, followed within two days by warmer and rain.
1016-1022 (30-30.20)	Falling Fast	South to East	Warmer and rain within 24 hours.
>=1022 (30.20)	Falling Fast	South to East	Warmer and rain within 36 hours.
1022 (30.20)	Falling Fast	West to North	Cold and clear, followed by warmer rain.
>=1022 (30.20)	Steady	Variable	No early change.
<=1016 (30.00)	Falling Slowly	South to East	Rain within 18 hours continuing a day.
<=1016 (30.00)	Falling Fast	SE-NE	Rain with high wind, clearing within 2 days, colder.
<=1016 (30.00)	Rising	South to West	Clearing and colder within 12 hrs.
<=1009 (29.80)	Falling Fast	South to East	Severe storm of wind and rain imminent.
<=1009 (29.80)	Rising Fast	Going West	Clearing and colder.

Skills

Skills one should possess prior to a disaster and how to train them

"Talent you have naturally, Skill is only developed by hours and hours and hours of beating on your craft."
Will Smith

Introduction

This is a list of any skills relevant to prepping and a short description on each as well as a sentence on how you can train it. You can use this section to compare listed skills with your own to shear up any weaknesses you may have. A good goal to set yourself is to go through the list and work on one of the skills a weekend and complete the training section.

Everyone has a different set of skills which is simply a fact of life. Some may excel at programming, others at knitting and sports. As the potential leader of your bug-out group you should have knowledge about the skills each member of your team possesses. The last thing you want to do is give someone a job they are terrible at when they could be doing one they love and have a natural talent for. The rows below contain an incomplete list of skills that you may need in a disaster situation and how to train them beforehand. I recommend filling out the template skills analyser at the bottom of this section for each of your party members so you can understand and make the most of your teams skills.

Purpose	The aim of SKILLS is to have a complete list of the useful abilities which are of use in a survival situation. It also covers how these skills can be trained and honed prior to a disaster so that you're ready when one occurs. It also lays out the foundation for creating a party skills checklist so you can visually see the individual abilities of each member.
Lost?	• For information on a specific skill you wish to learn, find and read the corresponding category in this guide. • For a list of skill terms, see the ADDENDUM > Dictionary section.

Contents

1 Basic Attributes

SKILLS | Basic Attributes

These aren't skills you can typically train but are attributes of people that will make understanding them easier. This information would be useful on a spreadsheet detailing your party members and their strengths, weaknesses and limits.

Subheadings

1 Attributes

Name		The name of the person.	
Nickname		The nickname of the person if they have one.	
Codename		The codename of the person in case they have to be referenced stealthily.	
Age		How old the person is.	
Gender		The gender of the person.	
Nationality		The nationality of this person.	
Ethnicity		The ethnic background of this person.	
Social Class		The social class this person is currently part of.	

2 Location

Home Address		Where this person resides and sleeps at night.	
Work Address		The work address of this person (if any).	
Commonly At		The location this person is usually at outside of work.	
Country & Hometown		The country and town this person grew up in.	

3 Appearance

Build		The build of this person whether skinny, normal or obese.	
Skin Colour		White, Olive, Tan, Black etc.	
Hair Colour		The colour or colours of their hair.	
Eye Colour		The colour or colours of their eyes.	
Accessories		Such as glasses, watch, earrings, necklace etc.	
Face Shape		The spare of their face such as oval, round, slim or chubby.	
Distinguishing Features		Any features that immediately stand out when you meet that person.	
Dress		How this person usually dresses such as conservative or casual.	

4 Physical Attributes

Strength		How much weight the person can carry in their arms.	Training: Train your physical strength by going to the gym regularly.
Back Strength		How much weight the person can carry on their back comfortably.	Training: Walking around with a heavy backpack can accustom you to the weight of a BOB.
Speed		How fast the person can move.	Training: Sprinting short distances from stopped and see how far you get in 1 minute.
Fitness (Cardio)		How far the person can run/jog unencumbered.	Training: Short and long distance running to get your body used to running/jogging.
Agility/Acceleration		How fast the person can change direction, speed up and stop on their feet.	Training: Running through an obstacle course darting around and between objects.
Flexibility		The range of movement a person has.	Training: Stretching and warming up muscles. Limbo-ing, "avoiding laser beams".

5 Measurements

Size		How big or small the person is.	
Weight		How heavy the person is.	
Height		How tall the person is.	

6 Skills

Known Skills		This persons education level.	
Known Talent		The line of work and job this person has.	
Past Experience		How switched-on this person is.	

7 Education & Work

Education		This persons education level.	
Occupation		The line of work and job this person has.	
Intelligence		How switched-on this person is.	

8 Allegiances

Nationality		The country which this person was born.	
Allegiances		Any other allegiances this person has ties to.	
Religion		The religion of this person.	

9 Mannerisms

Mannerisms		Recognisable mannerisms this person does frequently such as blinking or touching their face.	
Habits		Habits this person has such as smoking.	
Speech		The way this person speaks whether it's fast, slow or hard to understand.	
Accent		The accent this person has.	
Style		How this person presents themselves such as elegant or shabby.	

10 Health

Health		The general health and wellbeing of this person.	
Medical Conditions		Medical conditions that affect this person such as asthma or diabetes.	
Medication		Any medication this person takes on a recurring basis.	
Disabilities		Any disabilities the person may have, whether physical or mental.	

11 Character

Confidence		How confident this person is.	

12 Personality

MBTI Personality		The MBTI personality of this person.	
Technology Dependence		How dependent the person is on technology such as a mobile.	
Lifestyle Dependence		How dependent the person is on their current lifestyle and how they will react if SHTF.	

2 Preparedness Skills

Each skill below has the following fields:
- Importance: How important this skill is to know based on a preparedness skillset rated on a number between 1-5
- Skill: The name of the skill
- Skill Description: A short description of the skill
- Training: How you can train this skill

Subheadings

		1. Camping	2. Looting	3. Bartering	4. Scouting		
		5. Fire Building	6. Fire Lighting	7. Water Acquisition	8. Water Purification		
		9. Caches	10. Gear Maintenance	11. Electricity			

1 Camping

Importance	Skill	Skill Description	Training
3	Camping	Camping skills will make accustomization to living outdoors easier such as sleeping with strange noises around and lying on hard ground.	Training: Camping in the great outdoors in various locations, climates and environments.

3	**Tent Pitching**	How fast and accurately you can pitch and tear down your tent.	Training: Training requires timing yourself on how fast you can erect your tent and then again to pack it up.
2	**Leave No Trace**	Leaving a campsite exactly as you found it to help prevent litter and being tracked.	Training: Camping and then ensuring that nobody can tell you've been staying there.
4	**Self Contained Camper**	Living out of a bag while camping so you can flee if required.	Training: Camping and being ready to flee the area at any moment.
5	**Campsite Security**	Keeping an eye and ear out for threats while camping.	Training: Camping and maintaining a lookout and ear-out for threats.

2 Looting

Importance	Skill	Skill Description	Training
	Object Recognition	The ability to quickly see an object and ascertain its value and uses.	Training: Moving through an unknown building and knowing where the valuable items are likely to be.
	Object Uses	The ability to see an object for uses besides its primary use.	Training: Picking any random object and working out how else you could use it.
	Looting Speed	The speed an efficiency you can clear rooms taking what you need.	Training: Moving quickly through unknown rooms looking for items you need and taking them swiftly.
	Siphoning Fuel	Siphoning fuel from other cars.	Training: By siphoning fuel from other cars into your own either using a pump or your mouth.

3 Bartering

Importance	Skill	Skill Description	Training
	Bartering	The ability to barter for items you need with a profit.	Training: Bartering with people for goods and trying to get the best deal.
	Negotiating	Negotiating with hostiles for some form of return such as hostages, stolen items etc.	Training: Can be trained by bartering with money to buy it at a lower price.

4 Scouting

Importance	Skill	Skill Description	Training
	Feature Recognition	Knowing land terrains and features.	Training: Hiking through unknown terrain and saying out loud what type of terrain is around you.
	Perception	Knowing what's going on around you and keeping an eye on the enemy.	Training: Sitting on a bench in a city and taking note of everything around you.

5 Fire Building

Importance	Skill	Skill Description	Training
	Fire Lighting	Knowing how to light a fire in any condition.	Training: By lighting fires in sun, rain, a storm, wind etc.
	Tinder Identification	Identifying tinder in the bush.	Training: Either experiment on potential tinder near you or look for already identified tinders.
	Hidden Fire	Creating a smokeless pit fire to stay stealthy.	Training: By creating a pit fire with minimum smoke and visibility.
	Finding Dry Wood	Finding dry wood in a wet environment.	Training: Search for dry woods in a damp or rainy environment and try to light a fire.
	Split Firewood	Splitting firewood to put on a small fire.	Training: By splitting firewood with an axe, taking note of health and safety.
	Chainsawing	Using a chainsaw to fell trees effectively.	Training: Cutting down trees with a chainsaw.
	Batoning	Using a knife and a log to split wood into manageable pieces.	Training: Splitting wood with a knife and a heavy, flat object.

6 Fire Lighting

Importance	Skill	Skill Description	Training
	Using Flint	Knowing how to use flint and a striker to create a fire.	Training: By starting fires with only a flint and steel.
	Bow Drill	Using a bow drill to start a fire.	Training: Starting a fire with a bow drill from scavenged materials.
	Fire Piston	Using a fire piston to start a fire.	Training: Light fires using a fire piston.
	Chemical Fire	Using chemicals to start a fire.	Training: Light a fire using any chemicals you have handy.
	Electrical Fire	Using electricity to start a fire.	Training: Creating a fire from a variety of batteries such as AA, C, 18650 or a car battery.
	Solar Fire	Using the sun to start a fire.	Training: Try to light a fire with a magnifying glass or parabolic mirror.

7 Water Acquisition

Importance	Skill	Skill Description	Training
	Find Flowing Water	Finding flowing water using geographical features.	Training: Finding rivers or other flowing water by looking at the landscape layout.
	Find Still Water	Finding still water using geographical features.	Training: Finding bodies of water such as oceans, lakes or puddles by looking at the landscape layout.
	Find Vegetation Water	Find water from vegetation.	Training: Look for and collect water which is trapped by or in plants.
	Find Animal Water	Knowing how to use the water in animals to drink.	Training: Obtain water from animals which have been trapped, fished or hunted.
	Atmospheric Collection	Collecting water from the atmosphere.	

Importance	Skill	Skill Description	Training
	Condensation Collection	Collecting condensation for drinking.	Training: Collect dew by wiping dewy grass with a cloth and wringing it into a bucket.
	Water Table Collection	Collecting water from an underground water table	Training: Locating and pumping water from a water table.
	Finding Groundwater	Finding clean groundwater and springs to drink from.	Training: Looking for natural springs and obtain water from them by digging into the earth.
	Evapotranspiration	Acquiring water from small bushes and shrubs.	Training: Place transparent bags over vegetation until water is collected in the bottom of them.

8 Water Purification

Importance	Skill	Skill Description	Training
	Water Filter Construction	Crafting your own water filter from bush materials.	Training: Building a water filter from sand, stones and moss.
	Modern Water Filtration	Filtering water using modern filtration methods.	Training: Filtering water with a purchased filter as per the instructions.
	Additive Purification	Purification using water additives like Calcium Hypochlorite.	Training: Kill bacteria in water by using pot perm or calc hypo (among others) to treat it.
	Boiling	Boiling water to kill pathogens.	Training: Boil water for the correct amount of time depending on altitude.
	Distillation	Distilling water to remove pathogens.	Training: Distil water.
	SODIS	Using solar disinfection to kill parasites.	Training: Fill a clear bottle or bag with water and leave it out in the sun.
	Flora-transpiration	Using flora to generate drinking water.	Training: Put clear bags around fresh vegetation gather water from evaporated and condensed water.
	Desalination	Knowing different ways to remove salt from water.	Training: Remove salt from water using distillation or other methods.
	Solar Still	Using a solar still to generate fresh drinking water.	Training: Build a solar still in sand or dirt and collect water.
	UV Purification	Purification of water using UV light.	Training: Kill bacteria in water by using a UV light for the required amount of time.
	Electrolytic Purification	Purifying water using salt and electrolysis.	Training: Use an electrolytic generator to create a chlorine compound and mix it with the water to be purified.

9 Caches

Importance	Skill	Skill Description	Training
	Storing Caches	Knowing how to store caches properly to avoid being found.	Training: Planting multiple caches without being seen and documenting them well.
	Locating Caches	Locating stored caches you've previously hidden months earlier.	Training: Finding caches you've hidden or locating geocaches.
	Location Marking	Marking locations you've hidden assets and knowing how to read them later.	Training: Return to old cache sites and try to use your markings to find it again.

10 Gear Maintenance

Importance	Skill	Skill Description	Training
	Gear Knowledge	How well the person knows and uses their gear.	Training: Go camping and use every piece of gear, pushing its capability.
	Gear Repairing	Knowing how to repair gear with any available resources if required.	Training: Trained by repairing anything and everything as it breaks with whatever is on hand.
	Gear Maintenance	Knowing how to properly maintain and look after all gear except weapons	Training: Proper maintenance of your gear from gas stoves to water filters.
	Gas Equipment	Lighting and operating gas lanterns or stoves which run on kerosene, petrol etc.	Training: Light gas lanterns, cooktops, kerosene lanterns etc.

11 Electricity

Importance	Skill	Skill Description	Training
	Electrical Systems	Understanding circuits, power, electricity, wiring etc.	Training: Build simple circuits, make simple repairs etc.
	Generator Maintenance	Using and maintaining a generator safely.	Training: Use a generator to power your equipment in an open space.
	Understanding Batteries	Knowing types and sizes of batteries, capacity, how to recharge them etc.	Training: Research different batteries, voltages, amps and safe recharging methods.
	Solar Power	Understanding how solar power works, positioning of panels and power generation.	Training: Set up a solar system to run your electronics and charge batteries.

3 Food Skills

Subheadings

1. Food Craft	**2. Consumption**	**3. Cooking**	**4. Cooking Methods**
5. Fishing	**6. Foraging**	**7. Gardening**	**8. Preservation**

1 Food Craft

Importance	Skill	Skill Description	Training

	Baking	Know how to bake bread and other food.	Training: Bake some bread with locally sourced ingredients.
	Cake	Knowing how to bake a cake.	Training: Bake a simple cake from easily obtainable ingredients.
	Beer Making	How to brew beer for consumption and trading.	Training: Brew some beer ensuring it's safe to drink.
	Butter Churning	Churning milk into butter for consumption.	Training: Buy some milk and churn it into cream and then further into butter.
	Cheese Making	Churning Butter into cheese for consumption.	Training: Buy some milk and churn it into cream then cheese.

2 Consumption

Importance	Skill	Skill Description	Training
	Nutrition	Knowing nutrition values of foods and what's required for daily intake.	Training: Learn about the nutritional values of food and what you need to survive.
	Energy Requirements	Knowing how much energy is in foods and what you need personally.	Training: Understanding energy values and how many calories you need to survive.

3 Cooking

Importance	Skill	Skill Description	Training
	Campfire Cooking	How to cook over a fire accounting for the variable heat.	Training: Cook over the flames of a fire.
	Coal Cooking	Cooking over hot coals	Training: Cook over hot coals instead of the flame.
	Gas Cooking	Cooking food on a gas stove.	Training: Cook food on a gas stove.
	Solar Cooking	Cooking food using the sun's heat.	Training: Cook food using the heat of the sun.
	Chemical Bag Cooking	Cooking food in a chemical bag.	Training: Cook food in a chemical bag.
	Electric Cooking	Cooking food on an electric stove.	Training: Cook food on an electric stove.

4 Cooking Methods

Importance	Skill	Skill Description	Training
	Spit Roasting	Knowing how to roast meats on a spit.	Training: Cook food on a spit.
	Grilling	Knowing how to grill foods.	Training: Grill food.
	Frying	Knowing how to fry foods.	Training: Fry food.
	Rotisserie	Knowing how to cook food on a rotisserie.	Training: Cook food on a rotisserie.
	Baking	Knowing how to bake foods.	Training: Bake some foods such as bread and cakes.
	Deep Frying	Knowing how to deep fry foods.	Training: Deep fry some foods.
	Pressure Cooking	Knowing how to use and cook with a pressure cooker.	Training: Cook food and can food in a pressure cooker.
	Roasting	Knowing how to roast foods.	Training: Roast some food.
	Steaming	Knowing how to steam foods.	Training: Steam some foods such as vegetables.
	Steeping	How to steep tea.	Training: Make some tea and steep some wild edibles like pine needles.

5 Fishing

Importance	Skill	Skill Description	Training
	Hand Fishing	Knowing how to hand fish for food.	Training: Catch fish with only your hands.
	Spear/Harpoon Fishing	Knowing how to spear fish for food.	Training: Catch fish by using a spear.
	Netting	Knowing how to net for food.	Training: Catch fish by using a net.
	Angling	Knowing how to fish with a rod for food.	Training: Catch fish by using a rod, line and bait.
	Bow Fishing	Knowing how to fish with a bow for food.	Training: Catch fish by using a bow.
	Fish Trapping	Knowing how to trap fish for food.	Training: Trap fish using cages etc.
	Boat Fishing		

6 Foraging

Importance	Skill	Skill Description	Training
	Identifying	Identifying what plants are edible.	Training: Try to identify edible plants.
	Harvesting Wild Food	Harvesting wild foods safely without damaging the plant or food.	Training: Harvest wild food properly to maximise the gain from them and to avoid spoilage.
	Taste Unknown Plants	Know how to taste foreign foods for edibility.	Training: Test if foods are edible by using the unknown plant procedure. (Be Careful of Poisons)

SKILLS | Food Skills | Gardening

7 Gardening

Importance	Skill	Skill Description	Training
	Planting	When, where and how to plant food.	Training: Plant vegetables and fruit using different methods.
	Maintenance	Maintaining plants in the garden.	Training: Care for your plants until they produce food.
	Watering	How when and how much to water plants.	Training: Water each plant the correct amount for your chosen gardening method.
	Pruning	Pruning plants to remove dead branches and shoots to keep them healthy.	Training: Prune your plants properly to remove dead branches to keep them healthy.
	Harvesting	Harvesting plants properly to maximise gain.	Training: Harvest any food you have grown.
	Maintaining Soil	Maintaining soil Ph and other features to help plants grow properly.	Training: Understand the composition and maintain the soil of your plants.
	Pest Extermination	How to get rid of pests eating your plants.	Training: Use different methods to try and reduce or remove the amount of pests on your plants.

SKILLS | Food Skills | Preservation

8 Preservation

Importance	Skill	Skill Description	Training
	Cheese Waxing	Waxing cheese to extend the lifespan.	Training: Wax some cheese whether purchased or churned.
	Smoking	Smoking food to extend the lifespan.	Training: Smoke various types of food such as fish.
	Dehydrating	Dehydrating food to extend the lifespan.	Training: Dehydrate foods such as fruit.
	Canning	Canning food to extend the lifespan.	Training: Can different types of food safely such as meat and vegetables.
	Curing	Curing meats to extend the lifespan.	Training: Cure meats by rubbing them with salt, sugar or herbs.
	Mylar Bagging	Sealing food in a mylar bag to extend the lifespan.	Training: Seal food in mylar bags like rice and wheat.

SKILLS | Outdoor

4 Outdoor Skills

SKILLS | Outdoor Skills

Subheadings

1. Hunting	**2. Field Dressing**	**3. Shelter**	**4. Navigation**
5. Plant Identification	**6. Animal Identification**	**7. Insect Identification**	**8. Weather**
9. Geography			

SKILLS | Outdoor Skills | Hunting

1 Hunting

Importance	Skill	Skill Description	Training
	Trapping	The ability to set traps and catch animals.	Training: Set traps to catch small game like rabbits.
	Tracking	Using game tracks and signs of animals to track and find them.	Training: Find and track animals to their den.
	Trail Marking	The marking and reading of signs on trails that you've left to navigate by.	Training: Walk along known hiking trails and identify signs and markings.
	Scent Camouflage	Camouflaging your scent so animals aren't deterred by you.	Training: Disguise your scent around popular animal locations so they don't detect you.

SKILLS | Outdoor Skills | Field Dressing

2 Field Dressing

Importance	Skill	Skill Description	Training
	Filleting	The acquisition of meat from an animal.	Training: Fillet some fish properly.
	Removing Gizzards	The ability to identify and remove the waste products of animals without breaking them open.	Training: Remove the entrails and waste products from hunted animals.
	Small Game Dressing	Preparing small game such as rabbits for cooking.	Training: Cutting open small animals and preparing them for cooking.
	Large Game Dressing	Preparing large game such as deer for cooking.	Training: Cutting or quartering large animals to prepare them for cooking.

SKILLS | Outdoor Skills | Shelter

3 Shelter

Importance	Skill	Skill Description	Training
	Shelter Building	Knowing how to build various types of temporary shelters from local materials.	Training: Build temporary shelters out of twigs, leaves and logs.
	Hammock Hanging	Hanging a hammock up safely and securely.	Training: Set up a hammock.
	Knot Tying	Knowing how to tie knots for shelter construction which will hold securely.	Training: Practise a variety of different knots.

4 Navigation

Importance	Skill	Skill Description	Training

SKILLS | Outdoor Skills | Navigation

	Compass Navigation	The ability to use a compass and map to navigate to a location.	Training: Navigate to different locations with a variety of compasses.
	Sun Navigation	Using the sun to find north and to navigate by.	Training: Navigate to locations using only the sun.
	Star Navigation	Using the stars to find north and to navigate by year round.	Training: Navigate to certain locations using only the stars.
	GPS Navigation	Using a GPS to find your location and navigate to others.	Training: Navigate using a GPS system.
	Watch Navigation	Using your watch to find north in both hemispheres.	Training: Find direction using a watch.
	Feature Navigation	Navigation by use of the surrounding environment.	Training: Navigate in an unknown location to find resources such as rivers, the ocean etc.
	Map Making	Documenting new maps for a location if you don't have any.	Training: Explore a new location and map prominent features to navigate by.
	Pace Counting	Keeping track of your paces so you don't get lost as easily.	Training: While hiking keep track of your paces and in turn your distance travelled.

5 Plant Identification

SKILLS | Outdoor Skills | Plant

Importance	Skill	Skill Description	Training
	Edible Identification	Identifying plants in their natural habitat.	Training: Identify local edible plants.
	Poisonous Identification	Identifying which plants are toxic by ingestion or skin contact.	Training: Identify local poisonous plants
	Natural Remedies	Knowing which plants have medicinal properties that you can use.	Training: Research local plants which have medicinal properties and practise applying them.

6 Animal Identification

SKILLS | Outdoor Skills | Animal

Importance	Skill	Skill Description	Training
	Animal Identification	Identifying animals in their natural habitat.	Training: Learn about your local animals and the types of animals.
	Animal Deterrence	Deterring animals to prevent an attack.	Training: Practise by avoiding animals and researching what to do in animal attacks.

7 Insect Identification

SKILLS | Outdoor Skills | Insect

Importance	Skill	Skill Description	Training
	Edible Insect Identification	Identifying insects.	Training: Research and learn what insects are edible.
	Poisonous Identification	Identifying poisonous insects.	Training: Research local poisonous creatures.
	Insect Deterrence	Knowing how to deter insects to prevent bites and illness.	Training: Research how to avoid insects targeting you.

8 Weather

SKILLS | Outdoor Skills | Weather

Importance	Skill	Skill Description	Training
	Cloud Identification	Identifying different types of clouds.	Training: Lay on the grass and try to identify each cloud as it goes by or look out the window every few hours.
	Weather Prediction	Predicting the weather which is likely to follow certain weather patterns.	Training: Understand barometric pressure and how it influences weather patterns and look for other patters in clouds and timing.
	Preserving Heat		

9 Geography

SKILLS | Outdoor Skills | Geography

Importance	Skill	Skill Description	Training
	Regional Knowledge	How much knowledge about the local area the person has.	Training: Learn about your town, the electoral candidates, the shops, the topography, weather etc.
	Urban/City Survival	Knowing how to survive in an urban or city environment, particularly in a post apocalyptic environment.	Training: Very hard to train and it's not recommended to stay in cities during disasters but research prepping daily.
	Forest Survival	Knowing how to survive in a forest environment.	Training: Travel to and try to survive in a forest climate for a week.
	Desert Survival	Knowing how to survive in a desert or sandy environment.	Training: Travel to and try to survive in a desert for a week.
	Ocean Survival	Knowing how to survive on an ocean in a boat.	Training: Travel to and try to survive in a boat for a week and desalinate your own water.
	Jungle Survival	Knowing how to survive in a jungle.	Training: Travel to and try to survive in a jungle climate for a week.
	Island Survival	Knowing how to survive on an island surrounded by water.	Training: Travel to and try to survive on a large island for a week.
	Arctic Survival	Knowing how to survive in a frozen arctic environment.	Training: Travel to and try to survive in an arctic climate for a week.
	Mountain Survival	Knowing how to survive in a mountainous environment.	Training: Travel to and try to survive in a mountain climate for a week.
	Plains Survival	Knowing how to survive in a flat grassy plains style environment.	Training: Travel to and try to survive on a grassy plain for a week, preferably one with few trees and identifiable features.

5 Communication Skills

SKILLS

Communication Skills

Subheadings

		1. Communication	2. Foreign Language	3. Radio	4. Visual		
		5. Signalling					

1 Communication

Importance	Skill	Skill Description	Training
	Leadership Skills	How well you can lead a group of people and make good decisions for the best of them all.	Training: By leading a group on a hiking trip or something similar.
	Teamwork Skills	How well the person works within a team environment.	Training: By working in a team whether in a work environment or casual environment.
	Effective Communication	The communication skills of the individual and how effectively they get a point across.	Training: Being part of a work environment strengthens this skill substantially.
	Conflict Management	How well the person deals with conflict between others or themselves.	Training: Being a boss or manager where you have the chance to mediate conflicts.
	Listening	How well the person listens to others and understands them.	Training: Practise listening to people when they talk and remembering everything they say while keeping the conversation going.
	Reliable	The reliability of the person, whether they are on time or late.	Training: Trained by trying to keep your word and only saying what you know you can accomplish.
	Respectful	Whether the person has respect for others and follows the hierarchy.	Training: Respecting those tho are higher in the food chain and being kind to those under you. Particularly parents and elders.
	Trustworthy	Whether the person can be trusted to keep their word or if they often betray and backstab others for their own gain.	Training: Keep your word when you commit and be a good steward with what you've been trusted with.
	Constructive / Positive	The optimism of the person, determining whether they look for the best or the worst in situations.	Training: Being an optimistic person in all situations but particularly when things aren't going as planned.
	Organised	How organised the person is with their ideas, content and time.	Training: Organise your day and scheduled events while planning ahead for the future ones.
	Persuasion	How good this person is at persuading others to do something they weren't intending.	Training: Try to persuade or nudge someone in a direction you want them to go in.

2 Foreign Language

Importance	Skill	Skill Description	Training
	English	Speaking fluent English.	Training: Take an English class online or digitally.
	Mandarin	Speaking fluent Mandarin.	Training: Take an Mandarin class online or digitally.
	Spanish	Speaking fluent Spanish.	Training: Take an Spanish class online or digitally.
	Japanese	Speaking fluent Japanese.	Training: Take an Japanese class online or digitally.
	Hindi	Speaking fluent Hindi.	Training: Take an Hindi class online or digitally.
	Arabic	Speaking fluent Arabic.	Training: Take an Arabic class online or digitally.
	Portuguese	Speaking fluent Portuguese.	Training: Take an Portuguese class online or digitally.
	Russian	Speaking fluent Russian.	Training: Take an Russian class online or digitally.
	French	Speaking fluent French.	Training: Take an French class online or digitally.
	Bengali	Speaking fluent Bengali.	Training: Take an Bengali class online or digitally.
	German	Speaking fluent German.	Training: Take an German class online or digitally.

3 Radio

Importance	Skill	Skill Description	Training
	HAM Communication	Having a license and knowing how to operate a HAM radio.	Training: Purchase a HAM radio and licence and communicate with other HAM users.
	2 Way Communication	Knowing how to operate a two way radio.	Training: Practise using your radios in a variety of situations including ones which may block the signal.
	SW Radio	Listening to short-wave radio stations.	Training: Learn how to operate and receive signals with a SW radio.

4 Visual

Importance	Skill	Skill Description	Training
	Flag Semaphore	Knowing the flag codes when an individual on a ship holds them up.	Training: Look at pictures of various flag semaphore and try to identify them.
	Sign Language	Knowing sign language to communicate with the deaf or communicate silently.	Training: Watch videos of sign language and try to read them.
	Flag Codes	Knowing the flag codes used on ship masts.	Training: Look at pictures of various flag codes and try to identify them.
	Body Language	Reading and interpreting body language to ascertain intent.	Training: Interpreting other peoples body language while they are speaking to anyone.

5 Signalling

Importance	Skill	Skill Description	Training
	Mirror Signalling	Signalling for help using a pocket mirror.	Training: Get a friend and position them at a distant location and try to get their attention with a mirror.
	Flare Signalling	Signalling for help using flares, either handheld or fired.	Training: Get a friend, position them at a distant location and try to get their attention with a flare.
	Smoke Signalling	Signalling for help using smoke from fires.	Training: Get a friend, position them at a distant location and try to get their attention with a flare.
	Whistle Signalling	Signalling for help using a whistle.	Training: Get a friend and position them out of line of sight within a certain radius and see if they can locate you with a whistle.

6 Homesteading Skills

Subheadings

		1. Animal Husbandry	**2. Horsemanship**	**3. Housework**	**4. Construction**		
		5. Trades	**6. Hygiene**	**7. Household Crafts**			

1 Animal Husbandry

Importance	Skill	Skill Description	Training
	Beekeeping	The keeping of bees for a means of food.	Training: Get some bees and take care of their needs and retrieve honey.
	Chicken Cooping	The keeping of chickens for a means of food.	Training: Get some chickens and take care of them, harvesting eggs when you can.
	Raising Rabbits	The keeping of rabbits for a means of food.	Training: Get some rabbits and take care of them.
	Raising Dogs	The raising of dogs for companionship or farm assistance.	Training: Get a dog and take care of them. Training them to accomplish tasks where possible.
	Raising Cows	The keeping of cows for a means of food.	Training: Get some cows and take care of their needs.
	Raising Sheep	The keeping of sheep for a means of food and clothing.	Training: Get some sheep and take care of their needs, shearing them where necessary.
	Cow Milking	The ability to milk a cow for a means of food.	Training: Milk your cows or see if you can milk some local cows with permission.
	Raising Pigs	The keeping of pigs for a means of food.	Training: Get some pigs and take care of their needs.

2 Housework

Importance	Skill	Skill Description	Training
	Raising Horses	The raising of horses for transport or labour.	Training: Get a horse and take care of it.
	Riding Horses	The ability to ride horses for a swift and quiet movement.	Training: Take horse-riding lessons and eventually jumping lessons.
	Horseback Shooting	Knowing how to shoot a bow from a horse.	Training: Practise shooting from horseback if you own a horse.
	Horseback Scouting	Scouting new locations on horseback swiftly and silently.	Training: Take a horseback adventure or take your own horse to unknown locations and scout them out.

3 Housework

Importance	Skill	Skill Description	Training
	Ironing	Iron clothes to remove creases.	Training: Practise by ironing your clothes every day even if you won't wear them.
	Washing Dishes	Washing dishes properly to maintain hygiene.	Training: Wash dishes in a bucket or other container as if you were camping.
	Cleaning	Cleaning the campsite or homestead for hygienic purposes.	Training: Keep your rooms and bench tops tidy and germ free.

4 Construction

Importance	Skill	Skill Description	Training
	Earth Oven		
	Shelter Building		
	Masonry Oven		

5 Trades

Importance	Skill	Skill Description	Training
	Plumbing	Knowing how plumbing systems work to repair your home.	

	Skill	Skill Description	Training
	Electrical	Knowing how electrical systems work to repair your home.	
	Carpentry	Building furniture from scratch.	
	Blacksmithing	Knowing how to smith your own weapons, armour and furniture.	
	Tool Making	Crafting your own tools via blacksmithing or whittling.	
	Shoemaking	Crafting and repairing your own shoes.	

6 Hygiene

Importance	Skill	Skill Description	Training
	Clothes Washing	Washing clothes without a washing machine.	
	Camp Hygiene	Maintaining good camp hygiene to stay healthy.	
	Shower Construction	Building your own shower to clean yourself.	
	Waste Disposal	Knowing proper waste disposal.	

7 Household Crafts

Importance	Skill	Skill Description	Training
	Candle Making	Crafting candles for additional lighting methods.	
	Soap Making	Knowing how to make soap for hygienic purposes.	Training: Try to make your own soap.
	Washing Powder	Creating your own washing powder for ease of washing clothes.	

7 Crafting Skills

Subheadings

1. Fire Crafts	**2. Tool Making**	**3. Weapon Making**	**4. Furniture Crafting**
5. Fire Crafting	**6. Needlework**	**7. Woodworking**	

1 Fire Crafts

Importance	Skill	Skill Description	Training
	Crafting a Bow Drill		
	Crafting a Fire Plough		

2 Tool Making

Importance	Skill	Skill Description	Training
	Air Filter Creation		

3 Weapon Making

4 Furniture Crafting

Importance	Skill	Skill Description	Training
	Bed Crafting	Knowing how to craft a bed from resources such as wood.	
	Chair Crafting	Knowing how to craft chairs from resources such as wood.	
	Table Crafting	Knowing how to craft a table from resources such as wood.	
	Shelf Crafting	Knowing how to craft shelves that attach to the frames of houses.	

5 Fire Crafting

Importance	Skill	Skill Description	Training
	Charcoal Making	Create charcoal to clean objects and heal illnesses.	

	Activated Charcoal	Used to heal illnesses and clean objects.	

6 Needlework

Importance	Skill	Skill Description	Training
	Knitting	To create your own clothes and cold weather gear.	
	Crocheting	To create your own clothes and cold weather gear.	
	Sewing	Knowing how to sew to repair clothing.	

7 Woodworking

Importance	Skill	Skill Description	Training
	Whittling	Whittle objects to use in the kitchen or to keep away boredom.	
	Carving	Carve objects to keep occupied or use later.	
	Boat Making	Craft boats for travel to remote locations.	
	Wood Processing	Includes chopping, splitting and whittling wood.	

8 Medical Skills

Subheadings

		1. First Aid	2. Herbal Healing	3. Fitness	4. Medicating		
		5. Bandaging	6. Animal / Insect Attacks	7. Recognise Symptoms			

1 First Aid

Importance	Skill	Skill Description	Training
	Basic First Aid	Knowing the use for first aid items and how to apply them when the time comes.	
	First Aid Trauma	Knowing the use for advanced trauma items and how to apply them.	
	Heimlich Manoeuvre	Knowing how to perform this manoeuvre to save a life.	
	CPR	How to use CPR to save a life.	Training: Attend a CPR class so you know the correct procedure.
	Know ABC	How to use ABC to save a life.	
	Know DCAP-BTLS	Useful to save a life.	
	Know OPQRST	How to use OPQRST to save a life.	
	Know RICE	How to use RICE to save a life.	
	Know SAMPLE History		
	Know SOAP Note		
	Use a Defibrillator	How to use a defibrillator to restart a heart.	

2 Herbal Healing

Importance	Skill	Skill Description	Training
	Identify Medical Herbs	Knowing what wild plants can use used for medical poultices.	
	Make Poultices	Creating poultices from wild herbs to produce a healing effect when applied.	
	Applying Poultices	Knowing where and how to apply wild herb medical poultices.	

3 Fitness

Importance	Skill	Skill Description	Training
	Backpacking	The ability to carry a backpack over long distances.	Training: Fill your pack with gear and head out on a hike.
	Stretching	Know how to stretch before working out.	Training: Research how to stretch different muscle groups and learn them off by heart.
	Jogging	Have the ability to jog long distances.	Training: Jog for 30 minutes around your area.
	Cardio Training	Strengthening your heart to prevent heart related problems.	
	Flexibility	Be flexible and manoeuvrable.	

SKILLS Medical Skills Skills

	Strength		
	Endurance		

4 Medicating

Importance	Skill	Skill Description	Training
	Treat Shock	Know the signs of shock and how to treat it.	
	Treat Anaphylactic Shock	Know the signs of anaphylactic shock and how to treat it.	Training: Pretend your friend is going into anaphylactic shock and administer their epi-pen.
	Treat Seizures	Know the signs of a seizure and what to do in that situation.	
	Tourniquet Use	Using a tourniquet in the right circumstance for the right amount of time.	
	Treating Burns	Categorizing burns and knowing how to treat them.	
	Treat Choking	Understand different types of choking and the types of treatments you can use.	
	Treat Cardiac Arrest	What to do when someone goes into cardiac arrest and how to recognise the signs.	
	Childbirth	How to deliver a baby in a safe manageable way.	
	Hypoglycaemia		
	Treat Dislocations	How to treat dislocations and get the bone back into the socket.	
	Treat Poisoning	What to do in a case of poisoning and how to recognise the signs.	

5 Bandaging

Importance	Skill	Skill Description	Training
	Wound Sanitisation	The cleaning of wounds of dirt and the killing of pathogens and bacteria.	Training: Smear a bit of dirt onto a leg and then pretend to treat it as if it were real.
	Wound Dressing	Dressing wounds with clean bandages.	
	Break Immobilisation	Knowing the different ways to immobilise limbs if they are broken.	Training: Practise immobilizing different limbs on a friend.

6 Animal / Insect Attacks

Importance	Skill	Skill Description	Training
	Treat Snakebites	Knowing what to do when a snake bites someone.	Training: Knowing which snakes are poisonous in your area. Simulate a poisonous snake bite and wrap bandages around the area.
	Treat Spider Bites	Knowing what to do when a spider bites someone.	Training: Know which spiders are poisonous in your area. Simulate a poisonous spider bite and wrap bandages around the area.
	Treat Bee/Wasp Stings	Knowing what to do when a bee/wasp stings someone.	
	Remove Ticks / Leeches	Knowing how to remove ticks and leeches safely.	Training: You could purposely get a leech sucking your blood to train you getting it off.
	Rabies Treatment	Knowing how to treat a bite from a rabid animal.	
	Vertebrate Bites	Knowing what to do when a vertebrate bites someone.	
	Arthropods Bites	Knowing what to do when an arthropod bites someone.	

7 Recognise Symptoms

Importance	Skill	Skill Description	Training
	Dehydration Signs	Knowing the signs of dehydration and how to treat it.	
	Heatstroke Signs	Knowing the signs of heatstroke and how to treat it.	
	Frostbite Signs	Knowing the signs of frostbite and how to treat it.	
	Hypothermia	Identifying hypothermia in a person and how to treat it.	
	Stroke Signs	Identifying a stroke in a person and how to treat it.	Training: Take a class or watch videos of people having strokes and learn the signs.
	Recognise Shock	Identifying shock in a person and how to treat it.	
	Altitude Sickness	Identifying altitude sickness in a person and how to treat it.	
	Asphyxiation	Identifying asphyxiation signs in a person and how to treat it.	
	Heart Attack Signs	Identifying heart attack signs in a person and how to treat it.	
	Hair Tourniquet		

9 Combat Skills

Subheadings

		1. Unarmed	2. Bladed Weapons	3. Thrown/Shot Weapons	4. Ranged		
		5. Guns	6. Explosives	7. Threat Identification			

1 Unarmed

Importance	Skill	Skill Description	Training
	Karate		Training: Start a karate class.
	Jujutsu		Training: Start a jujutsu class.
	Boxing		Training: Take up boxing.
	Judo		Training: Start a judo class.
	Kickboxing		Training: Start a kickboxing class.
	Muay Thai		Training: Start a muay thai class.
	Krav Maga		Training: Start a krav maga class.
	Hapkido		Training: Start a hapkido class.
	Pencak Silat		Training: Start a pencak silat class.
	Wing Chun		Training: Start a wing chun class.
	Opportunistic Weapons	Items which are around you that could be used as weapons such as chairs and books.	Training: Have a mock fight with a friend using only items around you at the time.

2 Bladed Weapons

Importance	Skill	Skill Description	Training
	Knife	Knowing knife combat and how to use it properly.	
	Sword	Knowing sword combat and how to use it properly.	Training: Practising swordsmanship on a dummy or punching bag using a weighted wooden stick.
	Nunchaku		
	Hidden Blade		
	Mace		
	Battleaxe		

3 Thrown/Shot Weapons

Importance	Skill	Skill Description	Training
	Spear	Knowing how to throw spears effectively.	Training: Practise throwing them at a tree on your property.
	Throwing Knives	Knowing how to throw throwing knives effectively.	Training: Practise throwing them at a tree on your property.
	Chakram	Knowing how to throw chakram effectively.	Training: Practise throwing them at a board on your property.
	Ballistic Knife	Knowing how to shoot ballistic knives effectively.	Training: Practise shooting it at a tree on your property.
	Tomahawks	Knowing how to throw tomahawks effectively.	Training: Practise throwing them at a tree on your property.
	Shuriken	Knowing how to throw shuriken effectively.	Training: Practise throwing them at a board on your property.
	Bolas	Knowing how to throw bolas effectively.	Training: Practise throwing them at a target on your property.

4 Ranged

Importance	Skill	Skill Description	Training
	Compound Bow	Knowing how to shoot a compound bow effectively.	Training: Go to an archery range and practise shooting.
	Recurve Bow	Knowing how to shoot a recurve bow effectively.	Training: Go to an archery range and practise shooting.
	Longbow	Knowing how to shoot a longbow effectively.	Training: Go to an archery range and practise shooting.
	Crossbow	Knowing how to shoot a crossbow effectively.	Training: Go to an archery range and practise shooting.
	Fletching Bows	How to create your own bows from local wood.	Training: Head out into the wild and find bowmaking materials and try to build one.

	Fletching Arrows	How to create your own arrows from local wood.	
	Slingshot	Knowing how to shoot a slingshot effectively.	
	Sling	Knowing how to use a sling and rocks effectively.	
	Blowgun	Knowing how to shoot a blowgun effectively.	

5 Guns

Importance	Skill	Skill Description	Training
	Marksmanship	Training to become an accurate shooter.	
	Maintenance	Knowing how to maintain and look after a gun.	
	Reloading	Reloading a weapon swiftly and efficiently.	
	Gun Repairs	Repairing a gun with spare parts or found components.	
	Gun Safety	Knowing how to use a gun safely and effectively.	
	Ballistic Types	Knowing what effects different types of ammo have.	

6 Explosives

Importance	Skill	Skill Description	Training
	Molotov Cocktail	Knowing how to throw a molotov correctly.	
	Grenade	Knowing how to throw a grenade properly.	Training: Buy a training grenade to practise with and research how to throw them properly.
	Pipe Bomb	Knowing how to arm a pipe bomb properly.	
	Landmine	Knowing how to arm and avoid landmines.	

7 Threat Identification

Importance	Skill	Skill Description	Training

10 Transport Skills

Subheadings

1. On Foot	2. Driving	3. Cycling	4. Air
5. Sea			

1 On Foot

Importance	Skill	Skill Description	Training
	Hiking	Walking through unfamiliar terrain swiftly for great distances without tiring.	
	Backpacking	How used you are to using and hiking with a backpack.	
	Mountaineering	The ability to traverse rough terrain and steep slopes swiftly.	
	Climbing	Climbing up and down obstacles if they are blocking your route.	
	Sprinting	The ability to sprint fair distances to escape danger.	

2 Driving

Importance	Skill	Skill Description	Training
	Driving	Knowing how to drive a motor vehicle, whether manual or automatic.	
	Vehicle Maintenance	Maintaining vehicles to an optimum condition and performing regular checks.	Training: Research and maintain your vehicle yourself such as air filter change, light changes, oil changes etc.
	Vehicle Repairs	Repairing vehicles when they become damaged.	
	Evasive Driving	Avoiding obstacles in a rapidly changing environment.	
	Change a Tyre	Knowing how to change a tyre if it becomes punctured.	Training: Practise changing your tyre a few times every few months so you don't forget the skill.

	Repair a Tyre	Repairing a tyre with scavenged materials if needed.	
	Snow Driving	Driving in slippery and cold conditions.	
	Flood Driving	Driving through flood waters and gauging if it's safe to do so.	
	Jump Starting	Starting a cars engine using another car.	

3 Cycling

Importance	Skill	Skill Description	Training
	Cycling	Knowing how to ride a bike and stay balanced.	
	Bike Maintenance	Keeping your bike in optimum condition, oiled and dirt free.	
	Bike Repair	Repairs such as fixing a chain and repairing a puncture.	

4 Air

Importance	Skill	Skill Description	Training
	Piloting	Knowing how to fly an aircraft safely.	
	Aircraft Maintenance	Maintaining aircraft to an optimum condition and performing regular checks.	

5 Sea

Importance	Skill	Skill Description	Training
	Swimming	Knowing how to swim and the hazards in oceans.	
	Driving Boats	Knowing how to drive motor boats.	
	Boat Maintenance	Maintaining boats to an optimum condition and performing regular checks.	
	Sailing	Controlling a boat with masts and sails.	
	Lifesaving	Saving someone's life who is drowning.	

11 Modern Skills

Subheadings

		1. Computing	**2. Life Skills**	**3. Infiltration Skills**	**4. Fuel**		
		5. Metalwork					

1 Computing

Importance	Skill	Skill Description	Training
	Typing	The speed and accuracy of your typing on PCs and mobiles.	Training: Practise by typing to friends and family often. Focus on accuracy rather than speed.
	Hacking	Whether or not you can hack computers, networks etc.	Training: Attempting to hack wireless networks then go on to something more challenging like modern technology or software.

2 Life Skills

Importance	Skill	Skill Description	Training
	Critical Thinking		
	Child Care	How good this person is with children and looking after kids.	Training: Set it on yourself to try and keep kids occupied with games at events or parties.
	Parenting	How good this person is at parenting a child.	Training: The best way is to watch a good parent in action as you shouldn't be parenting someone else's children.
	Reasoning		
	Imagination	How out of the box and vivid your imagination is.	Training: Imagine unique and possibly strange ways of accomplishing your tasks.
	Time Management	How well your time is spent.	Training: Write down how you currently spend your time and work out how you can be more efficient.
	Relationships	How well you maintain your relationships with others.	Training: Being a good friend and lending an ear when they need you. Loving your family and spouse.

3 Infiltration Skills

Importance	Skill	Skill Description	Training

	Lockpicking	Using lockpicks to open locked doors, safes and locks.	Training: Buy a lockpick set and practise picking the locks on your house and car, but starting off with practise clear locks.
	Pickpocketing	Stealing items off a mark without them knowing.	Training: Try to pick your friends pockets without them knowing while they're over - then give it back.
	Hotwiring	Starting a car through the manipulation of electrical cables.	Training: Varies with different cars but learn about hotwiring and then try to hotwire your own car.

4 Fuel

Importance	Skill	Skill Description	Training
	Creating Biodiesel	Knowing how to create biodiesel at home for vehicle fuel.	
	Creating Ethanol	Knowing how to create ethanol at home for vehicle fuel.	

5 Metalwork

Importance	Skill	Skill Description	Training
	Ammo Smithing	Crafting your own ammo at home.	Training: Set up a blacksmithing forge and ammo station so you can melt down metals to create your own ammo.
	Weapon Smithing	Smithing your own weapons at home on a forge.	Training: Practise forging a sword and knives at home with scrap metal.
	Armour Smithing	Smithing your own armour at home on a forge.	Training: Practise forging armour at home.
	Welding	Attaching two pieces of metal together.	Training: Weld some metal together or make something out of metal that required welding.

12 Tactical Skills

Subheadings

		1. Tactics	2. Evasion	3. Camouflage	4. Strategy		
		5. Security					

1 Tactics

Importance	Skill	Skill Description	Training
	Situational Awareness	Knowing what's going on around you at all times.	Training: Sit in a café or other city location and observe everything going on around you. Know where the exits are and try to memorise people who stand out and other important details.
	Conflict Avoidance	Avoiding conflict when wise to do so and knowing how to get out of heated situations.	Training: Start a mock fight with a friend and try to defuse the situation or get out fast.
	Conflict De-Escalation	Talking a person down or stepping down yourself to tone down a disruption.	Training: Have a friend come at you angrily and start a verbal conflict then try to talk them down.
	Sensing Danger	The ability to know when something is wrong before it happens.	Training: You could have a friend try to break into your house on a random day a few times every month to keep you alert at all times and to heighten your senses.
	Breaking Down Doors	Breaking down or opening doors swiftly, quietly and efficiently without injury to yourself.	Training: Hard to practise without expenses but you could always try to scout out an unknown house as quickly and quietly as possible while checking every room.
	Infiltration	Gaining access into an enemy occupied building and achieving specific outcomes.	Training: Infiltrate a friends house and leave with a specific object.
	Silent Movement	Moving between locations without making much noise.	Training: Try to move as silently as possible in different environments such as rain, fallen leaves and through a building.
	Scouting	Scouting new unknown locations.	Training: Go to an unknown location and investigate the area marking landmarks on a map so you can find them again later.
	Looting	Finding items needed to survive on in unknown locations.	Training: Borrow a friends house to loot everything you may need for survival as a practise.

2 Evasion

Importance	Skill	Skill Description	Training
	Losing a Tail	Losing a person who's following you.	Training: Have a friend tail you at a reasonable distance in a city environment and try to evade them.
	Evading Authorities	Keeping one step ahead of the CIA, police etc.	Training: Not really trainable, watch The Bourne Ultimatum maybe?

3 Camouflage

Importance	Skill	Skill Description	Training
	Grey Man	Knowing how to blend in to a crowd and avoid detection.	Training: Practise being unseen in urban environments. Be the person who blends in.

Importance	Skill	Skill Description	Training
	Personal Camouflage	Having the ability to camouflage yourself into the surrounding terrain.	Training: Identify where you want to camouflage yourself and buy some camo gear of the same style and try to blend in. Get a friend to take pictures from every angle.
	Shelter Camouflage	Camouflaging your shelter into the terrain to avoid detection.	Training: Camp out in the wild and try to hide your tent from every angle using natural materials.
	UV Camouflage	Tactics and skills for camouflage from UV detection.	Training: Camp out in the wild and use a UV camera to try and identify your position.
	Thermal Camouflage	Tactics and skills for camouflage from thermal imaging.	Training: Camp out in the wild and use a thermal camera to try and identify your position.
	Hiding in Plain Sight	Involves being the centre of attention, so much so that all suspicion on you is absolved. Also known as "Somebody Else's Problem".	Training: Dress so ridiculously that people try to avoid or ignore you completely, like dressing up as a clown and wandering in a park.

4 Strategy

Importance	Skill	Skill Description	Training
	Bug-Out Plan	Knowing how to make efficient and detailed bug out plans is a skill that takes time to develop.	Training: Create a bug out plan and test it out and then made adjustments to it.
	House Invasion Strategy	Knowing the best ways to defend your house or estate can only be accomplished by practice.	Training: Get some friends to invade your house so you can fix any weaknesses they may find.
	Strategy	Advanced strategies and tactics used in wars or conflicts.	Training: Get two families to have a mock firefight where you command your party where to go and what to do.

5 Security

Importance	Skill	Skill Description	Training
	Woodland Alarms	The ability to create alarms from bush materials to alert you of trouble.	Training: Set up some tripwire can alarms on your property and test them.

13 Mental Skills

Subheadings

		1. Personality	2. Psychological Skills	3. Mental Fitness	4. Ethics		

1 Personality

Importance	Skill	Skill Description	Training
	Stable Personality	A stable personality will assist in clear decision making and make you a strong leader.	Training: When faced with hard or emotional times try to remain at your median personality without being too affected by whatever emotion is being challenged.
	Self Understanding	Understand your body, mind and what you need to survive.	Training: Takes notes of what you eat, what you spend your time on and work out why you do them or eat it and whether or not it benefits you.
	Self Comfort	Be comfortable with yourself and your own thoughts.	Training: Spend a week or two alone, without other human interaction and try to find ways to be comfortable with yourself.
	Discipline	Follow through on commitments and keep your word.	Training: Have a routine and stick to it, but don't become predictable.
	Perfectionism	How perfectly you try to accomplish everything.	Training: Try to complete jobs or tasks before moving onto something else so there's no unfinished projects.

2 Psychological Skills

Importance	Skill	Skill Description	Training
	Perseverance	The ability to keep going no matter what challenges are facing you.	Training: If you're faced with challenges, trials or failures try to keep pushing through until you succeed.
	Creativity	Finding unique ways to accomplish a task that isn't obvious.	Training: Look for new and creative ways of doing your job or other tasks.
	Researching	Researching or experimentation is important for learning theories you didn't know.	Training: Practise by researching things you don't know very much about, soon you should be able to find information much faster.
	Strategic Thinking	Creative thoughts about safety, security and planning enemies moves before them.	Training: Try to look for unique ways to do preparedness related activities specific to you.
	Adaptability	Adapting to any circumstance life or weather may throw at you.	Training: Throw yourself a few curve-balls in life and adapt to the situation like pretending your car won't start.
	Alertness	Staying alert for risks, threats or dangers.	Training: Keep your mind on possible threats and potential exits throughout the day whenever you can and soon it will be second nature.

3 Mental Fitness

Importance	Skill	Skill Description	Training

	Fear Control	Quell or contain any fears that may start to bubble up.	Go into situations that may scare you such as holding a non dangerous spider if you're afraid of them.
	Positive Mental Attitude	Have a strong and focused mindset on what you want to achieve and know you will survive.	Training: Focus on the positives in any situation you may be faced with no matter how trivial.

4 Ethics

Importance	Skill	Skill Description	Training
	Strong Morals	Have strong morals and stick by them in tough times.	Training: When situations arise that challenge your ethics or morals, be sure to stick by them.
	Religious Conviction	Stay with your religion and beliefs in all situations.	Training: Know the ins and outs of your religion and stick to what you believe in hard times.
	Code of Conduct	Have a code of conduct and treat others well.	Training: Set some rules for living by and try to stick to them at all times.
	Good Samaritan Law	Know the good Samaritan law to help others out.	Training: When people are in need around you, be the one to help them and go the extra mile.

14 Skills Analyser

The skills analyser is used for detailing the strengths and weaknesses of individuals, but particularly bug-out party members. Below is a breakdown of skills into smaller units which are easier to recognise.

Knowledge	How much information the individual knows about the subject. **Example:** Someone who's watched a lot of videos on prepping but has never put it into action.
Level 0	No prior knowledge of this skill.
Level 1	A small amount of knowledge on this skill.
Level 2	They know quite a bit of information but are still in the early stages.
Level 3	Someone who knows about half the information on a skill.
Level 4	They know most of what there is to learn about the skill.
Level 5	Someone who knows everything there is to know about a skill.
Experience	How much real life experience the person has had. **Example:** Someone who's been actively prepping for years but hasn't researched how do it more efficiently.
Level 0	Absolutely no experience in this skill.
Level 1	Someone with a small amount of experience in that skill.
Level 2	A person with a moderate amount of skill who has been doing it a while.
Level 3	An apprentice level of skill where they should be able to perform it by themselves quite easily.
Level 4	An extremely skilled person doing it very well every time.
Level 5	A master of that skill, doing it flawlessly every time.
Talent	The natural talent and ability the individual has in this skill. **Example:** Someone who picks up new prepping skills and pushes the boundaries so naturally.
Level 0	No natural talent whatsoever.
Level 1	Only a small amount of natural talent.
Level 2	A person with a slightly less than average amount of talent.
Level 3	They have quite a talent for this skill and can perform it quite easily.
Level 4	A person who has a wonderous talent for this skill who pushes the boundaries.
Level 5	Someone with an absolutely marvellous affinity for this skill, always on the leading edge.

Example

This is an example on how to create a list of the skills of the individuals in your bug out party. Each letter with a number beside them represents the skill above and how that person ranks. The total score is made with an average of the three numbers below. (E.g. 2+2+3 = 7, ÷ 3 = 2.3)

	Person 1	Person 2	Person 3	Person 4	Person 5						
Leadership	**2.3** K2, E2, T3	**1.6** K2, E2, T1	**0** K0, E0, T0	**0.3** K1, E0, T0	**N/A** K0, E0, T0						

Crafting

Projects and crafting ideas for your home or campsite

"The desire to create is one of the deepest yearnings of the human soul."
Elder Uchtdorf

Introduction

This section discusses craft-able objects you can create at home or the campsite such as chairs, ovens or shampoo.

Purpose	The aim of CRAFTING is to provide a list of crafting recipes to allow the creation of furniture, clothing, stoves, household consumables such as soap and candles, kitchen equipment, whittled items, weapons, ammunition and glass objects. This section finishes with a list of tools and their primary purpose.
Lost?	• If you're looking for information on the types of materials used to craft with, see the MATERIALS section. • For information on building a signal fire to be seen or to signal others, see the COMMUNICTION section. • If you want to build and set traps, see the HUNTING section. • For more information about crafting shelters, see the SHELTER section. • If you want to craft a weapon out of resources you have, see the OFFENCE section.

4 Kitchen Items

Stoves & Cooktops

Camp Grill	How to build stoves and cooking ranges.

CRAFTING | Kitchen Items | Stoves & Cooktops

Camp Grill	Food placed on wire grid above or below heat, cooked by thermal radiation.
Rotisserie	A slow cooking process where the food is skewered on a spit and rotated slowly to cook evenly. Peg two sticks with a Y fork at the end into the ground. Place another stick with a bend at the end across the top ensuring that it has been cleaned first prior to adding food.
Earth Oven	An oven pit in the ground used to trap heat and bake, smoke or steam food. Wrap food in banana leaves or similar and place underground with hot coals.
Masonry Oven	An oven consisting of a baking chamber make of brick, concrete, stone or clay. Used for heating, baking, drying or cooking foods. Find sufficient bricks/rocks to create the oven with.
Dehydrating Rack	Removes the moisture from foods using a fan and low heat to preserve them longer.
Sun Stove	

5 Camp Recipes

These are recipes for useful non-edible items such as candles, shampoo or soap.

Herbal Shampoo

Prep: min **Cook:** min **Yield:** 7serv	Pic	**Description:** **Prep Time:** **Cook Time:** **Yield:**
Ingredients	• 2 tbsp. shampoo base or liquid castile soap • 1 cup distilled water • 1/4 cup of fresh herbs or 3 tbsp. of dried herbs (see choices below) • 1 tsp. apricot kernel oil or almond oil • 2 drops essential oil of your choice (if making for children, Roman chamomile is recommended) • Edible Wilds in Recipe: Dandelion, Horsetail, Red Clover • Herbs for normal hair: dandelion, horsetail, red clover. • Herbs for oily hair: lemongrass, white willow bark, strawberry leaves, watercress. • Herbs for dry hair: comfrey root, elder flowers, orange blossoms.	
Instructions	1. Place herbs in a Pyrex bowl. Boil water and then pour over the herbs. Let steep 20 minutes. 2. Strain liquid from the herbs. Into the liquid add the liquid castile soap or shampoo base; then the almond or apricot kernel oil; mix thoroughly. 3. Scent with essential oil and mix again. Pour into refillable plastic container.

Laundry Soap	

6 Fletching

Fletching is the crafting of bows and arrows.

Bows

Arrows

7 Woodworking

The woodworking category helps you identify wood types, guidance on felling trees and what you can use the resulting wood for.	"Measure twice, cut once, then force it to fit."

Woodcutting Tools

A list of tools which can be used to cut trees, logs and branches.

Identifying Trees
Different trees have a huge variety of purposes, from better firewood to better at whittling to better for constructing houses and bows. You should choose the wood you will be using carefully or it may have catastrophic consequences. For a list of features to determine the type of tree see the PLANTS section. For a list of known tree types and useful features see the MATERIALS section.

Saws

A saw is a tool consisting of a tough blade, wire, or chain with a hard toothed edge. It is used to cut through material, very often wood though sometimes metal or stone. The cut is made by placing the toothed edge against the material and moving it forcefully forth and less forcefully back or continuously forward. This force may be applied by hand, or powered by steam, water, electricity or other power source. An abrasive saw has a powered circular blade designed to cut through metal or ceramic.

Wire Saw	A wire saw is a saw that uses a metal wire or cable for cutting. Industrial wire saws are usually powered. There are also hand-powered survivalist wire saws suitable for cutting branches. Wire saws are classified as continuous (or endless, or loop) or oscillating (or reciprocating). Sometimes the wire itself is referred to as a "blade". Wire saws are similar in principle to band saws or reciprocating saws, but they use abrasion to cut rather than saw teeth. Depending on the application, diamond material may or may not be used as an abrasive. The wire can have one strand or many strands braided together (cable). A single-strand saw can be roughened to be abrasive, abrasive compounds can be bonded to the cable, or diamond-impregnated beads (and spacers) can be threaded on the cable. Wire saws are often cooled and lubricated by water or oil. One major advantage of wire saws is their smaller kerf, as compared to a blade. Another is the precision of the cut. Their main disadvantage is the slower speed. Other disadvantages include a greater chance the wire will break and any surface imperfections can cause errors in the cut.
Hand Saw	In woodworking and carpentry, hand saws, also known as "panel saws", are used to cut pieces of wood into different shapes. This is usually done in order to join the pieces together and carve a wooden object. They usually operate by having a series of sharp points of some substance that is harder than the wood being cut. The hand saw is a bit like a tenon saw, but with one flat, sharp edge. There are two main types of saw teeth: the 'cross cut' saw teeth and the 'rip' saw teeth. These cut into the wood using different mechanisms. Wood is composed of many long cells running length-ways. Thus, crosscut saws have sawteeth that are usually shaped, often with a metal file, in such a way that they form a series of tiny knifelike edges. The wood cells are contacted by the knife-edge of the tooth and cut. Rip saws, on the other hand, are usually shaped so that they form a series of tiny chisel-like edges. The wood cells are contacted by the chisel and 'ripped' apart from the bundle of other cells. It is common that people do not recognize the difference and use saws both ways. However, a rip saw is much faster than a cross-cut saw when cutting with the grain but leaves a very rough cut, often with splinters on the surface, and has more difficulty maintaining a straight cut when cutting across the grain. The cross-cut saw can cut in any direction but is much slower than needs be when cutting with the grain.
Two-Man Saw	A two-man saw (known colloquially as a "misery whip") is a saw designed for use by two sawyers. While some modern chainsaws are so large that they require two persons to control, two-man crosscut saws were primarily important when human power was used. Such a saw would typically be 1 to 4 m (4 to 12 feet) long, and sometimes up to 5 m (16 feet), with a handle at each end. In some cases, such as when felling Giant Sequoias, sawblades could be brazed together end-to-end in order to create longer saws. The technique in using a two-man saw involved a sawyer standing at each end. Together the sawyers would alternate pulling the saw through the wood. If the kerf began closing, causing the saw to bind, wedges would be inserted behind the sawblade in order to keep the kerf open. Cutting from underneath a suspended log, called "underbucking", might also have been used if binding became a big problem. Many variations on the design were used, but they mainly fell into two types. Felling saws were used to fell the trees, and bucking saws were used to cut felled trees into lumber. The two applications require slightly different designs: a felling saw has a narrower blade, allowing wedges to be more easily inserted, while a bucking saw has a wider blade, giving it more strength. Two-man saws were designed to cut in both directions. Careful tooth design was necessary to clear the sawdust during the cut.

Axes

These are different types of axes you may find.

Hatchet	Fine for chopping up kindling or tackling the occasional small tree. A good hatchet should ideally include a hickory handle, have a well-weighted head, and a balanced feel. It's the balanced feel that helps you strike accurately each time, felling a tree much quicker than a cheaper hatchet.
Felling Hatchet	These axes are catered to the felling of trees and chopping larger logs. This time around, the handle is longer, the head is angled more aggressively and usually, the handle is designed to produce a powerful swing.
Splitting Maul	Similar in size to a felling axe, yet this time its job is to split logs into kindling for a fire. The axe head will have a less aggressive, more concave blade to it, allowing you to split the wood across the grain, rather than cut into it.
Tomahawk	These are the axes you see frequently on camping trips. They tend to be used incorrectly for firewood collecting and clearing brush, something a quality machete would be a better fit for.
Tactical Axe	A good tactical axe, is not usually made of hickory, or any type of wood. They're generally made of forged steel, with helpful notches and serrated edges to help with specific tasks. A great example of this are climbing axes, which feature special cut-outs and parts to cut rock or help attach bolts to rock faces.
Viking/Danish Axe	A standard issue Viking axe is huge. They can easily be 6ft in height, with different sizes depending on the user (you can also be fitted for a Viking Axe, just like a suit).
The Double Bit Axe	This axe is a cumbersome beast, yet it's dual head is more useful than you'd think. One side of the double bit axe is always much sharper than the other. It's this side that you use to fell a tree or cut wood.
Battle Axe	Unlike the Viking Axe, the battle axe is much smaller and designed to be held in one hand. They're extremely powerful weapons, with a heavy cut head that's designed to carry as much power through the swing, and ultimately onto your target.

Mechanical Cutting

Ways logs can be cut by mechanical or electrical means.

Chainsaw

A chainsaw is a portable, mechanical saw which cuts with a set of teeth attached to a rotating chain that runs along a guide bar. It is used in activities such as tree felling, limbing, bucking, pruning, cutting firebreaks in wildland fire suppression and harvesting of firewood. Chainsaws with specially designed bar and chain combinations have been developed as tools for use in chainsaw art and chainsaw mills. Specialized chainsaws are used for cutting concrete. Chainsaws are sometimes used for cutting ice, for example for ice sculpture and in Finland for winter swimming. Someone who uses a saw is a sawyer.

Log Splitter

Chipper / Mulcher

Sawmill

Cutting Wood

Felling a Tree

Felling is the process of cutting down individual trees, an element of the task of logging. See the "Fuel" section for the difficulty level of felling various types of trees.

Preparation

Survey	Survey the area around the tree for structures. Take a look at the area around the tree to make sure there aren't structures or other trees in the area where you want it to fall. Things like power lines, fences, and roads should all be considered before you fell a tree. You'll want there to be an area that's cleared out where the tree is free to fall. Cutting down a tree so that it falls into another tree could start a potentially dangerous domino effect. Examine the tree for stability and lean. Make sure that your tree is healthy and free of disease or the cutting down process could be unpredictable. Similarly, you'll want to make sure that the tree isn't leaning significantly in a certain direction because then you won't be able to control the direction it falls in.
Fall Path	Determine the fall path of the tree. The fall path should be free of structures, roads, and other trees. Make sure that there's enough space for the tree to fall on its side without colliding with anything else. Estimate the height of the tree, then use a tape measure to measure the distance from the base of the tree to an area that's free of objects. This will be your fall path. To control the fall path, you'll cut a notch in the side of the tree that you want it to fall on.
Debris	Pick up sticks and debris near the tree. Sticks, logs, and stones could trip you as you try to get away from the falling tree. Remove anything from around the tree that could cause you to trip or fall.
Escape Route	Plan an escape route for after the tree falls. Once you get to know the area around you, you can establish a route to walk in as the tree is falling. You should never stand or walk in front or behind a falling tree. Make sure there is a clear path to walk in and step at least 15 feet (4.6 m) to the side of the tree as it falls.

Saw Felling

Step 1	Make a horizontal cut on the side you want the tree to fall on. Put the teeth of the handsaw 1–2 feet (0.30–0.61 m) above the tree's roots and move it back and forth to create a horizontal cut. Continue cutting through the tree until you've made it 1/3 of the way through.
Step 2	Hatchet a 70-degree front cut above the horizontal cut. Once the horizontal cut has been made, you can start hatchetting above the cut to create the notch. Use both hands and swing a hatchet above your head and down into the side of the tree at an angle. Continue cutting at the tree until you've made a defined notch, but don't go past 1/3 of the tree's width.
Step 3	Saw through the tree on the opposite side of the notch. Go to the other side of the tree and repeat the pattern, but this time saw all the way through the tree to the notch. As you get closer to the notch, get ready to quickly walk away because the tree will fall.
Step 4	Walk out of the way of the tree as it falls. Quickly walk down the path that you cleared out before. If you did everything correctly, the tree will fall in the direction of the notch.

Axe Felling

Step 1	Cut a v-shaped notch (kerf) about waist high into the tree in the direction you want the tree to fall. Cut to a depth of about 1/3 the diameter of the tree.
Step 2	Cut another notch on the opposite side about a foot above the first. The wood between the two cuts creates a "hinge," holding the tree in place as it begins to fall.
Step 3	Expand the width of the first notch in an upward direction until it approaches the height of the second notch. When the tree begins to fall, make your way to safe distance back along the escape route. Be aware of any branches on nearby trees that might become entangled with the falling tree.

Chainsaw Felling

Step 1	Cut on a notch at a 70-degree angle. Decide the direction that you want the tree to fall because this is the side of the tree that you'll cut the notch. Turn on the chainsaw and carefully cut down into the tree at a 70-degree angle. The top of the notch should be the shallowest part of the cut, while the bottom of the notch will be the deepest area of the cut. The chainsaw should not go more than 1/3 through the tree. The bottom of the notch cut should be 1–2 feet (0.30–0.61 m) off the ground. Hold onto the handle tightly with both hands so you have full control over the chainsaw.
Step 2	Make a horizontal cut 1/3 through the tree. Use the chainsaw and make a clean, horizontal cut at the base of the notch that you created. This cut will make the bottom of the notch straight. Do not go further than 1/3 through the tree.
Step 3	Make a bore cut through the other side of the tree. A bore cut is when you insert the tip of the saw blade into the tree instead of cutting the tree from its side. Line up the chainsaw blade 1–2 inches (2.5–5.1 cm) away from the edge of the notch cut, and push it all the way through the tree. Then, continue sawing into the opposite direction of the notch until you make a clean horizontal cut through the other end of the tree. This will weaken the tree but won't cause it to fall over.
Step 4	Hammer wedges into the bore cut. Insert a wood cutting wedge into the bore cut that you created and hammer it 1–2 inches (2.5–5.1 cm) into the bore cut. Go to the opposite side of the tree and hammer another wedge into the opposite side of the tree.
Step 5	Cut through the remaining portion of the bore cut. Position the chainsaw on the opposite end of the notch and cut through the remaining wood connecting the tree together. If you've done everything correctly, the tree should start to slowly fall in the direction of the notch.
Step 6	Stand clear of the tree. You'll hear the tree crack and see it start to fall over towards the notch. As soon as you see this, turn off your chainsaw and walk down the predetermined path that you created earlier. Stand at least 15 feet (4.6 m) away from the tree.

CRAFTING Woodworking Cutting Wood Splitting Whittling Wood Types Types of Cuts

Limbing

Limbing in logging is the process of removing branches from the trunk of a fallen tree.

Hewing

Hewing is the process of converting a log from its rounded natural form into lumber (timber) with more or less flat surfaces using primarily an axe.

Log Bucking

Bucking is the process of cutting a felled and delimbed tree into logs.

Splitting Wood

Wood splitting is the breaking up of logs into smaller pieces generally for firewood.

Chopping Area	

Chainsawing

Whittling

Whittling may refer either to the art of carving shapes out of raw wood using a knife or a time-occupying, non-artistic (contrast wood carving for artistic process) process of repeatedly shaving slivers from a piece of wood. Softwoods are the best for whittling because they cut nice and easy. After you've learned the basics of whittling, feel free to move on to harder woods. No matter which kind of wood you use, look for wood with a straight grain as it is easier to whittle than wood that has the grain going in multiple directions. Avoid wood with lots of knots–those are a booger to whittle. For generations, whittlers have used nothing but their trusty pocket knife to create ruggedly handsome works of art. And some whittling purists will argue that the pocket knife is the only acceptable tool for true whittling. Pocket knives are certainly an excellent choice because they're so portable. Anytime you find a good piece of wood, you can just whip out your pocket knife and start sculpting your wooden masterpiece.

Whittling Tips
- Keep your knife sharp and the blade should glide right through the wood.
- Take extra precaution and cut away from your hands.
- Take it slowly, whittling is as relaxing as it is useful.
- Using gloves early on while understanding the different strokes can save your hands.
- Sometimes it's easy to tell the direction of the grain on a piece of wood simply by looking at it. Cuts made with the grain will peel away smoothly; cuts made against the grain will give resistance and eventually split. Cuts against the grain cause your wood to tear, split and the resistance makes whittling much more difficult.

Wood Types

These are the best types of woods you can use to whittle with.

Basswood	It's a good wood to whittle with because it's soft and doesn't have much grain.
Pine	It's soft, cuts easily, and is readily available. But it has its drawbacks. Some whittlers think pine doesn't hold detail very well. And if you're using a fresh pine twig or branch, you'll have to regularly clean the sticky sap off your knife while you're whittling.
Balsa	Balsa wood is a soft, inexpensive, lightweight wood that's perfect for beginning whittlers.
Twigs / Branches	Twigs and branches from most kinds of trees make for great whittling. There's nothing more enjoyable than sitting around a campfire and whittling away at a twig while you talk to your buddies. Wooden knives are a popular item to whittle from a tree branch.

Types of Cuts

These are the types of cuts you can use to whittle with.

Straightaway Rough Cutting	Use this cut at the very beginning of your project to carve your project's general shape. Hold the wood in your left hand and your knife firmly in your right. Make a long, sweeping cut with the grain and away from your body. Don't cut too deep or you might split the wood. Make several, thin slices to reduce the wood to the desired size and shape.
Pull Stroke (Pare Cut)	If you've ever seen an old-timer whittle, chances are you saw him using the pull stroke. It's the most used cut in whittling. To perform this cut, imagine you're paring an apple. Hold the wood in your left hand, the knife in your right with the blade facing towards you. Brace your right thumb against the wood, and squeeze your right fingers in order to draw the blade to your right thumb. Make your stroke short and controlled. Keep your right thumb out of the path of the blade. For added safety, wear a thumb pad. The pull stroke gives you lots of control over your blade and is best for detailed cuts.
Push Stroke (Thumb Pushing)	Sometimes where you want to cut won't allow you to do the pull stroke. That's when it's time to bust out the push stroke. Hold the wood in your left hand and the knife firmly in your right hand with the blade facing away from you. Place both your right and left thumbs on the back of the knife blade. Push the blade forward with your left thumb while your right thumb and fingers guide the blade through the wood. The push stroke, like the pull stroke, gives you greater control over your knife for detailed cuts.

Items to Whittle

You can whittle any item you want, but here's a few common ones to help you choose.

Kitchen Utensils	Spoon, fork, knife, cup, plate.
Useful Camp Items	Tent Stake, Fishing Spear, Whistle, Arrows.
Entertainment	Chess Board, Chess Pieces, Checker Board, Playing Cards, Pendant.
Gifts	Sentimental value objects like dolphins, stars, ducks, symbols, cross.
Advanced Items	Boat, Mural, Clock, Artwork.

8 Carpentry

Joint Types

Butt Joint		The end of a piece of wood is butted against another piece of wood. This is the simplest and weakest joint. Of those, there is the a) T-butt, b) end-to-end butt, c) T-lap d) Miter butt and e) edge-to-edge butt.
Mitre Joint		Similar to a butt joint, but both pieces have been bevelled (usually at a 45 degree angle).
Lap Joint		The end of a piece of wood is laid over and connected to another piece of wood. This is the next simplest and weakest joint.
Bridle Joint		Also known as open tenon, open mortise and tenon, or tongue and fork joints, this joint is where the through mortise is open on one side and forms a fork shape. The mate has a through tenon or necked joint. Bridle joints are commonly used to join rafter tops, also used in scarf joints and sometimes sill corner joints in timber framing.
Dowel Joint		The end of a piece of wood is butted against another piece of wood. This is reinforced with dowel pins. This joint is quick to make with production line machinery and so is a very common joint in factory-made furniture.
Finger Joint		Also known as a box joint, is a corner joint with interlocking fingers. Receives pressure from two directions.
Dovetail Joint		A form of box joint where the fingers are locked together by diagonal cuts. More secure than a finger joint.
Dado Joint		Also called a housing joint or trench joint, a slot is cut across the grain in one piece for another piece to set into; shelves on a bookshelf having slots cut into the sides of the shelf, for example.
Groove Joint		Like the dado joint, except that the slot is cut with the grain.
Tongue and Groove		Each piece has a groove cut all along one edge, and a thin, deep ridge (the tongue) on the opposite edge. If the tongue is unattached, it is considered a spline joint.

Mortise and Tenon		A stub (the tenon) will fit tightly into a hole cut for it (the mortise). This is a hallmark of Mission Style furniture, and also the traditional method of jointing frame and panel members in doors, windows, and cabinets. This joint is a good strong joint to use.
Birdsmouth Joint		Also called a bird's beak cut, this joint used in roof construction. A V-shaped cut in the rafter connects the rafter to the wall-plate.
Cross Lap		A joint in which the two members are joined by removing material from each at the point of intersection so that they overlap.
Splice Joint		A joint used to attach two members end to end.

9 Blacksmithing

Blacksmithing has been an essential skill for thousands of years, allowing the crafting of swords, armour and metal equipment.

Subheadings

1 Anvil

An Anvil is used to place your heated metal on so you can work it. Typically, working it means pounding it with a hammer but there are other ways to work heated metal. The pointed horn is made so you can hammer curved shapes out of your metal. The holes are so you can insert various types of jigs and moulds so you can do even more varied work. Typically an anvil will have markings on it that will display the company that made it and the weight of the anvil. As far as the weight goes there are several different ways that this is done. American made anvils will often be marked in pounds, European anvils often marked in kilograms and older anvils, particularly from great Britain could have a peculiar marking system called "Hundred Weight". It will be shown as three digits with a dot between each digit.

Something like this: 2 - 2 - 6

The HundredWeight Anvil marking: the first digit is multiplied by 112 pounds, the second digit is multiplied by 28 and the last digit is the remaining pounds. And all three of these results are added together. So an anvil marked with 2-2-6 would actually weigh 286 pounds.

Anvil Features

These are the features of an anvil.

Horn	Used for forming curves in metal
Cutting Table	Used for cutting metal. You don't want to cut metal on the face of the anvil. It could cause damage. The cutting table usually is of a softer metal than the face of the anvil.
Face	Where you do most of your hammering.
Pritchel Hole	A hole used to punch holes through metal.
Hardy Hole	Tools are placed in this so you can work use the tool. A good example would be a hot cut tool. it is placed in the hardy hole and it has a cutting edge on the top. So you place the metal to be cut on top of this tool then strike it.
Base	Hold the feet and adds strength.
Feet	Help stabilize the anvil while hammering.
Heel	The back end of the anvil opposite the horn.
Hardy Attachments	

2 Forge

This is the place where fire heats up steel and iron to a high temperature. The forge needs an air supply , bellows or fan, to blow on the fuel source in order to bring the temperature of the fire up above normal burning temperature. And forges come in a lot of different configurations. The forge is of course where you heat the metal. But you have to get the metal really hot and this takes a few distinct things including some kind of air source that will blow a strong air current on the coals. This raises the temperature significantly. In medieval times they used something called a bellows that had to be hand pumped or hand cranked. Nowadays we use an electrical device like a fan or blower. The Basic Idea - The coal or charcoal is placed in the container and cantered right in the middle where the brake drum is.

The blower blows a stream of air right up into it. The pipe extends down from the fire pot and it has a spring loaded cover on it.This way I can easily open it up and clean it. Coal is a great material for burning because it burns at a much higher temperature than regular wood, and depending on the amount of air that is available it can burn very hot - in excess of 3,500°F. The available air is important because it is a chemical reaction that is happening. And if you blow air through the coal you make more air available for the chemical reaction. Hardwood Lump Charcoal It is hardwood that has been burnt under pressure which concentrates the carbons. This causes it to burn much hotter than regular wood.

Types of Forges
- Mini Whitlox Wood-Fired Forge
- Atlas Knife Company Gas Forge
- Handy Forge
- Atmospheric Forge

Sword Forge
But we very much need something like this so we can harden, temper, anneal, and normalize a sword. To do these things you have to heat up the whole sword so you need a long forge with a long enough fire pit. That's what this forge is all about. A sword forge also solves the problem of heat treating a sword if you made it with the stock removal method. With that method you don't need a forge or an anvil. You can shape the whole thing with hand tools. But... you still have to heat treat the whole blade of the sword. And this is where the sword forge comes into use. Cut a 55 gallon drum in half longitudinally. This is the bulk of the forge. Add legs to it. They can be welded on or bolted on. Be sure to put it at a comfortable height to reach in and work on things. Now you need to put a tuyere in so the airflow can get in there. The feed tuyere is in the centre of the tube so the air can be distributed evenly to both sides. That tube that goes the length of the forge has a whole lot of holes drilled in it. And you can see that it stands up off the bottom of the barrel by about two inches. This is so it will be the right height for the fire bricks that will go in later. I will show you that. This illustration gives you a good look at the paddle system inside the forge. By rotating the rods we can rotate the paddies and control the airflow to sections of the forge. This picture shows the forge now completed. I have placed firebricks in it and a screen.

Forge Construction
The basic set up is an old rusty brake drum with a few pieces of pipe and hair dryer. This is really all you need and you can stand the whole thing up on top of some cinder blocks. In the case of this forge we used the deck from an old broken lawn mower. The deck is the part that protects the spinning lawn mower blade. We simply turned it over and it forms a nice pit for the charcoal. The drum brake is on top and the trap door is on the bottom. This trap door remains closed while the forge is going and you open it up to clean out all the fallen soot and coal. The most difficult thing here is to connect the pipes together and connect the pipe to the drum brake. You can do this all with welding or you can actually use plumbing pipes and thread it all together. Just be sure you don't use any galvanized piping. It can give off a toxic fume (lead). Attaching the Hair Dryer to the Tube: It really doesn't matter how you do this. As long as the hair dryer is a reasonable distance from the actual fire pot of the forge. I used some rubber hosing and clamps. You can just use duct tape. If the hair dryer is very close to the fire pot you might want to consider disconnecting the heating coils inside the hair dryer. The Trap Door: Also doesn't matter too much but you definitely need a trap door. It should have some kind of a way to seal it closed while forging and then easily open it afterwards so you can clean out all the debris and coal.

Coal Selection

There are variables when it comes to coal. Just like there are variables with everything else. Some of the things you might consider are the type of forge you have, the type of forging you want to do, the amount of money you want to spend among other things. But a good rule of thumb is that you can get a bituminous coal that is metallurgical grade. You can't go wrong with it. You get a hot fire and low smoke, low sulphur.

Amount: This of course depends on how much forging you will be doing. If you are doing an afternoon of forging then 20 pounds of hardwood lump charcoal should be plenty and 5 pounds of coal should do.
Temperature: The hardwood lump charcoal burns the coolest but it is more than adequate for most forging. I have used it many times to make knives and swords. Bituminous coal is the next coal, it is a softer coal and it burns hotter than the lump charcoal. Anthracite coal is a hard coal and it burns the hottest.

For amateur blacksmithing it doesn't matter much. Use whatever you can get. It is when you want to do some really good forging that you need to think about the coal. For example: Need to worry about the carbon content of a sword you are making? Or the impurities that it will pick up? Then you might want to consider a coal that is metallurgy grade. Got a lot of forging to do and need to efficiently get through it? Then you might want the hottest fire which is given with anthracite. If you are just tinkering around with blacksmithing it doesn't matter a whole lot what you use and I recommend you pick up a bag of Hardwood Lump Charcoal. I use it all the time and like it a lot. A 20 pound bag will last you a few hours of forging. Depending on how you use it.

Want to start out with a small amount of coal so you can get a sense for it. Depending on your forge and what you are doing you should be able to get a day of forging out of a 16 pound box of it. It is bituminous coal which means it is the softer coal and easy to light. But very hot.

Bituminous Coal	It is metallurgical coal which is superb for blacksmithing. That means high heat, good carbon content, low smoke and low sulphur content for clean burning.
Anthracite Coal	It is harder and the nuggets are more defined.

3 Techniques

The object of blacksmithing is to manipulate metal into a variety of shapes and there are a lot of different ways to do this. You of course heat up the metal in a forge then you manipulate it in a variety of ways on the anvil. Twisting and straightening metal are pretty straightforward and easy to understand but folding takes a little bit of extra know how. When you are folding over metal like I show you in the video you are forming air gaps between the layers. These air gaps have to be removed or it will cause weakness in the metal. You do this two ways: First by heating and hammering. This fuses and forges the metal into one piece but there still could be air gaps and you remove these by liberally sprinkling something called borax on the metal! This use of Borax is called using flux on the metal and it actually serves several purposes. It helps prevent the metal from oxidizing and it lowers the melting point of scale on the metal making it more liquid and helping it to squirt out contaminants.

Metal Techniques

Folding	When you are folding over metal like I show you in the video you are forming air gaps between the layers. These air gaps have to be removed or it will cause weakness in the metal. You do this two ways: First by heating and hammering. This fuses and forges the metal into one piece but there still could be air gaps and you remove these by liberally sprinkling something called borax on the metal.
Twisting	
Straightening	

Drawing Out Metal	It is the act of making a piece of heated metal thinner and longer, or thinner and wider.

Hammering Techniques

Parallel	Hammer flat onto the piece of metal.
Angle	Angle the hammer and the metal.
Half Face Near	Hammer the metal flat on the nearest edge to you.
Half Face Far	Hammer the metal flat on the furthest edge from you.
Edge Hammer Near	Hammer the metal flat on the nearest edge to you.
Edge Hammer Far	Hammer the metal flat on the furthest edge from you.
Back Face	Hammer the metal from the side of the anvil.
Shearing	Hammering the metal downwards over the edge of the anvil.

4 Steel Types

There are quite a few grades of steel that are used by knife makers and some others that I haven't mentioned are W2, W3, 02, 06, D1, L2 and L6.

Galvanized Steel	This is one of the most important aspects of safety when it comes to blacksmithing. Galvanized steel should not be used in any aspect of smithing. It shouldn't be put in a forge and it shouldn't be used as part of a forge. This latter aspect sometimes happens when people buy galvanized pipes to use as part of their forge. Galvanized steel gives off a toxic and even deadly gas when heated. If you are in doubt about your steel being galvanized talk to an experienced blacksmith or avoid the steel totally.
Heat and Burns	We all know that the fire and the coals and the flames are hot and dangerous. So... take precautions against that. But, one thing we often don't consider as a beginner is that steel or other metals in your forge might not be glowing red but still might be dangerously hot! So be careful handling metals in your forge. The end of the steel or iron that is glowing hot is dangerous yes, but the other end that doesn't glow red might also be hot!
Apparel	Long Sleeves Leather and long pants - Sparks fly and you can't predict when or where they will fly. You should always wear long sleeves and long pants when blacksmithing. You should also preferably wear some kind of a heat protecting welding apron.
Repetitive Stress Injuries	If you are blacksmithing a whole lot you should be conscious of the fact that swinging a hammer thousands of times can cause serious repetitive stress injuries. So, be conscious of good hammer technique and watch for unusual aches and pains in your hand, shoulder and elbow. One thing to watch for is to not place your thumb on the handle of the hammer when hammering. Wrap your thumb around the handle.

5 Steel Temperature

Below is a colour temperature guide for determining the heat of a metal.

Colour	Manipulation	°C	°F
White	Forging Temperature	1315°C	2400°F
Bright Yellow	Forging Temperature	1093°C	2000°F
Dark Yellow	Forging Temperature	1037°C	1900°F
Orange Yellow	Forging Temperature	982°C	1800°F
Orange	Forging Temperature	926°C	1700°F
Orange Red	Forging Temperature	871°C	1600°F
Bright Red	Forging Temperature	815°C	1500°F
Red	Forging Temperature	760°C	1400°F
Medium Red		704°C	1300°F
Dull Red		648°C	1200°F
Slight Red		593°C	1100°F
Very Slightly Red		537°C	1000°F
Dark Grey	Tempering Temperature	426°C	800°F
Blue	Tempering Temperature	301°C	575°F
Dark Purple	Tempering Temperature	282°C	540°F
Purple	Tempering Temperature	271°C	520°F
Brown / Purple	Tempering Temperature	260°C	500°F
Brown	Tempering Temperature	248°C	480°F
Dark Straw	Tempering Temperature	240°C	465°F
Light Straw	Tempering Temperature	229°C	445°F
Faint Straw	Tempering Temperature	198°C	390°F

6 Weapons

Steels for Knifemaking

One of the first challenges you face when making a knife is getting the right steel. For the most part you will be using tool steel. This is pretty standard stuff for knifemaking. But there are a lot of different types of tool steel and they all have different characteristics when it comes to how they are treated, how they are worked and how they are as a final knife. Steel is an alloy -that is a melding of two or more different ingredients. And in the case of tool steel it is a combination of Iron and Carbon.

Pure Iron, also known as "Wrought Iron" is no good for knife making because it is very soft and very brittle. When a certain amount of carbon is added to Iron it becomes much stronger and tougher. Steel is a combination of Iron and Carbon and the amount of carbon that is added to the steel makes a big difference.

Just a small amount of carbon is added and the strength of the steel is significantly improved and this continues up to about .65% of added carbon where maximum strength is achieved. Adding more carbon does continue to improve the wearability and durability of the steel all the way up to around 1.5% carbon added.

So this adding of carbon to the steel in this range creates something typically called plain carbon steels and blacksmiths will work within this range of about .4% to 1.5%. There are quite a few different type of tool steel that are used in knifemaking and for the most part they are determined by the amount of carbon added to the Iron and the amount of some other type of ingredient such as Chromium or Nickel. The addition of these other ingredients add some beneficial characteristics.

01 Tool Steel	Contains about 1% carbon and has small amounts of chromium and tungsten added. These make it a great candidate for oil quenching. It is more stable than steels that are water quenched. You harden then temper this steel. Harden by heating to red-orange then quickly dipping and swirling in oil. You temper by heating to a colour controlled temperature. (The colour changes as the tempering changes for example you want to temper the edge to a certain point of hardness and strength but you don't want to temper the whole blade to that same hardness)
D2 Tool Steel	Contains about 1.5% carbon and also has chromium and molybdenum added . The chromium which is about 12% adds significant stain resistance and wear and corrosion resistance.
440C Tool Steel	This grade of steel is popular for pocket knives and smaller knives. It is good for making blades that are smaller and that get lighter use. It is also stain resistant. Typically the carbon content for this type of steel can vary from between .95% and 1.2% and it has 16 -18% chromium added.
154CM Tool Steel	This is a very strong steel that has great corrosion resistance and good edge holding power. This is achieved by replacing some of the Chromium content with molybdenum. It has 1.05% carbon, 14% Chromium and 4% Molybdenum along with small amounts of Manganese and Silicon.

Types of Knifemaking

Stock Removal Method	The Stock Removal Method of knifemaking: This is where you start out with a piece of steel, draw a pattern out on it and then use tools to cut out the profile of the blade. You get the whole knife including tang to the exact shape you want. You can use any number of metal working tools including a hacksaw, jeweller's saw, cut off grinder, bench grinder, belt sander and more. This method is often the method of choice for beginners because it requires less of an investment in time and skill. And you still make a perfectly beautiful knife.
Forging Method	This method is quite a bit different than the stock removal method. You work your billet or piece of steel on the anvil to bring it to the desired knife shape.

Steels for Knifemaking
You can get off to a good knifemaking start with a piece of flat stock tool steel. The size of the stock will of course depend on the size of the knife you make but if you are just generally wanting to make a few knives you can do a nice job with stock that is between 1/16 and 3/16 inch thick and about 2" wide. From there it is a matter of the length you want. Recommended to start with either 01 or D2.

See the MATERIALS > Metal section for more information on different types of steel.

Damascus Steel Knife

Materials
- 1 blank knife billet (of Damascus steel)
- A piece of hardwood for the handle
- Amazing Mould putty to make a mould of the handle
- Amazing Clear Cast to make the clear acrylic handles
- About 6 inches of 1/4" brass rod for the pins
- About 6 inches of 1/8" steel rod to pin the finger guard
- Hacksaw, mill files
- Memory paper
- 4" belt sander (optional)

The first thing you need to do is draw out your knife. Keep it within the size of your blank of steel. How do you want the knife to look? How much blade? How much handle? Put your hand on that drawn handle. Would it be large enough? If you have never done any knifemaking or metal work I recommend you keep it very simple with a minimal of sharp curves and angles. This is because sharp curves are more challenging to cut. And finally I settled on this. I like it. It has a bit of curve to it but it isn't too crazy. Should function well as a knife and be comfortable. Now trace your pattern all the way around the perimeter of it. This is so you have something called the profile of the knife. You can also think of it as the outline. Cut that pattern out. It is now a template for your knife. Apply an adhesive to the template. Coat the whole thing. If you have a spray adhesive you should use it. We want a good and even adhesion.

Now affix that template to your piece of steel. You should carefully look over the piece of steel. How do you want the pattern to show off the best? Flip the bar over, turn it left/right. Decide what section would be best where the blade is and then adhere your template to the steel. Now let's flex our muscles and start doing the actual work. Start our with a hacksaw and cut all the way around the template. Remove as much steel as you can. A hacksaw isn't great for curves but you can get somewhat of a curve out of it. Just do the best you can. Take your time and remove as much of the stock as you can. This is why it is called the stock removal method of knife making. You are simply removing all the stock around the pattern of the blade. You can make multiple cuts. Take out pieces as you can. Try different angles of cuts. Continue removing steel any way you can with the hacksaw.

Now use any other tools you have available to you in order to get it down to the actual template shape. The next step I did was use a 4 inch belt sander with an 80 grit belt. I used a variety of metal working tools to achieve my profile. They include mill files, a one inch belt sander and a dremel for the hard to reach curves. And there you go. Keep at it until your knife is profiled. It looks good. Touch it up with some emory paper. Lets start by making the bevel in the blade. I drew it out with a sharpie. This is what we are looking for on both sides of the blade. We do it with a file. And we use a mill file. The picture here shows a close-up of a Mill File. There is no crosshatching. A quick note about filing your blade - You have to follow good form with your filing. First off always use a Mill file. This is the kind of file that has only one set of angled grooves. This is rather than something called a bastard file that has a crosshatch of grooves.

The bastard file will leave a rough finish. And, when filing you only file in the forward direction. See how in the previous picture I am holding the handle with one hand and pressing down on the front part of the file with the other hand? This is the technique you want to use. Press down as you move forward, then lift the file right off the knife and return to start. File forward, lift and return, file forward, lift and return. Ok, the bevel is off to a good start. We continue this on both sides of the blade. I made and used a file jig to make the filing easier and more accurate. I will be posting a tutorial on how to make one of these. Look for that link here. I recommend you don't file it all the way down to a sharp cutting edge. This makes the steel very thin. And it could cause challenges when hardening and tempering the knife with heat. That thin steel could easily overheat. Next we make the brass finger guard. I start by making one out of foam board so I can tinker with sizes and the feel of it. When it looks good, make it out of brass. To cut the brass finger guard I first drilled a hole at the end of the slot. Then I cut out the slot with a hacksaw. And finished it off with a file.

Next drill the handle holes according to the template. I am drilling quarter inch holes because I will be using quarter inch brass rod stock. I am going to make the handle out of a clear epoxy resin. But first I need a mould so I can cast the resin. And I do this by first making the handle pieces out of wood. The thickness here is about an inch and a half. That gives us a little bit of extra when we carve it down. I first drilled out the holes in the whole block so they are an exact match to each other and to the knife. Then I cut that handle right down the middle, creating the two handle halves. Each is about 3/4 of an inch thick. At this point you could call these two wooden handle halves knife scales. Next assemble the handles to the blade and pin it all together with wooden dowels. I am using wooden dowel because this is just a temporary assembly.

Secure it in a vice and use a rasp to shape the handle to what you want. These handles are nice but we want to make clear resin handles so that we can see the Damascus pattern through them. We are going to use a very easy method to make moulds of the handles. This is something called amazing mould putty. Yup, it is actually called that. You mix equal portions together. Mix it quickly. You only have a few minutes of workable time. Form it around the wooden handles. Once the mould has set, according to the directions of the particular product you use, you can remove the handle pieces. Next we mix up a two part resin. Equal amounts of each.

And then pour it into the moulds. Now we let it set according to the directions. In the case of this product it will take between 24 and 48 hours to fully cure. The purchased blank of Damascus steel is annealed. This means it is soft and workable by tools. Which is a good thing. Otherwise we wouldn't have been able to cut and file it. But this is no good as a functioning knife. It needs to be strengthened by hardening and tempering. This will make the knife durable and strong. It will keep a sharp edge. Yet it will still have some resiliency so it doesn't shatter or crack. Our first step is to heat up the blade of the knife. We don't have to worry much about the handle. We focus on the blade. We are going to heat it up to about 1500 fahrenheit. It will be glowing red hot. And at this temperature the crystalline structure of the steel will have change. But how do we know when it is at the right temperature? We check it with a magnet. The steel is magnetic.

When it gets to the temperature we need it will lose its magnetism. So, as it is getting red hot check it with a magnet. Once a magnet no longer sticks to it, put it back in the fire for another 30 seconds. Then quickly and efficiently plunge it into the quench. It needs to drop by about 500°F in less than a second. This will give us a good hardening. About the quenching liquid. This will depend on the type of steel or steels in your knife. Generally with Damascus water is used. It will help with the quick dropping of temperature. It is also a bit more risky. The quick drop in temperature may crack the knife. I am using used motor oil that I have pre warmed by plunging a hot iron into it. This technique potentially doesn't give us as good a quench but it does decrease the risk of cracking. We may get a knife that is not as hardened as it could be. It is a trade off. The knife is now hardened. You can check it by gently running a file over it. You will hear the difference. It will be like sliding a file over glass. The file won't bite the steel it will glide over it. Next we will temper the knife. In it's current state it is very hard. But it is also brittle. If you were to drop it onto a hard surface it could possibly shatter. That is not a good characteristic of a knife.

What we want is to find a balance where it is strong and tough so it will be durable and hold a good edge. Yet we want it to be soft enough to take use without cracking or shattering. We find this balance of characteristics by now tempering the blade which is heating it to a bit of softness. Start by cleaning off the knife with some emory paper. As we are heating it we will watch the changing colours of the steel. Now we are going to slowly heat the blade to about 500 fahrenheit. Do this slowly. Place the knife a distance from the fire like you see here. And notice how I have the spine of the knife toward the fire. This is a good technique and it helps prevent the thin edge of the blade from heating too quickly. How do we know when we have achieved the right temperature? We can't check it with a magnet this time. That would be about 1500 F. But we can monitor the colour changes as it heats up. We bring it up to wheat colour. This knife is just about there. You can see it starting to turn wheat. A little bit more. Quench it once it gets to wheat colour. The knife has been blackened by the forge. Clean all that off with a fine grit emory paper. And then clean the whole thing very thoroughly with acetone. We want to get it very clean. Any impurities on the blade will impede the etching.

About Etching: There are a lot of different ways to etch a steel blade. The method we use is pretty traditional and it has been done this way successfully for a long time. But it uses toxic chemicals. So... this is something not to be done lightly and only by adults with some skill.

Safety Note: I am using Ferric Chloride for the etching. It is a very commonly used acid for the making of circuit boards. It must be handled carefully and you should take all safety precautions including gloves and a respirator. And, once you are done with it you should neutralize it with baking soda then dispose of it properly by contacting your local municipality and asking them where to bring hazardous waste. Do not pour it down the drain. Research the handling and use of ferric chloride more thoroughly before ordering and using it.

If all of this is a bit intimidating there are alternative etching methods such as using vinegar and salt. I diluted the ferric chloride by mixing it with distilled water. I used three parts water and 1 part ferric chloride. And note that when mixing water and acid you always add the acid to the water. Never ever add the water to the acid. This is important. Things like this are why I recommend researching this whole thing a bit more if you are going to use it for etching. Interesting Tip about etching in acid. You might think that the stronger the acid the better. But this isn't really the case. We don't want a fast etch. This will leave it irregular, pitted and unsightly. We want a nice slow etch. It will be much better. I diluted my acid and then soaked the knife in it for 15 minutes. And I am confident that it would have been even better if I would have brought the soak time up to 30 minutes. Just use the minimum amount needed to cover the knife.

No need to mix up more than is needed. Carefully, using a wire, set the knife into the acid so it is completely covered. You can carefully check on the progress of the etch. And when it is ready you can transfer it to a neutralizing bath. That second tub is water mixed with a large amount of baking soda (Calcium Carbonite). Once it has been neutralized you should then rinse it very thoroughly with plain water before handling it. We have waited more than 24 hours and the handles are cured so we remove them. Now, if needed clean up the handle pieces. I used a light grit emory paper. It is a bit frosted and we will clarify it later by adding a coat of casing resin to it later, after we have completed the knife. Now drill out the holes in those resin handles. Use the knife itself as a guide.

Next we glue those handle pieces to the knife and pin them in place with brass pins. I am using a gorilla glue clear epoxy resin. I want a clear epoxy so we can still see the Damascus through the handle. Mix together equal parts of the epoxy then spread a thin coat on both sides of the knife. Note something in this picture. I have mounted the brass finger guard on the knife before attaching the handle. You can do it either way but be sure you have a nice clean edge between the two. This may take some sanding of the handles or the brass. To attach that brass guard I drilled two holes all the way through. And then pinned with 1/8 steel pins. Apply the handles and pin them in place. And clamp the handle in place. Use any tools you have available to get the shape and the form of it just the way you want it. This includes the finger guard matching the handle well. I used a 1 inch belt sander. And I used a file to bring down the brass pins so they are flush with the handle. I also used the file on the finger guard. And we finish off the knife by cleaning up the resin handles. They are cloudy and the filing and sanding has further clouded them. Mix up a small batch of the same resin you used to cast the handles. Then paint that on. It will clear up the handles. Now we can see the Damascus pattern through the handles. It will improve as the resin dries.

Rebar Knife

Rebar is a readily available building material. There is lots of it around and it is pretty cheap. It is also pretty easy to work with. So, in terms of blacksmithing it is a nice material for beginners to work with. In this tutorial I show you how to make a simple knife with it. And along the way I show you a few different techniques like bending steel and hardening/tempering it. We leave the ribbing on part of the knife creating a nice looking spine. We flatten out the blade. We make the first curve on the handle using a hammer. We make the second curve on the handle using a turning tool in the Hardy Hole. Here is our piece of Rebar. It is fifteen inches long. We start by heating one end and flattening out the blade. We don't flatten it completely to the blade shape. We are just getting it to the rough shape of the blade we want in terms of size, thickness and length. Notice how you can see the ribs on this side of the blade. Let's leave those alone. They will look good on the spine of the knife. This is something to think about when working with materials. Sometimes they have a nice attribute that we want to take advantage of or use. With the basic shape of the blade done we are going to turn it around and work on the handle.

Let's start by hammering in the point at the very end. Once the point is done we want to make the curves in the handle. There are two curves, a small one and a large one. We want to make the small curve first. This is an important thing to note when making curves. Sometimes you have to be conscious of which curves to do first. This is because once you put a curve in you might have difficulty getting at the metal to make subsequent curves. So, before curving you should think about the best way to do it. For this knife it is definitely easier to make the outer curve (the smaller curve) first. This is an easy curve, not very sharp so we can do this with the hammer directly on the anvil like you see in this picture. Now, to get the larger curve in the knife we are going to use something called a hardy tool. It goes in the square hole in the anvil. This particular tool is made for turning steel and making curves.

We put the knife in the tool and then pull on it with a pair of pliers. See how it bends around one of the posts? Easy enough to do. You can make all kinds of curves and curls with this tool. So, I tinker with that curve a bit to get it just the way I want it. Ok, now we return to the blade and finish rough shaping it into an actual blade. I also round out the end of the blade. It is difficult to see here but I am holding the knife on the anvil on its edge not on its flat and I am rounding off the edge. And notice how the spine is still pretty intact with the initial rebar pattern. We like that a lot! And finally we finish it off by tapering the blade. The spine or back part of the blade remains thick, while we hammer the cutting edge so it is thinner. We want this to be a nice sloping bevel from thick to thin. Ok! The forging is done and it looks pretty good. We can take it into the shop and work on it some more. When it comes to the shop work we follow a certain process that is common when working with any kind of tool. We start with the rough work, usually with power tools. Then we move on to the more detailed work, usually with hand tools. Now we take the knife into the shop and we have two tasks - clean it and shape it. You can use power tools for this and you can use hand tools, or any combination of each. The picture shows me using a four inch belt sander. In the background you can also see the one inch belt sander and a grinder. The knife is cleaned and close to final shape. Next we move on to files. To further refine the shape and the finish.

A quick note about filing your blade - You have to follow good form with your filing. First off always use a Mill file. This is the kind of file that has only one set of angled grooves. This is rather than something called a bastard file that has a crosshatch of grooves. The bastard file will leave a rough finish. The picture here shows a close-up of a Mill File. There is no crosshatching. And, when filing you only file in the forward direction. See how in the previous picture I am holding the handle with one hand and pressing down on the front part of the file with the other hand? This is the technique you want to use. Press down as you move forward, then lift the file right off the knife and return to start. File forward, lift and return, file forward, lift and return. Then we move on to a series of emory paper. Just for the polishing of the blade. You do this through a series of grits starting with coarse grit and moving through subsequently finer grits. Typically you start around 100 grit and then movie on to 200, 400 and 600. This gives us a decent polish. Now we need to finish off the blade, so it is back out to the forge to harden and temper the blade so it is useable as a knife. The first thing we want to do is harden the blade. we do this by heating it to red hot. That will be about 1,500°F.

We know we have it at the right temperature by using a magnet on it. When it is red hot heck it with a magnet. When it no longer sticks you have reached the right temperature. This is called Curie temperature. The steel has changed its molecular arrangement and is now very hard. You will get good at finding this temperature just by the colour of the steel. I can see that this is not quite hot enough and it needs to glow more red before it is at the right temperature. Now, to lock those molecules in their hardened configuration you quench the knife in oil. This cools it very quickly not allowing the molecules to go back to their original pattern. But, hardened steel is very brittle! It can easily shatter or crack. So we actually want to soften it up a little bit. This process of softening it is called tempering. We monitor the process of tempering by checking the colour of the steel as we heat it.

We know the steel is at the right temperature when it is wheat in colour. So.. clean off the blade of the knife with emory paper. It is very easy to clean at this point. Now we will be able to see the steel as it changes colour in the forge. We want to heat it slowly and only to about 450-500°F. To do this you put something over the forge like this that will support the knife blade about six inches from the fire. This way it heats slowly. Rotate and turn the knife over regularly. Monitor it closely. This is just about right. A little bit more heat and the wheat colour will darken more. Just be careful not to overheat it. A blue/plum colour will set in. That means it is getting too soft. Once it gets to that wheat colour quench it again. This quench isn't as hot so it won't be as dramatic. Just a little smoke this time. And that's it. The knife is now hardened and tempered. Which means it has strength. It will keep an edge very well. Yet it has a little flexibility to it so it won't snap easily. Now we just need to do the final sanding. Use emory paper, starting around 100 grit and work your way up as high as you want. The higher the grit you go the more mirror-like the finish of the blade. You can go as high as 1500 to give you a mirror like finish. Congratulations! Your Rebar Knife is done!

Railroad Spike Knife

This is an easy blacksmithing tutorial. It is one of the first projects that a person might make when first starting out in the craft. It is pretty much a staple project of the art. We do a down and dirty, quick and easy knife. If you are new to blacksmithing this is a great project to start out with. And you don't need a whole lot of guidance for this project. You can pretty much visualize the shape of the knife and then hammer it into that shape. Variety of hammers - they make a big difference when it comes to blacksmithing. Watch the video if you want to see the various hammers in action. The more blacksmithing you do the more hammers you are going to accumulate. Okay! Inspect the spike. A little bit of rust is quite ok. The forge will burn it off. No need to try to remove it. Heat it nice and evenly. But you don't have to worry much about the butt of the spike. We aren't going to be working that part of it. This looks great. It has a nice even colour and needs just a little bit more heating.

Once it's heated give it some hits with a heavy hammer. I am using a 3 1/2 pound hammer here. Just to start to flatten out the blade end of it. And do this evenly on this side, then flip it over and do it on the other side too. Now, I am not hammering directly flat down on it. We don't want to flatten it exactly even. We are leaning toward one side of it. That is because the spine of the knife is thicker than the blade. See how the Blade is starting to take shape? And see how you can now determine which side is the actual edge to be sharpened is. This is what the leaned hammering does. And just like that, with a little bit of hammering our knife is starting to take shape. So, continue heating and hammering. As you are doing this you will start to get a feel for the malleability of the metal and you will get a sense from that and from the colour as to when it should go back in the forge for more heating.

Now we start to define the difference between the blade and the handle. This is where the blade is flatter and it flares into the handle. How do we do this? We do something called half face near hammering. This is where we put the piece on the edge of the anvil and hit it with the hammer with the centre of the hammer right about at the edge of the anvil. Hitting it right about where the white arrow shows. This area of the knife where the blade tapers into the handle is called the choil of the knife. Keep an eye on the spine of the knife. Working it will distort it a lot which is ok. Just keep looking at it and bringing it back into shape along a centre line. And you can see how you have to hammer one side of the knife and then flip the knife over and hammer the other side. This will keep it along the centre line. (White line is added to show the imaginary centre line.) Ok, it is looking good and the major shape has been formed. Now we can switch to a lighter hammer and do some more work on it. But with the lighter hammer we can get more accurate. Ok, starting to look pretty good. It is pretty straight and starting to thin out nicely. It needs more work because it is still way too thick for a knife. Keep at it. Keep hammering, flattening and straightening.

But with the lighter hammer. I like the shape. It is just the way I want it. Now I switch to an even lighter hammer to do the lighter detail work, further getting it right about to where I want it. Don't try to get it exactly to your final knife shape. We will do that work with sanding. Keep it a little oversized in every dimension. We are just about done with the blacksmithing part of this knife so one more thing to show you. Remember that half face near hammering we did at the choil? Well, we can further work on this with a cross peen hammer and a ball peen hammer. this will allow us to shape it exactly how we want. One final step. Now I want to smooth it out and give it a fairly flat and even surface. I do this with a nice smooth hammer. A planishing hammer would be great for this. I am using the flat end of a ball peen hammer. The Forging is done and this is what we have. Just a little bit of work left to do to finish off this knife. We are going to use whatever power tools we have in order to do two things. We are cleaning it up and doing the final shaping. Cleaning it up isn't polishing. We will do that by hand.

And during this process I actually switched belts. I started out with a heavy grit and moved on to a medium grit in this picture. This is for the same reason we switched hammers at the forge. We do heavy and rough work first and move consecutively down to the medium then finer work. The first belt is around a 50-80 grit. This second belt is around 120-150. And at any time during this process you can also use a file to shape it. If you don't have a belt sander you can do all of this shaping and cleaning work with a file. Note about the file: You use a file called a Mill file. This only has one set of cutting lines. You don't use a bastard file (it has a crosshatch). And with the mill file you only file in the forward direction. You don't go back and forth with the file. Do the filing to get the knife to it's final shape. This picture shows the correct type of file (Mill file) see how there is just a series of cutting lines parallel to each other? There is no crosshatching.

HARDENING AND TEMPERING
Ok, just a little bit more to go. We need to heat treat this knife so it is strong and durable and will hold a nice sharp edge. There are a few different ways to do this and you can use the forge. But in this tutorial I am going to use a plumbers torch. First we harden the knife. We do this by heating up the blade to red hot. This will be about 1,500°F. You know it is at the right temperature when a magnet no longer sticks to it. Once it is at the desired temperature quench it quickly in oil. Any kind of oil will do; vegetable or motor oil, used or new. Doesn't matter. The knife is now hardened. But hardened means it is also brittle and susceptible to shattering when being used so we want to soften it up a bit. This softening is called tempering. And we temper it by heating it up just a little bit. To around 500°F. But how do we know when it is at the right temperature? We know this by the colour of the steel as it heats. Once the knife has cooled clean it up with emory paper. This is very easy to do. The scale comes right off.

Slowly and with the flame further away, heat the blade up until it turns a wheat colour. That is the right temperature. Try to keep it even along the length of the blade. Move the flame! This knife has started the wheat colour but could go a little bit further. It is pretty close though so I am going with it. Quench it again. And that's it. The knife is hardened and tempered. Now we just need to polish it up to give it a nice shine. We do this with a series of emory paper. As before we start with the heavy grits and work our way through the finer grits. I usually start around 80-100, switch to 180, then 220, 400 and 600. If you want it mirror polished you can continue like this all the way up to around 1200 grit which is almost like a sheet of paper fine. And that's it! Your Railroad Spike Knife is done.

Sub Hilt Knife

Push Dagger

Medieval Rondel

Karambit Fighting Knife

Throwing Knife

Dagger

Sword

This is a quick overview of the steps normally taken to make a traditional sword. There are variations on this process but this gives you a nice overview of the whole thing and how to do it. This is the most common way swords are made. It takes six distinct steps:

1	Forging A bar of the desired metal or combination of metals is heated in a forge and then it is hammered into shape. This hammering process can take a long time. This is called drawing out the sword. The sword is worked on in sections (usually around 6 inches in length) and repeatedly hammered and heated until the sword comes into the desired shape. This process is repeated and the sword is often heated then allowed to cool without hammering. This is required by the metal to keep the desired properties of strength and flexibility.
2	Annealing When the final shape is complete the total sword is heated and then allowed to cool very slowly. Often it is wrapped in an insulating material to slow down this cooling. It can take as long as 24 hours and this process is called Annealing and this makes the sword soft and easy to grind.
3	Grinding Now the blacksmith uses a grinder to work out the edge and point of the sword. This would also be when any engraving is added. This is not a completed sword yet. It is still much too soft.
4	Hardening Now the sword is heated to a very high temperature and then placed into a quenching tank. This quenching allows it to cool quickly and evenly which will harden the metal.
5	Tempering Again the blade is heated and quenched. But now the heating is at a much lower temperature than was used at the hardening. This heating/quenching cycle may be repeated several times. This tempering allows the blade to be strong but not brittle. It will have a certain amount of flexibility yet still retain its sharp edge.
6	The sword blade itself is now complete. Now the additional parts will be added such as the pommel the guard and the hilt.

8 Bullets

9 Melting Precious Metals

Melting Silver

Silver is the most common of the precious metals. It's used in jewelry, electronics, medical supplies, and a number of industrial uses. Until the end of the nineteenth century, silver was also a major medium of currency throughout the world. As a result, silver is abundant in our world. As an abundant precious metal, people today like to work with it for a number of reasons. However, while silver is attractive and is a good metal for beginners to start with, melting any metal is a relatively complicated thing to do if you have no experience. Fortunately, with some knowledge, work, and the proper supplies, it's possible for someone with no experience to begin melting and casting silver at home.

Preparation

Secure items to melt. You need to find some items to melt down. Luckily, although silver is considered a rare metal, it is fairly common in our day-to-day activities. Some of the most common uses for silver are jewelry, although we can still find a substantial amount of silver coins, as well as silver in industrial applications.
● Traditional uses for silver include creating coins, jewelry, decorative items and cutlery. These items are most commonly used when melting silver.
● Industrial uses of silver include batteries, ball bearings, soldering or brazing other metal items, as an industrial catalyst to create chemicals, and in electronics such as circuit boards, membrane switches, and television screens. Be careful when melting anything that might contain hazardous materials.
● Emerging technologies which utilize silver include medical, solar energy, and water purification. Silver minimizes bacterial growth by interrupting the ability of the bacteria to form chemical bonds and is used to prevent the spread of bacteria and to promote healing.

Get a foundry crucible. A foundry crucible is a container that is used for metal production. Crucibles are made of clay, aluminum, graphite, and silicon carbide. They are extremely heat resistant and will not melt under the same circumstances as the metal you are trying to melt down.
● Make sure you get a crucible that is an appropriate size for your project and is in good shape. Avoid old crucibles with cracks or excessive wear.
● You will use your crucible to store your silver as it melts and turns into its molten form.
● You will then poor the molten silver out of the crucible into a cast or mold.
● You can purchase a foundry crucible at a local casting supply store or at many online retailers.

Find some good heavy-duty crucible tongs. Crucible tongs will be used to move your crucible if you need to. These are an important element, because your crucible will be way too hot for you to touch it with your hands or even with gloves. Make sure:
● Your tongs are rated to be used with a crucible.
● Your tongs are in good working order.
● Your tongs are large enough to move your crucible.
● Purchase your crucible tongs at local hardware or metal casting stores or online.

Buy a graphite stir rod. You should get yourself a good graphite stir rod. You'll use the stir rod to stir your molten silver and to make sure that it is completely melted before you cast it in a mold.
● Make sure you get one that is rated properly.
● Make sure you buy one that is long enough for whatever level of melting you'll be doing.
● Purchase your graphite stir rod at a local casting supply shop or online.

Secure a furnace or a blow torch. The furnace or torch is what you'll be using to heat your silver to its melting point. As such, the furnace or blow torch are critical items in melting silver. Depending on the amount of melting you'll be doing, you can choose between a furnace or torch. Consider:
● A furnace might be prohibitively expensive if you are only doing small-scale melting like several ounces every couple of weeks. However, if you're doing projects every weekend or more often, you should consider a furnace.
● A blow torch might be inefficient if you are melting substantial amounts of silver.
● If you are starting out, you might want to start with a blow torch and then move up to a furnace once you are committed to melting silver.
● These items may be purchased from a metal casting supplier, specialty hardware stores, or online.

Make or create a mold or cast. Molds and casts will be the way you shape your molten silver to create a final product. As a result, they are critical for your silver melting operation. Consider:
● Molds and casts can be made from wood, certain alloys, ceramic, or clay.
● Molds and casts may be one of the most inexpensive of your supplies.
● You can make your own molds or casts or buy them from specialty casting stores in your community or from online retailers.
● To make your mold: pick a material and like wood or clay. Carve or shape your material to the size and using the detail desire. If you're using ceramic or clay, you'll need to fire them at temps over 1,000 degrees Fahrenheit or 537 degrees Celsius.

Purchase safety equipment to protect yourself. Melting silver, or any other metal for that fact, is potentially very dangerous. You need to get yourself some good safety equipment to protect yourself. Remember to take lots of care when you melt silver, and do not do so unless you are properly protected. Make sure to get:
● Industrial-grade goggles that are rated to protect against molten metal.
● Industrial-grade gloves rated to protect against molten metal.
● Industrial-grade apron rated to protect against molten metal.
● Industrial-grade face shield rated to protect against molten metal.
● You can purchase safety equipment from metal casting supply shops or from online retailers.

Melting

Put on your safety gear and secure the area. Before you even start the process of melting and molding your silver, you need to take out and put on all of your safety gear. Melting any type of metal is a very dangerous activity, so there is no reason to take any chances.
● Put on your goggles, your gloves, your apron, and your face shield.
● Take out your skimming rod and any other materials you'll need during the process.
● Inform family or roommates about what you're doing and lock up any dogs or other pets in an area far from your smelting workshop.

Place the crucible with the silver object on or in your furnace. The first thing you need to do is to put your silver in the crucible and place it on or in your furnace. This will vary depending on the type of furnace you have. You don't want to heat up your furnace and then place your crucible inside, as this will increase the chance of you hurting yourself.

Heat the furnace to a temperature which exceeds the melting point of silver. The first thing you need to do is heat your furnace to the appropriate temperature. Depending on what type of furnace you have, this might take a little or a lot of time. Consider:
● The melting point of silver is 1,763 degrees Fahrenheit or 961.8 degrees Celsius.
● Monitor the temperature inside your furnace as it heats. Most furnaces include a temperature gauge to help you monitor it. If not, have one installed.
● Don't remove the silver until it is completely melted.
● Only use your furnace outside or in an extremely well-ventilated area designed for foundry work.

Apply your blow torch to the silver, if you've chosen to use a blow torch. If you're using a smaller crucible and are melting on a smaller scale, you might have chosen to use a blow torch to melt your silver. If this is the case, take your blow torch and apply it to the silver. Keep your torch on the silver and it will slowly heat the silver up.
● Make sure you know how to use your blow torch before you start to melt your silver.
● Direct the flame directly at the silver item.
● Temperature will be difficult to monitor with a blow torch. However, many blow torches come with a temp. gauge attached. If you don't have one, just wait for the silver to melt completely.
● The amount of time it takes to melt the silver will depend, based on the alloy composition, as well as the size of the object.
Break large silver objects into smaller pieces and melt them in small batches to allow a more even distribution of heat which results in a quicker melting process.

Molding

Remove the crucible once the silver has melted. Once your silver is melted, you're going to need to remove your crucible from the furnace (if that's what you've used), and get ready to cast your molten silver. Be careful doing this, as it is potentially dangerous. Make sure to:
● Put on your gloves.
● Take your heat resistant tongs and grip the crucible.
● Place the crucible next to your cast or mold.
● Make sure you wear shoes and your other safety equipment.
● If you're using a blow torch, take your tongs and move the crucible next to the mold you'll be using.

Skim the slag off of your sliver. Using your graphite stir rod or another tool, skim the slag off the top of your molten silver. Slag is impurities and other materials that have separated from the silver during the melting process. Slag might be a result of non-silver items being melted with silver, or it may be the result of the silver having impurities in it. Regardless of the reason, always skim and remove your slag before you pour and cast your silver.
● Take your rod and gently and evening slide it over the top of the molten silver.
● Then slide the flat side of your rod underneath the slag and lift it out of the silver.
● Place your slag someone safe, as you might want to melt it again to remove excess silver.

Pour the silver into the mold, quickly. Once you've removed the crucible from the furnace, and sat it next to your mold, you should quickly pour the molten silver into the mold. You need to do this quickly while the silver is still liquid. Don't move too quickly, as you don't want to spill the silver or hurt yourself. If the silver does begin to firm up into solid state, just put it back into the furnace to heat it back up.
● Melted silver can be poured directly into molds, or casts, to create a number of items including jewelry, decorative items, cutlery, tableware, and containers.
● Pour very carefully and slowly so that you get all of the silver into the cast or mold and that you get the proper shape and angles that you want.
● Depending on the size of your silver casting project, you may need to utilize centrifugal force to allow the silver to reach all areas of the cast.
● Wait for your silver to cool and harden.

Dump your silver out of the mold. Wait a few minutes for your silver to cool. This could take from 2 minutes to 20 minutes depending on the size and depth of your silver. Ultimately, judging when to dump your silver is an art and depends on a number of factors including the type of mold. In the end, you'll learn by trial and error, but consider:
● Depending on your mold, it might be better to wait longer and having to break your mold instead of recasting the silver.
● Once the silver appears dry, give it another minute for the interior to cool off a little more.
● When dumping your silver, make sure you are wearing hand safety mitts, your apron, and even head gear. This will protect you from splash back if you do empty the mold too early.
● Pick up your mold and bang it on a hard surface. It should come right out.

Quench your silver. After you've dumped your silver out of the mold, you'll need to quench your silver. Quenching is the process in which silver is cooled and hardened by being submerged in water. This is the final stage of smelting silver.
● Take your tongs and pick up the silver bar or item.
● Slowly submerge the silver in clean/distilled water.
● As you submerge it, the water around the silver will boil and will produce steam.
● Leave the silver submerged for several moments -- until the boiling and steam have subsided.
● Remove your silver from the water and enjoy!

11 Tools

Tools arguably are the most valuable asset in any homestead. You can create anything if you have the right tools for the job. Below is a list of tools sorted by category which you are likely to need if you invest into a homestead.

Subheadings

		1. Wood & Metalwork Tools	2. Exterior Tools	3. Interior Tools	4. Medical Tools		
		5. Fitness Tools	6. Specialised Tools				

1 Wood & Metalwork Tools

Woodwork Tools

Manual Woodwork Tools

Hammer	For hitting nails, knocking things into place or breaking items.
Saw	Cuts through wood.
Chisel	Used for shaping wood.
File	For filling down sharp surfaces or making minor adjustments.
Planer	Takes a thin layer off of the material, used by hand in long sweeping motions.
Moisture Meter	Measures moisture content in various materials, such as wood, building materials, or soil.
Screwdriver	For inserting or removing screws of various sizes. It's recommended to have a kit of screwdrivers with different heads.
Clamps	For holding two pieces of material together.
Framing Square	Right angles in construction
Graphometer	For measuring angles.

Electric Woodworking Tools

Electric Drill	Easier to insert or remove screws than with a screwdriver. Requirements: ● Battery Pack or ● Electricity
Electric Circular Saw	Generally cuts in straight lines through thicker materials. Requirements: ● Battery Pack or ● Electricity
Electric Jigsaw	For cutting intricate patterns into materials. Requirements: ● Battery Pack or ● Electricity
Electric Planer	Takes a thin layer off of the material by a rapidly spinning blade. Requirements: ● Battery Pack or ● Electricity
Hammer Drill	A drill that combines rotary drilling with a rapid hammering action, for drilling into hard, brittle materials like concrete or brick. Requirements: ● Battery Pack or ● Electricity
Palm Sander	A compact, handheld power sander typically used for fine finishing and smoothing surfaces in small or confined areas. Requirements: ● Battery Pack or ● Electricity
Orbital Sander	A sander that moves its pad in small, rapid, eccentric circles, producing a smooth, swirl-free finish. Requirements: ● Battery Pack or ● Electricity

Metalwork Tools

Manual Metalwork Tools

Tin Snips	Cutting tools resembling heavy-duty scissors used for manually shearing and shaping thin sheet metal.
Punch Set	A collection of tools used to create precise holes or indentations in metal.

Smithing Tools

These are some basic smithing tool you will likely need to get into the craft.

Anvil	For shaping the metal.
Cross Peen Hammer	For hammering the metal. 2 and 3 pound cross peen. Has a thin horizontal end.
General Tongs	For holding the hot metal.
Furnace	To heat the metal in.
Billows	To increase the furnace temperature further.
Skimmer	Remove dross prior to pouring.
Lift-Out Tongs	Grips the crucible.
Pouring Tongs	For pouring the metal out.
Face Helmet	To protect from heat.
Metal Moulds / Patterns	For pouring the metal into.
Wolf Jaw Tongs	Have ridges and shapes that help grasp different shaped objects.
Leather Apron	A heat resistant piece of clothing used for protection from heat and sparks.
Leather Welding Gloves	A heat resistant piece of clothing used for protection from heat and sparks.
Steel Capped Boots	To prevent foot damage if hot metal or tools are dropped.
Coal Rake	To manipulate the fire.
2 Metal Buckets	For Quenching and Sand.
Large Metal Bucket	To hold ash.
Shovel	For coal and ash.
Borax	Used for welding steel pieces together.
Hardy Cut Off Tool	Attaches to anvil and used to cut hot steel.
Large Bastard Files	Used for rapid removal of significant amounts of material from metal, shaping, and preliminary smoothing before finer finishing.
4 Inch Belt Sander	A power tool used for aggressive material removal, grinding, shaping, and finishing larger metal surfaces with abrasive belts.
Vice	This is a very useful tool for a blacksmith. And often times a smith will have something called a leg vice.

1 Inch Belt Sander	A smaller, more precise sander used for detailed grinding, shaping, and finishing in tighter spaces or for smaller metalwork pieces.
Electric Angle Grinder	A versatile handheld power tool used with various abrasive discs for cutting, grinding, deburring, and polishing metal.
Bench Grinder	A stationary tool featuring two abrasive wheels used for sharpening tools, grinding, shaping, and deburring metal workpieces.
Hardy Benching Tool	An anvil accessory that fits into the hardy hole of an anvil, used for cutting, bending, or punching hot metal.
Blacksmith Coal	A type of coal used as fuel in a blacksmith's forge to heat metal to forging temperatures, making it pliable for shaping.
Quench	This is a bin or some other kind of container that contains a fluid like water or oil.
Pritchel Tool	To pierce a hole in metal. Place the work over the hole then punch through it.
Fullering Tool	The fuller is the groove in the blade of a knife or sword. It is commonly referred to as the blood groove.
Cold Chisel	Used for marking and scoring metal while it is cold.
Wire Brush	As steels and irons are heated they accumulate slag and scale. This needs to be firmly brushed off.

Fixed Machining Tools

Stationary Tools

Drill Press	A tool used for accurately drilling precise and consistent holes into various materials.
Table Saw	A woodworking tool with a circular blade protruding through a table for precise straight cuts in large pieces of wood.
Welding Machine	A power tool used to join pieces of metal by heating them to melting point and fusing them together.
Bench Grinder	A tool featuring two abrasive wheels used for sharpening tools, grinding, shaping, and deburring various materials.
Router	A handheld or table-mounted power tool used to hollow out areas in wood, primarily for decorative edges or grooves.
Band Saw	A power tool with a continuous loop blade running on two wheels, for cutting irregular shapes, curves, and resawing wood.
Radial Arm Saw	A machine where the saw blade is mounted on a sliding arm, primarily used for making accurate crosscuts in wood.
Jointer	Used to create a flat, straight edge on a piece of wood, preparing it for subsequent operations like gluing or planing.

2 Exterior Tools

Gardening Tools

Pick Axe	
Hoe	
Pitchfork	For moving hay bales easily.
Rake	Makes raking leaves and other debris easier.
Shovel	
Trowel	
Dibbler	
Wheelbarrow	Used for transporting relatively small amounts of earth, sand or other substances.

Tree Tools

Axe	Used to cut down large trees.
Pole Pruner	
Pruning Saw	
Shears	For trimming small twigs and shoots.
Hedge Shears	
Bypass	
Lopper	
Bow Pruning Saw	

3 Interior Tools

Manual Kitchen Tools

Measuring Cups	Liquid and dry goods.
Measuring Spoon	A spoon used to measure an amount of an ingredient, either liquid or dry.
Can Opener	Opens Cans.

Small Kitchen Appliances

Kettle	Heats water to the boiling point.
Toaster	Toasts bread.

Fixed Kitchen Appliances

Oven	Used for cooking or baking foods in. Requirements: ● Electricity
Stove	Used for cooking foods in a pan on. Requirements: ● Electricity or Gas

Microwave	Quickly reheats food using radio waves. Requirements: ● Electricity
Sink	Holds water for washing up in.
Dishwasher	Washes dishes automatically. Requirements: ● Electricity

Household Equipment

Vacuum Cleaner	Removes the dust and particles from the floor.
Iron	Removes the crinkles in clothing.

4 Medical Tools

Glucometer	Blood Glucose. (Diabetes)
Spirometer	The lung capacity.
Sphygmomanometer	Blood pressure.
Cardioverter / Defibrillator	To correct arrhythmias of the heart or to start up a heart that is not beating.
Endoscope	To look inside the gastrointestinal tract, used mainly in surgery or by surgical consultants.
Surgical Scissors	Used for dissecting or cutting.
Hypodermic Needle / Syringe	For injections and aspiration of blood or fluid from the body.
Ophthalmoscope	To look at the retina.
Otoscope	To look into the external ear cavity.
Proctoscope	To look inside the anal canal and lower part of the rectum.
Reflex Hammer	To test motor reflexes of the body.
Bedpan	For patients who are unconscious or too weak to sit up or walk to the toilet to defecate.
Cannula	To create a permanent pathway to a vein (or artery) for the purpose of repeated injections or infusion of intravenous fluids.
Catheter	To drain and collect urine directly from the bladder (primary use); also to act as a makeshift oxygen tube, etc.
Dialyser	To remove toxic materials from the blood that are generally removed by the kidneys; used in case of renal failure.
Electrocardiograph Machine	To record the electrical activity of the heart over a period of time.
Enema Equipment	To passively evacuate the rectum of faeces.
Surgical Scissors	Used for dissecting or cutting.
Hypodermic Needle / Syringe	For injections and aspiration of blood or fluid from the body.
Infection Control Equipment	As in gloves, gowns, bonnets, shoe covers, face shields, goggles, and surgical masks for preventing nosocomial or healthcare-associated infection.
Instrument Sterilizer	To sterilize instruments in absence of an autoclave.
Kidney Dish	As a tray for instruments, gauze, tissue, etc.
Stethoscope	To hear sounds from movements within the body like heart beats, intestinal movement, breath sounds, etc.
Thermometer	To record body temperature.
Measuring Tape	For length, height, head circumference and girth measurements.
Medical Halogen Penlight	To see into the eye, natural orifices, etc. and to test for pupillary light reflex, etc.
Nasogastric Tube	For nasogastric suction or the introduction of food or drugs into the body.
Nebulizer	To produce aerosols of drugs to be administered by respiratory route.
Oxygen Mask and Tubes	To deliver gases to the mouth/nostrils to assist in oxygen intake or to administer aerosolized or gaseous drug
Pipette / Dropper	To measure out doses of liquid, specially in children.
Suction Device	To suck up blood or secretions.
Thermometer	To record body temperature.
Transfusion Kit	To transfuse blood and blood products.
Tuning Fork	To test for deafness and to categorize it.
Ventilator	To assist or carry out the mechanical act of inspiration and expiration so the non-respiring patient can do so; a common component of "life support".
Watch / Stopwatch	For recording rates like heart rate, respiratory rate, etc.; for certain hearing tests.
Weighing Scale	To measure weight.
Crocodile Forceps	To remove foreign bodies from ear or nasal cavities.

5 Fitness Tools

Pedometer	Measures steps.
Heart Rate Monitor	
Stopwatch	Measures time and lap times.
Weights	Allows strengthening of certain muscle groups.
Jump Rope	
Exercise Bike	
Treadmill	
Rowers	

6 Specialised Tools

The following tools are used for measuring various phenomenon on earth.

CRAFTING Tools Specialised Tools

Pen and Paper Tools

Protractor	Measures angles, typically only those drawn on paper.
Ruler	For measuring length.
Compass	For finding direction.

Weather

Anemometer	Measures windspeed.
Barometer	Measures air pressure.
Ceilometer	Height of a cloud base
Disdrometer	Size, speed, and velocity of raindrops
Evaporimeter	Rate of evaporation
Hygrometer / Psychrometer	Humidity
Nephoscope	Measures the speed and direction of clouds.
Rain Gauge	Measures the amount of rain fallen.
Seismometer	Measures seismic waves such as during earthquakes.
Thermometer	Measures the temperature.
Wind Vane	Measures wind direction.

Solar

Actinometer	Measures the heating power of sunlight.
Pyranometer	Measures solar radiation.
Pyrheliometer	Measures direct solar insolation.

Light

Colorimeter	Measures Colour
Densitometer	Degree of darkness in photographic or semitransparent material
Light Meter	Light (in photography)
Lux Meter	Intensity of light
Photometer	Illuminance or irradiance
Spectrometer	Properties of light
Spectrophotometer	Intensity of light as a function of wavelength
Tintometer	Colour

Brewing

Alcoholmeter	Alcoholic strength of liquids
Nephelometer	Particles in a liquid.
Refractometer	Sugar concentration of sap and syrup.
Breathalyser	Breath alcohol content
Saccharometer	Amount of sugar in a solution
Zymometer	Fermentation

Unpowered Bench Tools

Saw Horse	A raised platform used for sawing and drilling through wood on.
Work Bench	For tinkering, sawing, drilling etc.
Tool Storage Wall	Storage of all the tools in the shed / garage.
Rip Fence	
Mitre Gauge	

Vehicle Tools

Jack	Used to hold a tyre off the ground allowing you to change it.
Winch	For pulling cars from ditches and mud.
Tool Kit	For simple repairs if required.
Hydrometer	Measures the density of a fluid, aka the charge of a battery.
Accelerometer	Physical, accelerations
Dynamometer	Force, torque or power
Fuel Gauge	Fuel levels
Odometer	Distance travelled
Speedometer	Speed, velocity of a vehicle
Tacheometer	Measures distance.
Tachometer	Revolutions per minute, rate of blood flow, speed of aeroplanes

Electrical Tools

CRAFTING Tools Specialised Tools Electrical Tools

Multimeter	Measures AC and DC voltage, resistance, amperage.
Wattmeter	A device used to measure the electric power (in watts) consumed or produced by an electrical circuit or load.
Voltmeter	Mmeasures the electric potential difference (voltage) between two points in an electrical circuit.
Ammeter	Measures the electric current (in amperes) flowing through a specific point in an electrical circuit.
Electricity Meter	Measures the total amount of electrical energy consumed over a period.
Electrometer	A voltmeter with extremely high input impedance, for measuring very small electric charges without drawing much current.
Frequency Counter	An electronic instrument used to measure the frequency of a repetitive electrical signal, typically in hertz (Hz).
Galvanometer	A sensitive electromechanical instrument used for detecting and measuring small electric currents.
Ohmmeter	A device used to measure the electrical resistance (in ohms) of a component or circuit.
Potentiometer	Voltage (term is also used to refer to a variable resistor)

Plumbing Tools

CRAFTING Tools Specialised Tools Plumbing Tools

pH Meter	Measures pH (chemical acidity/basicity of a solution)
Mass Flow Meter	Mass flow rate of a fluid travelling through a tube
Pressure Measurer	Measure the pressure in a pipe.
Pipe Cutters	To cut metal and plastic piping.
Pipe Cleaning	Cleaning house piping.
Wrenches	For tightening large bolts on things like cars.
Pipe Benders	For bending metal pipes.

Measuring Tools

CRAFTING Tools Specialised Tools Measuring Tools

Tape Measure	Measures distance often in construction.
Bubble Level	Measures the tilt and angle of a surface somewhat in-accurately.
Sliding Bevel	A woodworking tool used to copy, transfer, and mark specific angles for cutting or joining materials.
Layout Square	A measuring and marking tool used for quickly marking accurate 90-degree and 45-degree angles, as well as straight lines.
Calipers	Calipers are measuring instruments used to accurately determine the internal, external, or depth dimensions of an object.
Clock	Tells the time in either analog or digital format.
Dosimeter	Exposure to hazards, especially radiation; radiation of item.
Geiger Counter	Ionizing radiation. (alpha, beta, gamma, etc.)
Inclinometer	Angle of a slope.
Load Cell	Measurement of force.
Osmometer	Osmotic strength of a solution, colloid, or compound matter of an object.
Pycnometer	Measures fluid density.
Radiometer	Radiant flux of electromagnetic radiation
Weighing scale	Weight

Positioning Tools

CRAFTING Tools Specialised Tools Positioning Tools

Altimeter	Measures altitude.
Binoculars	Magnifies distant objects. First # - Magnification, Second # - Objective Size
Wind Sock	Indicates strength and direction of wind.
Anemometer	Measures wind speed up to 200kph, wind direction, wind chill factor and min & max temperature.
Clinometer	Measures angles, elevation or slope.
Compass	Direction of North
Sextant	Location on earth's surface (used in naval navigation)

Knots

Tying knots and using rope skills like rappelling

"It was like looking at a knot, knowing it was a knot,
but not knowing how to untie it. I had to map for this life."
Laurie Halse Anderson

Introduction

Knots are a valuable addition to your skillset allowing you to tie up items, pitch a tent and rappel down a rock face. It contains the various types of knots you are likely to use in a disaster situation.

Purpose	The aim of KNOTS is to inform the reader of the different types of knots available for different uses. It attemps to present the best knot for each situation one might encounter and includes a detailed description on how to tie it. There is also a section on the different types of robe available and the purpose for each type.
Lost?	● To find out what kind of rope you should have in your BOB, see the GEAR section. ● The best use for this section is to compliment the SHELTER category when constructing any kind of shelter. ● For a list of the knot terms, see the ADDENDUM > Dictionary section.

Contents

1 Rope

A rope is an indispensable lifeline for a climber, rescuer, etc. It is one of the few elements in the protection system that is not backed up by other equipment, and one that absolutely must not fail. An understanding of the design and construction of ropes as well as knowledge of their selection, use and care, is crucial to reducing the risks associated with their use. Ropes used for climbing are dynamic - they are designed to stretch when fallen on, absorbing and dissipating the energy generated by the fall. Static ropes, such as those used in rescue work are designed with minimal stretch and should never be used for climbing. Although static and dynamic ropes look the same they are not interchangeable. Static ropes are not climbing ropes - never use a static rope for climbing or any application where dynamic loads may be encountered. Climbing ropes utilize a kernmantle construction consisting of a core (kern) covered by a sheath (mantle). The core is the main load bearing element, and largely determines a rope's major characteristics, such as maximum impact force, and number of test falls held.

The sheath is braided tightly around the core and its primary purpose is to protect the core against abrasion, although the sheath also helps determine a rope's handling characteristics. Maximum breaking strength is the load whereby a single strand of rope (free of knots or sharp bends) breaks. High breaking strengths are desirable, especially in static life support and rescue ropes. Knots, bends, edges and falls all reduce maximum breaking strength. For example, the breaking strength of a given rope over a carabineer with a diameter of 10 millimetres (0.39 in) is approximately 30% less than the maximum breaking strength. Smaller diameter carabineers or rock edges reduce the strength even further. Sharp edges are extremely dangerous and are the main cause of rope failure. Use of double or twin ropes reduces this danger considerably. Static elongation is the stretch of a rope when weighted with a 79.8kg (176 lb) load. A low static elongation is desirable for rappelling and hauling.

Maximum impact force is the maximum load transmitted to the climber during a fall. The UIAA specifies a maximum impact force of 1,152 kg (2,540 pounds) for single ropes and 798 kg (1,760 pounds) for double ropes. A rope with a low maximum impact force absorbs more of the energy generated in a given fall than a rope with a high maximum impact fore, thus transmitting less energy to the protection system and to the falling climber. However, low impact force is often associated with high rope stretch, which may increase the climber's chances of hitting a ledge or the ground. The number of test falls held indicates how many UIAA certified falls a given rope can sustain before breaking. The testing procedure - dropping a 79.8 kg (176 pound) weight attached to an 2.5m (8.25 foot) length of rope a distance of 5m (16.5 feet) - yields a very severe fall which would be difficult to duplicate in any but the worst actual climbing situation. It is important to note that ropes lose elasticity, and their ability to absorb energy, when subjected to repeated falls.

Subheadings

1 Rope Attributes

Several attributes of a rope's design and construction are important to consider.

Flexibility	If a rope is too stiff, knots are difficult to tie and may even untie themselves. The more flexible the rope, the easier it is to tie knots and have them stay tied.
Water	Ropes absorb water, increasing the weight of the rope greatly. In cold weather absorbed water freezes, making the rope stiff and unmanageable (ice crystals also reduce rope strength). Many climbing ropes are treated with a water repellent coating to help prevent moisture absorption. "Dry" ropes will not saturate immediately when subjected to moisture; therefore, they will remain lighter and stronger than untreated ropes. Sheath weave also affects water absorption. Ropes with tightly woven sheaths absorb water slower than ropes with loose woven sheaths, and in some instances untreated ropes with tight sheaths absorb less moisture than dry treated ropes with loose sheaths.
Abrasion Resistance	Abrasion resistance is the rope's ability to resist fraying. Weave patterns, flexibility, and treatments all affect a rope's abrasion resistance.
Kinking	Every rope kinks. Help prevent kinking by properly uncoiling the rope from the manufacturer's coil. Place your arms inside the main coil. Spin your arms, allowing the rope to un-wind. Do not pull the rope; let it unravel as your arms rotate. Further kinking problems are generally due to improper coiling techniques (i.e. loop coils), and rappel devices (i.e. fig. 8's and Munter hitches).
Hand	Hand" describes how a rope feels and handles. Diameter, weave pattern, coatings/treatments, sheath tightness, sheath material, and production quality all help determine a rope's hand.

2 Rope Selection

First, determine whether a dynamic or static rope is best for your intended use. Always use a dynamic rope for lead climbing. Static ropes may be used for rappelling, rescuing, caving, top roping, and hauling where there is no chance of significant impact loading. Typically, climbing ropes sold in the United States carry a CE mark and a tag stating rope diameter, length, manufacturer's statement on number of falls held, maximum impact force, weight per meter, and classification of rope (single, double, etc.).

Single ropes are the most common and are identified by the number "1" inside a circle on the label at either end of the rope. Single ropes vary in diameter from 9.8 to 11 millimetres. Thick ropes last longer and usually hold more falls. Small diameter ropes are lighter and easier to clip into protection, making them the preferred choice for high-end lead climbing and glacier travel.

Double ropes (or half ropes) are used only in pairs. These ropes range from 8.2 to 9 millimetres in diameter and are identified by a number "1/2" within a circle on the label at the end of the rope. Double ropes may be clipped alternately through the protection, reducing rope drag and decreasing the chances of rope failure over an edge. Twin ropes are a third classification offered by some manufacturers and are certified by the UIAA. These are delineated by a "f" symbol on the UIAA label.

Both of the twin ropes are clipped through every protection point. The strands should never be separated. Twin ropes are uncommon in the United States. Double and twin ropes are designed to be used with a matching rope. Use of unmatched ropes will cause undue wear on one of the ropes, usually the one with the lowest working elongation or greatest diameter. Bi-coloured ropes change colours or sheath patterns at the midpoint. This feature allows you to easily find the centre of the rope.

Rope Inspection
Inspect your rope before and after each use. It is the user's responsibility to know the history of the rope and to determine when it should be retired; keep a rope log on how many times it has been used and the number of falls held. When in doubt, retire your rope. Generally, a rope should be discarded after holding a long hard fall, if it has flat or soft spots, becomes stiff, or shows sheath damage. Retire a rope after no more than four years of occasional use, two years of weekend climbing, or one year of active use. Retiring a rope after only six months of hard use isn't uncommon; some climbing gym ropes wear out after only a few weeks of intensive use. Also, multiple short lead falls (common in sport climbing), bounding rappels, and shock-loaded top rope falls can have a cumulative negative effect on the rope's shock-absorbing capacity.

3 Rope Care

KNOTS Rope Rope Care

- Always protect your rope at potential abrasion points.
- Most ropes are retired because they become frayed, not because of the number of falls held.
- Watch for sharp edges like rock crystals, bolt hangers, glass, and even pack grommets, which can cut a rope's sheath.
- Retire your rope if you can see the core at an abraded area or if the rope feels lumpy or flat in spots.
- Keep your rope clean.
- Dirt shortens rope life by causing internal as well as external abrasion.
- Transport and store your rope in a protective bag or pack.
- Wash a dirty rope in cold water using mild, non detergent soap.
- Adding fabric softener while washing improves rope flexibility by lubricating the fibres.
- Do not bleach your rope.
- Air dry your rope away from direct sunlight.
- Do not dry it in a dryer.
- Store your rope away from heat, sunlight and chemicals.
- Protect your rope from all compounds containing acids, alkalis and oxidizing agents.
- Avoid contact with battery acid and bleach.
- Avoid contact with petroleum substances such as gasoline and oil which do not appreciably affect nylon ropes by themselves but may contain additives that can cause damage.
- These substances also attract dirt which causes the rope to wear more quickly.
- Always use proper rappelling techniques.
- Fast rappels, bounding, or swinging can damage your rope.
- Some rappel devices place a sharp bend in the rope which creates excessive heat build up and stresses the rope's fibres, leading to accelerated wear.
- Never use a climbing rope for any purpose other than for what it was intended.
- It is not for towing cars, trimming trees, working on roof, etc.
- Never step on a rope, stepping on a rope grinds dirt into the rope fibres, causing excessive wear.

4 Rope Types

The choice between single, half, twin and static ropes depends on what type of climbing you do.

Single Ropes

These are best for trad climbing, sport climbing, big-wall climbing and top roping. The vast majority of climbers buy single ropes. The name “single” indicates that the rope is designed to be used by itself and not with another rope as some other rope types are. Single ropes come in many different diameters and lengths, making them suitable for a wide range of climbing disciplines, and they're generally easier to handle than two-rope systems. Some single ropes are also rated as half and twin ropes, allowing you to use them with any one of the three climbing techniques. It's important to only use a rope as it was designed and tested to be used. Single ropes are marked with a circled 1 on each end of the rope.

Half Ropes

	Advantages	Disadvantages
These are best for trad climbing on wandering multi-pitch rock routes, mountaineering and ice climbing. When climbing with half ropes, you use two ropes. As you ascend, clip one rope to protection on the left and the other to protection on the right. When done correctly, this allows the ropes to run parallel and straight, thereby reducing rope drag on wandering routes. Half ropes have a couple advantages and disadvantages compared to single ropes:	● Half-rope technique reduces rope drag on wandering routes. ● Tying the two ropes together when rappelling allows you to go twice as far as you can with a single rope. ● Two ropes provide redundancy if one gets damaged during a fall or cut by rockfall.	● Half ropes require more skill and effort to manage compared to a single rope due to the fact that you're climbing and belaying with two ropes. ● The combined weight of two ropes is heavier than a single rope. (However, you can share the load with your climbing partner by each carrying one rope.)

Half ropes are designed and tested only for use as a matching pair; don't mix sizes or brands. Some half ropes are also rated as twin ropes, allowing you to use them with either technique. There are also some triple-rated ropes that can be used as half, twin and single ropes for maximum versatility. It's important to only use a rope the way it was designed and tested to be used. Half ropes have a circled ½ symbol on each end.

Twin Ropes

	Advantages	Disadvantages
These are best for trad climbing on non-wandering multi-pitch rock routes, mountaineering and ice climbing. Similar to half ropes, twin ropes are a two-rope system. However, with twin ropes, you ALWAYS clip both strands through each piece of protection, just like you would with a single rope. This means there will be more rope drag than with half ropes, making twin ropes a good option for non-wandering routes. On the plus side, twin ropes tend to be a bit thinner than half ropes, making for a lighter and less bulky system.	● Tying the two ropes together when rappelling allows you to go twice as far as you can with a single rope. ● Two ropes provide redundancy if one gets damaged during a fall or cut by rockfall.	● Twin ropes require more skill and effort to manage compared to a single rope due to the fact that you're climbing and belaying with two ropes. ● The combined weight of two ropes is heavier than a single rope. (However, you can share the load with your climbing partner by each carrying one rope.)

Just as with half ropes, twin ropes are designed and tested only for use as a matching pair; don't mix sizes or brands. Some twin ropes are also rated as half ropes, allowing you to use them with either technique. There are also some triple-rated ropes that can be used as twin, half and single ropes for maximum versatility. It's important to only use a rope as it was designed and tested to be used. Twin ropes have a circled infinity symbol (∞) on each end.

Static Ropes

These are best for rescue work, caving, climbing fixed lines with ascenders and hauling loads. Static ropes excel in situations where you don't want the rope to stretch, such as when you are lowering an injured climber, ascending a rope, or hauling a load up with the rope. Never use a static rope for top roping or lead climbing as they are not designed, tested or certified for those types of loads.

5 Rope Diameter

Affects the rope's weight and durability and determine its best use. Generally speaking, a skinnier rope is lighter. However, skinnier ropes can be less durable and require more skill to safely belay with. Thicker-diameter ropes can be more abrasion-resistant and often stand up better to frequent use. If you're top roping at the local crag, you'll probably want a thicker rope. If you're hiking long distances for multi-pitch climbs, you'll want a skinnier, lighter rope.

Single Ropes up to 9.4mm	Ropes in this range are very lightweight, making them ideal for long multi-pitch climbs where weight is important. However, skinny single ropes are not rated to hold as many falls as thicker ropes, they are harder to handle and they tend to be less durable. If you plan to do lots of top-roping or take repeated falls while figuring out the moves on a sport climb, choose a thicker rope. Be aware that a skinny rope can move quickly through a belay device, so you need a very experienced and attentive belayer to climb with one.
9.5 – 9.9mm single Ropes	A single rope in this range is good for all-around use, including trad and sport climbing. These ropes are light enough to take into the mountains yet durable enough for top-roping at the local crag. They're generally more durable than very skinny ropes and they are easier to handle.
Single Ropes 10mm and above	Ropes with a diameter of 10mm and above are best for gym climbing, frequent top roping, figuring out the moves on sport routes and big-wall climbing. These styles of climbing can wear out a rope faster so it's wise to go with a thicker, more durable rope.
Half and twin Ropes	Half ropes typically have a diameter of about 8 – 9mm, while twin ropes are usually about 7 - 8mm thick.
Static Ropes	Static ropes have a diameter of 9 – 13mm, and are commonly measured in inches, so you may see the diameter stated as 7/16", for example.

6 Rope Length

Affects the rope's weight and durability and determine its best use. Dynamic ropes for rock climbing range in length from 30m to 80m. A 60m rope is the standard and will meet your needs most of the time. If you're unsure what length rope you need for a particular climbing area, it's best to ask other climbers and consult a guidebook.

Outdoor Climbing Ropes	When deciding what length to buy, remember that your rope needs to be long enough so that half its length is equal to or greater than the route or pitch you'll be climbing. For example, if a climbing route is 30m long, then you need at least a 60m rope to be able to climb up and be lowered back down off of an anchor at the top of the climb. Some modern sport-climbing routes require a 70m rope in order to lower to the ground.
Indoor Climbing Ropes	Shorter-length ropes, about 35m long, are commonly used for gym climbing because indoor routes tend to be shorter than outdoor routes. Again, be sure the length of rope is long enough to lower a climber.
Static Ropes	Static ropes for rescue work, caving, climbing fixed lines with ascenders and hauling loads come in a variety of lengths and are sometimes sold by the foot so you can get the exact length you need.

7 Rope Weight

The overall weight of a climbing rope is largely determined by the diameter and length. Generally, a skinnier rope will be lighter than a thicker rope, but core construction is a factor that can make a skinny rope heavier than a thick rope. It's standard for weight of dynamic climbing ropes to be listed as grams per meter (eg. 58 g/m), making it easy to compare rope weight regardless of the overall length. Use the grams per meter number and the length of a rope to calculate a rope's overall weight. Weight for static ropes is often given as weight per foot.

8 Rope Features

Look for these features when you are comparing climbing ropes. They can make a difference in performance and ease of use.

Dry Treatment	When a rope absorbs water, it gets heavier and is less able to withstand forces generated in a fall (the rope will regain all of its strength when dry). When it's cold enough for absorbed water to freeze, a rope gets stiff and unmanageable. To combat this, some ropes include a dry treatment that reduces water absorption. Dry-treated ropes are more expensive than non-dry-treated ropes so consider whether or not you need dry treatment. If you primarily sport climb, a non-dry rope is probably sufficient since most sport climbers will pull their ropes and go home when it rains. If you will be ice climbing, mountaineering or multi-pitch trad climbing, you will encounter rain, snow or ice at some point, so choose a dry-treated rope. Dry ropes can have a dry core, a dry sheath or both. Ropes with both offer the greatest moisture protection.
Middle Mark	Most ropes include a middle mark, often black dye, to help you identify the middle of the rope. Being able to identify the middle of your rope is essential when rappelling.
Bicolour	Some ropes are bicolour, which means they have a change in weave pattern that clearly differentiates the two halves of the rope and creates a permanent, easy-to-identify middle mark. This is a more effective (if more expensive) way to mark the middle of a rope than black dye because dye can fade and become difficult to see.
End Warning Marks	Some ropes include thread or black dye showing that you are coming to the end of the rope. This is helpful when you're rappelling or lowering a climber.

9 Rope Safety

Looking at these ratings while thinking about what type of climbing you will be doing can help you choose a rope. The Union Internationale des Associations d'Alpinisme (UIAA) is the international mountaineering and climbing federation that creates safety standards to which all climbing ropes must adhere. Independent labs are responsible for carrying out the tests. All dynamic ropes carried by REI pass the UIAA tests. The packaging on dynamic climbing ropes lists the test results for UIAA safety standards, including fall rating, static elongation, dynamic elongation and impact force. Looking at these ratings while thinking about what type of climbing you will be doing can help you choose a rope.

Fall Rating	The UIAA tests ropes to see how many falls they can hold before failing. Lab falls create much greater force than most real-world climbing falls. Therefore, the fall rating is mostly a comparative value. Single ropes are tested by dropping an 80kg weight onto the rope, half ropes are tested by dropping a 55kg weight on a single strand, and twin ropes are tested by dropping an 80kg weight on 2 strands. All single ropes and half ropes must withstand a minimum of 5 UIAA falls. Twin ropes must withstand a minimum of 12 UIAA falls. All ropes that meet the UIAA fall rating standard are safe for climbing. A rope with a higher fall rating may mean that that rope will last longer than a rope with a lower rating. However, always inspect your rope closely after a severe fall and consider retiring it if any damage is detected.
Static Elongation	Static elongation, also called working elongation, is the amount that a dynamic rope stretches with an 80kg weight hanging from it. Elongation on single and twin ropes cannot exceed 10 percent of the total rope length and half ropes cannot exceed 12 percent. Static elongation is important to consider when top-rope climbing, hauling gear and climbing fixed ropes with ascenders. Higher static elongation generally indicates less efficiency because energy is wasted through rope stretch.

Dynamic Elongation	Dynamic elongation is the distance the rope stretches during the first UIAA fall. Higher elongation equals a longer fall, so generally speaking, a lower number is better because less stretch may prevent a falling climber from hitting a ledge or the ground. However, less dynamic elongation means a higher impact force on the climber, belayer and gear. The UIAA allows ropes to stretch no more than 40 percent of the length of the entire rope.
Impact Force	Impact force is the amount of force in kilonewtons that is put on the falling weight during the first UIAA fall. A lower number indicates less force on the falling climber, the belayer and the gear. The higher the dynamic elongation, the lower the impact force. Lower impact forces make for a soft landing on the rope when you fall, but with that usually comes greater stretch, which can be less efficient when top roping.

2 Rope Techniques

While all climbers aspire to reach the top of a pitch, getting back down is every bit as important. Lowering on belay is what most of us do when we start climbing. Rappelling is another essential skill, though, for you to become a well-rounded climber. Lowering requires a belay partner, while in rappelling the climber self lowers. Rappelling comes in handy in a number of scenarios, including:

- Having no approach trail to access the base of your climb (like on a sea cliff).
- The wall has a lot of loose rocks and you want to clean the route before you climb.
- You have an injured climber and a rescue from the top of the climb is warranted.
- You want to minimize wear and tear on an anchor system (like one that has rappel rings) after you've cleaned the anchor and need to get down.
- Any situation when climbing down, lowering and walking off are all not possible or not preferable.

Belay

Climbing Anchors

Lasso

3 Arborist Knots

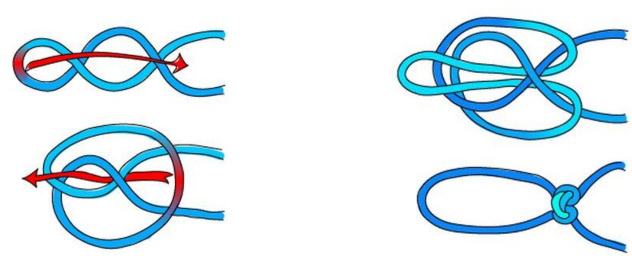
An arborist or tree surgeon is a professional in the practice of arboriculture, which is the cultivation, management, and study of individual trees, shrubs, vines, and other perennial woody plants in dendrology and horticulture. These knots are designed to help keep them attached to the tree.

Other Arborist Knots

- Water Knot
- Zeppelin Bend
- Trucker's Hitch
- Running Bowline
- Bowline on a Bight
- Valdotain Tresse
- Stopper Knot
- Alpine Coil
- Backup Knot
- Blake's Hitch
- Bowline
- Prusik Hitch
- Autoblock Knot
- Slippery Eight Loop
- Distel Hitch
- Double Fisherman
- Figure Eight

Alpine Butterfly Knot

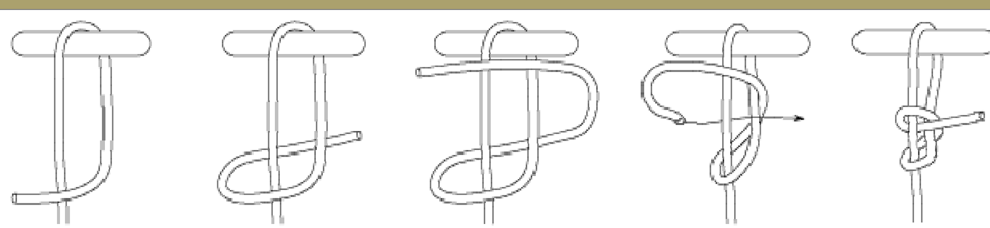
Alpine Butterfly Knot (Butterfly Loop)
Forms a secure loop in the middle of the rope.



1. Make a loop in the rope and twist it one full rotation into an eight shape.
2. Fold the top of the eight down around the bottom of the eight.
3. Now up and out through the lower opening of the eight and pull tight.

Buntline Hitch

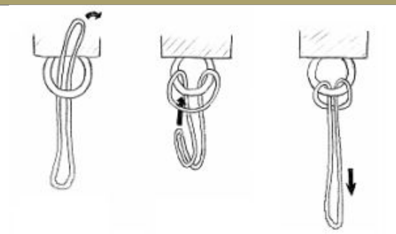
Buntline Hitch
Tie items to the end of a rope.



1. Pass the end of a line through the object being attached to the rope. Bring free end up and cross over, then under the standing line.
2. Bring the free end to the front of the knot and you will now finish by tying a half hitch around the standing line.
3. This is the completed knot prior to tightening.
4. Pull the knot tight and slide down onto the attached object.

Cow Hitch

Cow Hitch
Tie a rope to a post or object.



1. Wrap end of rope around object from behind.
2. Cross behind standing line.
3. Wrap tag end around object in opposite direction as first wrap (half hitch) and feed through opening created by wrap.
4. Pull both ends to tighten the knot.

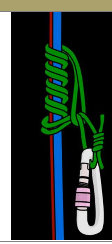
Half Hitch

Half Hitch
Basic overhand knot.

1. Pass the end of a rope around the object and tie an overhand knot.
2. For the Two Half Hitches, repeat with a second overhand knot in the same direction.

Klemheist Knot

Klemheist Knot
Climber Knot



1. Place a loop consisting of cordage no more than 1/2 the diameter of the main line behind the static line.
2. Make a wrap around the static line with the loop on the right.
3. Repeat two more times working from bottom to top.
4. Feed left hand loop through loop on right.
5. Pull left hand loop back over to left side of static line and pull down hard to set the knot.
6. Grasp entire knot and slide up the static line. Load and grip the knot to the static line with weight to the loop.

Munter Hitch

Munter Hitch
Climbing belay knot.

1. Make a loop in the rope and slip the loop into a locking carabineer. Form a second loop with the line crossing opposite the first loop.
2. Slip second loop into the carabineer and lock carabineer.
3. Make sure the strand carrying the load is next to the spine of the carabineer.

Timber Hitch

Timber Hitch
Secure a rope around a post.

1. Pass the working end of a rope around the object and take a turn around the standing part.
2. Tuck the working end back around itself three times with the lay of the rope.
3. Add one or two half hitches near the hauling end for hoisting and to keep load from twisting.

4 Bends

A bend is a knot used to join two lengths of rope.

Other Bend Knots
- Double Overhand Stopper
- Heaving Line Knot
- Monkey Fist
- Double Fisherman

Carrick Bend

Carrick Bend
Join heavy ropes together.

1. Form a basic loop with the larger size rope (white rope in illustration) and lay loop on top of and across working end of second rope.
2. Remember the sequence: over, under, over, under, over and pass working end of second rope around first loop and itself following the sequence.
3. The ends come out of opposite sides of the knot. The knot loses its beautiful symmetry when tightened.
4. The ends should be seized to the standing parts if the ropes are large.

Sheep Shank

Sheep Shank
To shorten a rope.

1. Take up slack in rope and make underhand loops as shown at A and B.
2. Pass bight A1 through loop A, and bight B1 through loop B.
3. Pull free ends of rope in opposite directions. Maintain tension on knot.

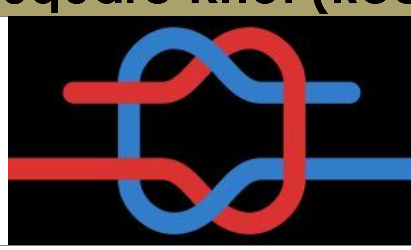
Sheet Bend

Sheet Bend
Join ropes of unequal size.

1. Form a loop in the end of one rope. Pass the free end of the rope to be joined under the opening of the loop, around both parts of the first rope and back under itself.
2. Pull all four ends to tighten.
3. Two wraps around both parts of the first rope make a Doubled Sheet Bend.

Square Knot (Reef Knot)

Square Knot
Secure non critical items.



1. Tie two over hand knots. First, right over left and twist. Then left over right and twist.
2. Make sure both parts of the rope exit the knot together!

Stopper Knot

Stopper Knot
Stopper knot for the end of a rope.

1. Form a small loop at the end of a line by running tag end over standing line.
2. Tie an overhand knot around standing line.
3. Pull overhand knot tight and feed tag end through noose (loop) end.
4. Pull tag end all the way through and slide knot down tight.
5. Pull both ends tight.

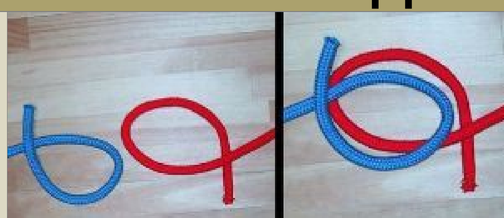
Water Knot

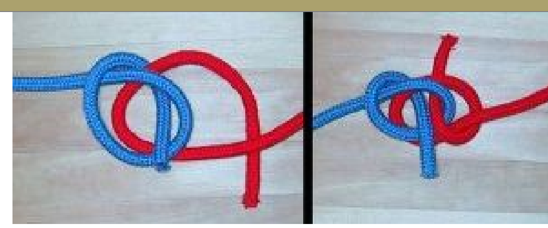
Water Knot
Best knot for webbing.

1. Tie an overhand knot in one end of the webbing leaving the desired length of the loop free.
2. Retrace the knot in the opposite direction with the other end of the webbing and.
3. Pull tight. Make sure the free ends are a couple inches long to visually inspect for slippage during use.

Zeppelin Bend

Zeppelin Bend
Easy to untie knot for joining two ropes.





1. An easy way to start the Zeppelin knot is to form a "6" with one rope with the running line under, and form a "9" with the other rope with the running line over. Then lay the 6 partially over the 9.
2. Take the end of the 6 and pass it through the opening of the 9 and the 6.
3. Repeat with the end of the 9 in the opposite direction - through the opening of the 6 and through the opening of the 9.
4. Pull ends tight.

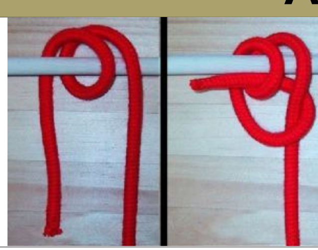
5 Boating Knots

Knots for boats and rigging.

Other Boating Knots
- Zeppelin Bend
- Water Knot
- Alpine Butterfly Knot
- Bowline
- Running Bowline
- Heaving Line Knot
- Double Bowline Knot
- Carrick Bend
- Buntline Hitch
- Spanish Bowline
- Bowline On A Bight
- Common Whipping
- Stevedore Stopper Knot
- Sailor's Coil

Anchor Bend

Anchor Bend
A good knot for tying an anchor to a rope.



1. Make two turns around the shackle, leaving turns open.
2. Pass free end behind the standing line and feed the free end through the first turns and pull tight.
3. Now tie a half hitch around the standing line and pull tight.
4. Seize the free end or tie the knot with a long tag end and tie a backup knot such as one half of a Double Fisherman's (see Backup Knot) with the tag end around the standing part.

Cleat Hitch

Cleat Hitch
To tie a rope to a cleat on a boat or dock.

1. Take a turn around the base of the cleat, and then bring the line over the top of the cleat. Wrap the line back under the arm of the cleat opposite the first turn, then back over the top of the cleat.
2. Wrap under the first arm a 2nd time and then back over the top of the cleat. You have now made a figure eight pattern over and around the cleat.
3. Now form an under hand loop and slip that loop over the arm of the cleat, which pins the free end under the last wrap.
4. Pull the free end tight and you have the neat, tidy and secure Cleat Hitch.

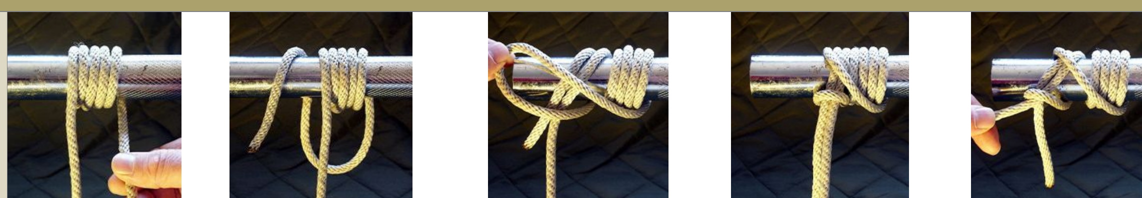
Halyard Hitch

Halyard Hitch
Compact and reliable knot for shackles and rings.

1. Pass the end of a rope through the shackle and make a turn around the standing line.
2. Make a second turn around the standing line below the first turn.
3. Bring the end of the rope back up to the top of the knot and feed the end down through the two loops just created.
4. Pull working end to tighten the knot and then pull the standing line to seat the knot against the shackle.

Icicle Hitch

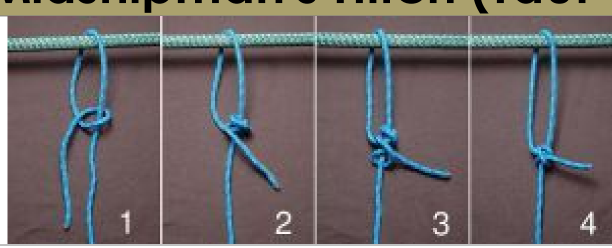
Icicle Hitch
Slide and grip knot useful to hoist a post.



1. Wrap working end of rope around the post four times. Then pass the standing line behind the wraps and pass it over the post leaving a hanging loop behind the wraps.
2. Take the hanging loop by its longest part and pass the loop in front of the working end on the front side of the post and pass the loop over the end of the post.
3. Tighten everything up and pull down on the standing line to further tighten the wraps around the post. Spread the wraps out on the post to hoist the post vertically.

Midshipman's Hitch (Taut-line Hitch)

Midshipman's Hitch
Creates an adjustable loop.



1. Pass the working end of a rope around an object such as a post or cleat. Pass the working end around the standing line creating the first Half Hitch.
2. Pass it around again, working back away from the object toward the standing line. Pull tight. This forms an Awning Hitch that can take load while the next step is tied.
3. Now make a half hitch in the same direction outside of the loop around the standing line. Pull the knot tight. The Midshipman's Hitch can now be slid on the standing line when there is no load and will hold tight when load is applied.

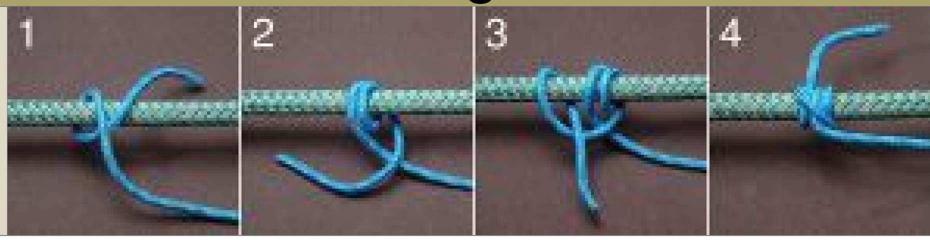
Mooring Hitch

Mooring Hitch
Quick release knot.

1. Make a turn around a post and then form a loop with the free end exiting the loop on the inside (leave longer free end than illustrated).
2. Grasp the standing line and pull a section through your loop.
3. Grasp a section of the free end (but not the very end) and pull part way through the new loop.
4. Tighten the knot by pulling down on the standing line. Release the knot by pulling the free end.

Rolling Hitch

Rolling Hitch
Secure a line to a post.



1. Wrap the end of a line around an object. Repeat, crossing over the standing line a second time.
2. Wrap a third time around the object but wrap above the standing line so as to not cross over it.
3. Pass the free end under the last wrap and pull tight.

Trucker's Hitch

Trucker's Hitch
Load securing knot.

1. Tie one end of rope to fixed object such as car bumper. About mid way on the rope tie a slippery half hitch to form a loop in the middle of the line. Be sure the loop part is formed with the slack part of the rope or it will tighten down on itself under pressure.
2. Make a wrap around another fixed point opposite the tie-in point and feed free end through the loop.
3. Using the loop as a pulley, pull down with the free end as tight as you can and secure the knot with two half hitches around one or both lines.

6 Climbing Knots

For climbing up rocks, trees and slopes.

Other Climbing Knots
- Zeppelin Bend
- Water Knot
- Stopper Knot
- Figure Eight
- Backup Knot
- Klemheist Knot
- Bowline on a Bight
- Alpine Butterfly Knot
- Girth Hitch
- Farmer's Loop
- Munter Hitch
- Distel Hitch
- Double Fisherman

Alpine Coil

Alpine Coil
To carry a coil of rope over your shoulder.

1. Bring both ends to the top of the newly made coil and form a bight in one of the ends.
2. Wrap the working end of the other rope around the strands of the coil and the bight, working forward as shown.
3. Tuck the working end of the rope being wrapped around through the bight first formed.
4. Pull the standing end of the bight to capture the working end tight.

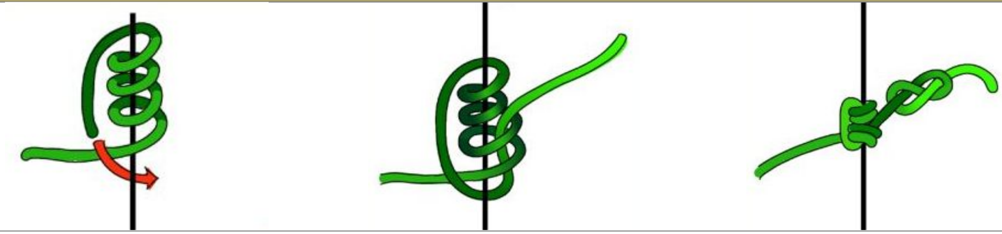
Autoblock Knot

Autoblock Knot
Friction knot for descending/rappelling.

1. Wrap your Autoblock Hitch cord four or five times around the rappel ropes. Use a thin cord such as 5mm or 6mm static cordage. Use up most of the cord on the wraps. The more wraps that you use, the more friction generated.
2. Then clip both ends of the cord into the locking carabineer on your harness leg loop. Lock the carabineer so the cord can't come undone. Finally, arrange all the wraps so they're neat and not crossed.

Blake's Hitch

Blake's Hitch
Arborist ascending/descending knot.



1. Wrap line four times around other rope, working from bottom to top.
2. Leave room in 2nd wrap to accommodate tag end of rope.
3. Run tag end down to and over standing line, behind static rope and out through 2nd wrap.
4. Tighten knot and finish with a stopper knot (Figure Eight) at the end of the line.

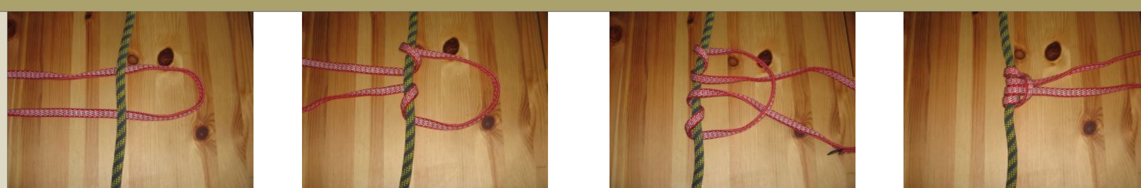
Bowline

Bowline
Forms a secure loop.

1. Lay the rope across your left hand with the free end hanging down. Form a small loop in the line in your hand.
2. Bring the free end up to and pass through the eye from the under side (the rabbit comes out of the hole).
3. Wrap the line around the standing line and back down through the loop (around the tree and back down the hole).
4. Tighten the knot by pulling on free end while holding standing line

Prusik Hitch

Prusik Hitch
Secures a movable loop to another line.



1. Make a sling of cordage (no more than 1/2 the diameter of main rope).
2. Tie a Girth Hitch around the main rope.
3. Pass the loop of the sling back through the centre of the Girth Hitch three or four more times.
4. Load with weight to make sure it

Running Bowline

Running Bowline
A slip knot.

1. Double the end of a rope and wrap tag end over then under standing line and up to side of new loop created.
2. Make a small loop on the topside of the original loop by twisting the line over itself.
3. Feed tag end through the small loop.
4. Wrap tag end once around topside of large loop and back down through small loop.
5. Pull tag end tight creating fixed loop that the main line can slip through.

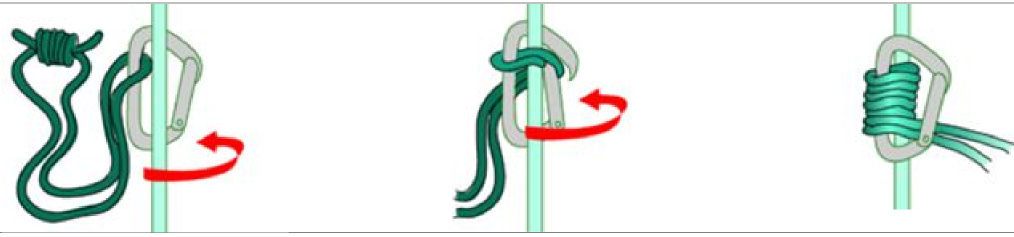
7 Hitch Knots

For tying a rope to an object.

Other Hitch Knots
- Valdotain Tresse
- Trucker's Hitch
- Timber Hitch
- Sledge Knot
- Rolling Hitch
- Prusik Hitch
- Mooring Hitch
- Midshipman's Hitch
- Munter Hitch
- Klemheist Knot
- Icicle Hitch
- Halyard Hitch
- Half Hitch
- Girth Hitch
- Distel Hitch
- Cow Hitch
- Cleat Hitch
- Autoblock Knot
- Blake's Hitch
- Anchor Bend
- Buntline Hitch

Bachmann Knot

Bachmann Knot
Friction hitch for ascending/descending.



1. Construct a strop of rope (not more than 1/2 the diameter of the vertical rope) or use a pre-made strop.
2. Clip the strop into the carabineer.
3. Hold the carabineer against the vertical rope and wrap the strop around the rope and pass through the carabineer.
4. Repeat, wrapping around the vertical rope and through the carabineer again (an additional wrap can be made if there is room in the carabineer).
5. Apply load to the end of the strop to bind the knot in place with friction.

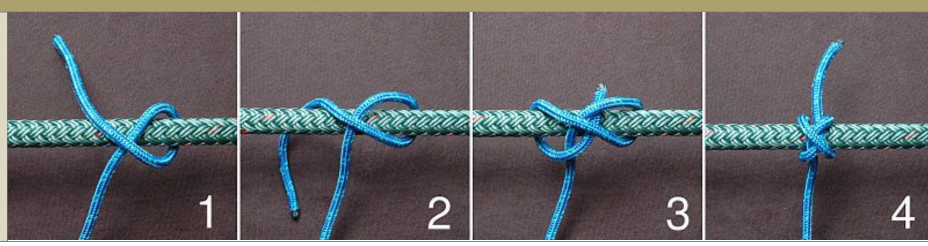
Barrel Hitch

Barrel Hitch
To hoist a barrel or drum.

1. Stand the barrel on the lifting rope.
2. Tie a simple overhand knot across the top.
3. Spread the overhand knot until it opens wide enough to slip over the sides of the barrel.
4. Adjust to embrace the top third of the barrel.
5. Tie a Bowline Knot with the ends of the rope to join together and lift.

Constrictor Knot

Constrictor Knot
Tie up a bundle of items.



1. Starting in front of the objects, make one wrap from right to left around the object(s) to be bound and cross over in the front.
2. Wrap around the object again.
3. Feed the working end back under the two wraps making sure you first cross over the standing line.
4. Pull both ends to tighten up the knot.

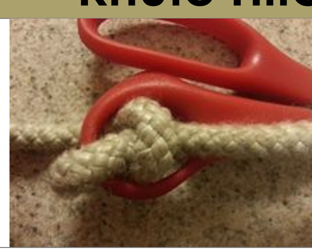
Highwayman's Hitch

Highwayman's Hitch
Quick release knot.

1. Double line to make the first bight in the rope and place bight behind post, rail or spar.
2. Make a second bight in the standing line and pass that bight through the first bight.
3. Give a little pull on the working end to tighten down on the second bight and hold it in place.
4. Take the working (which should be longer than it appears in the accompanying illustration) and make a third bight.
5. Pass the third bight through second and pull on the standing line to tighten the knot.
6. The knot holds with tension on the standing part and can be released with a tug on the working end.

Knute Hitch

Knute Hitch
Attach a lanyard to an object.



1. Tie a figure eight knot or other stopper knot in the end of the lanyard.
2. Form a bight and pass bight through the hole in the tool.
3. Pass the stopper knot through the bight and tighten the bight down by pulling on the standing line.

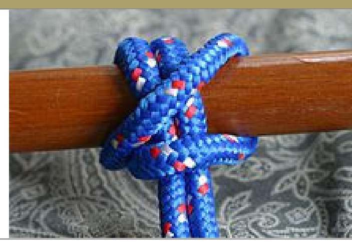
Marl

Marl
Arborist timber hitch alternative.

1. Tie a Running Bowline around the end of the log or branch. When pulled tight, it will cinch down to secure the log.
2. Run the rope a short way down the below the Running Bowline and wrap around the log.
3. Feed end of rope under the wrap just made, effectively tying an overhand knot.
4. Repeat once or twice more.

Pile Hitch

Pile Hitch
Attach a rope to an object.



1. Double end of a line into a loop and wrap around post or object from front to back.
2. Cross over standing lines and slide open end of loop over top of post.
3. Pull tight.

Rolling Bend

Rolling Bend
Secure a line to a post.

1. Wrap working end around object three to four times and then back around standing part.
2. Wrap working end around object again.
3. Finish knot with two half hitches with working end. Pull tight and maintain tension with standing line.

Schwabish Hitch

Schwabish Hitch
Arborist friction hitch.

1. Make four wraps around main static rope with a hand tied or sewn prusik or spliced eye split tail friction cord.
2. After fourth wrap bring wrapping tail down and make an additional wrap at bottom of other wraps in opposite direction while tying a half hitch around other rope. This results in both tails exiting the knot together.
3. Join eyes in front and clip together with a carabineer.

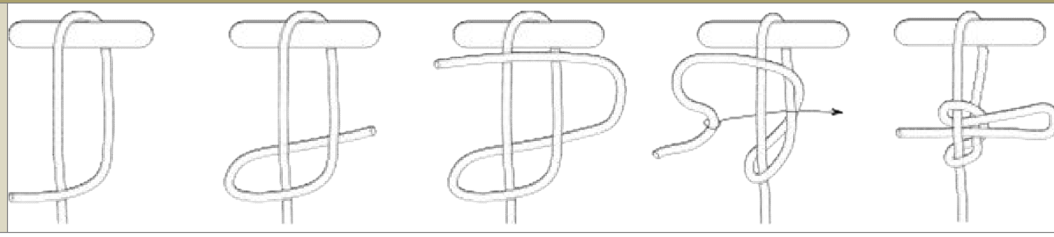
Slip Knot

Slip Knot
A knot for a sliding loop.

1. Make a loop by doubling line back onto itself.
2. Run tag end back toward loop and lay over the doubled lines.
3. Make one or two turns with the tag end around doubled lines and through new loop created.

Slipped Buntline

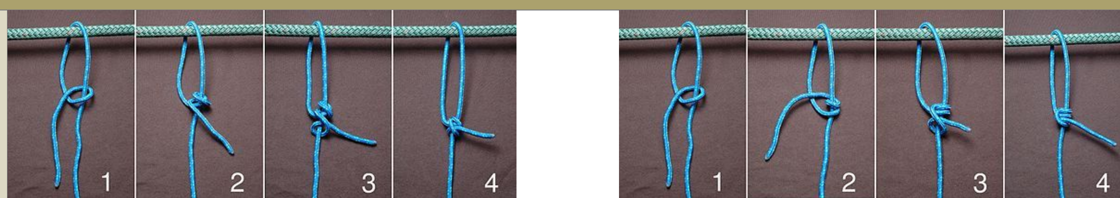
Slipped Buntline
A quick release knot.



1. Wrap working end around object and run end behind loop just created.
2. Bring working end back to front of knot and grasp in middle of working part.
3. Feed bight just formed between front and back lines of original loop.
4. Carefully tighten the knot. To release the knot, pull on tag end.

Tautline Hitch

Tautline Hitch
An adjustable knot.



1. Make a turn around a post or other object several feet from the free end.
2. Coil the free end twice around the standing line working back toward the post.
3. Make one additional coil around the standing line on the outside of the coils just made.
4. Tighten the knot and slide it on the standing line to adjust tension.

Tautline Hitch to Rope

Tautline Hitch to Rope
A movable knot on another line or object.

1. Lay line across rope or object you are attaching it to and make two downward wraps.
2. Move the working end up across the wraps and pass behind rope.
3. Make two more wraps around the rope, passing inside the working end.
4. Tighten down the wraps and grasp entire knot to slide up or down. A load on the standing line grips the knot to the rope or object.
5. A Figure Eight or other stopper knot should be tied in the end of the working end for security.

Adjusting
Once snug and set, the hitch can be adjusted as needed. To tighten the line with respect to a load attached to the standing part, the user can grasp the standing part with one hand inside of the loop and pull toward the anchor object. The hitch may be grasped with the other hand and as slack develops within the loop, the hitch slid away from the anchor object, taking up the slack and enlarging the loop. To loosen, the hitch may be slid toward the anchor object, making the loop smaller and lengthening the standing part.

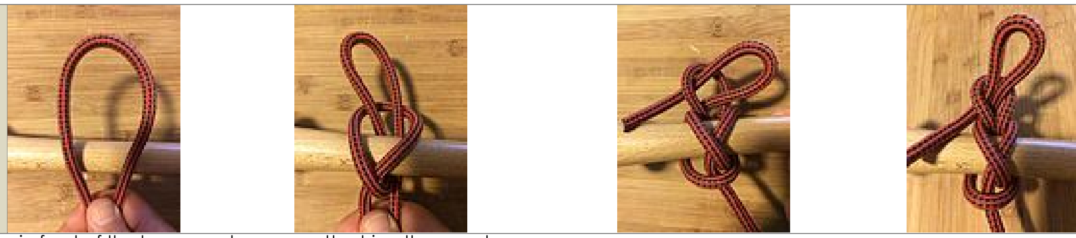
Transom Knot

Transom Knot
A lashing knot that ties two poles together.

1. Pass the working end behind the upright spar and back across the rope.
2. Now pass the working end behind the upright spar below the horizontal spar.
3. Working back toward the top, tuck the working end under both turns.
4. Pull both the working end and the standing part to tighten the knot. Trim ends if desired.

Tumble Hitch

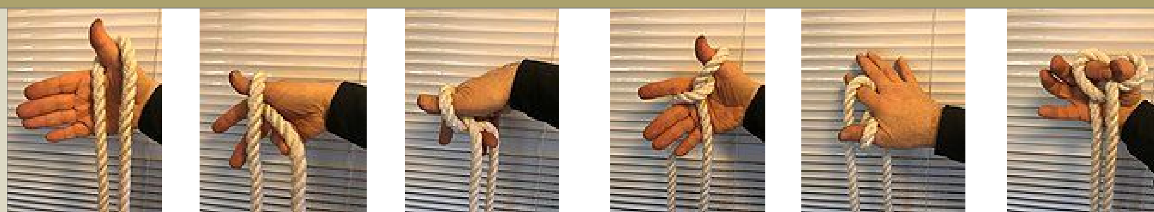
Tumble Hitch
A good quick release knot.



1. Form a bight in the rope in front of the bar or post you are attaching the rope to.
2. Now form a bight in the working end and run that bight behind the bar and pass it through the loop created by the first bight formed. A slight tug on the standing line can help to hold the second loop in place.
3. Pass working end behind standing line.
4. Pass working end in front of standing line.
5. Form another bight in the working end and run behind bar and pass up and through the 2nd loop.
6. Tighten the knot by applying load to the standing line while adjusting the knot down onto the final pass of the working end. Release the knot with a pull to the working end.

Clove Hitch

Clove Hitch
Secures rope to a solid structure quickly.



1. Wrap the free end of a rope around a post.
2. Crossover itself and around the post again.
3. Slip working end under last wrap.
4. Pull tight.

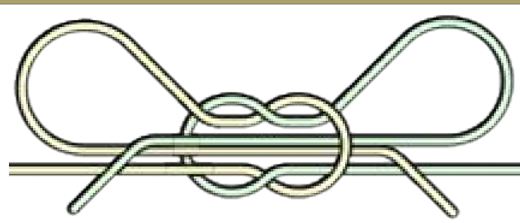
8 Loop Knots

For making loops.

Other Loop Knots
- Running Bowline
- Alpine Butterfly Knot
- Bowline
- Spanish Bowline
- Bowline on a Bight

Better Bow Knot

Better Bow Knot
A more secure shoelace knot.



1. Begin as if tying the standard shoelace knot with an overhand knot.
2. Make a loop on one side.
3. Now wrap two times around the loop. Be sure to wrap both these turns around the end of your thumb or finger.
4. Form a second loop at the end of the line you made the wraps with and push it through the space made by your thumb or finger while making the wraps.
5. Pull both loops in opposite directions.
6. Tighten and adjust loops.

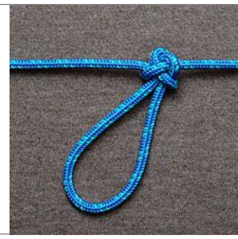
Double Bowline Knot

Double Bowline Knot
A more robust bowline knot.

1. Lay the rope across your left hand with the free end hanging down. Form a small loop in the line in your hand.
2. Repeat to form a second small loop below the first.
3. Bring the free end up to and pass through both small loops from the under side (the rabbit comes out of the hole).
4. Wrap the line around the standing line and back down through the two loops (around the tree and back down the hole).
5. Tighten the knot by pulling on free end while holding standing line.

Farmer's Loop

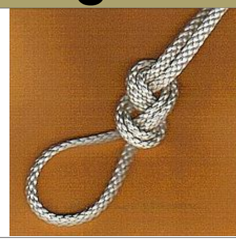
Farmer's Loop
Form a secure loop in the middle of a rope.



1. Start by wrapping the rope around your palm three times, letting the ends hang.
2. Next, lift the middle loop over the right loop (which becomes the middle).
3. In the same manner, pull the new middle loop over the left loop.
4. Again, middle over right.
5. Now middle over left, and pull out a little further to make the final loop of desired size.

Figure Eight

Figure Eight
The strongest knot for a loop at the end of a rope.



1. Tie a single eight in the rope two feet from its end. Pass the free end through any tie-in point if desired.
2. Retrace the original eight with the free end leaving a loop at the bottom of the desired size.
3. Pull all four strands of rope to cinch down the knot.

Honda Knot

Honda Knot
The lasso knot.

1. Tie a loose overhand knot at the end of a rope.
2. Now tie a tight overhand knot at the very end of the rope for a “stopper” and bring the end back through one side of the overhand knot.
3. Tighten down the loose overhand knot and pull the stopper knot up tight. That is the circular Honda Knot.
4. Now feed the main line through the Honda to form a lasso of any size.

Slippery Eight Loop

Slippery Eight Loop
An adjustable loop knot.

1. Begin by tying a Figure Eight at the end of a rope with enough extra line to make a loop of the desired size.
2. Leave the Eight loose and bring the working end back to the top of the knot.
3. Pass behind the standing line and feed the end through the Eight as illustrated.
4. Pull the knot tight. Adjust the size of the loop by alternately pulling the working end or one side of the loop.

Yosemite Bowline

Yosemite Bowline
A very secure loop knot.

1. First, tie a regular Bowline with a little longer working end: Lay the rope across your left hand with the free end hanging down. Form a small overhand loop in the line in your hand.
2. Bring the free end up to and pass through the loop from the under side and wrap line around standing line ("around the tree").
3. Feed line back down through the loop. That completes the regular Bowline.
4. Now wrap tag end around the front of the loop and follow exactly the path of the standing line up through the top eye, finishing on the right side of the standing line as you look at the knot from the front.
5. The tightening of this knot must be done exactly right to set it in the right order! Take the standing part and the bottom of the loop and pull tight. That tightens the original Bowline (which must be done first!).
6. Tug on the working end to tighten the Yosemite Finish. If you were to tighten the knot with the working end first you actually lose the original bowline and the knot isn't a secure knot. (To gain the benefits of the Yosemite Finish, it must be tied carefully and correctly. Many climbers do not trust using this knot with their life.)

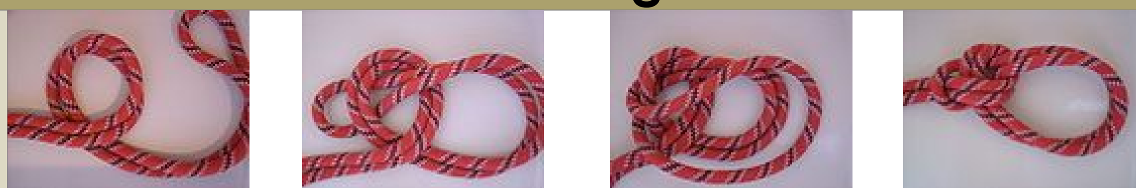
9 Rescue Knots

Useful for search and rescue or survival.

Other Rescue Knots
- Bowline
- Alpine Butterfly Knot
- Figure Eight
- Zeppelin Bend
- Water Knot
- Blake's Hitch
- Backup Knot
- Stopper Knot
- Farmer's Loop
- Munter Hitch
- Running Bowline
- Autoblock Knot

Bowline on a Bight

Bowline on a Bight
Forms a loop in the middle of a line.



1. Double a section of line and form a loop or "eye" in the line.
2. Pass the free end up through the eye forming a double loop below the eye.
3. Spread open the free end and bring it down to the bottom of the double loop.
4. Pass over double loop and continue up to top of eye.
5. Seat the knot by pulling on the double loop while holding the standing line.

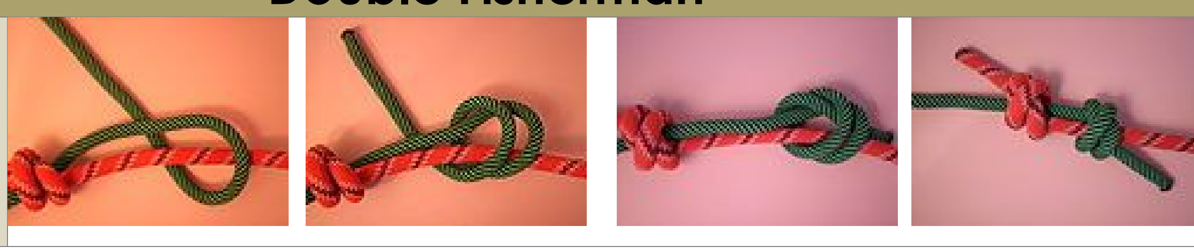
Distel Hitch

Distel Hitch
Arborist friction hitch.

1. Make four wraps around main static rope with a hand tied or sewn prusik or spliced eye split tail friction cord.
2. After fourth wrap bring wrapping tail down and make an additional wrap at bottom of other wraps in same direction while tying a half hitch by tucking tail under itself in the front of the knot.
3. Join eyes in front and clip together with a carabineer.

Double Fisherman

Double Fisherman
Join two ropes.



1. Lay the ends of two lines parallel to each other.
2. Coil the free end of one rope twice around the second rope and pass it back through the inside of the coils.
3. Repeat with second rope in opposite direction.
4. Pull free ends to tighten knots, then standing lines to slide knots together.

Fireman's Coil

Fireman's Coil
Coil a rope with a quick release.

1. Make a coil with your rope by looping it in circles. Use one hand to make the circles and the other to hold them in place.
2. Take the working end of rope (the end after the last coil is made) and make a loop mid rope at the top of the coils.
3. Take hold of the working end just below the loop and bring to back side of coil and run it up through the loop. That essentially makes a loop going through a loop.
4. Tighten down the first loop onto the second loop. This loop can be used for a hanging hook. Pull on the end of the rope to release.

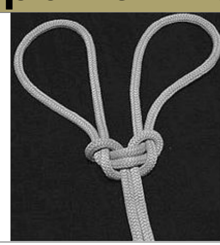
Sledge Knot

Sledge Knot
Bind things together very firmly.

1. Wrap working end of rope around items to be lashed together twice.
2. Pass working end behind standing line.
3. Wrap working end around standing line and itself three times working from bottom of knot up toward top of knot.
4. After passing the working end over the front of both ropes for the third time, wrap behind only the left side rope and feed working end down through the top most loop formed.
5. Next, pass end over the next two parts of lower loop and BEHIND bottom part of lower loop.
6. Tighten the knot by pulling first on the working end to tighten up the loops.
7. Now pull on the standing line to move the knot up to your anchor point, just like any slip knot and continue pulling and working the knot tighter and tighter.

Spanish Bowline

Spanish Bowline
A double loop knot.



1. Make a loop in the end of a rope and tuck the loop under the parallel lines.
2. Make a twist in each of the two sides of the loop, twisting in toward the centre with the outer part of the loops.
3. Now take the left loop and insert it in and through the right loop, moving first under then over the ropes it is crossing.
4. Grasp the new small lower loop by each side and pull those sides through the loops above.
5. Once you have the ropes part way through pull the two vertical ropes to help tighten down the knot.
6. Adjust the loops and pull everything very tight.

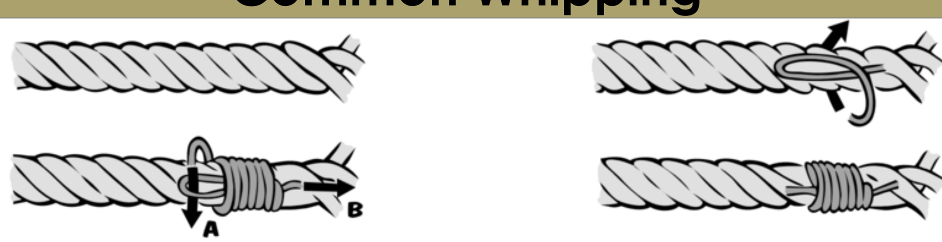
10 Misc Knots

Uncategorised knots for special purposes.

Other Misc Knots
- Alpine Coil
- Backup Knot
- Fireman's Coil
- Sledge Knot
- Stopper Knot

Common Whipping

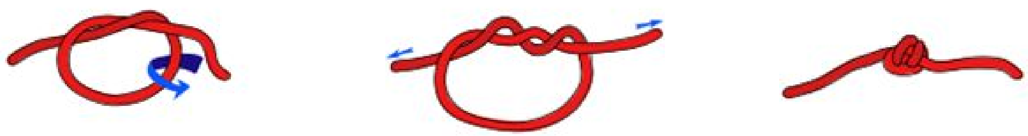
Common Whipping
Whipping knot to keep end of rope from unravelling.



1. Lay the twine along the rope and make a bight back along the rope. Note that the rope should be whipped a short distance (one and a half times the diameter) from its end.
2. Begin wrapping the twine around the rope and bight of twine securely.
3. Wrap until the whipping is one and a half times wider than the rope is thick.
4. Run the working end of the twine through the bight. Carefully pull on the standing end of the twine until the bight and working end are pulled under the whipping (Note: It is normally necessary to maintain tension on the working end to prevent the bight from being dragged completely through otherwise the whipping will fall apart.)
5. Cut the twine flush with the edges of the whipping to give the rope end a finished look.

Double Overhand Knot

Double Overhand Knot
Easy to tie stopper knot at end of rope.



1. Tie an overhand knot at the end of a rope but do not tighten the knot down.
2. Pass the end of the line through the loop created by the first overhand knot.
3. Tighten the knot down while sliding it into place at the end of the line. Be sure to leave some tail sticking out from the end of the knot.

French Whipping

French Whipping
Whipping knot to keep end of rope from unravelling.

1. Near the end of the rope, tie a simple overhand knot leaving a short tag end and a long working end.
2. Lay the tag end on top of the rope and begin making half hitches over the tag end and around the rope end being whipped.
3. Continue this same process of tying half hitches around the rope and burying the tag end in the new wraps.
4. Once you have wrapped past the tag end and approximately one to one and a half times the diameter of the rope being whipped, you will now secure the knot by leaving two half hitches open and inserting the working end through both loops of the half hitches.
5. You can repeat this a second time if desired.
6. Pull the working end very tight and trim close to the wraps.

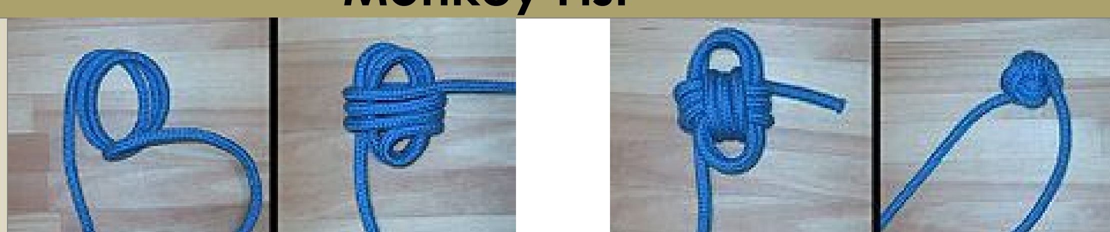
Heaving Line Knot

Heaving Line Knot
Adds weight to the end of a rope.

1. Double end of line.
2. Make 2 - 5 wraps around outside of both parts of doubled line.
3. Tuck tag end through loop.
4. Pull tight.

Monkey Fist

Monkey Fist
Decorative ball shaped knot.



KNOTS Misc Monkey Fist

1. Take your rope and with the long working end make three wraps around the fingers of your hand.
While holding the first set of turns in place, make three more turns passing outside the middle of the first three turns.
Finish this step by passing the working end around one side of the first set of turns. This sets up the working end for the next step which passes the end through the inside of the previous wraps.
2. Now make three turns around the set of wraps made in the previous step, passing through the inside of the knot. Double check that you have made the same number of turns for each step.
3. Finishing the knot: At this point a round object can be inserted in the centre of the wraps or the standing end of the rope can be tucked inside either with or without a stopper knot at the end as well. Working slowly begin tightening by working on each wrap, starting near the buried stopper knot and finishing with the other end of the rope. Do not pull too hard on the first few wraps. You will need to work your way through the knot more than once. The use of a small screwdriver or awl can help on the last tightening session through the knot.

KNOTS Misc Knots Sailor's Coil

Sailor's Coil

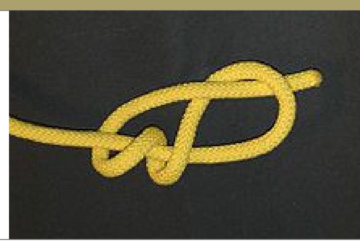
Sailor's Coil
Coil for storing rope at sea.

1. Coil the rope by making consecutive circles of the rope of equal size, gathering them up with one hand while using the other hand to make the circles.
2. Make a single hitch around a section of the coil. Then make a second hitch to the left of the first hitch.
3. Pull end tight.

KNOTS Misc Knots Stevedore Stopper

Stevedore Knot

Stevedore Knot
A bulky stopper knot for the end of a rope.



1. Form a bight in the end of the rope. Pass the working end over the standing line and continue around making one complete turn around the standing line.
2. Repeat 2-3 making a second complete turn around the standing line, working back towards the end of the rope.
3. Pass the end down through the original bight and tighten down the turns. Pull on both ends to tighten down the stopper knot.

Animals

Animal types, tracks, poisonous creatures and edibility

"An animal's eyes have the power to speak a great language."
Martin Buber

Introduction

This section contains animals found on the planet grouped by various means to help you identify them and whether they can help you or injure you.

Purpose	The aim of ANIMALS is to inform the reader on the most dangerous and poisonous creatures on the planet. It also includes information on their geographic region, habitat and information on what to do if you're bitten or stung.
Lost?	• If you've been bitten or stung by one of the animals listed here, go to the INJURY > Animal & Plant section. • For information on raising and caring for tame animals, see the ANIMAL HUSBANDRY section. • For utilizing animals for transport, see the TRANSPORT section. • For animals as pets, see the ENTERTAINMENT section. • If you want to prepare a captured animal for consumption, see the FIELD DRESSING section. • For defence against animals and insects such as mosquitos, see the DEFENCE section. • For information on dangerous animals by region, see the GEOGRAPHY section. • For animal-based disasters such as locust swams, see the NATURAL DISASTERS section.

Contents

1 Animal Tracks

These are any animal tracks you may encounter in the wild to either help determine what wildlife is in the area, what threats may be in the area and what kinds of traps to set.

Identification

Animals are around us in the woods, but we often don't know they are there. They lurk in the thick brush, hide in the trees or are nocturnal and only come out at night. You sometimes see the scat they leave behind, but if conditions are right, you may stumble upon some tracks. Animal tracks in snow, mud, sand or any other soft substrate are easier to spot and you may have to look up and look around you when tracking to find them. Take some time to examine the surrounding environment - you may find other signs of the animal or additional clues to help you ID the print. Use the tips and tricks below to figure out what animal just crossed your path.

Walking Patterns

The first thing you should look for when you find an animal track is the track pattern. There are four unique track patterns which will help you narrow down the group of animals that are responsible for the print.

Zig-Zaggers (Perfect Walkers)	Perfect walkers walk very carefully to conserve energy. Their rear paw/hoof will land in the spot where their front paw previously fell. This gait leaves a zig-zag pattern that is easy to spot. Deer, moose, fox, coyote, bobcat are perfect walkers.
Waddlers	Waddlers appear to move one side of their body and then the other side when they walk. Their rear foot does not land in the print of front foot. Their track is comprised of four prints. Bear, skunk, woodchuck, raccoon, muskrat, beaver, porcupine are waddlers.

Bounders	Bounders place their front feet down, and in one motion they leap forward by lifting up their front feet and putting their rear feet in the exact spot where the front feet previously landed. Their tracks appear as two paws that fall side-by-side. Otters, weasels and other mustelids are bounders.
Hoppers	Hoppers move by placing their rear feet slightly ahead of their front feet and pushing off so their front feet land first and their back feet land in front. This pattern of leapfrogging is found in rabbits and rodents like mice, red squirrels, and chipmunks.

Track Characteristics

Finding the track pattern helps you narrow down the animal you are trying to identify into larger groups, but that is only the first step of identification. You need to get up close and personal with the print, examining the details such as the size of each print, the number of toes, and more.

Width/Length	Width and length help you tell the difference between closely related animals. Within the canines, a fox print will be smaller than a wolf print. Be aware that there is some overlap. A wolf pup may have the same size print as an adult fox. In these cases, you need to look for other clues, such as the tracks of the mother wolf or multiple tracks from a litter of fox kits. There also may be scat nearby as well.
Number of Toes	The number of toes is important to tell the major groups of animals apart! Bear have five toes, while canines and felines have four, for example.
Nails	Nails are a huge find when you can see them! Canines tend to leave a nail print while felines don't since they can retract their nails. There is some grey area -- a feline may bring out its nails because it is on alert or a dog won't sink down enough to imprint its nails. Look for additional prints and other tracks to help fill in these blanks.
Depth	Depth is useful when comparing tracks left in the same substrate at the same time. The heavier the animal, the deeper the print it will leave. Be careful when comparing prints from different locations and times. A deer could make a print that resembles a moose because it is walking on mud softened by a recent rainstorm.
Front/Rear	Front and rear paws may have a slightly different size and shape, depending on the animal. Most guidebooks will have measurements for both prints.
Webbing	Webbing is usually found on animals that frequently swim in the water.
Stride and Straddle	Stride and straddle measure the gate of an animal and can be used to distinguish between two very closely related prints. Stride is measured from the heel of one print to the heel of the other print on the same side. Straddle is the measurement of the width of the track from the outside of the right track to the outside of the left track.

Animal Categories

Canine Tracks

Canine prints are distinctive -- the overall shape is oval with four twos and a heel pad that is concave at the bottom. The four toes point forward and are held closely together with the two front toes often lining up side-by-side. There usually are claws visible in the track and they also point forward. Because of the arrangement of the toes and pad, you can draw an "X" through the canine print. When comparing front and rear tracks, the fore prints of all members of the dog family are significantly larger than the hind print.

Wolf	Wolves are among the largest canines, and their paws are the biggest in the group with a long (4") and wide print.
Coyote	Coyotes are slightly smaller than wolves and have a print that is more narrow (2.5 to 3.5") than the wolf.
Fox	The fox is the smallest canine in the group and have the smallest print (2 to 3"), almost dainty when compared to their bigger cousins. Fox tend to drag their feet and also have more hair in their paws producing a print that is fuzzy around the edges and has a small pad imprint.
Dog	A domestic dog can have a similar sized print to wolf or coyote making it difficult to tell them apart. If you can find a set of prints, you can usually tell the difference by how the two animals walk. Wild animals like wolves and coyotes tend to walk in a straight line to conserve energy, while dogs zig-zag and circle around quite a bit when they are walking. Domestic dogs also tend to splay their toes, producing a track with toes and nails that are pointing outward. Another difference is the nails -- dog nails are thick and blunt while wild canines leave thin and sharp nail prints.

Feline Tracks

Feline prints have four toes and a heel pad with three lobes at the bottom edges that are shaped like a bubble letter "M". Cats actually have five toes up front and four toes in the back, but the extra toe up front does not appear in the tracks. Feline prints are as wide as they are long, making them more round in shape than a canine. Felines also have a leading toe much like a person's middle finger. You can draw a "C" through between the pad and toes of a feline print.

Cougar/ Mountain Lion	Among the felines, cougar tracks are the largest (greater than 3"), about the size of the domestic dog.
Lynx	Though smaller in stature, lynx tracks are the same size as a cougar, but are not as defined due to the fur around their paws.
Bobcat	Bobcats have smaller tracks (2") that are often confused with coyote or fox. Look for a lack of nails and a round-shaped print to identify the bobcat track from its canine counterparts.
House Cat	The prints of a house cat are small (1 to 1.5"). Similar to the domestic dog, the house cat also tends to meander when walking and does not try to conserve energy.

Hoof Tracks (Large)

Ungulates have a split hoof with two toes that leave a distinct imprint. Ungulates can be divided into two main groups based upon the shape of their toes. One group has toes that curve forming a heart-shaped print, while the other have toes that are rounded and leave a round or even square-shaped print.

Moose	Moose are among the largest of the hooved animals and have two toes that curve together into a point forming almost a heart shape print. Moose are heavy and sink down deep into snow allowing the dew claws to sometimes appear in the track. Their tracks measure 5-7" long, about the size of your hand.
Deer	Deer, like moose, have two toes that curve sharply together forming almost a heart shape print. The prints are smaller in size than a moose measuring 2-3.5".

Elk	Elk are similar to moose and deer, but their toes are rounder and not as sharply tapered at the tips. The prints measure 3-5", placing them right in between the deer and moose. Dew claws sometimes appear in deep snow or when the elk is galloping.
Bison	Bison also have two toes in their hooves, but their toes are rounder and they print doesn't taper to a point like the deer, moose and elk. Their print is wide and more round than heart-shaped. It measures 4.5 to 6".
Cow	Cow prints are often confused with bison since they share the same round shape and relative size. The easiest way to tell them apart is to know your surroundings. Is there a farm nearby?

Hoof Tracks (Small)

Mountain goats, bighorn sheep and wild hogs have the same two-toed hooves as their bigger ungulate cousins, but the shapes of their hooves reflect their lifestyle and habitat.

Mountain Goats	To help them climb, mountain goats have toes that spread when they step, creating a distinctive V shape at the top of their print.
Bighorn Sheep	Bighorn sheep have an elongated hooves that are easily confused with those from a deer. In general, the bighorn sheep prints have straighter edges and are less pointed than a deer. They are more blocky and less shaped like a heart.
Wild Hog	The wild boar track is often confused with the deer since they are about the same size. The shape is the discriminating feature. The boar has toes that are wider, rounder and blunter than the deer and don't come to a point like the deer. Hogs also have a dew claw that rests slightly outside the print.

Bird Tracks

Bird tracks can be grouped into categories based upon whether they live mainly in trees or on the ground. Tree dweller tend to hop on the ground and leave a pair of prints behind, while ground birds will leave alternating tracks.

Crow	The crow has the standard bird track with three thin forward-facing toes and one rear-facing toe. They are hoppers and leave a pair of prints approximately 2-2.5" long.
Grouse	Grouse are small ground birds that have a game bird track with only three forward facing toes. They measure about 2" long.
Turkey	Turkey also are ground birds like the grouse and have a similar game bird track. Turkey are much larger than a grouse measuring 4" long.
Duck	The duck has the same toe arrangement as the game birds, but the webbing gives its print a distinctively different shape. Duck also tend to wander and leave a maze of tracks.

Small Animals

These small mammals produce small prints, so you have to look closely at the prints and the track patterns to tell them apart. It's a diverse group with hoppers and waddlers that range from the forest to the river's edge. With the exception of the rabbit and armadillo, most of these small mammals have five toes on their front and rear feet.

Raccoon	If you see a print that looks like the hand of a baby, then it is likely a raccoon. Raccoon have five toes that resemble a human hand. The front print is smaller (1-3") and has a C-shaped heel pad, while the rear print has a longer (1.5-4") heel pad. Raccoon waddle when they walk.
Opossum	With five fingers and a human hand shape, opossum tracks resemble the raccoon, but there is one major difference. Opossum have opposable thumbs on their hind feet that appear in their prints. They are the only North American mammal with opposable thumbs. Opossum also tend to stagger when they walk
Otter	Look for signs of otter on muddy or snowy river banks where you can find prints and trough from belly-sliding into the water. They have five toes on their feet and short claws that give their prints a pointed look. Their toes are partially webbed which sometimes show up in the mud.
Skunk	Skunk have five toes on their hind and front feet. Unlike most mammal that have large hind feet, and small front feet the front and hind feet of the skunk are approximately the same size. They also have claws that show up in many of their prints.
Rabbit	Rabbits are hoppers and move by placing their larger hind feet ahead of their smaller front feet. Unlike squirrels which keep their feet next to each other as they hop, rabbits stagger their feet producing a "Y" shaped track.
Armadillo	Armadillo are only found in the southeast and south central US so you don't have to worry about their tracks in the rest of the US. Armadillo have four long toe prints with a sharp claw at the tip. The front print shows a distinct "V" between the middle toes. They also have a scaly tail they drag behind them that often obscures their tracks.

Reptile / Amphibian

Reptiles and Amphibians have very different life cycles, but they share a similar feature -- they all have long toes that provide extra grip for walking, hopping and climbing.

Alligator	The first thing you notice about an alligator track is not its four toes or its foot shape, but the large through its tail creates as it walks. Look for a central trough with pairs of prints on either side. Another key is the size -- alligators have large feet. The front prints have five toes and are wide in the heel while the rear prints are longer and have four toes with a narrow, pointed heel.
Lizards	Unlike an alligator, lizards are lightweight and don't leave much of a track. Lizards may leave light scuff from their feet and a small tail drag. The tail drag tends to be straighter and more pronounced than other tail-bearing animals like mice.
Frogs	Frogs have four bulbous toes in their front and five in their hind prints. Their front toes point slightly inward producing a "K" shaped print, while their rear toes slope upward and outward. Their belly sometimes appears in the track. They are hoppers with their front feet often landing between their much larger hind feet.

Rodents

Rodents are a very diverse group of mammals, and their tracks reflect their diversity. You have to think about habitat, body shape, and track pattern as much as the individual prints. All rodents leave behind front tracks with four toes and hind tracks with five toes.

Beaver	You can tell a beaver is nearby by the dams they build and the gnawed trees they leave behind. They have webbed hind feet with 5 toes (4.5-7"), but their tracks often are hard to find. You rarely see the four-toed front prints (2.5-3.5") because the hind print wipes out the front print when they waddle as they walk. And sometimes you don't even see any prints at all as the beaver's large tail can wipe out all their tracks.
Porcupine	Porcupines move slowly and waddle when they walk. They also are climbers and have both big heel pads and long toes with claws. Usually, you will only see their pads in their prints (1-2") along with an occasional trail drag. These pads have a rough surface that aids in climbing and can be seen in soft mud. Each print points inward because they are pigeon-toed. In winter, porcupines are so low to ground that they leave a deep trough in the snow.
Muskrat	Muskrat tracks are hand-like much like the raccoon, but smaller measuring approximately 2-3". Their prints have five long finger-like toes on their hind foot and four long fingers on their front. Muskrat tracks are found near marshes, beaver ponds, and similar slow-moving waterways.
Mouse	Mice, like squirrels, are hoppers. Their larger back feet (0.5-1") land slightly ahead of their smaller front feet (0.25-0.5") producing a cluster of four prints. Mice prints are very small may show a tail drag.
Squirrel	Squirrels are hoppers with their larger back feet (1.5-2") landing slightly ahead of their smaller front feet (1-1.5"). Their feet tend to land side-by-side producing a repeating series of four distinct prints. These tracks often meander from tree to tree.

Bear Tracks

You can't miss a bear track -- its paw is huge with five rounded toes and a wide heel pad. Black and Grizzly Bear tracks can be hard to differentiate. Geographic location can help narrow down the possibilities.

Black Bear	A black bear has short claws and its toes spread out in a curve over its foot pad. Generally going to be smaller than Grizzly Bear paw.
Grizzly Bear	A grizzly has long claws that extend out further from their toes. Its toes also are held closer together, forming almost a straight line above the foot pad.

2 Poisonous Creatures

A section identifying poisonous creatures of the world. This only includes creatures that have poison and exclude creatures that can injure you by other means.

Subheadings

1. Snakes	2. Spiders	3. Scorpions	4. Insects
5. Other Arthropods	6. Toxic Birds	7. Mammals	8. Lizards
9. Amphibians	10. Fish	11. Cephalopods	12. Cnidarians

1 Snakes

Snakes are elongated, legless, carnivorous reptiles of the suborder Serpentes. Like all other squamates, snakes are ectothermic, amniote vertebrates covered in overlapping scales. Many species of snakes have skulls with several more joints than their lizard ancestors, enabling them to swallow prey much larger than their heads with their highly mobile jaws. To accommodate their narrow bodies, snakes' paired organs (such as kidneys) appear one in front of the other instead of side by side, and most have only one functional lung. Some species retain a pelvic girdle with a pair of vestigial claws on either side of the cloaca. Lizards have evolved elongate bodies without limbs or with greatly reduced limbs about twenty-five times independently via convergent evolution, leading to many lineages of legless lizards. Legless lizards resemble snakes, but several common groups of legless lizards have eyelids and external ears, which snakes lack, although this rule is not universal. The snakes below are ordered from most venomous to least venomous, but don't be fooled - they can all kill you under the right circumstances.

Treatment
The application of a compression bandage above the wound and the availability and administration of a polyvalent (broad-spectrum) antivenom in the local hospital can save your life.

Dubois' Sea Snake

Aipysurus duboisii, also known as the Dubois' sea snake or reef shallows sea snake, is a species of venomous sea snake. Adults of A. duboisii grow up to 148 cm (4.86 feet) in total length (including tail) but usually to around 80 cm (2.6 feet). The head is slightly wider than the neck with nostrils on its upper part and nasals contacting each other.

Eyes are separated from supralabial scales by a row of large subocular scales. Dorsal scales are usually smooth, but sometimes have a small keel or small knobs. Individuals vary significantly in colour and its body patterns. The tail is relatively long; the chin and throat have lighter colour than rest of the body.

Habitat
Its geographic range includes Papua New Guinea, New Caledonia and the northern, eastern and western coastal areas of Australia, that is the Coral Sea, Arafura Sea, Timor Sea and Indian Ocean. They live at depths up to 80 meters (262 feet) in coral reef flats, sandy and silty sediments which contain seaweed, invertebrates and corals or sponges that can serve as shelter.

Venom
The fangs are 1.8 mm long, which are relatively short for a snake, and the venom yield is 0.43 mg. Aipysurus duboisii is a crepuscular species, meaning that they are most active at dawn and dusk. It is the most venomous sea snake, and one of the top three most venomous snakes in the world. The most venomous sea snake in the world and one of the top three most venomous snakes in the world

Aggressiveness
They have medium aggressiveness, i.e., will bite if provoked, but not spontaneously.

Inland Taipan

The inland taipan (Oxyuranus microlepidotus), also commonly known as the western taipan, the small-scaled snake, or the fierce snake, is an extremely venomous snake of the taipan (Oxyuranus) genus. The inland taipan is dark tan, ranging from a rich, dark hue to a brownish light-green, depending on season. Its back, sides and tail may be different shades of brown and grey, with many scales having a wide blackish edge. These dark-marked scales occur in diagonal rows so that the marks align to form broken chevrons of variable length that are inclined backward and downward.

The lowermost lateral scales often have an anterior yellow edge. The dorsal scales are smooth and without keels. The round-snouted head and neck are usually noticeably darker than the body (glossy black in winter, dark brown in summer), the darker colour allowing the snake to heat itself while only exposing a smaller portion of the body at the burrow entrance.

The eye is of average size with a blackish brown iris and without a noticeable coloured rim around the pupil. It has 23 rows of dorsal scales at midbody, between 55 and 70 divided subcaudal scales, and one anal scale. The inland taipan averages approximately 1.8 metres (5.9 ft) in total length, although larger specimens can reach total lengths of 2.5 metres (8.2 ft). Its fangs are between 3.5 and 6.2 mm long (shorter than those of the coastal taipan).

Habitat
It's endemic to semi-arid regions of central east Australia. The inland taipan inhabits the black soil plains in the semi-arid regions where Queensland and South Australia borders converge. Because it lives in such remote locations, the inland taipan seldom comes in contact with people; therefore it is not considered the most deadly snake in the world overall, especially in terms of disposition and human deaths per year. The word "fierce" from its alternative name describes its venom, not its temperament.

Venom
The inland taipan is the most venomous snake in the world. Its venom, drop for drop, is by far the most toxic of any snake. Unlike most snakes, the inland taipan is a specialist mammal hunter so its venom is specially adapted to kill warm-blooded species. It is estimated that one bite possesses enough lethality to kill at least 100 fully grown men, and, depending on the nature of the bite, it has the potential to kill someone in as little as 30 to 45 minutes if left untreated.

The average quantity of venom delivered by this species is 44 mg and the maximum dose recorded is 110 mg, compared to the Indian cobra (Naga raja) 169 mg/max 610 mg, and the North American eastern diamondback rattlesnake (Crotalus adamanteus) 410 mg/max 848 mg etc. The median lethal dose (LD50), subcutaneous (the most applicable to actual bites) for mice is 0.025 mg/kg (0.01 mg/kg subcutaneous, in bovine serum albumin).

Compared to the beaked sea snake (Enhydrina schistosa) 0.164 mg/kg, Indian cobra 0.565 mg/kg, North American eastern diamondback rattlesnake 11.4 mg/kg, etc., the inland taipan has a smaller venom yield than its cousin the coastal taipan yet its venom is almost four times as toxic. One bite's worth of venom is enough to kill 100 fully grown men. It is an extremely fast and agile snake that can strike instantly with extreme accuracy, often striking multiple times in the same attack, and it envenoms in almost every case.

Although extremely venomous and a capable striker, in contrast to the rather aggressive coastal taipan, the inland taipan is usually quite a shy and reclusive snake, with a placid disposition, and prefers to escape from trouble. However, it will defend itself and strike if provoked, mishandled, or prevented from escaping.

Clinical Effects
The mortality rate is high in untreated cases:
Dangerousness of bite: Severe envenomation likely, high lethality potential.
Rate of envenoming: >80%
Untreated lethality rate: >80%

Inland taipans adapt to their environment by changing the colour of the skin during seasonal changes. They tend to become lighter during summer and darker during the winter. This seasonal colour change serves the purpose of thermoregulation, allowing the snake to absorb more light in the colder months.

Aggressiveness
Many reptile keepers consider it a placid snake to work with.
Inland taipans are rarely encountered in the wild by the average person because of their remoteness and brief above-ground appearance during the day. So long as a person is not creating much vibration and noise the inland taipan may not feel alarmed or bothered by a human presence. However, caution should be exercised and a safe distance maintained as it can inflict a potentially fatal bite. The inland taipan will defend itself and strike if provoked, mishandled, or prevented from escaping. Firstly, but not always, it makes a threat display by raising its forebody in a tight low S-shaped curve with its head facing the threat. Should the person choose to ignore the warning the inland taipan will strike. It is an extremely fast and agile snake that can strike instantly with extreme accuracy, and it envenoms in almost every case.

Symptoms
The first local and general symptoms of a bite are local pain and variable non-specific effects which may include headache, nausea, vomiting, abdominal pain, diarrhoea, dizziness, collapse or convulsions leading to major organ effects: neurotoxicity, coagulopathy, rhabdomyolysis or renal failure/damage and finally death. Inland taipan snake venom contains potent presynaptic neurotoxins (toxins in venom that cause paralysis or muscle weakness). Also present are postsynaptic neurotoxins, which are less potent but more rapid acting than the presynaptic neurotoxins. Presynaptic neurotoxins disrupt neurotransmitter release from the axon terminal. This takes days to resolve and does not respond to antivenom.

Eastern Brown Snake

The eastern brown snake, often referred to as the common brown snake, is an extremely venomous snake of the family Elapidae, native to eastern and central Australia and southern New Guinea. Considered the world's second-most venomous land snake after the Inland Taipan and based on its LD50 value (subcutaneous) in mice, it is responsible for about 60% of snake-bite deaths in Australia. The eastern brown snake is of slender to average build with no demarcation between its head and neck.

Its snout appears rounded when viewed from above. Most specimens have a total length (including tail) up to 1.5 m (4.9 ft), with some large specimens reaching 2 m (6.6 ft). The maximum recorded size for the species is 2.4 m (7.9 ft). There is evidence that snakes from the northern populations tend to be larger than those from southern populations. The adult eastern brown snake is variable in colour. Its upperparts range from pale to dark brown, or sometimes shades of orange or russet, with the pigment more richly coloured in the posterior part of the dorsal scales. Eastern brown snakes from Merauke have tan to olive upperparts, while those from eastern Papua New Guinea are very dark grey-brown to blackish. It has a dark tongue. The iris is blackish with a paler yellow-brown or orange ring around the pupil.

Habitat
The eastern brown snake is found along the east coast of Australia, from Malanda in far north Queensland, along the coasts and inland ranges of Queensland, New South Wales, Victoria, and to the Yorke Peninsula in South Australia. Disjunct populations occur on the Barkly Tableland and the MacDonnell Ranges in the Northern Territory and the far east of the Kimberley in Western Australia, and discontinuously in parts of New Guinea, specifically northern Milne Bay Province and Central Province in Papua New Guinea, and the Merauke region of Papua Province, in the Indonesian part of New Guinea. It is common in south-eastern Queensland between Ipswich and Beenleigh. The eastern brown snake is found in most habitats except dense forests. It has become more common in farmland and on the outskirts of urban areas, benefitting from agriculture due to the increased numbers of its main prey, the introduced house mouse.

Venom
The eastern brown snake is considered to be the second-most venomous terrestrial snake in the world, behind only the inland taipan of central east Australia. It is the most commonly encountered dangerous snake in Adelaide, and is also found in Melbourne, Canberra, Sydney, and Brisbane. It is classified as a snake of medical importance by the World Health Organization. Clinically, the venom of the eastern brown snake is known to cause diarrhoea, dizziness, collapse or convulsions, renal failure, paralysis, and cardiac arrest. Without medical treatment, bites can be fatal. As this species tends to initiate its defence with nonfatal bites, the untreated mortality rate in most snakebite cases reported is 10–20%, a relatively low figure.
As a genus, brown snakes accounted for 41% of identified snakebite victims in Australia between 2005 and 2015, with 15 deaths recorded.

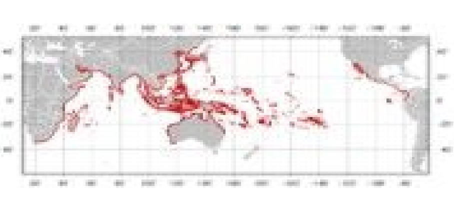
Aggressiveness
The eastern brown snake reacts when confronted with one of two neck displays. During a partial display, the snake raises the front part of its body horizontally just off the ground, flattening its neck and sometimes opening its mouth. In a full display, the snake rises up vertically high off the ground, coiling its neck into an S shape, and opening its mouth. The snake is able to strike more accurately from a full display and more likely to deliver an envenomed bite. Due to the snake's height off the ground in full display, the resulting bites are often on the upper thigh.

Behaviour
The eastern brown snake is active during the day, though it may retire in the heat of hot days to come out again in the late afternoon. It is most active in spring, with males venturing out earlier in the season than females, and is sometimes active on warm winter days. Individuals have been recorded basking on days with temperatures as low as 14 °C (57 °F). Occasional nocturnal activity has been reported. Australian naturalist David Fleay reported it could outpace a person running at full speed. Many people mistake defensive displays for aggression. A field study in farmland around Leeton that monitored 455 encounters between eastern brown snakes and people found that the snake withdrew around half the time and tried to hide for almost all remaining encounters. In only 12 encounters did the snake advance. They noted that snakes were more likely to notice dark clothing and move away early, reducing the chance of a close encounter. Close encounters were more likely if a person was walking slowly, but a snake was less likely to be aggressive in this situation.

Yellow Bellied Sea Snake

Hydrophis platurus, commonly known as the yellow-bellied sea snake, yellowbelly sea snake or pelagic sea snake, is a species of snake from the subfamily Hydrophiinae (the sea snakes) found in tropical oceanic waters around the world except for the Atlantic Ocean. The yellow-bellied sea snake, as the name implies, has a distinctive bicolor pattern with a yellow underbelly and brown back, making it easily distinguishable from other sea snake species.

Yellow-bellied sea snakes, like many other species of sea snake, are fully adapted to living their whole lives at sea: mating, eating and giving birth to live young (ovoviviparous). Adaptations to aquatic life include the reduced ventral scale size, laterally compressed body and paddle-tail for swimming, valved nostrils and palatine seal for excluding seawater, and cutaneous gas exchange for prolonging dive times.



Habitat
The yellow-bellied sea snake is one of the most widely distributed snakes in the world. It is completely pelagic and is often observed on oceanic drift lines, using surface currents and storms to move around the ocean. Their distribution appears to be largely determined by favourable water temperatures, oceanic currents and recent formation of land bridges that have blocked farther dispersal. The yellow-bellied sea snake has an extensive distribution covering the entire tropical Indo-Pacific, as well as extending to Costa Rica, southern California, and northern Peru. It is the only sea snake to have reached the Hawaiian Islands. The sea snake has also been reported in colder waters such as the coasts of southern California, Tasmania, and New Zealand, a country that would otherwise be free of snakes were it not for the infrequent visits of yellow-bellied sea snake and banded sea kraits. These cold water occurrences are believed to be linked with el Niño events or severe storms.

Venom
The venom of this species is highly potent, like that of other sea snakes. The subcutaneous LD50 of the venom is 0.067 mg/kg and the venom yield per bite is 1.0–4.0 mg. Yellow-bellied sea snake venom contains several different neurotoxins and two other isotoxins. Sea snake venom can cause damage to skeletal muscle with consequent myoglobinuria, neuromuscular paralysis or direct renal damage. The venoms of significant species of sea snake are neutralised with Commonwealth Serum Laboratories Ltd (of Melbourne, Australia) sea snake (Enhydrina schistosa) antivenom.

Peron's Sea Snake

Hydrophis peronii, commonly known as the spiny-headed seasnake, Peron's sea snake, or the horned sea snake, endemic to the western tropical Pacific Ocean. It is the only sea snake with spines on the head. Like other members of the family, Hydrophiidae or Elapidae, it is venomous. It is sometimes placed in its own genus Acalyptophis. The spiny-headed seasnake is a medium-size snake, with the diameter of the neck only one third to two fifths the diameter of the thickest part of the body.

The head is small and the tail flattened laterally. The supraoculars are raised, and their free borders are pointed. This species reaches a snout-vent length of up to 1.23 m (4.0 ft). Dorsally, it is grayish, pale olive, or tan, with dark crossbands, which are narrower than the spaces between them and taper to a point on the sides of the belly. Ventrally, it is uniform whitish or with a series of dark crossbars alternating with spots.

Habitat
It is found in the Gulf of Siam, Thailand, Vietnam, the South China Sea, the coast of Guangdong and Strait of Taiwan, the Philippines, Indonesia, New Guinea, New Caledonia, the Coral Sea Islands, Papua New Guinea, and Australia, (North Territory, Queensland, West Australia, & possibly New South Wales). It prefers seas with sandy beds and coral reefs.

Coastal Taipan

The coastal taipan (Oxyuranus scutellatus), or common taipan, is a species of large, extremely venomous snake in the family Elapidae. The species is native to the coastal regions of northern and eastern Australia and the island of New Guinea. According to most toxicological studies, this species is the third-most venomous land snake in the world. The coastal taipan is the longest venomous snake in Australia. Adult specimens of this species typically attain sexual maturity around 1.2 m (3.9 ft) in total length (including tail).

More mature specimens can grow to between 1.5 and 2.0 m (4.9 and 6.6 ft). Other taipans, including the inland taipan, attain broadly similar sizes although they tend to be slightly smaller in average size. A specimen of an average 2 m (6.6 ft) total length weighs around 3 kg (6.6 lb). The head of the coastal taipan is long and narrow like that of the African black mamba, but without the "coffin" shape.

The two species are strongly convergent in several aspects of morphology, ecology and behaviour. O. scutellatus has an angular brow and is lighter-coloured on the face. The body is slender and colouration can vary. It is often uniformly light olive or reddish-brown in colour, but some specimens may be dark gray to black. The colouration is lighter on the sides of the body, and the ventral side (the belly) is usually a creamy-white to a pale light yellow in colour, and is often marked with orange or pink flecks. Individuals undergo a seasonal change in colour, becoming darker in winter and fading in summer.

Habitat
The coastal taipan occurs only in Australia and the island of New Guinea, which comprises two Indonesian provinces on the west side of the island and the nation of Papua New Guinea on the east side of the island. Found in northern and eastern Australia, the coastal taipan, despite its name, can live in habitats hundreds of kilometres away from the nearest beach. Its geographical range extends from north-western Western Australia, the Northern Territory, across Cape York Peninsula and down eastern Queensland into northern New South Wales (as far south as Grafton). However, the coastal taipan is not found in regions where the maximum winter temperature is below 20 °C (68 °F). The second subspecies (Oxyuranus scutellatus canni) is found throughout the island of New Guinea, with higher concentrations of the snake being found in the nation of Papua New Guinea.

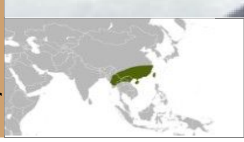
Venom
Oxyuranus scutellatus is the world's third-most venomous snake. Its venom contains primarily taicatoxin, a highly potent neurotoxin affecting the nervous system and the blood's ability to clot. Bite victims may experience headache, nausea/vomiting, collapse, convulsions, paralysis, internal bleeding, myolysis (destruction of muscle tissue), and kidney damage. In cases of severe envenomation, death can occur as early as 30 minutes after being bitten, but the average is around 2.5 hours. The time between a bite and death depends on various factors such as the nature of the bite and the constitution of the victim.

Aggressiveness
It is not a confrontational snake and will seek to escape any threat. When cornered, though, it can become very aggressive and may strike repeatedly.

Many-Banded Krait

The many-banded krait (Bungarus multicinctus), also known as the Taiwanese krait or the Chinese krait, is a highly venomous species of elapid snake found in much of central and southern China and Southeast Asia. The species was first described by the scientist Edward Blyth in 1861. The many-banded krait is a medium to large sized species of snake, averaging 1 to 1.5 m (3.3 to 4.9 ft) in length, with maximum lengths reaching 1.85 m (6.1 ft). Its body is slender and moderately compressed. The scales of this species are smooth and glossy, with a noticeably distinct vertebral ridge.

The colour of the snake is black to dark bluish-black with approximately 21–30 white or creamy white cross bands along the entire length of its upper body. More banding is seen in longer than average sized specimens. The tail is short and pointed, that is also black in colour with alternating white cross bands, of which there are 7–11. The belly of the snake is usually white in colour, but could be an off white or creamy white.



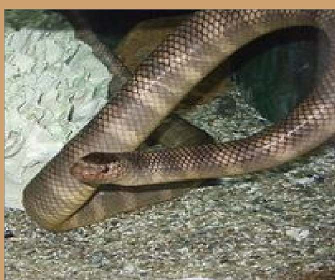
Habitat
This species is found throughout Taiwan (including the Archipelagos of Matsu and Kinmen), in the central and southern regions of mainland China (in the provinces of Hainan, Anhui, Sichuan, Guangdong, Guangxi, Hunan, Hubei, Yunnan, Guizhou, Jiangxi, Zhejiang, and Fujian), Hong Kong, Myanmar (Burma), Laos, and northern Vietnam. It may also be found in Thailand.

Venom
The venom of the many-banded krait consists of both pre- and postsynaptic neurotoxins (known as a-bungarotoxins and β-bungarotoxins, among others). By weight, almost half of the protein content of the venom is composed of β-bungarotoxins.
The average venom yield from specimens kept on snake farms is about 4.6 mg—19.4 mg per bite. Based on several LD50 studies, the many-banded krait is among the most venomous land snakes in the world.

Behaviour
The snake is nocturnal, and may be more defensive at night. It is, however, a timid and placid species of snake. In the daytime, it hides under stones or in holes. The snake appears from April and retreats into hibernation in November. It is considered to be more defensive than the Banded krait (Bungarus fasciatus), thrashing about as it is handled. Unlike other Bungarus species, who are primarily snake-eaters, the many-banded krait usually feeds on fish, but it is also preys on other species of snakes, including members of its own species. This species also feeds on rodents, eels, frogs, and occasionally lizards.

Symptoms
The local symptoms of victims bitten by the many-banded krait are usually neither serious swelling nor pain; the victims merely feel slightly itchy and numb. Systemic symptoms occur, in general, one to six hours after being bitten by this snake. Symptoms may include bilateral ptosis, diplopia, discomfort in the chest, general ache, weak feeling in limbs, ataxia, glossolysis, loss of voice, dysphagia, tunnel vision, and difficulty breathing. In case of serious bite, suppression of breathing may occur, leading to death. Hyponatremia is also seen, but less commonly. Estimated mortality rates associated with untreated bites from this species vary between studies from 25–35% to 70–100%. During the Vietnam War, American soldiers referred to the many-banded krait as the "two-step Charlies," in the mistaken belief that its venom was lethal enough to kill within two steps. The many-banded krait gathered worldwide attention after a juvenile individual bit and killed Dr. Joe Slowinski on September 11, 2001 in Myanmar. He died 29 hours after being bitten.

Black-Banded Sea Krait

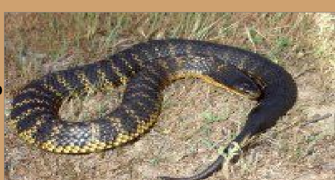


The black-banded sea krait, or Chinese sea snake (Laticauda semifasciata), known in Japan as erabu umi hebi, and Okinawa as the irabu, is a member of the Laticauda genus of sea snakes. It is found in most of the warm wāters of the western Pacific Ocean. This high snake frequents coral reef areas. It has a short head, thick trunk, and no easily discernible neck. The tail is simply extended skin, spread wide like a fin, and unsupported by any projection. Only 1 out of 3 will produce fangs. The stomach is comparatively wide. Massing together near the shore, they breed between narrow cracks in the reef and in caves. It is a nocturnal snake, rarely seen during the day.

It breathes air, so breaks the surface at least once every six hours. It is too slow to catch fish in a straight chase, so it hunts for fish hiding in the coral. Alternately, gathering in the hundreds, black-banded sea kraits form hunting alliances with yellow goatfish and bluefin trevally, flushing potential prey from narrow crannies in a reef the same way some moray eels do. The bite is highly venomous and paralyses the prey. Females lay their eggs on land.

Habitat
Generally, the species is found in Fiji, southern Japan and Singapore. Their venom is ten times stronger than that of a cobra, making them extremely dangerous. This snake does not bite humans unless it feels threatened.

Black Tiger Snake



See Below for the Tiger Snake Information.

Habitat
The black tiger snake is only found on the island of Tasmania. This species of snake inhabits dense woodland, heathy shrub land and dense tussock grassland, often around waterways and swamps.

Western Tiger Snake

Tiger snakes (Notechis scutatus) are a highly venomous snake species found in the southern regions of Australia, including its coastal islands, such as Tasmania. These snakes are highly variable in their colour, often banded like those on a tiger, and forms in their regional occurrences. All populations are in the genus Notechis, and their diverse characters have been described in further subdivisions of this group; they are sometimes described as distinct species and/or subspecies.

Notechis is a genus of large venomous snake in the family Elapidae restricted to subtropical and temperate regions of Australia. Tiger snakes are a large group of distinct populations, which may be isolated or overlapping, with extreme variance in size and colour. Individuals also show seasonal variation in colour.

The total length is typically about 1.2 metres The patterning is darker bands, strongly contrasting or indistinct, which are pale to very dark in colour. Colouration is composed of olive, yellow, orange-brown, or jet-black, and the underside of the snake is light yellow or orange. The tiger snake uses venom to dispatch its prey, and may bite an aggressor; they are potentially fatal to humans. Tolerant of low temperatures, the snake may be active on warmer nights. When threatened, they flatten their bodies and raise their heads above the ground in a classic prestrike stance.

Habitat
Tiger snakes are found in coastal environments, wetlands, and creeks where they often form territories. Areas with an abundance of prey can support large populations. The species' distribution extends from the south of Western Australia through to South Australia, Tasmania, including Savage River National Park up through Victoria, and New South Wales. Its common habitat includes the coastal areas of Australia.

Venom
Tiger snakes accounted for 17% of identified snakebite victims in Australia between 2005 and 2015, with four deaths recorded from 119 confirmed envenomations. Tiger snake venoms possess potent neurotoxins, coagulants, haemolysins, and myotoxins. Symptoms of a bite include localized pain in the foot and neck region, tingling, numbness, and sweating, followed by a fairly rapid onset of breathing difficulties and paralysis. In a study, the mortality rate from untreated bites is reported to be between 40 and 60%.

Treatment
Treatment is the same for all Australian venomous snakes. The pressure immobilization method is used to inhibit the flow of venom through the lymphatic system. Broad, thick bandages are applied over the bite, then down and back along the limb to the armpit or groin. The affected limb is then immobilized with a splint. Identification of the venom is possible if traces are left near the wound. Identifying the snake is not necessary if bitten in Tasmania, because the same antivenom is used to treat all Tasmanian snakes' bites. The availability of antivenom has greatly reduced the incidence of fatal tiger snake bites. Among the number of deaths caused by snakebite in Australia, those from tiger snakes are exceeded only by the brown snake.

Beaked Sea Snake

Enhydrina schistosa, commonly known as the beaked sea snake, hook-nosed sea snake, common sea snake, or the Valakadyn sea snake, is a highly venomous species of sea snake common throughout the tropical Indo-Pacific. This species is implicated in more than 50% of all bites caused by sea snakes, as well as the majority of envenomings and fatalities.

The rostral scale is longer than broad, and is in contact with four shields; frontal more long than broad, shorter than the parietals; nasals in contact with the two anterior labials; sometimes partially divided; one pre- and one or two postoculars; temporals I–3; seven or eight upper labials, fourth or third and fourth entering the eye, the last sometimes divided; anterior chin-shields rather indistinct, separated.

Scales with a tubercle or keel, in 50–70 rows; ventrals 230–314, slightly enlarged. The snake is usually uniformly dark grey above; sides and lower parts whitish. Young specimens olive or grey with black transverse bands, broadest in the middle. Length of head and body 1110 mm; tail 190 mm.

Distribution
It is found in the Arabian Sea and Persian Gulf (off Oman), south of the Seychelles and Madagascar, the seas off South Asia (Pakistan, India and Bangladesh), Southeast Asia (Myanmar (formerly Burma), Thailand, Vietnam). Snakes from Australia (Northern Territory and Queensland) and New Guinea are now provisionally identified as Enhydrina zweifeli, due to DNA tests that have shown they are not related to Enhydrina schistosa.

Habitat
These snakes are generally found in the coast and coastal islands of India. They are amongst the most common of the 20 kinds of sea snakes found in that region. They are active both during the day and at night. They are able to dive up to 100 m and stay underwater for a maximum of five hours before resurfacing. Sea snakes are equipped with glands to eliminate excess salt. They are venomous and notably aggressive, with some herpetologists describing them as "cantankerous and savage". About 1.5 milligrams of its venom is estimated to be lethal.

Venom
The venom of this species is made up of highly potent neurotoxins and myotoxins. This widespread species is responsible for the vast majority of deaths from sea snake bites (up to 90% of all sea snake bites). The LD50 value is 0.1125 mg/kg based on toxicology studies. The average venom yield per bite is approximately 7.9–9.0 mg, while the lethal human dose is estimated to be 1.5 mg.

Black Mamba

The black mamba (Dendroaspis polylepis) is a species of extremely venomous snake native to parts of Sub-Saharan Africa. First formally described by Albert Günther in 1864, it is the second-longest venomous snake after the king cobra; mature specimens generally exceed 2 metres (6.6 feet) and commonly grow to 3 m (10 ft). Specimens of 4.3 to 4.5 m (14.1 to 14.8 ft) have been reported. Its skin colour varies from grey to dark brown. Juvenile black mambas tend to be paler than adults and darken with age.

The species is both terrestrial (ground-living) and arboreal (tree-living); it inhabits savannah, woodland, rocky slopes and in some regions, dense forest. It is diurnal and is known to prey on birds and small mammals. Over suitable surfaces, it can move at speeds up to 16 km/h (10 mph) for short distances. Adult black mambas have few natural predators. The black mamba is a long, slender, cylindrical snake. It has a "coffin-shaped" head with a somewhat pronounced brow ridge and a medium-sized eye.

The adult snake's length typically ranges from 2 to 3 m (6 ft 7 in to 9 ft 10 in) but specimens have grown to lengths of 4.3 to 4.5 m (14.1 to 14.8 ft). It is the second-longest venomous snake species, exceeded in length only by the king cobra. The black mamba is a proteroglyphous (front-fanged) snake, with fangs up to 6.5 mm (0.26 in) in length, located at the front of the maxilla. The tail of the species is long and thin, the caudal vertebrae making up 17–25% of its body length. Black mambas weigh about 1.6 kg (3.5 lb) on average.

Distribution
The black mamba inhabits a wide range in Sub-Saharan Africa; its range includes Burkina Faso, Cameroon Central African Republic, Democratic Republic of the Congo, South Sudan, Ethiopia, Eritrea, Somalia, Kenya, Uganda, Tanzania, Burundi, Rwanda, Mozambique, Swaziland, Malawi, Zambia, Zimbabwe, Botswana, South Africa, Namibia, and Angola. The black mamba's distribution in parts of West Africa has been disputed.

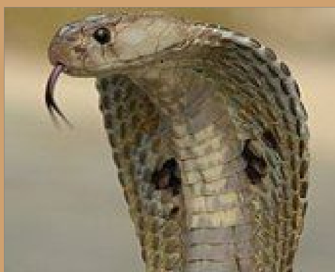
Habitat
The species prefers moderately dry environments such as light woodland and scrub, rocky outcrops and semi-arid savannah. It also inhabits moist savannah and lowland forests. It is not commonly found at altitudes above 1,000 m (3,300 ft), although its distribution does include locations at 1,800 m (5,900 ft) in Kenya and 1,650 m (5,410 ft) in Zambia. It is rated as a species of least concern on the International Union for Conservation of Nature (IUCN)'s Red List of Endangered species, based on its huge range across sub-Saharan Africa and no documented decline.

Behaviour
The black mamba is both terrestrial and arboreal. On the ground, it moves with its head and neck raised, and typically uses termite mounds, abandoned burrows, rock crevices and tree cracks as shelter. Black mambas are diurnal; in South Africa, they are recorded to bask between 7 and 10 am and again from 2 to 4 pm. They may return daily to the same basking site. Skittish and often unpredictable, the black mamba is agile and can move quickly. In the wild, black mambas seldom tolerate humans approaching more closely than about 40 metres (130 ft). When it perceives a threat, it retreats into brush or a hole. When confronted it is likely to engage in a threat display, gaping to expose its black mouth and flicking its tongue. It also is likely to hiss and spread its neck-flap.

Aggressiveness
In a threat display, the black mamba usually opens its inky-black mouth, spreads its narrow neck-flap and sometimes hisses. It is capable of striking at considerable range and may deliver a series of bites in rapid succession. Its venom is primarily composed of neurotoxins that often induce symptoms within ten minutes, and is frequently fatal unless antivenom is administered. Despite its reputation as a formidable and highly aggressive species, the black mamba only attacks humans if it is threatened or cornered.

Venom
The black mamba is the most feared snake in Africa because of its size, aggression, toxicity and speed of onset of symptoms. Unlike many venomous snake species, black mamba venom does not contain protease enzymes. Its bites do not generally cause local swelling or necrosis, and a tingling sensation in the bitten area might be the only initial symptom. The snake tends to bite repeatedly and let go, so there might be multiple puncture wounds. Its bite can deliver about 100–120 mg of venom on average. Bites were often fatal before antivenom was widely available. The venom is predominantly neurotoxic; symptoms often become apparent within ten minutes. Early neurological signs that indicate severe envenoming include metallic taste, drooping eyelids (ptosis) and gradual symptoms of bulbar palsy. Other neurological symptoms include miosis, blurred or diminished vision, paresthesia, dysarthria, dysphagia, dyspnea, difficulty handling oral secretions, an absent gag reflex, fasciculations, ataxia, vertigo, drowsiness and loss of consciousness, and respiratory paralysis. Other more general symptoms include nausea and vomiting, abdominal pain, diarrhoea, sweating, salivation, goosebumps and red eyes. The bite of a black mamba can cause collapse in humans within 45 minutes or less. Without appropriate antivenom treatment, symptoms typically progress to respiratory failure, which leads to cardiovascular collapse and death. This typically occurs in 7 to 15 hours.

Indian Cobra



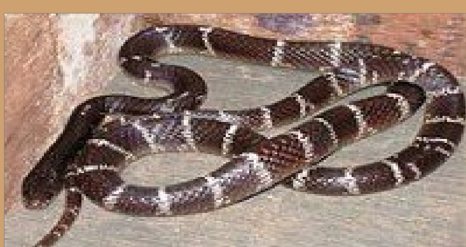
The Indian cobra (Naja naja) also known as the spectacled cobra, Asian cobra, or binocellate cobra is a species of the genus Naja found in India, Pakistan, Bangladesh, Sri Lanka, Nepal, and Bhutan, and a member of the "big four" species that inflict the most snakebites on humans in India. It is distinct from the king cobra which belongs to the monotypic genus Ophiophagus. The Indian cobra varies tremendously in colour and pattern throughout its range.

The ventral scales or the underside colouration of this species can be grey, yellow, tan, brown, reddish or black. Dorsal scales of the Indian cobra may have a hood mark or colour patterns. The most common visible pattern is a posteriorly convex light band at the level of the 20th to 25th ventrals. Salt-and-pepper speckles, especially in adult specimens, are seen on the dorsal scales. Specimens, particularly those found in Sri Lanka may exhibit poorly defined banding on the dorsum.

Habitat
The Indian cobra is native to the Indian subcontinent and can be found throughout India, Pakistan, Sri Lanka, Bangladesh, and southern Nepal. In India, it may or may not occur in the state of Assam, some parts of Kashmir, and it does not occur in high altitudes of over 2,000 metres (6,600 ft) and extreme desert regions. In Pakistan, it is absent in most of Balochistan province, parts of North-West Frontier Province, desert areas elsewhere and Northern Areas. The most westerly record comes from Duki, Balochistan in Pakistan, while the most easterly record is from the Tangail District in Bangladesh. As this species has been observed in Drosh, in the Chitral Valley, it may also occur in the Kabul River Valley in extreme eastern Afghanistan. There's been at least one report of this species occurring in Bhutan.

Venom
The Indian cobra's venom mainly contains a powerful post-synaptic neurotoxin and cardiotoxin. The venom acts on the synaptic gaps of the nerves, thereby paralysing muscles, and in severe bites leading to respiratory failure or cardiac arrest. The venom components include enzymes such as hyaluronidase that cause lysis and increase the spread of the venom. Envenomation symptoms may manifest between 15 minutes and 2 hours following the bite. The Indian cobra is one of the big four snakes of South Asia which are responsible for the majority of human deaths by snakebite in Asia. Polyvalent serum is available for treating snakebites caused by these species. Zedoary, a local spice with a reputation for being effective against snakebite, has shown promise in experiments testing its activity against cobra venom. The venom of young cobras has been used as a substance of abuse in India, with cases of snake charmers being paid for providing bites from their snakes. Though this practice is now seen as out-dated, symptoms of such abuse include loss of consciousness, euphoria, and sedation.

Common Krait



The common krait (Bungarus caeruleus), also known as Indian krait or blue krait) is a species of venomous snake of the genus Bungarus found in the jungles of the Indian subcontinent. It is a member of the "big four" species, inflicting the most snakebites on humans in India. The average length is 0.9 m (3.0 ft), but they can grow to 1.75 m (5 ft 9 in). Males are longer, with proportionately longer tails. The head is flat and the neck hardly evident. The body is cylindrical, tapering towards the tail. The tail is short and rounded.

The eyes are rather small, with rounded pupils, indistinguishable in life. The head shields are normal, with no loreals; four shields occur along the margin of the lower lip; the third and fourth supraoculars touch the eye. The scales are highly polished, in 15-17 rows; the vertebral row is distinctly enlarged and hexagonal. Ventrals number 185-225 and caudals 37-50, entire. Colouration is generally black or bluish black, with about 40 thin, white crossbars which may be indistinct or absent anteriorly.

The pattern, however, is complete and well defined in the young, which are marked with conspicuous crossbars even anteriorly; in old individuals, the narrow white lines may be found as a series of connected spots, with a prominent spot on the vertebral region. A white preocular spot may be present; the upper lips and the belly are white.

Habitat
This species is found in main Peninsular India from Sindh (Pakistan), to the West Bengal plains. It occurs throughout South India and Sri Lanka at elevations up to about 1600 m. It is also recorded from Afghanistan, Bangladesh, and Nepal. Its range comprises a wide variety of habitats. It is found in fields and low scrub jungle, as well as inhabited areas. It is known to take up residence in termite mounds, brick piles, rat holes, even inside houses. It is frequently found in water or in proximity to a water source.

Venom
The common krait's venom consists mostly of powerful neurotoxins, which induce muscle paralysis. Clinically, its venom contains presynaptic and postsynaptic neurotoxins. Kraits are nocturnal, so seldom encounter humans during daylight hours; incidents occur mainly at night. Frequently, little or no pain occurs from a krait bite, and this can provide false reassurance to the victim. Typically, victims complain of severe abdominal cramps, accompanied by progressive paralysis. If death occurs, it takes place about four to eight hours after the krait bite. Cause of death is general respiratory failure, i.e. suffocation. Often during the rainy season, the snakes come out of their hiding places and find refuge inside dry houses. If bitten by a krait while sleeping, a victim may not realize he has been bitten, as the bite feels like that of an ant or mosquito. The victim may die without waking up. Krait bites are significant for eliciting minimal amounts of local inflammation/swelling. This may help in species identification if the snake has not been seen. The few symptoms of the bite include: tightening of the facial muscles in one to two hours of the bite; inability of the bite victim to see or talk, and, if left untreated, the patient may die from respiratory paralysis within four to five hours. A clinical toxicology study gives an untreated mortality rate of 70-80%.

Behaviour
Behavioural differences during day and night time have been reported in B. caeruleus. During the day, it is sluggish and generally docile. It often hides in rodent holes, loose soil, or beneath debris, so is rarely seen. It often rolls its body into a loose, coiled ball, keeping its head well concealed. When in this 'balled' condition, the snake allows considerable handling, but overhandling often instigates bites. However, at night, the snake is very active and escapes by hissing loudly, or keeping still, occasionally biting the source of the annoyance. When agitated, it will coil up with its head concealed and body flattened, and makes jerky movements. It may also lift its tail. It is reluctant to bite, but when it does, it typically holds on for a while, which enables it to inject considerable amounts of venom. It may become aggressive at night if threatened since this is its active time.

Russell's Viper

Russell's viper is a species of venomous snake in the family Viperidae. of venomous Old World vipers. The single member species, D. russelii, is found in Asia throughout the Indian subcontinent, much of Southeast Asia, southern China and Taiwan. D. russelii can grow to a maximum length (body + tail) of 166 cm (5.5 ft) and averages about 120 cm (4 ft) on mainland Asian populations. Island populations may be slightly smaller on average. It is more slender than most vipers.

The head is flattened, triangular, and distinct from the neck. The snout is blunt, rounded, and raised. The nostrils are large, each in the middle of a large, single nasal scale. The lower edge of the nasal scale touches the nasorostral scale. The supranasal scale has a strong crescent shape and separates the nasal from the nasorostral scale anteriorly. The rostral scale is as broad as it is high.

Geography
D. russelii is found in India, Sri Lanka, Bangladesh, Nepal, Myanmar, Thailand, Pakistan, Cambodia, Tibet, China (Guangxi, Guangdong), Taiwan and Indonesia (Endeh, Flores, east Java, Komodo, and Lomblen Islands). The type locality is listed as "India". More specifically, this would be the Coromandel Coast, by inference of Russell (1796).

Habitat
D. russelii is not restricted to any particular habitat, but does tend to avoid dense forests. The snake is mostly found in open, grassy or bushy areas, but may also be found in second growth forests (scrub jungles), on forested plantations and farmland. It is most common in plains, coastal lowlands, and hills of suitable habitat. Generally, it is not found at altitude, but has been reported as far up as 2300–3000 m (7,500-9,800 ft). Humid environments, such as marshes, swamps, and rain forests, are avoided.

Venom
Envenomation symptoms begin with pain at the site of the bite, immediately followed by swelling of the affected extremity. Bleeding is a common symptom, especially from the gums and in the urine, and sputum may show signs of blood within 20 minutes after the bite. The blood pressure drops, and the heart rate falls. Blistering occurs at the site of the bite, developing along the affected limb in severe cases. Necrosis is usually superficial and limited to the muscles near the bite, but may be severe in extreme cases. Vomiting and facial swelling occur in about one-third of all cases. Kidney failure (renal failure) also occurs in approximately 25-30 percent of untreated bites. Severe disseminated intravascular coagulation also can occur in severe envenomations. Early medical treatment and early access to antivenom can prevent and drastically reduce the chance of developing the severe/potentially lethal complications.

Severe pain may last for 2–4 weeks. Locally, it may persist depending on the level of tissue damage. Often, local swelling peaks within 48–72 hours, involving both the affected limb and the trunk. If swelling up to the trunk occurs within 1–2 hours, massive envenomation is likely. Discoloration may occur throughout the swollen area as red blood cells and plasma leak into muscle tissue. Death from septicaemia or kidney, respiratory, or cardiac failure may occur 1 to 14 days after the bite or even later.

Aggressiveness
When threatened, they form a series of S-loops, raise the first third of the body, and produce a hiss that is supposedly louder than that of any other snake. When striking from this position, they can exert so much force that even a large individual can lift most of its body off the ground in the process. These snakes are strong and may react violently to being picked up. The bite may be a snap, or they may hang on for many seconds.

Behaviour
D. russelii is terrestrial and active primarily as a nocturnal forager. However, during cool weather, it alters its behaviour and becomes more active during the day. Adults are reported to be slow and sluggish unless pushed beyond a certain limit, after which they can become very aggressive. Juveniles, though, are generally more nervous. When threatened, they form a series of S-loops, raise the first third of the body, and produce a hiss that is supposedly louder than that of any other snake. When striking from this position, they can exert so much force that even a large individual can lift most of its body off the ground in the process.

Saw-Scaled Viper

Echis is a genus of venomous vipers found in the dry regions of Africa, the Middle East, Pakistan, India, and Sri Lanka. They have a characteristic threat display, rubbing sections of their body together to produce a "sizzling" warning sound. The name Echis is the Latin transliteration of the Greek word for "viper". Their common name is "saw-scaled vipers" and they include some of the species responsible for causing the most snakebite cases and deaths in the world. Twelve species are currently recognized. Saw-scaled vipers are relatively small snakes, the largest species (E. leucogaster, E. pyramidum) usually below 90 cm (35 in) long, and the smallest (E. hughesi, E. jogeri) being around 30 cm (12 in).

Habitat
Species of this genus are found in Pakistan, India (in rocky regions of Maharashtra, Rajasthan, Uttar Pradesh, and Punjab) and Sri Lanka, parts of the Middle East, and Africa north of the equator.

Venom
The venom of Echis species consists mostly of hemotoxins and cytotoxins. The genus is recognized as medically significant in many tropical rural areas. They are widespread and live in areas lacking modern medical facilities. Most victims are bitten after dark when these snakes are active. Most of these species have venom that contains factors that can cause a consumption coagulopathy and defibrination, which may persist for days to weeks. This may result in bleeding anywhere in the body, including the possibility of an intracranial haemorrhage. The latter classically occurs a few days following the bite. The amount of venom produced also varies. Reported yields include 20–35 mg of dried venom from specimens 41–56 cm in length, 6–48 mg (16 mg average) from Iranian specimens and 13–35 mg of dried venom from animals from various other localities. Yield varies seasonally, as well as between the sexes: the most venom is produced during the summer months and males produce more than females.

Behaviour
All members of this genus have a distinctive threat display, which involves forming a series of parallel, C-shaped coils and rubbing them together to produce a sizzling sound, rather like water on a hot plate. The proper term for this is stridulation. As they become more agitated, this stridulating behaviour becomes faster and louder. This display is thought to have evolved as a means of limiting water loss, such as might occur when hissing. However, some authors describe this display as being accompanied by loud hissing. These snakes can be fierce and will strike from the position described above. When doing so, they may overbalance and end up moving towards their aggressor (an unusual behaviour for snakes).

Fer-De-Lance

Bothrops asper is a highly venomous pit viper species ranging from southern Mexico to northern South America and is considered to be one of the most dangerous snakes in the western hemisphere. Sometimes referred to as the "ultimate pit viper", these snakes are found in a wide range of lowland habitats, often near human habitations. Its proximity to human habitations and temperament are likely the reasons why it is considered more dangerous to humans than others. Bothrops species can be distinguished by their broad, flattened heads which are set apart from the rest of their bodies. The head of this snake is light to dark brown or even black. Although usually absent, it may have occipital blotches or streaks that range from indistinct to distinct. The underside is most often pale yellow. This species has different patterns and colours on its dorsal and ventral sides and it exhibits a postorbital stripe. The ventral side is yellow, cream, or a whitish gray, with dark blotches that are more frequent closer to the posterior end.

Distribution
It is found in the Atlantic lowlands of eastern Mexico and Central America, including Guatemala, Belize, Honduras, Nicaragua, Costa Rica and Panama. An isolated population occurs in south-eastern Chiapas (Mexico) and south-western Guatemala. In northern South America, it is found in Colombia, Ecuador, Guyana and Venezuela. The type locality given is "Obispo, on the Isthmus of Darien" (Panama). This is mostly a lowland species that, in Mexico and Central America, occurs from about sea level to 1,200 to 1,300 meters (3,900 to 4,300 ft) altitude. In South America, it apparently ranges to considerably higher elevations: up to 2,500 metres (8,200 ft) in Venezuela and at least 2,640 metres (8,660 ft) in Colombia according to herpetologist Lancini.

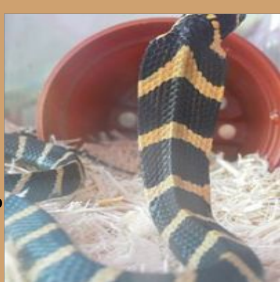
Habitat
This species likes moist environments, and occurs in most life zones located at low or middle elevations (up to 600 metres (2,000 ft)), excluding those with strong seasonal dry periods. They are, however, sometimes found at much higher elevations. This is true in the premontane forest in Costa Rica, the cloud forest of Guatemala and Mexico, or the lower montane wet forest in the Caribbean Region of Colombia and Ecuador. It chiefly inhabits tropical rainforest and evergreen forest, but it also occurs in drier areas of tropical deciduous forest, thorn forest and pine savannah near lakes, rivers and streams.

Venom
Together with Crotalus durissus, it is the leading cause of snakebite in Yucatán, Mexico. It is considered the most dangerous snake in Costa Rica, responsible for 46% of all bites and 30% of all hospitalized cases; before 1947, the fatality rate was 9%, but this has since declined to almost 0%. Bite symptoms include pain, oozing from the puncture wounds, local swelling that may increase for up to 36 hours, bruising that spreads from the bite site, blisters, numbness, mild fever, headache, bleeding from the nose and gums, hemoptysis, gastrointestinal bleeding, hematuria, hypotension, nausea, vomiting, impaired consciousness and tenderness of the spleen.

Aggressiveness
When cornered or threatened, this species can be very defensive and may exhibit an S-coiled defence display. Juveniles are often semiarboreal and even adults are sometimes encountered in bushes and low trees. Juveniles are also known to exhibit caudal luring, a use of their differently coloured tail tips to lure prey. Although both males and females display this behaviour, only males have bright coloured tail tips. Compared to the common lancehead, B. atrox, these snakes have been described as excitable and unpredictable when disturbed. They can, and often will, move very quickly, usually opting to flee from danger, but are capable of suddenly reversing direction to vigorously defend themselves. Adult specimens, when cornered and fully alert, should be considered dangerous. In a review of bites from this species suffered by field biologists, Hardy (1994) referred to it as the "ultimate pit viper".

Behaviour
This species is nocturnal and solitary. It is less active in colder and drier periods. B. asper is often found near rivers and streams, basking under the sun during the day and lying still while well camouflaged in leaf litter or under forest cover waiting to ambush prey (including rats and mice) that comes within range during the night.

King Cobra



The king cobra, also known as the hamadryad, is a venomous snake species in the family Elapidae, endemic to forests from India through Southeast Asia. It is threatened by habitat destruction and has been listed as Vulnerable on the IUCN Red List since 2010. It is the world's longest venomous snake. Adult king cobras are 3.18 to 4 m (10.4 to 13.1 ft) long. It preys chiefly on other snakes and occasionally on some other vertebrates, such as lizards and rodents. It is a dangerous snake that has a fearsome reputation in its range, although it typically avoids confrontation with humans when possible. The king cobra typically weighs about 6 kg (13 lb).

The skin of king cobra is dark olive or brown with black bands and white or yellow crossbands. The head is black with two crossbars near the snout and two behind the eyes. Adult king cobras are 3.18 to 4 m (10.4 to 13.1 ft) long. The longest known individual measured 5.85 m (19.2 ft). Its belly is cream or pale yellow. It has 17 to 19 rows of smooth scales. Ventral scales are uniformly oval shaped. Dorsal scales are placed in an oblique arrangement. Males have 235 to 250 ventral scales, while females have 239 to 265. The subcaudal scales are single or paired in each row, numbering 83 to 96 in males and 77 to 98 in females.

Habitat
The king cobra is distributed across the Indian subcontinent, Southeast Asia, and the southern areas of East Asia (where it is not common), in Bangladesh, Bhutan, Burma, Cambodia, China, India, Indonesia, Laos, Malaysia, Nepal, the Philippines, Singapore, Thailand, Vietnam and southern China. In India it has been recorded from Goa; Western Ghats of Karnataka, Kerala and Tamil Nadu; east coastline of Andhra Pradesh and Odisha; Sundarban mangroves; Himalayan foothills from Uttarakhand, Uttar Pradesh, Bihar, northern parts of West Bengal to most of the north-east region and Andaman Islands.

Venom
The venom of the king cobra consists primarily of neurotoxins, known as the haditoxin, with several other compounds. This species is capable of delivering a fatal bite and the victim may receive a large quantity of venom with a dose of 200 to 500 mg up to 7 ml. The toxins affect the victim's central nervous system, resulting in severe pain, blurred vision, vertigo, drowsiness, and eventually paralysis. If the envenomation is serious, it progresses to cardiovascular collapse, and the victim falls into a coma. Death soon follows due to respiratory failure. Bites from a king cobra may result in a rapid fatality which can be as early as 30 minutes after the envenomation. The king cobra's envenomation was even recorded to be capable of killing elephants within hours.

Aggressiveness
When annoyed, this species quickly attempts to escape and avoid confrontation. However, if continuously provoked, the king cobra can be highly aggressive. Wild king cobras, the snakes appear to be of rather placid disposition, and they usually end up being killed or subdued with hardly any hysterics. A good defence for anyone who accidentally encounters this snake is to slowly remove a shirt or hat and toss it to the ground while backing away.

Behaviour
A king cobra, like other snakes, receives chemical information via its forked tongue, which picks up scent particles and transfers them to a special sensory receptor (Jacobson's organ) located in the roof of its mouth. This is akin to the human sense of smell. When the scent of a meal is detected, the snake flicks its tongue to gauge the prey's location (the twin forks of the tongue acting in stereo); it also uses its keen eyesight; king cobras are able to detect moving prey almost 100 m (330 ft) away. Its intelligence and sensitivity to earth-borne vibration are also used to track its prey. Following envenomation, the king cobra swallows its struggling prey. King cobras, like all snakes, have flexible jaws. The jaw bones are connected by pliable ligaments, enabling the lower jaw bones to move independently. This allows the king cobra to swallow its prey whole, and swallow prey much larger than its head.

Malayan Krait

Bungarus candidus, commonly known as the Malayan krait or blue krait, is a highly venomous species of snake. The blue krait is a member of the elapid family. The Malayan krait may attain a total length of 108 cm (about 3.5 ft), with a tail 16 cm (6.3 in) long.

Dorsally, it has a pattern of 27-34 dark-brown, black, or bluish-black crossbands on the body and tail, which are narrowed and rounded on the sides. The first crossband is continuous with the dark colour of the head. The dark crossbands are separated by broad, yellowish-white interspaces, which may be spotted with black. Ventrally, it is uniformly white. An unbanded black phenotype also occurs in some populations e.g. Bali and reportedly in West and Central Java. The smooth dorsal scales are arranged in 15 rows, with the vertebral row much enlarged. The ventrals number 195-237; the anal plate is entire; and the single (undivided) subcaudals are 37-56 in number.

Habitat
It is found in southeast Asia from Indochina south to Java and Bali in Indonesia.

Common Death Adder

The common death adder (Acanthophis antarcticus) is a species of death adder native to Australia. It is one of the most venomous land snakes in Australia and globally. While it remains widespread (unlike related species), it is facing increased threat from the ongoing Australian cane toad invasion. The common death adder has a broad flattened, triangular head and a thick body with bands of red, brown and black with a grey, cream or pink belly.

It can reach a maximum body length of 70–100 centimetres (2.3–3.3 ft). Death adders possess the longest fangs of any Australian snake. Unlike the common or European adder (Vipera berus), the common death adder is a member of the snake family Elapidae, rather than the family Viperidae, which are not found in Australia.

Habitat
The common death adder occurs over much of eastern and coastal southern Australia – Queensland, New South Wales, Victoria and South Australia. It is more scarce in the Northern Territory, Western Australia and the west parts of South Australia. It is also native to Papua New Guinea. Common death adders are found in forests, woodlands, grasslands and heaths of the eastern coast of Australia. The death adder is a master of camouflage, due to its band stripes, hiding beneath loose leaf litter and debris in woodland, shrubland and grassland.

Venom
The common death adder venom contains highly toxic neurotoxin which can cause paralysis or even kill. It can deliver the fastest strike among all venomous snakes recorded in Australia. Human death can occur within six hours after the bite.

Western Green Mamba

The western green mamba (Dendroaspis viridis), also known as the West African green mamba or Hallowell's green mamba, is a long, thin, and highly venomous snake of the mamba genus, Dendroaspis. The western green mamba is a fairly large and predominantly arboreal species, capable of navigating through trees swiftly and gracefully. It will also descend to ground level to pursue prey such as rodents and other small mammals. The western green mamba is a very alert, nervous, and extremely agile snake that lives mainly in the coastal tropical rainforest, thicket, and woodland regions of western Africa.

Like all the other mambas, the western green mamba is a highly venomous elapid species. Its venom is a highly potent mixture of rapid-acting presynaptic and postsynaptic neurotoxins (dendrotoxins), cardiotoxins and fasciculins. Some consider this species to not be a particularly aggressive snake, but others have suggested that they are extremely nervous and are prone to attack aggressively when cornered.

The western green mamba is a long and very slender bodied snake with a long tapering tail. The average length of an adult snake of this species is between 1.4 metres (4.6 ft) and 2.1 metres (6.9 ft). Some specimens of this species can grow to maximum lengths of 2.4 metres (7.9 ft). The head is narrow and elongate, with a distinct canthus and slightly distinct from the neck. On rare occasions the neck may be flattened when the snake is aroused, but there is no hood. Eyes are medium in size with round pupils and a yellow brown iris.

Habitat
The western green mamba is native to West Africa. Different sources give slightly different ranges but generally agree that it occurs from Gambia and southern Senegal to Benin, including the intervening countries (from west to east) Guinea-Bissau, Guinea, Sierra Leone, Liberia, Cote d'Ivoire (Ivory Coast), Ghana, and Togo. In Togo it has a known northern limit to its distribution in Aledjo, but it might occur in forests of the more northerly Kara region Records from Nigeria might be unreliable, and its presence in the Central African Republic is similarly unclear. Some sources mention it also from the very southern tip of Mali along the border with Côte d'Ivoire, as well as from western Cameroon and Gabon.

Venom
The western green mamba's venom is similar to those of other members of the mamba genus (Dendroaspis), but differs from others in toxicity and the composition of the toxins. Human fatalities as a result of bites from this species are rare due to the fact that this species does not often cross paths with humans, but bites have occurred and the majority of the recorded bites have been fatal. The three species of green mambas, including the western green mamba, have venom toxicities that are similar to and comparable to many species of cobras, but green mamba bites often present with more severe and life-threatening symptoms in a shorter period of time.

Mortality rates are also higher among green mamba bite victims than with cobra bite victims. Although bites by Dendroaspis viridis are not well documented and the rate of bites, envenoming and fatality is not well known, it appears that bites attributed to this species produce more severe envenomation than bites caused by Dendroaspis angusticeps (eastern green mamba), but far less severe than bites caused by Dendroaspis polylepis (black mamba). When bitten, symptoms rapidly begin to manifest, usually within the first 15 minutes or less. The extraordinary speed with which the venom spreads through tissue and produces rapid manifestations of life-threatening symptoms is unique to mambas.

Common symptoms of a bite from a western green mamba include local pain and swelling, although uncommon, local necrosis can be moderate, ataxia, headache, drowsiness, difficulty breathing, vertigo, hypotension (low blood pressure), diarrhoea, dizziness, and paralysis. Left untreated, new and more severe symptoms rapidly progress. All symptoms worsen and the victim eventually dies due to suffocation resulting from paralysis of the respiratory muscles. Bites with envenomation can be rapidly fatal, which can be possible in 30 minutes.

Aggressiveness
Conflict with humans is low compared to some other species found in the region. Bites to people by this species are quite uncommon. Their mortality rate, however, is high; many of the recorded bites have been fatal. Rapid progression of severe, life-threatening symptoms are hallmarks of mamba bites. Bites with envenomation can be rapidly fatal.

Behaviour
This species is mostly diurnal, but may be active at night as well. It is an arboreal snake, but it does commonly go to the ground. In fact, it is equally at home hunting and feeding on prey on the ground or in trees. When it wants to sleep it seeks out tree branches that offer dense cover. It is a very quick, extremely agile, alert, and nervous snake. When confronted it will quickly attempt to escape (usually up a tree if possible) and avoid any sort of confrontation. If cornered, the western green mamba is highly dangerous and will show a fearsome display of aggression, loudly hissing and striking repeatedly.

Eastern Green Mamba

The eastern green mamba (Dendroaspis angusticeps), also known as the common mamba, East African green mamba, green mamba, or white-mouthed mamba, is a large, tree-dwelling, highly venomous snake species of the mamba genus Dendroaspis. This snake mostly inhabits the coastal regions of southern East Africa. Adult females average approximately 2.0 metres (6.6 ft) in length, and males are slightly smaller. Eastern green mambas prey on birds, eggs, bats, and rodents such as mice, rats, and gerbils. They are shy and elusive snakes which are rarely seen, making them somewhat unusual among mambas.

This elusiveness is usually attributed to the species' green colouration which blends with its environment, and its arboreal lifestyle. However, eastern green mambas have also been observed to use "sit-and-wait" or ambush predation like many vipers, unlike the active foraging style typical of other elapids, which may be a factor in the rarity of sightings.

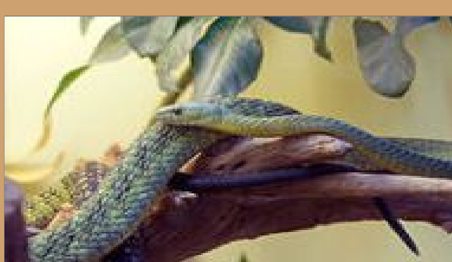
The eastern green mamba is a large, with a slightly compressed, and very slender bodied snake with a medium to moderately long tapering tail. Adult males average around 1.8 metres (5.9 ft) in total length, while females average 2.0 metres (6.6 ft) in total length. The head is narrow, elongate, and coffin-shaped, with a distinct canthus which is slightly distinct from the neck. When threatened or otherwise aroused in some way, this species is capable of flattening its neck area, though no real hood is formed.

Habitat
This species is indigenous to more coastal regions of southern Africa and east Africa. The eastern green mamba's range extends from Kenya south through Tanzania, Mozambique, Malawi, eastern Zimbabwe, eastern Zambia into South Africa as far as southern Natal and northern Pondoland. It can also be found in Zanzibar. The distribution of this species is assumed to be continuous, but reports seem to be scarce in regions within the species' range.

Venom
The eastern green mamba is a highly venomous snake. Like all other mamba species, the toxicity of individual specimens within the same species can vary greatly based on several factors including geographical region, age, seasonal variation, diet, and so on. Local swelling is variable and sometimes absent after mamba bites. However, patients bitten by the eastern green mamba develop swelling of the entire bitten limb and also show mild haemostatic disturbances (Warrell DA; MacKay et al. 1966). The rare cases of local tissue damage usually resulted from bites on the fingers or the use of a tight tourniquet. This species has caused bites to humans and many of the bites attributed to this species have often resulted in fatalities. The mortality rate of untreated bites is unknown but is thought to be quite high. Symptoms of envenomation by this species include swelling of the bite site, dizziness, and nausea, accompanied by difficulty breathing and swallowing, irregular heartbeat, convulsions, rapid progression to respiratory paralysis. Bites that produce severe envenomation can be rapidly fatal. Case reports of rapidly fatal outcomes, in as little as 30 minutes, have been recorded for this species.

Behaviour
The eastern green mamba is a diurnal, arboreal, and secretive species of snake, and it tends to spend most of its time above the ground in relatively dense brush, where it is well camouflaged. This species is not commonly found on land unless motivated by thirst, prey, or the need to bask in the sun (thermoregulation). It is an alert, nervous, excellent climber and extremely agile snake. It sleeps at night in a tree coiled up in leafy clumps rather than seeking a tree hollow (although sometimes found in them). In a study of the movement patterns of two adult specimens of this species over a 27-day period, the researcher found that their activity range areas to be very low, comparable to other predators who ambush prey rather than actively hunt them.

Jameson's Mamba



Jameson's mamba (Dendroaspis jamesoni) is a species of quick, highly arboreal and highly venomous snake of the family Elapidae. The species is endemic to Africa. Jameson's mamba is a large, slender elapid snake with smooth scales and a long tapering tail which typically accounts for 20 to 25% of its total length. The average total length (including tail) of an adult snake is approximately 1.5 meters (4.9 ft) to 2.2 meters (7.2 ft). It may grow as large as 2.64 meters (8 ft 8 in). Adults tend to be dull green across the back, blending to pale green towards the underbelly with scales generally edged with black. The ventral side, neck and throat are typically cream or yellowish in colour.

Jameson's mamba has a narrow and elongated head containing a small eye and round pupil. Like the western green mamba, the neck may be flattened. The subspecies D. jamesoni kaimosae, which is typically found in the eastern part of the species' range, features a black tail, while central and western examples typically have a pale green or yellow tail.

No significant sexual dimorphism has been observed between male and female snakes. Untreated envenomation may cause death within 30 to 120 minutes. However, the average death time for untreated bite victims is usually two to three hours post-envenomation, but it may take up to four to six hours or longer. The mortality rate of untreated bites is not exactly known, but it is said to be very high.

Habitat
Jameson's mamba occurs mostly in Central Africa and West Africa, and in some parts of East Africa. In Central Africa it can be found from Angola northwards to the Democratic Republic of Congo, Republic of Congo, Central African Republic, and as far north as the Imatong Mountains of South Sudan. In West Africa it ranges from Ghana eastwards to Togo, Nigeria, Cameroon, Equatorial Guinea and Gabon. In East Africa it can be found in Uganda, Kenya, Rwanda, Burundi and Tanzania. It is a relatively common and widespread snake, particularly across its western range.

Venom
Like other mambas, the venom of the Jameson's mamba is a highly neurotoxic venom. Its other components include cardiotoxins, and fasciculins. Its venom may also have hemotoxic and myotoxic components to it. The average venom yield per bite for this species is 80 mg, but some specimens may yield as much as 120 mg in a single bite. The SC LD50 for this species according to Brown (1973) is 1.0 mg/kg, while the IV LD50 is 0.8 mg/kg.

Caspian Cobra

The Caspian cobra (Naja oxiana), also called the Central Asian cobra, Oxus cobra, or Russian cobra is a species of venomous snake in the family Elapidae. The species is endemic to Central Asia. N. oxiana is medium in length, a heavy-bodied snake with long cervical ribs capable of expansion to form a hood. Anteriorly, the body is depressed dorsoventrally, and posteriorly it is subcylindrical. This species averages about 1 m (3.3 ft) in total length (including tail) and rarely reaches lengths over 1.5 m (4.9 ft). The head is elliptical, depressed, and slightly distinct from the neck, with a short, rounded snout and large nostrils. The eye is medium in size with a round pupil. The dorsal scales are smooth and strongly oblique, with the outer two or three scale rows larger than the remainder. Juveniles tend to be pale, with a faded appearance. Juveniles have noticeable dark and light cross-bands of approximately equal width around the body. Adults of this species are completely light to chocolate brown or yellowish, with some specimens retaining traces of juvenile banding, especially the first few dark ventral bands. This species has no hood mark and no lateral throat spots.

Habitat
N. oxiana occurs in the Transcaspian region. It is found in Turkmenistan, Uzbekistan, Kyrgyzstan, Tajikistan, north and east Afghanistan, north-eastern Iran, the northern half of Pakistan, from the Kashmir region east to the state of Himachal Pradesh in India, and in south-western Tajikistan. There is also some anecdotal evidence of it ranging as far north as the Aral Sea on the Uzbekistan/Kazakhstan border.

Venom
The bite of this species may cause severe pain and swelling, along with severe neurotoxicity. Weakness, drowsiness, ataxia, hypotension, and paralysis of throat and limbs may appear in less than one hour after the bite. Without medical treatment, symptoms rapidly worsen and death can occur soon after a bite due to respiratory failure. A woman bitten by this species in north-western Pakistan suffered severe neurotoxicity and died while en route to the closest hospital nearly 50 minutes after envenomation. Between 1979 and 1987, 136 confirmed bites were attributed to this species in the former Soviet Union. Of the 136, 121 received antivenom, and only 8 died. Of the 15 who did not receive antivenom, 11 died - a 73% mortality rate. Antivenom is not as effective for envenomation by this species as it is for other Asiatic cobras within the same region, like the Indian cobra (Naja naja), and massive amounts of antivenom are often required for patients. As a result, a monovalent antivenom serum is being developed by the Razi Serum and Vaccine Research Institute in Iran. The untreated mortality rate for this species is approximately 70-75%, which is among the highest of all cobra species of the genus Naja. In both Central Asia and Iran this species is responsible for high rates of snakebites and resulting mortality.

Behaviour
This terrestrial species is mainly diurnal, but it may be crepuscular and nocturnal in some parts of its range during the hottest months (July and August). It is a good climber and a good swimmer. It is often found in water and seldom found too far away from it. It feeds on small mammals, amphibians, and birds during the evening and early morning. The Caspian cobra will prey mainly on rodents, toads and frogs, occasionally fish, and birds and their eggs. Quick-moving and agile, this species lives in holes in embankments or trees.

Aggressiveness
N. oxiana is generally aggressive and bad-tempered. Although it will avoid humans as much as it can, it will become fiercely aggressive when threatened or cornered. Even juveniles tend to be very aggressive. When cornered and provoked, it will spread its hood, hiss, sway from side to side and strike repeatedly; it is not a spitter.

Forest Cobra

The forest cobra (Naja melanoleuca), also commonly called the black cobra and the black and white-lipped cobra, is a species of venomous snake in the family Elapidae. The species is native to Africa, mostly the central and western parts of the continent. It is the largest true cobra species with a total length (including tail) of up to 3.1 meters (10 feet). Although it prefers lowland forest and moist savannah habitats, this cobra is highly adaptable and can be found in drier climates within its geographical range. It is a very capable swimmer and is often considered to be semi-aquatic. The forest cobra is a generalist in its feeding habits, having a highly varied diet: anything from large insects to small mammals and other reptiles.

This species is alert, nervous and is considered to be a very dangerous snake. When cornered or molested, it will assume the typical cobra warning posture by raising its fore body off the ground, spreading a narrow hood, and hissing loudly. Bites to humans are less common than from other African cobras due to various factors, though a bite from this species is a life-threatening emergency.

The length of an average adult is 1.4 to 2.2 m (4.6 to 7.2 ft), but they may attain lengths of 3.1 metres (10 feet) in rare cases. Males and females grow to be similar in length, as there is no sexual dimorphism within this species. The head of this snake is large, broad, flattened and is slightly distinct from the neck. It is a slightly depressed, tapered and moderately thick bodied snake with a slender tail that is medium in length.

Distribution
The forest cobra occurs mainly in western and central Africa. It is found from Senegal, Guinea-Bissau, Guinea, south-eastern Mali, Sierra Leone, Liberia, Côte d'Ivoire, Burkina Faso, Ghana, Togo, Benin, Nigeria, Equatorial Guinea, Cameroon, and Gabon in western Africa to the Republic of Congo, the Democratic Republic of Congo, Central African Republic, and northern Angola in central Africa to western Kenya, Uganda, Rwanda, and Burundi in eastern Africa, and to fragmented parts of southern Africa, including the Natal.

Habitat
A snake of forest or woodland, it is the only one of Africa's cobras that will live in high forest. The forest cobras are snakes that are well adapted to many environments and the habitat of the forest cobra is strongly dependent on what part of its African range the snake originates from. Forest cobras originating in the southern African regions are typically found in savannah and grassland, but they can also be found in broken rock country. They are mainly found in the tropical and subtropical rainforest regions of west and central Africa. It also inhabits mangroves in western Africa.

Venom
The venom of this cobra is a postsynaptic neurotoxin and bites result in severe neurotoxicity. The forest cobra is one of the least frequent causes of snake bite among the African cobras, largely due its forest-dwelling habits but a bite by this species should be taken very seriously because it ranks as the 4th most venomous Naja (True Cobra) species. The symptomology is thought to be very similar to that of the Egyptian cobra (Naja haje).

Aggressiveness
When agitated, it rears up to a considerable height and spreads a long, narrow hood. It can strike quickly, to quite a long distance, and if molested and cornered, it will rush forward and make a determined effort to bite. It is an alert and agile species of cobra. Some authorities believe it is one of the most dangerous African snakes to be kept as many captive forest cobras are described to be particularly aggressive when handled. This species is not able to "spit" its venom.

Behaviour
The forest cobra is an agile, diurnal species that climbs well and is one of the most aquatic of the true cobras of the genus Naja. It is terrestrial, but it is fast, graceful climber, known to ascend trees to a height of 10 metres (33 feet) or more. It is quick moving and alert. It swims well and readily takes to the water; in some areas its main diet is fish and could be regarded as semi-aquatic. Although it is active mostly during the day (diurnal) in uninhabited areas, it can also be active by night (nocturnal) where it goes into urban areas. When not active, it takes cover in holes, brush piles, hollow logs, among root clusters or in rock crevices, or in abandoned termite mounds at forest fringe or clearings.

Philippine Cobra

The Philippine cobra (Naja philippinensis) also called northern Philippine cobra, is a stocky, highly venomous species of spitting cobra native to the northern regions of the Philippines. The Philippine cobra is called ulupong in Tagalog, carasaen in Ilocano and agawason in Cebuano-Bisaya. The Philippine cobra is a stocky snake of medium length with long cervical ribs capable of expanding, so when threatened, a hood can be formed. The average length of this species is 1.0 metre (3.3 ft).

The species can grow to lengths of 1.6 metres (5.2 ft) However, subpopulations of the species, particularly specimens from Mindoro Island, are said to attain lengths of 2 metres (6.6 ft), but these are unconfirmed claims. If true, however, 2 m would be very rare and would be considered the absolute maximum for this species.

The head is elliptical, depressed, slightly distinct from neck with a short, rounded snout and large nostrils. The eyes are moderate in size with dark brown and round pupils, typical of other cobra species and similar to other elapids in general. It has a fairly stocky build for an elapid, and adult snakes are uniformly light to medium brown, while the juveniles tend to be a darker brown in colour. They have 23-27 scale rows around the neck and 21 just above the middle part of the body; 182-193 ventrals, 36-49 subcaudals, and basal pairs are sometimes undivided.

Habitat
The Philippine cobra occurs mostly in the northern regions of the Philippines. They can be found on the islands of Luzon, Mindoro, Catanduanes, Azria and Masbate. This species likely may occur in other neighbouring islands, but this remains unconfirmed. Records from the Calamianes group and Palawan require confirmation. The Philippine cobra's habitat include low-lying plains and forested regions, along with open fields, grasslands, dense jungle, agricultural fields, and human settlements. This species of cobra is particularly fond of water, so it can be found very close to ponds, rivers, or large puddles of water.

Venom
The venom of the Philippine cobra is a potent postsynaptic neurotoxin which affects respiratory function and can cause neurotoxicity and respiratory paralysis, as the neurotoxins interrupt the transmission of nerve signals by binding to the neuromuscular junctions near the muscles. Research has shown its venom is purely a neurotoxin, with no apparent necrotizing components and no cardiotoxins. These snakes are capable of accurately spitting their venom at a target up to 3 metres (9.8 ft) away. The symptoms of a bite might include headache, nausea, vomiting, abdominal pain, diarrhoea, dizziness, and difficulty breathing. Bites by the Philippine cobra produce prominent neurotoxicity with minimal to no local signs. Complete Respiratory failure developed in 19 patients, and was often rapid in onset; in three cases, apnea occurred within just 30 minutes of the bite. There were two deaths, both in patients who were moribund upon arrival at the hospital. Three patients developed necrosis, and 14 individuals with systemic symptoms had no local swelling at all. Both cardiotoxicity and reliable nonspecific signs of envenoming were absent. Bites by the Philippine cobra produce a distinctive clinical picture characterized by severe neurotoxicity of rapid onset and minimal local tissue damage.

Cape Cobra

The Cape cobra (Naja nivea), also called the yellow cobra, is a moderate-sized, highly venomous species of cobra inhabiting a wide variety of biomes across southern Africa including arid savannah, fynbos, bushveld, desert and semi-desert regions. The species is diurnal and is a feeding generalist, preying on a number of different species and carrion. Predators of this species include birds of prey, honey badgers and various species of mongoose. The Cape cobra is also known as the "geelslang" (yellow snake) and "bruinkapel" (brown cobra) in South Africa.

The Cape cobra is a medium-sized species of cobra. Mature specimens are typically about 1.2 to 1.4 metres (3.9 to 4.6 ft) long, but may grow up to 1.6 metres (5.2 ft) in length. Males are slightly larger than females. Cape cobras vary widely in colouration, from yellow through golden brown to dark brown and even black.

In addition, individuals show a varying degree of black or pale stippling and blotches, and although colour and marking are geographically related, it is also possible to observe virtually all colour varieties at one location. For example, the Kalahari Desert specimens in Botswana and Namibia are usually more consistently yellow than the more southerly populations. However, at De Hoop, and other specific locations in the Western Cape, all colour variations have been recorded.

Habitat
The Cape cobra is endemic to southern Africa. In South Africa, where it most often occurs, the species occurs throughout the Western Cape, Northern Cape, Eastern Cape, Free State, and North West Province. It also is found in the southern half of Namibia, south-western Botswana, and western Lesotho. Although the Cape cobra has a smaller geographical range than any other African cobra, it occurs in a variety of different habitats. The preferred habitat of the species is fynbos, bushveld, karoo scrubland, arid savannah, the Namib desert and the Kalahari desert.

Behaviour
The Cape cobra is a diurnal species and actively forages throughout the day. During very hot weather it may become crepuscular, but is rarely if ever observed during the hours of darkness. It is a terrestrial snake, but will readily climb trees and bushes, and shows considerable agility in for example systematically robbing the nests of the sociable weaver. When not active, it hides in holes or under ground cover, such as brush piles, often remaining in the same retreat for some time. It is a quick moving and alert species, and although a report mentions that this species is generally calm when compared to some other African venomous snakes, it strikes readily if threatened. When disturbed and brought to bay the Cape cobra raises its forebody off the ground, spreads a broad hood and may hiss loudly. While on the defensive, it strikes unhesitatingly. If the threat remains motionless, the snake will quickly attempt to escape, but at any sign of movement will adopt its defensive posture again. The Cape cobra is more aggressive during the mating period.

Venom
The Cape cobra is regarded as one of the most dangerous species of cobra in all of Africa, by virtue of its potent venom and frequent occurrence around houses. The venom of this snake tends to be thick and syrupy in consistency and dries into shiny pale flakes, not unlike yellow sugar. The mortality rate for untreated bites is not exactly known, but is thought to be high. This can be due to various factors including the amount of venom injected, psychological state of the bitten subject, the penetration of one or both fangs, and so on. Mechanical ventilation and symptom management is often enough to save a victim's life, but cases of serious Cape cobra envenomation will require antivenom. When death does occur, it normally takes anywhere from an hour (in severe cases) to ten hours (or more) and it is often as a result of respiratory failure, due to the onset of paralysis. The antivenom used in case of a bite is a polyvalent antivenom produced by the South African Institute of Medical Research (SAIMR).

Jararaca

Bothrops jararaca is a species of pit viper endemic to southern Brazil, Paraguay, and northern Argentina. The specific name, jararaca, is derived from the Tupi words yarará and ca, which mean "large snake". Within its geographic range, it is often abundant and is an important cause of snakebite. No subspecies are currently recognized.

The drugs known as angiotensin converting enzyme (ACE) inhibitors, used for the treatment of hypertension and some types of congestive heart failure, were developed from a peptide found in the venom of this species. This is a slender and terrestrial species that grows to a maximum total length of 160 cm (63 in), although the average total length is much less.

The head scalation includes 5-12 intersupraoculars that are weakly keeled, 7-9 supralabials (usually 8) of which the second is fused with the prelacunal to form a lacunolabial, and 9-13 sublabials (usually 10-12). Midbody, there are 20-27 rows of dorsal scales (usually 23-25). The ventrals number 170-216 (rarely 218) and the 51-71 subcaudals are mostly paired.

Geography
This snake is found in southern Brazil, north-eastern Paraguay and northern Argentina (Misiones). The type locality is listed as "Lagoa d'Arara am Mucurî" (Brazil) by Wied-Neuwied in 1825. Occurs from near sea level to over 1,000 m altitude.

Habitat
The species prefers deciduous tropical forests and savannah country, as well as semitropical upland forests. It is said to favour open areas, such as farmland, with nearby vegetation cover.

Venom
This species is often abundant within its range, where it is an important cause of snakebite. It is the best-known venomous snake in the wealthy and heavily populated areas of south-eastern Brazil, where it was responsible for 52% (3,446 cases) of snakebites between 1902 and 1945, with a 0.7% fatality rate (25 deaths). The average venom yield is 25–26 milligrams (0.39–0.40 gr) with a maximum of 300 milligrams (4.6 gr) of dried venom. The venom is quite toxic. In mice, the median lethal dose (LD50) is 1.2-1.3 mg/kg intravenous, 1.4 mg/kg intraperitoneal and 3.0 mg/kg subcutaneous. For humans, the LD50 is estimated to be 210 milligrams (3.2 gr) subcutaneous. Typical envenomation symptoms include local swelling, petechiae, bruising and blistering of the affected limb, spontaneous systemic bleeding of the gums and into the skin, subconjunctival haemorrhage and incoagulable blood. The systemic symptoms can potentially be fatal and may involve haemostatic disorders, intracranial haemorrhage, shock and renal failure.

South American Bushmaster

Lachesis muta is a venomous pit viper species found in South America (including the island of Trinidad in the Republic of Trinidad and Tobago). Two subspecies are currently recognized, including the nominate subspecies described here. Adults grow to an average of 2 to 2.5 m (6½-8 feet), although 3 m (10 feet) is not too unusual. The largest recorded specimen was almost 3.65 m (12 feet) long, making this the largest of all vipers and the longest venomous snake in the western hemisphere.

Lachesis muta is the third longest venomous snake in the world. Weight in this species is estimated at an average of 3 to 5 kg (6.6 to 11.0 lb), somewhat less than the heaviest rattlesnakes or Bitis vipers, such as gaboon viper, and rhinoceros vipers. The head is broad and distinct from the narrow neck. The snout is broadly rounded. There is no canthus.

A pair of small internasals is present, separated by small scales. The supraoculars are narrow. Other parts of the crown are covered with very small scales. Laterally, the second supralabial forms the anterior border of the loreal pit, while the third is very large. The eye is separated from the supralabials by 4-5 rows of small scales.

Distribution
Found in South America in the equatorial forests east of the Andes: Colombia, eastern Ecuador, Peru, northern Bolivia, eastern and southern Venezuela, the island of Trinidad in the Republic of Trinidad and Tobago, Guyana, Surinam, French Guiana and much of Brazil. The type locality is "Surinami" (Surinam). It occurs in primary and secondary forests; adjacent fields and cleared areas. In Trinidad it tends to prefer hilly and mountainous regions.

Venom
Some reports suggest that this species produces a large amount of venom that is weak compared to some other vipers. Others, however, suggest that such conclusions are not accurate. These animals are badly affected by stress and rarely live long in captivity. This makes it difficult to obtain venom in useful quantities and good condition for study purposes.

Gaboon Viper

The Gaboon viper (Bitis gabonica) is a viper species found in the rainforests and savannahs of sub-Saharan Africa. Like all vipers, it is venomous. It is the largest member of the genus Bitis, and it has the longest fangs – up to 2 inches in length (5 cm) – and the highest venom yield of any snake. No subspecies are currently recognized.

Adults average 125–155 cm (4 to 5 feet) in total length (body + tail) with a maximum total length of 205 cm (81 in) for a specimen collected in Sierra Leone. The sexes may be distinguished by the length of the tail in relation to the total length of the body: approximately 12% for males and 6% for females. Adults, especially females, are very heavy and stout.

Habitat
This species can be found in Guinea, Ghana, Togo, Nigeria, Cameroon, Equatorial Guinea, Gabon, Republic of the Congo, DR Congo, northern Angola, Central African Republic, South Sudan, Uganda, Kenya, eastern Tanzania, Zambia, Malawi, eastern Zimbabwe, Mozambique, and northeast KwaZulu-Natal Province in South Africa. Mallow et al. (2003) also list Sierra Leone and Liberia in West Africa. The type locality is given as "Gabon" (Africa). The Gaboon viper is usually found in rainforests and nearby woodlands, mainly at low altitudes, but sometimes as high as 1500 m. Spawls et al. (2004) mention a maximum altitude of 2100 m. According to Broadley and Cock (1975), it is generally found in environments that are parallel to those occupied by its close relative, B. arietans, which is normally found in more open country.

Aggressiveness
If threatened, they may hiss loudly as a warning, doing so in a deep and steady rhythm, slightly flattening the head at the expiration of each breath. Despite this, they are unlikely to strike unless severely provoked; however, they are one of the fastest-striking snakes in the world, so care should be taken in handling them. There have been numerous descriptions of their generally unaggressive nature. Sweeney (1961) wrote they are so docile that they "can be handled as freely as any non-venomous species", although this is absolutely not recommended. In Lane (1963), Ionides explained he would capture specimens by first touching them lightly on the top of the head with a pair of tongs to test their reactions. Hissing and anger was rarely displayed, so the tongs were usually set aside and the snakes firmly grasped by the neck with one hand and the body supported with the other as he picked them up and carried them to a box for containment. He said the snakes hardly ever struggled.

Behaviour
Primarily nocturnal, Gaboon vipers have a reputation for being slow-moving and placid. They usually hunt by ambush, often spending long periods motionless, waiting for suitable prey to pass by. On the other hand, they have been known to hunt actively, mostly during the first six hours of the night. In Kumasi, Ghana, they were regularly killed around some stables in an open area with the forest some 500 meters away — a sign that they were hunting rats in the grassland. They are usually very tolerant snakes, even when handled, and rarely bite or hiss, unlike most vipers. However, bites by bad-tempered individuals do occur.

Venom
Bites from this species are extremely rare, due to their unaggressive nature and because their range is limited to rainforest areas. Due to their sluggishness and unwillingness to move even when approached, bites most often occur due to persons accidentally stepping on a Gaboon viper, but even then in some cases this does not guarantee a bite. However, when a bite does occur, it should always be considered a serious medical emergency. Even an average bite from an average-sized specimen is potentially fatal. Antivenom should be administered as soon as possible to save the victim's life if not the affected limb. In humans, a bite from a Gaboon viper causes rapid and conspicuous swelling, intense pain, severe shock and local blistering. Other symptoms may include uncoordinated movements, defecation, urination, swelling of the tongue and eyelids, convulsions and unconsciousness. Blistering, bruising and necrosis may be extensive. There may be sudden hypotension, heart damage and dyspnoea. The blood may become incoagulable with internal bleeding that may lead to haematuria and haematemesis. Local tissue damage may require surgical excision and possibly amputation to any affected limb. Healing may be slow and fatalities during the recovery period are not uncommon.

Chinese Cobra

The Chinese cobra (Naja atra), also called Taiwan cobra, is a species of cobra in the family Elapidae, found mostly in southern China and a couple of neighbouring nations and islands. It is one of the most prevalent venomous snakes in China and Taiwan, which has caused many snakebite incidents to humans.

This medium-sized snake is usually 1.2 to 1.5 metres (3.9 to 4.9 ft) long, but they can grow to a maximum length of 2 metres (6.6 ft) though this is rare. The hood mark shape is variable from spectacle, mask to horseshoe or O- shape and is often linked to light throat area on at least one side. The throat area is clearly defined light which is usually with a pair of clearly defined lateral spots.

The Chinese cobra is iridescent black with a number of distant transversal double lines of a yellow colour. The abdominal surface is pearl or slaty coloured. The dorsal colour of the Chinese cobra is usually brown, grey or black, with or without narrow, light transverse lines at irregular intervals which are especially prominent in juveniles. The upper head is usually the same colour as the tail and dorsal part of the body, while the sides of the head are lighter in colour. Specimens with other colours on their dorsal surface, such as white, yellow or brown do occur.

Distribution
This species is found in south-eastern China (including the provinces of Sichuan, Fujian, Guangdong, Guangxi, Guizhou, Hunan, Hubei, Zhejiang, and the Island province of Hainan), Hong Kong, northern Laos, northern Vietnam, and Taiwan, where it is much more common in the south.

Habitat
Its typical habitat is woodlands, shrublands, grasslands, and mangroves. This species is adaptable to a wide range of terrain including grassland plains, jungle, open fields and even heavily populated regions. As an adaptable species, it occurs in a wide variety of habitats across its range. It can be found in rice paddy fields in maritime lowlands to various types of montaine forests, though it avoids dark forest with closed canopy. In primary monsoon season and rain forests, Naja atra inhabits clearings and riverbanks.

Venom
The Chinese cobra is a highly venomous member of the true cobras (genus Naja). Its venom consists mainly of postsynaptic neurotoxins and cardiotoxins. Four cardiotoxin-analogues I, II, III, and IV, account for about 54% of the dry weight of the crude venom and have cytotoxic properties. The distribution of the venom of the Chinese cobra has been studied in mice using a whole-animal radiographic technique. Results indicate that venom accumulates primarily in the kidney (marked localization in the cortex) with little or no activity in the brain of mice sacrificed one to two minutes after intravenous injection of massive dose levels of venom. Although this is not a spitting cobra, some individuals (mostly specimens from Guizhou Province) are capable of ejecting venom towards a threat within a distance of 2 metres (6.6 ft). In Taiwan there were 593 recorded cases of envenomation by the Chinese cobra from 1904–1938, of those 87 cases were fatal which is a 15% mortality rate. This is higher than mortality rates for Naja naja (the Indian cobra). Local symptoms in victims caused by a Chinese cobra bite are wound darkening, localized redness and swelling, pain, insensibility, and invariably blisters and necrosis. Necrosis is a serious problem in cases of cobra bite as it may persist for many years after the general recovery of the victim. The following systemic symptoms may also occur: chest discomfort, fever, sore throat, difficulty in swallowing, loss of voice, weak feeling in limbs, walking haltingly, general ache, lockjaw, and difficulty in breathing. Fatality occasionally occurs. The antivenom is widely available and deaths are much rarer than they used to be.

Behaviour
The Chinese cobra is a very alert, seldom cornered, but if confronted will raise its forebody and spread its hood and strike readily if necessary. Adults can be very aggressive, but the younger tend to be more aggressive as they are more nervous to the things surrounding them. The Chinese cobra usually escapes to avoid confrontation with humans. The snake is terrestrial, diurnal and crepuscular. This species has been observed hunting during all daylight periods and as late as 2–3 hours after sunset from March to October, with ambient temperatures of 20–32 °C (68–90 °F).

Monocled Cobra

The monocled cobra (Naja kaouthia), also called monocellate cobra, is a cobra species widespread across South and Southeast Asia and listed as Least Concern by IUCN. The monocled cobra has an O-shaped, or monocellate hood pattern, unlike that of the Indian cobra, which has the "spectacle" pattern (two circular ocelli connected by a curved line) on the rear of its hood. Coloration in the young is more constant. The dorsal surface may be yellow, brown, gray, or blackish, with or without ragged or clearly defined cross bands.

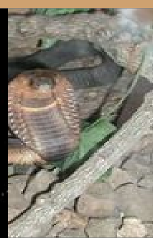
It can be olivaceous or brownish to black above with or without a yellow or orange-coloured, O-shaped mark on the hood. It has a black spot on the lower surface of the hood on either side, and one or two black cross-bars on the belly behind it. The rest of the belly is usually the same colour as the back, but paler. As age advances, the snake becomes paler, wherein the adult is brownish or olivaceous.

Habitat
Monocled cobras are distributed from India in the west through to China, Vietnam and Cambodia. They are also found on the Malay Peninsula and are native to Bangladesh, Bhutan, Myanmar, Laos, Nepal, and Thailand.
These cobras can adapt to a range of habitats, from natural to anthropogenically impacted environments. They prefer habitats associated with water, such as paddy fields, swamps, and mangroves, but can also be found in grasslands, shrublands, and forests. The species also occurs in agricultural land and human settlements including cities. They can be found at elevations of up to 1,000 m (3,300 ft) above sea level.

Venom
The monocled cobra causes the highest fatality due to snake venom poisoning in Thailand. Envenomation usually presents predominantly with extensive local necrosis and systemic manifestations to a lesser degree. Drowsiness, neurological and neuromuscular symptoms will usually manifest earliest; hypotension, flushing of the face, warm skin, and pain around bite site typically manifest within one to four hours following the bite; paralysis, ventilatory failure or death could ensue rapidly, possibly as early as 60 minutes in very severe cases of envenomation. However, the presence of fang marks does not always imply that envenomation actually occurred. In a preliminary study, extract of Mimosa pudica plant has been shown to possibly have neutralizing effects on the toxins present in this venom.

Aggressiveness
Monocled cobras are terrestrial and most active at dusk. In rice-growing areas, they hide in rodent burrows in the dykes between fields and have become semi-aquatic in this type of habitat. Juveniles feed mostly on amphibians whereas adults prey on small mammals, snakes and fish. When disturbed they prefer to take flight. However, when threatened they will raise the anterior portions of their bodies, spread their hood, usually hiss loudly, and strike in an attempt to bite and defend themselves. They are often found in tree holes and areas where rodents are plentiful. Some populations of the monocled cobra have the ability to spit venom.

Egyptian Cobra



The Egyptian cobra is a species of venomous snake in the family Elapidae. Naja haje is one of the largest cobra species native to Africa, second to the forest cobra (Naja melanoleuca). The Egyptian cobra is one of the largest cobras of the African continent. The head is large and depressed and slightly distinct from the neck. The neck of this species has long cervical ribs capable of expanding to form a hood, like all other cobras.

The snout of the Egyptian cobra is moderately broad and rounded. The eye is quite big with a round pupil. The body of the Egyptian cobra is cylindrical and stout with a long tail. The length of the Egyptian cobra is largely dependent on subspecies, geographical locale, and population.

The average total length (including tail) of this species is between 1 and 2 metres (3.3 and 6.6 ft), with a maximum total length of just under 3 metres (9.8 ft). The most recognizable characteristics of this species are its head and hood. The colour is highly variable, but most specimens are some shade of brown, often with lighter or darker mottling, and often a "tear-drop" mark below the eye. Some are more copper-red or grey-brown in colour.

Range
The Egyptian cobra ranges across most of North Africa north of the Sahara, across the savannahs of West Africa to the south of the Sahara, south to the Congo basin and east to Kenya and Tanzania. Older literature records from southern Africa and the Arabian Peninsula refer to other species (see Taxonomy section below).

Habitat
Naja haje occurs in a wide variety of habitats like, steppes, dry to moist savannahs, arid semi-desert regions with some water and vegetation. This species is frequently found near water. The Egyptian cobra is also found in agricultural fields and scrub vegetation. It also occurs in the presence of humans where it often enter houses. It is attracted to villages by rodent pests (rats) and domestic chickens. There are also notes of the Egyptian cobra swimming in the Mediterranean sea, so it seems to like water where it has been found quite often.

Venom
The venom affects the nervous system, stopping the nerve signals from being transmitted to the muscles and at later stages stopping those transmitted to the heart and lungs as well, causing death due to complete respiratory failure. Envenomation causes local pain, severe swelling, bruising, blistering, necrosis and variable non-specific effects which may include headache, nausea, vomiting, abdominal pain, diarrhoea, dizziness, collapse or convulsions along with possible moderate to severe flaccid paralysis. Unlike some other African cobras (for example the red spitting cobra), this species does not spit venom.

Behaviour
The Egyptian cobra is a terrestrial and crepuscular or nocturnal species. It can however, be seen basking in the sun at times in the early morning. This species shows a preference for a permanent home base in abandoned animal burrows, termite mounds or rock outcrops. It is an active forager sometimes entering human habitations, especially when hunting domestic fowl. Like other cobra species, it generally attempts to escape when approached, at least for a few metres, but if threatened it assumes the typical upright posture with the hood expanded, and strikes. This species prefers to eat toads, but it will prey on small mammals, birds, eggs, lizards and other snakes.

Banded Water Cobra

Naja annulata (formerly Boulengerina annulata), commonly known as the banded water cobra or the ringed water cobra, is a species of water cobra native to western and central Africa. The species is one of the two species of water cobras in the world, the other one being the Congo water cobra (Naja christyi).

It has medium-sized dark eyes with round pupils. The body is cylindrical; the tail is long. The scales are smooth and glossy, in 21-23 rows at midbody. Adults grow to an average of 1.4 to 2.2 metres (4.6 to 7.2 ft) in length, but they can grow to a maximum of 2.7 metres (8.9 ft).

Habitat
Scales are smooth, indicating the largely aquatic life of this species. It is capable of spreading a narrow, yet impressive hood. Body colours are mostly glossy brown, grayish-brown, or reddish-brown with black bands all along the body. The belly is pale yellow, while the tail is wholly black.

Habitat
This species is found in parts of central and western Africa, in Burundi, Cameroon, Central African Republic, Democratic Republic of Congo, Republic of Congo, Equatorial Guinea, Gabon, Rwanda, and the province of Cabinda in Angola, as well as along the Burundian, Tanzanian and Zambian shores of Lake Tanganyika. It is largely an aquatic species and rarely is found far away from water.

Venom
The venom of this species is not well studied, but it is believed that the venom is dangerously neurotoxic, like that of most elapids. A study listed the intraperitoneal (IP) LD50 of this species at 0.143 mg/kg.

Aggressiveness
It is a secretive species and is seldom encountered by humans. It is active by day and night, though it is usually more active by day. This largely aquatic snake spends most of its time in the water. It is an excellent swimmer and is capable of remaining under water for up to 10 minutes and diving to depths of 25 metres (82 ft). It is a slow mover on land, and it tends to hide among rocks, in holes or overhanging tree roots at the shoreline. It also makes use of any man-made structures, such as bridges and jetties, to hide. It is generally not aggressive, and if approached in water, it will swim away swiftly and on land will attempt to escape into water. If threatened on land, it will rear up and spread its narrow, yet prominent hood and it may hiss loudly, but it tends not to make any forward movements. It will only bite when provoked.

Congo Water Cobra

Naja christyi (formerly Boulengerina christyi), commonly known as the Congo water cobra or Christy's water cobra, is a species of venomous snakes belonging to the family Elapidae. The species is native to Sub-Saharan Africa. This species was formerly in the genus Boulengerina, but more recent research by Wallach et al. has shown that Boulengerina is actually a subgenus and Boulengerina christyi is a synonym of Naja christyi. This species has no known subspecies.

N. christyi is a medium to moderately long, somewhat compressed, moderately slender-bodied, but heavily built snake, with a medium length tapering tail. The head is short, with an indistinct canthus, and is distinct from the neck. The neck is capable of being spread into a hood.

The eyes are relatively small in size with round pupils. The dorsal scales are smooth and shiny. The average total length (including tail) of an adult specimen is around 1.1 metres (3.6 ft), but it may grow to upwards of 2.3 metres (7.5 ft) The rostral is once and a half as broad as deep, and is just visible from above.

Habitat
N. christyi has a small geographic range. It occurs in western Democratic Republic of Congo, the southern half of the Republic of Congo, a very small portion of south-eastern Gabon, and in the province of Cabinda in far northern Angola. N. christyi is found most commonly in or near water, in lowland bushy or wooded areas along banks of lakes, rivers, and streams. It is limited to the lower Congo River and nearby wet forested areas.

Behaviour
Not much is known about N. christyi. However, it is believed to be active by day and night. It is a semi-aquatic snake which spends much of its time in the water. An excellent swimmer. It tends to hide amongst rocks, in holes or overhanging tree roots at the shore line. It also makes use of any man-made structures such as bridges and jetties to hide. Generally this is not an aggressive snake. If approached in water it will swim away swiftly. If threatened on land it will rear up, spread its narrow hood and hiss. It may strike if it's provoked extensively.

Venom
The venom of N. christyi is not well studied, but it is believed that the venom is dangerously neurotoxic, like that of most elapids. A study listed the intraperitoneal (IP) LD50 of this species at 0.12 mg/kg. At least one human has been reported to have been bitten by this species. The individual had only mild symptoms (headache, local pain), but this species is capable of causing serious envenomation of humans. No specific antivenom currently produced against this species' venom.

Black Desert Cobra

Walterinnesia is a genus of venomous snakes in the family Elapidae. The genus contains two species, known commonly as desert black snakes or black desert cobras, which are endemic to the Middle East. Walterinnesia aegyptia was long considered to be the only species within the genus. However, it was recently found that the eastern populations actually represent a different species, Walterinnesia morgani. W. aegyptia is entirely black in colour, and has highly shiny scales. These snakes are medium in length, with a medium, cylindrical body and a short tail.

Their average length is 0.5 meters (1 ft 8 in), but they can grow to lengths of 1.8 meters (5 ft 11 in). Their head is moderately small, broad, flattened and slightly distinct from the neck. The snout is broad, sharply edged with a distinct canthus rostralis.

The eyes are small in size with round pupils. Dorsal scales are smooth anteriorly and weakly keeled on the posterior part of the body and tail. They are very glossy throughout. Dorsal scale count 27 (24 to 29) - 23 (21 - 25) - 17. Unlike other snakes commonly referred to as "cobras", the black desert cobra rarely rear up or produces a hood before striking in defence.

Geography
They are native to the Middle East. Walterinnesia aegyptia is found in the countries of Egypt, Lebanon, Jordan, Israel, north-western Saudi Arabia, and Kuwait. It may also be found in areas of Syria that border Lebanon, as well as the deserts of Qatar.

Habitat
These species occur in the desert (excluding completely sand deserts such as the ad-Dahna Desert). They can also be found in semi-desert scrublands and rocky terrain, extending into the foothills of vegetated Mediterranean terrain. They are also often found near human habitation in irrigated agricultural settlements.

Venom
W. aegyptia is highly venomous. The subcutaneous LD50 for the venom of W. aegyptia is 0.4 mg/kg. For comparison, the Indian cobra's (Naja naja) subcutaneous LD50 is 0.80 mg/kg, while the Cape cobra's (Naja nivea) subcutaneous LD50 is 0.72 mg/kg. This makes W. aegyptia (the desert black snake) a more venomous snake than both. Like many elapid snakes, the venom is primarily neurotoxic and effects of envenenomation are from systemic circulation of the toxins rather than from local effect on tissue near the site of injection.

Behaviour
The desert black snakes are nocturnal and are strictly terrestrial snakes. They are most active around midnight. They actively pursue and forage for their prey and rather than envenomate their prey with an open mouth, they'll usually bite their prey sideways at short distances and often use constriction and suffocation techniques in addition to their venom to kill their prey. There are reports of these snakes being aggressive when molested, but like most snakes, they will usually try to escape rather than immediately bite or face their threat. Venom is not injected immediately when they bite, but released seconds later with chewing movement.

Samar Cobra

The Samar cobra (Naja samarensis) also called Peters' cobra, southern Philippine cobra or Visayan cobra, is a highly venomous species of spitting cobra native to the Visayas and Mindanao island groups of the Philippines. The Samar cobra is a species of spitting cobra that can grow up to 1.4 meters in length. Their colouring varies from a black and yellow to green.

Habitat
The Samar cobra is endemic to the southern Philippines. Specifically, the Visayas and Mindanao island groups. Habitat can vary widely from mountainous jungle to tropical plains. They can live close to human settlements.

Behaviour
Like the Philippine cobra (Naja philippinensis), the Samar cobra feeds mostly on rodents. They will also prey upon frogs and reptiles. Since their main food source is attracted to rice paddies and human settlements, this species often comes into conflict with people.

Venom
The Samar cobra's venom is a potentially deadly neurotoxin, with cytotoxic properties as well. Envenomations can result in respiratory distress and paralysis, as well as considerable tissue necrosis around the bite site. They are noted for their nervous behaviour, and are quick to strike as well as to spray venom, which they generally aim towards the face and eyes. If venom gets in the eyes, it causes extreme pain and mechanical damage to the eyeball. If not properly flushed out, it can result in permanent blindness due to its tissue destroying properties. Antivenin for the Samar cobra is produced in the Philippines, but is not widely available due to this species' restricted distribution and thus, relatively low numbers of individuals.

Indochinese Spitting Cobra

The Indochinese spitting cobra (Naja siamensis) also called the Thai spitting cobra, Siamese spitting cobra or black-and-white spitting cobra, is a species of spitting cobra found in Southeast Asia. This is a medium-sized cobra with a rather thin body compared to other cobras. The body colour of this species is variable from grey to brown to black, with white spots or stripes. The white patterning can be so prolific that it covers the majority of the snake.

The highly distinctive black and white colour phase is common in central Thailand, specimens from western Thailand are mostly black, whereas individuals from elsewhere are usually brown. The hood mark can be spectacle-shaped, irregular or missing altogether, especially in adults. Adults average 0.9 to 1.2 metres (3.0 to 3.9 ft) long, and can reach a maximum of 1.6 metres (5 ft) though this is very rare.

Habitat
It is found in Southeast Asia, including Thailand, Cambodia, Vietnam, and Laos. May occur in eastern Myanmar but no records are known. It occupies a range of habitats including lowlands, hills, plains, and woodland. It can also be found in jungle habitat and it is sometimes attracted to human settlements because of the abundant populations of rodents in and around these areas.

Venom
Like most other spitting cobras, its venom is primarily a postsynaptic neurotoxin and cytotoxin (necrotizing or tissue-death). The LD50 of its venom is 1.07-1.42 mg/gram of mouse body weight. Bite symptoms include pain, swelling and necrosis around the wound. The bite of this snake is potentially lethal to an adult human. Deaths, which generally happen due to paralysis and consequent asphyxiation, mainly occur in rural areas where the procurement of antivenin is difficult. If the snake spits venom into the eyes of an individual, the individual will experience immediate and severe pain as well as temporary and sometimes even permanent blindness.

Aggressiveness
It is a primarily nocturnal species. It shows variable temperament depending on the time of day it is encountered. When threatened during daylight hours, the snake is generally timid and seeks refuge in the nearest burrow. However, when the snake is threatened at night, it is more aggressive and is more likely to stand its ground, rear up and display its hood and spit out its venom. If spitting venom doesn't work, it will strike and bite as a last resort. When biting, this species tends to hold on and chew savagely. It usually feeds on rodents, toads, and other snakes.

Black-Necked Spitting Cobra

The black-necked spitting cobra (Naja nigricollis) is a species of spitting cobra found mostly in sub-Saharan Africa. They are moderately sized snakes that can grow to a length of 1.2 to 2.2 m (3.9 to 7.2 ft) in length. Their coloration and markings can vary considerably. They prey primarily on small rodents. They possess medically significant venom, although the mortality rate for untreated bites on humans is relatively low (~ 5–10%, in endemic regions under 1%). Like other spitting cobras, they can eject venom from their fangs when threatened (one drop over 7 metres (23 ft) and more in perfect accuracy).

The neurotoxic venom irritates the skin, causing blisters and inflammation, and can cause permanent blindness if the venom makes contact with the eyes and is not washed off. N. nigricollis is a moderately sized, venomous snake with a moderately distinct head; the shape of the head is due primarily to two large venom glands found on each side of the head. Its colour can vary depending on region of origin. Some specimens are black or pale grey with a yellow or reddish ventral side with a broad, black neck band, often with an orange or pinkish bar on the neck. Other specimens can be yellowish-brown or have a yellow copper colour and are missing the bandings around the neck and the reddish colour on the belly.

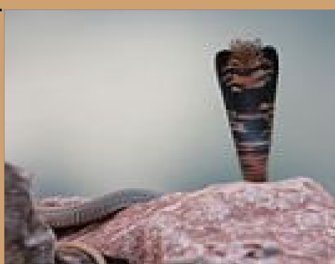
Habitat
The species is very common and is widespread through much of sub-Saharan Africa and is found in western, eastern, central, and parts of southern Africa. It is absent from the rainforests of the Congo Basin. It has been recorded from Angola, Benin, Burkina Faso, Cameroon, Central African Republic, Chad, Democratic Republic of the Congo (except in the centre), Congo, Ethiopia, Gabon, Ghana, Guinea Bissau, Guinea, Ivory Coast, Kenya, Liberia, Mali, Niger, Nigeria, Senegal, Sierra Leone, Gambia, Mauritania, Sudan, Tanzania, Somalia, Togo, Uganda, Zambia.

Venom
The venom of Naja nigricollis is somewhat unusual among elapids in that it consists primarily of cytotoxins, but with other components also. It retains the typical elapid neurotoxic properties while combining these with highly potent cytotoxins (necrotic agents) and cardiotoxins. Bite symptoms include severe external hemorrhaging and tissue necrosis around the bite area and difficulty breathing. Although the mortality rate in untreated cases is low (~ 5–10%), when death occurs, it is usually due to asphyxiation by paralysis of the diaphragm.

Behaviour
Unlike other snakes, Naja nigricollis can be either nocturnal or diurnal depending on the time of year, geographic location, and average daytime temperature. This adaptability allows the snake to better regulate its body temperature and to gain access to the most abundant food sources of a particular area. It feeds primarily on small rodents, such as small rats and mice, birds, and fishes, but will also eat lizards, eggs, and other snakes.

Aggressiveness
Like other spitting cobras, this species is known for its ability to project venom at a potential threat. The venom is an irritant to the skin and eyes. If it enters the eyes, symptoms include extreme burning pain, loss of coordination, partial loss of vision, and permanent blindness. N. nigricollis is known for its tendency to liberally spit venom and bite with only the slightest provocation. This species is sometimes found in captivity, and wild-caught individuals are generally nervous and prone to spitting. Captive-bred animals tend to be much more docile and calm when compared to their wild-caught counterparts.

Mozambique Spitting Cobra



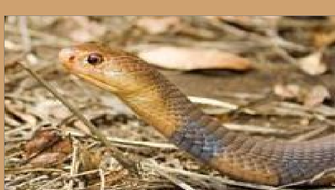
The Mozambique spitting cobra is a highly venomous species of spitting cobra native to Africa. In colour the snake is slate to blue, olive or tawny black above, with some or all scales black-edging. Below, salmon pink to purple yellowish, with black bars across the neck and ventrals speckled or edged with brown or black; young specimens sometimes have pink or yellow bars on the throat. The average length of adults is between 90 cm - 105 cm (3-3½ feet), but largest specimen actually measured was a male 154 cm (5 feet) long. (Durban, Kwa-Zulu Natal, South Africa).

Distribution
This species is the most common cobra of the savannah regions of the tropical and subtropical Africa. The distribution includes Natal, as far south as Durban, Mpumalanga Province Lowveld region, south-eastern Tanzania and Pemba Island and west to southern Angola and northern Namibia. Younger specimens are much more frequently encountered in the open at daytime. Unlike the Egyptian Cobra, this species prefers localities near water, to which it will readily take when disturbed.

Habitat
This snake is nervous and temperamental. When confronted at close quarters, it can rear up as much as two-thirds of its length and spread its long narrow hood, and will readily "spit" in defence, usually from a reared-up position. The venom can be propelled 2–3 metres (6½-10 feet), with great accuracy. The spitting cobra might bite instead of spitting, depending on its circumstances, and like the rinkhals it may feign death to avoid further molestation.

Venom
It is considered one of the most dangerous snakes in Africa. Its venom is about as toxic as the American Mojave rattlesnake, considered the world's most venomous rattlesnake. Like the rinkhals, it can spit its venom. Its bite causes severe local tissue destruction (similar to that of the puff adder). Venom to the eyes can also cause impaired vision or blindness. The venom of this species contains postsynaptic neurotoxin and cytotoxin. There have been only a few fatalities resulting from bites of this species but survivors are mostly disfigured.

Mali Cobra



The Mali cobra, also called the Katian spitting cobra, is a species of spitting cobra found in West Africa.

Range
This species ranges from Senegal to Cameroon, with recorded sightings in Gambia, Guinea-Bissau, far northern Guinea, Southern Mali, Ivory Coast, Burkina Faso, Northern Ghana, Togo, South-western Niger and Nigeria.

Habitat
This species occurs in both tropical and subtropical grasslands, savannahs, and shrublands.

Rinkhals

The rinkhals, also called the ringhals or ring-necked spitting cobra, is a species of venomous elapid found in parts of southern Africa. It is not a true cobra in that it does not belong to the genus Naja, but instead belongs to the monotypic genus Hemachatus. While rinkhals bear a great resemblance to true cobras they also possess some remarkable differences from these, resulting in their placement outside the genus Naja.

Coloration varies throughout its distribution area, but a characteristic of the species is the belly is dark with one or two light-coloured crossbands on the throat. Their average length is 90–110 cm. Some individuals may have a mostly black body, while others are striped. Rinkhals scales are distinct from those of Naja cobras in that they are ridged and keel-like.

Habitat
The rinkhals generally prefers grassland habitats because it allows them to blend in with the surroundings. Rinkhals also may live in swamps around southern Africa.

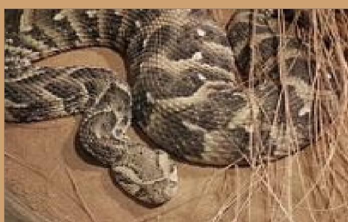
Venom
The venom of the rinkhals is neurotoxic and partially cytotoxic, and is less viscous than that of other African elapids. When confronting a human, it generally aims its venom at the face. If the venom enters the eyes, it causes great pain. A polyvalent antivenom is currently being developed by the Universidad de Costa Rica's Instituto Clodomiro Picado

Aggressiveness
If distressed, the rinkhals spreads its hood, showing its distinctive, striped neck. It is a spitting cobra, and can spray its venom up to 2.5 m. Its spitting mechanism is primitive and it has to rear up and fling its body forward to spray its venom. It is also known to fake death by rolling onto its back with its mouth agape.

Behaviour
The rinkhals has a varied diet. Its main prey is toads, but it also eats small mammals, amphibians, and other reptiles.
Rinkhals are unique amongst African cobras in being ovoviviparous. They give birth to 20–35 live young, but as many as 65 young have been recorded.

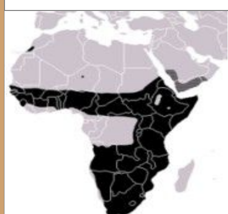
Bite Symptoms
Local symptoms of swelling and bruising is reported in about 25% (a quarter) of cases. General symptoms of drowsiness, nausea, vomiting, violent abdominal pain, cramps and vertigo often occur, as does a mild pyrexial reaction.

Puff Adder



Bitis arietans is a venomous viper species found in savannah and grasslands from Morocco and western Arabia throughout Africa except for the Sahara and rain forest regions. It is responsible for causing the most snakebite fatalities in Africa owing to various factors, such as its wide distribution, frequent occurrence in highly populated regions, and aggressive disposition. Two subspecies are currently recognized, including the nominate subspecies described here. The average size is about 1m (39.3 inches) in total length (body + tail) and very stout.

Large specimens of 190 cm (75 in) total length, weighing over 6.0 kg (13.2 lbs) and with a girth of 40 cm (16 in) have been reported. Specimens from Saudi Arabia are not as large, usually no more than 80 cm (31 in) in total length. Males are usually larger than females and have relatively longer tails. The head has a less than triangular shape with a blunt and rounded snout.



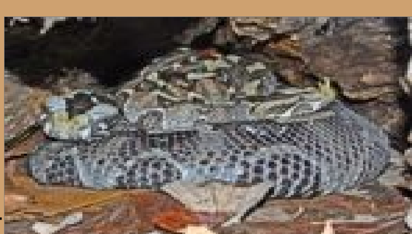
Range
This species is probably the most common and widespread snake in Africa. It is found in most of sub-Saharan Africa south to the Cape of Good Hope, including southern Morocco, Mauritania, Senegal, Mali, southern Algeria, Guinea, Sierra Leone, Côte d'Ivoire, Ghana, Togo, Benin, Niger, Nigeria, Chad, Sudan, Cameroon, Central African Republic, northern, eastern and southern Democratic Republic of the Congo, Uganda, Kenya, Somalia, Rwanda, Burundi, Tanzania, Angola, Zambia, Malawi, Mozambique, Zimbabwe, Botswana, Namibia and South Africa. It also occurs on the Arabian peninsula, where it is found in south-western Saudi Arabia and Yemen.

Habitat
It is found in all habitats except true deserts, rain forests, and (tropical) alpine habitats. It is most often associated with rocky grasslands. It is not found in rainforest areas, such as along the coast of West Africa and in Central Africa (i.e., central DR Congo); it is also absent from the Mediterranean coastal region of North Africa. On the Arabian peninsula, it is found as far north as Ta'if. It has been reported to be found in the Dhofar region of southern Oman.

Venom
This species is responsible for more snakebite fatalities than any other African snake. This is due to a combination of factors, including its wide distribution, common occurrence, large size, potent venom that is produced in large amounts, long fangs, their habit of basking by footpaths and sitting quietly when approached. In humans, bites from this species can produce severe local and systemic symptoms. Based on the degree and type of local effect, bites can be divided into two symptomatic categories: those with little or no surface extravasation, and those with haemorrhages evident as ecchymosis, bleeding and swelling. In both cases there is severe pain and tenderness, but in the latter there is widespread superficial or deep necrosis and compartment syndrome. Serious bites cause limbs to become immovably flexed as a result of significant haemorrhage or coagulation in the affected muscles. Residual induration, however, is rare and usually these areas completely resolve. Other bite symptoms that may occur in humans include edema, which may become extensive, shock, watery blood oozing from the puncture wounds, nausea and vomiting, subcutaneous bruising, blood blisters that may form rapidly, and a painful swelling of the regional lymph nodes.

Behaviour
Normally a sluggish species, it relies on camouflage for protection. Locomotion is primarily rectilinear, using the broad ventral scales in a caterpillar fashion and aided by its own weight for traction. When agitated, it can resort to a typical serpentine movement and move with surprising speed. Although mainly terrestrial, these snakes are good swimmers and can also climb with ease; often they are found basking in low bushes. One specimen was found 4.6 m above the ground in a densely branched tree. If disturbed, they will hiss loudly and continuously, adopting a tightly coiled defensive posture with the fore part of their body held in a taut "S" shape. At the same time, they may attempt to back away from the threat towards cover. They may strike suddenly and fast, to the side as easily as forwards, before returning quickly to the defensive position, ready to strike again. During a strike, the force of the impact is so strong, and the long fangs penetrate so deeply, that prey items are often killed by the physical trauma alone. The fangs apparently can penetrate soft leather. They can strike to a distance of about one third of their body length, but juveniles will launch their entire bodies forwards in the process. These snakes rarely grip their victims, instead releasing quickly to return to the striking position.

Rhinoceros Viper



Bitis nasicornis is a venomous viper species found in the forests of West and Central Africa. A large viper, known for its striking coloration and prominent nasal "horns." No subspecies are currently recognized. Large and stout, it ranges in total length (body + tail) from 72 to 107 cm (about 28 to 42 inches). Spawls et al. (2004) mentioned a maximum total length of 120 cm (47 in), but admitted this is exceptional, quoting an average total length of 60–90 cm (about 24–35 inches).

Females grow larger than males. The head is narrow, flat, triangular and relatively small compared to the rest of the body. The neck is thin. It has a distinctive set of two or three horn-like scales on the end of the nose, the front pair of which may be quite long. The eyes are small and set well forward. The fangs are not large: rarely more than 1.5 cm (0.59 in) long.

Habitat
It is found from Guinea to Ghana in West Africa, and in Central Africa in the Central African Republic, southern Sudan, Cameroon, Gabon, Congo, DR Congo, Angola, Rwanda, Uganda and western Kenya. The type locality is listed only as "interior parts of Africa." This snake occurs in forested areas, rarely venturing into woodlands.

Venom
Bitis nasicornis is considered to be one of the most dangerous snakes in Africa. Small doses of the snake's primarily hemotoxic venom can be deadly. This is unlike the Gaboon viper, the largest of the vipers, which uses a considerably larger amount of venom. Bitis nasicornis has both neurotoxic, as well as hemotoxic venom, as do most other venomous snakes. The hemotoxic venom in rhinoceros vipers is much more dominant. This venom attacks the circulatory system of the snake's victim, destroying tissue and blood vessels. Internal bleeding also occurs. When not in use, the rhino viper's fangs are folded up into the roof of the snake's mouth. The snake has the ability to control the movement of its fangs. Simply because the rhino viper may open its mouth does not mean that the fangs will flip down into place. These fangs penetrate deep into the victim and the small doses of venom flow through the hollow fangs into the wound.

Aggressiveness
They are slow moving, but capable of striking quickly, forwards or sideways, without coiling first or giving a warning. Holding them by the tail is not safe; as it is somewhat prehensile, they can use it to fling themselves upwards and strike. They have been described as generally placid creatures, less so than B. gabonica, but not as bad-tempered as B. arietans. When approached, they often reveal their presence by hissing, said to be the loudest hiss of any African snake—almost a shriek.

Behaviour
Primarily nocturnal, they hide during the day in leaf litter, in holes, around fallen trees or tangled roots of forest trees. Their vivid coloration actually gives them excellent camouflage in the dappled light conditions of the forest floor, making them almost invisible. Although mainly terrestrial, they are also known to climb into trees and thickets, where they have been found up to 3 m (9.8 ft) above the ground. This climbing behaviour is aided by a partially prehensile tail. They are sometimes found in shallow pools and have been described as powerful swimmers. They are slow moving, but capable of striking quickly, forwards or sideways, without coiling first or giving a warning. Holding them by the tail is not safe; as it is somewhat prehensile, they can use it to fling themselves upwards and strike.

King Brown Snake

The mulga snake (Pseudechis australis) is a species of venomous snake found in Australia. It is one of the longest venomous snakes in the world, and is the second-longest in Australia (surpassed only by the coastal taipan). Its alternative common name is king brown snake, although it is a species in the genus Pseudechis (black snakes) and only distantly related to true brown snakes.

Mulga snakes are large, venomous snakes growing up to 2.5 to 3.0 m (8.2 to 9.8 ft) in length in the largest specimens, although 1.5 m (4.9 ft) is a more typical length for an average adult. It is exceeded in length among venomous snakes only by the Asiatic king cobra, some species of African mambas, genus Lachesis (bushmasters) of the American neotropics, and the Australian taipan.

A good-sized adult mulga snake of 2.0 to 2.5 m (6.6 to 8.2 ft) length can weigh 3 to 6 kg (6.6 to 13.2 lb), and mulga snakes are often heavier than the co-occurring taipans. The colour of the snakes differs from area to area within their range; they can be a light brown colour in the desert to a dark, brown-blackish colour in the cooler regions of Queensland, South Australia, and New South Wales. This snake is robust, with a wide head and smooth snout.

Habitat
Mulga snakes occur in most states of Australia except for Tasmania. Its range includes all of the Northern Territory, most parts of Western Australia, Queensland, New South Wales, and South Australia. It may also be found in the western parts of the Australian Capital Territory. Mulga snakes inhabit woodlands, hummock grasslands, chenopod scrublands, and almost bare gibber or sandy deserts, usually sheltering near humans under timber, rubbish piles, burrows, and deep soil cracks. They are not found in rainforests.

Venom
The mulga snake accounted for 4% of identified snakebite victims in Australia between 2005 and 2015, with no deaths recorded. It is classified as a snake of medical importance by the World Health Organization.
The mulga snake venom consists of myotoxins. Black snake antivenin is used to treat bites from this species, after a CSL venom detection kit has returned a conclusive result for mulga snake envenomation, and signs indicate antivenin use is required. Venomous snakes normally only attack humans when disturbed. Mulga snakes have been noted, however, to bite people who were asleep at the time.

Red-Bellied Black Snake

The red-bellied black snake (Pseudechis porphyriacus) is one of eastern Australia's most commonly encountered snakes. Averaging around 1.25 metres (4 ft 1 in) in length, it has glossy black upperparts, bright red or orange flanks and a pink or dull red belly. It is not an aggressive species and generally retreats from encounters with people, but can attack if provoked. Although its venom is capable of causing significant illness, no deaths have been recorded from its bite, which is less venomous than other Australian elapid snakes.

The venom contains neurotoxins, myotoxins, coagulants and has haemolytic properties; victims can also lose their sense of smell. Common in woodlands, forests and swamplands, the red-bellied black snake often ventures into nearby urban areas. It forages in bodies of shallow water, commonly with tangles of water plants and logs, where it hunts its main prey item, frogs, as well as fish, reptiles and small mammals.

The red-bellied black snake has a glossy black top body with a light-grey snout and brown mouth, and a completely black tail. It lacks a well-defined neck, its head merges seamlessly into the body. Its flanks are bright red or orange, fading to pink or dull red on the belly. The red-bellied black snake is on average around 1.25 metres (4 ft 1 in) long, the largest individual recorded at 2.55 m (8 ft 4 in). Males are generally slightly larger than females. The red-bellied black snake can have a strong smell, which some field experts have used to find the snakes in the wild.

Habitat
The red-bellied black snake is native to the east coast of Australia, where it is one of the most commonly encountered snakes. It can be found in the urban forest, woodland, plains and bushland areas of the Blue Mountains, Canberra, Sydney, Brisbane, Melbourne, Cairns and Adelaide. The Macquarie Marshes mark a western border to its distribution in New South Wales, and Gladstone in central Queensland marks the northern limit to the main population. To the south, it occurs across eastern and central Victoria, and extends along the Murray River into South Australia. There are disjunct populations in the southern Mount Lofty Ranges in South Australia, and in North Queensland. The red-bellied black snake is most commonly seen close to dams, streams, billabongs and other bodies of water, although they can venture up to 100 m (350 ft) away, including into nearby backyards. In particular, the red-bellied black snake prefers areas of shallow water with tangles of water plants, logs or debris.

Venom
Bites from red-bellied black snakes can be very painful—needing analgesia—and result in local swelling, prolonged bleeding and even local necrosis, particularly if the bite is on a finger. Severe local reactions may require surgical debridement or even amputation. Symptoms of systemic envenomation—including nausea, vomiting, headache, abdominal pain, diarrhoea or excessive sweating—were thought to be rare, but a 2010 review found they occurred in most bite victims. Most people also go on to develop an anticoagulant coagulopathy in a few hours. This is characterised by a raised aPTT, and subsides over 24 hours. It resolves quickly with antivenom.

Aggressiveness
The red-bellied black snake is generally not an aggressive species, typically withdrawing when approached. If provoked, it will recoil into a striking stance as a threat, holding its head and front part of its body horizontally above the ground and widening and flattening its neck. It may bite as a last resort. It is generally active by day, though night-time activity has occasionally been recorded. When not hunting or basking it may be found beneath timber, rocks and rubbish or down holes and burrows.

Behaviour
Red-bellied black snakes can hide in multiple places in their habitat including logs, old mammal burrows and grass tussocks. They can flee into water and hide there; one was reported as staying submerged for 23 minutes. When swimming they may hold their full head or the nostrils above the water's surface. At times they may float without moving on the water surface looking like a stick. Within their habitat, red-bellied black snakes appear to have ranges or territories that they are familiar with and generally remain within. A 1987 field study in three New South Wales localities found that these areas vary widely, from 0.02 to 40 ha (0.05 to 100 acres) in size. Within their territory, they may have some preferred places to reside. Snakes are active when their body temperatures are between 28 and 31 °C (82 and 88 °F). They also thermoregulate by basking in warm sunny spots in the cool early morning and rest in shade in the middle of hot days, and may reduce their activity in hot dry weather in late summer and autumn. Rather than entering true hibernation, red-bellied black snakes become relatively inactive over winter retreating to cover and at times emerging on warm, sunny days. Their dark colour allows them to absorb heat from sunshine more quickly.

Dugite

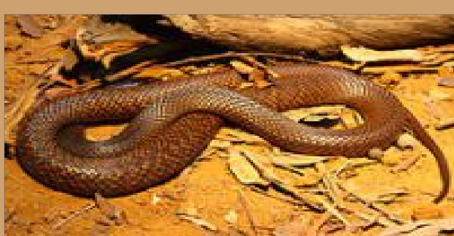
The dugite is a species of venomous, potentially lethal, snake native to Western Australia, a member of the family Elapidae. The dugite is a venomous snake, considered dangerous. It is coloured grey, green, or brown. The colours vary widely between individuals and are an unreliable means of identifying the species. Black scales can be scattered over the body; their scales are relatively large with a semi-glossy appearance. The most distinguishing characteristic is the head that can be rather small and indistinct from the neck. A dugite's body is long and slender in build and can grow up to 2 m (6 ft 7 in) in total length (including tail), but the typical size is roughly 1.5 m.

Habitat
P. affinis is found in southern parts of Western Australia and in remote coastal parts of western South Australia.
The dugite occupies a wide variety of habitats ranging from coastal dunes and heathlands to shrub lands and woodlands. It also appears to thrive in heavily degraded habitats such as golf courses, industrial areas, and open agricultural farmlands. The dugite has increased in population since the opening up of its natural habitats and introduction of the house mouse due to the mouse being a main food source for it. In the Perth metropolitan area, the dugite is one of the most common snakes found next to buildings. In areas of human population, the snake will take temporary shelter under concrete slabs, fibro sheeting, roofing tin, and such, although in more natural habitats, it will shelter under rocks and in abandoned termite mounds. It also burrows during the winter.

Venom
The venom of P. affinis is potentially one of the most lethal in the world, causing coagulopathic and procoagulant effects. Dugites generally avoid biting humans, but risks of encounters rise when they are most active during the mating season through October and November.
The last death attributed to a dugite was in Fremantle (South Beach) on 15 August 2015. A woman was bitten on her heel mid-afternoon while walking alone. She walked home and later collapsed whilst her husband was taking her to her car to transport her to the hospital. The ambulance was called, arriving 5 minutes later, but medics were unable to revive her. In January 2011, a seven-year-old Perth boy was bitten and temporarily paralysed after a dugite entered his bedroom and wrapped itself around his arm while he slept. After receiving immediate medical attention, he made a full recovery.

Behaviour
In the wild, dugites may be sheltering beneath logs or rocks. When disturbed, they are very shy and often slither away, but they will defend themselves if cornered. The species is diurnal. On hot days, activity occurs mainly in the morning, and to lesser extent in the afternoon.

Western Brown Snake



Pseudonaja nuchalis, commonly known as the western brown snake or gwardar, is a species of very fast, highly venomous elapid snake native to Australia. Its colour and pattern are rather variable, depending largely on its location. Some experts assert that the western brown's wide variation in appearance and extensive distribution mean that the western brown species in fact covers multiple related, but separate species with three derivative species now officially recognised, P. nuchalis, P. aspidorhyncha, and P. mengdeni.

The name gwardar is a word meaning "go the long way around" in an Aboriginal language. This may be regarded as advice for people who come across the species in the wild: that is, while P. nuchalis is generally cautious, shy and inclined to retreat rather than attack, it will defend itself if cornered.

The western brown snake grows up to 1.8 m (5.9 ft) in total length (including tail). Its back can feature shades of orange-brown with flecks and bands, or appear plain. Its belly is cream to orange with pink blotches. Some individuals have jet black heads (this can cause it to be confused with the black-headed python), while others feature a black 'V' shape on the back of their neck, below their head.

Habitat
The western brown has a wide distribution and is found across most of the Australian continent, including all of the Northern Territory, as well as most of Queensland, Western Australia, and some of Victoria. The western brown is a ground dwelling snake which prefers drier habitats but is also found in coastal eucalypt forests, woodlands, and grasslands. Although the western brown is not an arboreal species, it is not uncommon for it to climb small shrubs or trees. It also hides in crevices and under rocks, and in urban areas can be found under rubbish or tin piles.

Venom
Although the western brown snake's venom is not the most toxic in the brown snake genus, its average delivery contains a relatively high quantity of venom, and thus the western brown snake has high potential to deliver a deadly bite. Its venom contains neurotoxins, nephrotoxins, and a procoagulant, although humans are not usually affected by the neurotoxins. The bite is usually painless and difficult to see due to their small fangs. Human symptoms of a western brown snake bite are headache, nausea/vomiting, abdominal pain, severe coagulopathy, and sometimes kidney damage. In dogs and cats, paralysis is also likely to occur.

Behaviour
The western brown snake is known to be very aggressive when disturbed or threatened, but like most snakes, will usually prefer to retreat from danger. It may develop nocturnal habits during the warmer months but is otherwise active during the day and enjoys lots of sunlight. The Western Brown snake has also been known to practise cannibalism, although this is not common. Western brown snakes kill their prey with a combination of venom and constriction.

Tiger Rattlesnake

The tiger rattlesnake, Crotalus tigris, is a highly venomous pit viper species found in the south-western United States and north-western Mexico. No subspecies are currently recognized. The specific name tigris, Latin for "tiger", refers to the many narrow dorsal crossbands, which create a pattern of vertical stripes when viewed from the side. The tiger rattlesnake is easily identified by its small, spade-shaped head, which is about 1/25 of its total body length. It has the smallest head of any rattlesnake, and a large rattle.

The colour pattern consists of a gray, lavender, blue-gray, pink, or buff ground colour that usually turns to pink, pale orange, or cream on the sides. Tiger rattlesnakes are the only rattlesnake with crossbands on the anterior portion of their bodies, with a series of 35 to 52 gray, olive, or brown bands across the dorsum consisting mainly of heavy punctations. These crossbands have vague borders and are wider dorsally than laterally.

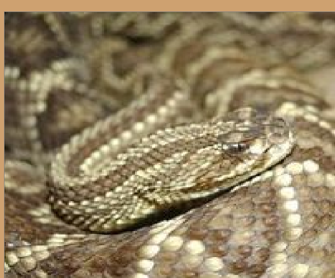
Habitat
The species' range extends from central Arizona south through south-central Arizona in the United States, to southern Sonora, Mexico, including Isla Tiburón in the Gulf of California and was recently discovered in the southern Peloncillo Mountains of Arizona. The type locality is described as "Sierra Verde and Pozo Verde". The latter is a spring located on the Sonora side of the US-Mexico border, near Sasabe. According to Stejneger (1893), this spring is on the western slope of the southern Sierra Verde, which is also known as the Sierra del Pozo Verde. In these areas, the tiger rattlesnake is observed at elevations from sea level to about 1,465 m (4,806 ft) Reported occurrences at higher elevations have not been confirmed. Tiger rattlesnakes habitats include rocky desert canyons, foothills, and bajadas, in vegetation zones ranging from thornscrub, ocotillo-mesquite-creosote bush, saguaro-paloverde, mesquite grassland, and chaparral to tropical deciduous forest (southern Sonora) and the lower edge of oak woodland. In south-eastern Arizona, this snake occurs strictly in rocky areas in winter and spring, but uses edges of arroyos in summer. It is a terrestrial species, but may climb into low vegetation.

Venom
Although it has a comparatively low venom yield, its toxicity is considered to be the second highest of all rattlesnake venoms (next to the mojave), and the second highest of all snakes in the Western Hemisphere. There is very little information available for bite symptoms. Human bites by the tiger rattlesnake are infrequent, and literature available on bites by this snake is scarce. The several recorded human envenomations by tiger rattlesnakes produced little local pain, swelling, or other reaction following the bite, and despite the toxicity of its venom no significant systemic symptoms.

The comparatively low venom yield (6.4–11 mg dried venom) and short 4.0 mm (0.40 cm) to 4.6 mm (0.46 cm) fangs of the tiger rattlesnake possibly prevent severe envenoming in adult humans. However, the clinical picture could be much more serious if the person bitten was a child or a slight build individual. The early therapeutic use of antivenom is important if significant envenomation is suspected. Despite the low venom yield, a bite by this rattlesnake should be considered a life-threatening medical emergency. Untreated mortality rate is unknown but this snake has a very high venom toxicity and its bites are capable of producing major envenomation.

Behaviour
Tiger rattlesnakes are terrestrial snakes and are nocturnal during the hot summer (June–August), but become diurnal and crepuscular during the fall season. They hibernate during the late fall and winter in rock crevices or animal burrows. In spite of being ground-dwelling, their activity is not restricted to the ground. They swim readily and have been found in bushes 60 cm (24 in) above the ground. Little information is available concerning communication and perception among tiger rattlesnakes. However, like other pit vipers, tiger rattlesnakes have heat-sensing pits (located on each side of the face between the eye and nostril) to detect warm-blooded predators and prey.

Cascabel



Crotalus durissus is a venomous pit viper species found in South America. The most widely distributed member of its genus, this species poses a serious medical problem in many parts of its range. Currently, nine subspecies are recognized, including the nominate subspecies described here. This large Neotropical rattlesnake grows to a length of 1.5 m (4.9 ft), and rarely to a maximum length of 1.9 m (6.2 ft). It has two distinct stripes starting at the base of the head. Within the lines, the colour is lighter than the stripes.

Habitat
C. durissus is found in South America except the Andes Mountains. However, its range is discontinuous, with many isolated populations in northern South America, including Colombia, Venezuela, Guyana, Suriname, French Guiana and northern Brazil. It occurs in Colombia and eastern Brazil to south-eastern Peru, Bolivia, Paraguay, Uruguay, and northern Argentina. Also, it occurs on some islands in the Caribbean, including Morro de la Iguana, Tamarindo and Aruba. The type locality given is "America. It prefers savannah and semi-arid zones. It has been reported to occur in littoral xerophilous scrub, psammophilous and halophilous littoral grassland, thorny xerophilous scrub, tropophilous deciduous and semideciduous scrub, as well as tropophilous semideciduous seasonal forest in the northwest of Venezuela. In the Chaco region of Paraguay, it is found in the drier, sandier areas.

Venom
Bite symptoms are very different from those of Nearctic species due to the presence of neurotoxins (crotoxin and crotamine) that cause progressive paralysis. Bites from C. d. terrificus in particular can result in impaired vision or complete blindness, auditory disorders, ptosis, paralysis of the peripheral muscles, especially of the neck, which becomes so limp as to appear broken, and eventually life-threatening respiratory paralysis. The ocular disturbances are sometimes followed by permanent blindness. Phospholipase A2 neurotoxins also cause damage to skeletal muscles and possibly the heart, causing general aches, pain, and tenderness throughout the body. Myoglobin released into the blood results in dark urine. Other serious complications may result from systemic disorders (incoagulable blood and general spontaneous bleeding), hypotension, and shock. Hemorrhagins may be present in the venom, but any corresponding effects are completely overshadowed by the startling and serious neurotoxic symptoms.

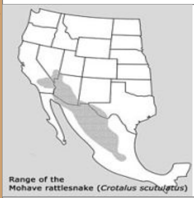
Mojave Rattlesnake

Crotalus scutulatus (common names: Mojave rattlesnake, Mojave green,) is a highly venomous pit viper species found in the deserts of the south-western United States and central Mexico. It is perhaps best known for its potent neurotoxic-hemotoxic venom, which is considered the world's most potent rattlesnake venom.

Two subspecies are recognized, including the nominate subspecies described here. This species grows to an average of less than 100 cm (3.3 ft) in length, with a maximum of 137.3 cm (4.50 ft). The colour varies from shades of brown to pale green depending on the surroundings. The green hue found among Mojave rattlesnakes has led to them being known as "Mojave greens" in some areas.

Like C. atrox (the western diamondback rattlesnake), which it closely resembles, C. scutulatus has a dark diamond pattern along its back. With C. scutulatus, the white bands on the tail tend to be wider than the black, while the band width is usually more equal in C. atrox. Additionally, C. scutulatus has enlarged scales on top of the head between the supraoculars, and the light postocular stripe passes behind the corner of the mouth. In C. atrox, the crown is covered in small scales, and the light postocular stripe intersects the mouth.

Geography
This snake is found in the south-western United States in southern California, southern Nevada, extreme south-western Utah, most of Arizona, southern New Mexico, and some of Texas. It also ranges southward through much of Mexico to southern Puebla. It is found in deserts and other areas with xeric vegetation from near sea level to about 2500 m altitude. No type locality is given. Smith and Taylor (1950) proposed "Wickenburg, Maricopa County, Arizona" (USA), while Schmidt (1953) listed the type locality as "Mojave Desert, California" (USA).



Range of the Mohave rattlesnake (*Crotalus scutulatus*)

Habitat
Primarily a snake of high desert or lower mountain slopes, it is often found near scrub brush such as mesquite and creosote, but may also reside in lowland areas of sparse vegetation, among cacti, Joshua tree forests, or grassy plains. It tends to avoid densely vegetated and rocky areas, preferring open, arid habitats.

Venom
The Mojave rattlesnake is one of the world's most venomous snakes. The most common subspecies of Mojave rattlesnake (type A) has a neurotoxic venom that is considered to be the most debilitating and potentially deadly of all rattlesnakes, and even matching several elapids. However, chances for survival are very good if medical attention is sought as soon as possible after a bite. In people bitten by venom A Mojave rattlesnakes (those outside the relatively small Venom B area in south-central Arizona), the onset of serious signs and symptoms can be delayed, sometimes leading to an initial underestimation of the severity of the bite. Significant envenomations (as with all snakebites, the quantity of venom injected is highly variable and unpredictable) can produce vision abnormalities and difficulty swallowing and speaking. In severe cases, skeletal muscle weakness can lead to difficulty breathing and even respiratory failure. Contrary to popular belief, fatalities are uncommon. This is largely due to the wide availability of antivenom.

Behaviour
C. scutulatus is most active from April to September, and brumates alone or in small groups during the winter. Ambush predators, they eat mostly small rodents and lizards. Females bear live young, from two to 17 (average about eight), from July through September. Although they have a reputation for being aggressive towards people, such behaviour is not described in the scientific literature. Like other rattlesnakes, however, they will defend themselves vigorously when disturbed.

Malayan Pit Viper

Calloselasma is a monotypic genus created for a venomous pit viper species, C. rhodostoma, which is endemic to Southeast Asia from Thailand to northern Malaysia and on the island of Java. No subspecies are currently recognized. Attains an average total length of 76 cm (30 in), with females being slightly longer than males. Occasionally, they may grow as long as 91 cm (36 in). A specimen with a total length of 81 cm (32 in) has a tail 9 cm (3.5 in) long.

Dorsally it is reddish, grayish, or pale brown, with two series of large, dark brown, black-edged triangular blotches, which are alternating or opposite. There is also a thin dark brown vertebral stripe, which may be interrupted or indistinct in some specimens. The upper labials are pink or yellowish, and powdered with brown. There is a broad, dark brown, black-edged diagonal stripe from the eye to the corner of the mouth, with a narrower light-coloured stripe above it. Ventrally it is yellowish, uniform or powdered or spotted with grayish brown.

The smooth dorsal scales are arranged in 21 rows at midbody. Ventrals 138-157; anal plate entire; subcaudals 34-54 pairs. Snout pointed and upturned. Rostral as deep as broad. Two internasals and two prefrontals. Frontal as long as or slightly longer than its distance from tip of snout, as long as or slightly shorter than the parietals. 7-9 upper labials. Loreal pit not in contact with the upper labials. This is the only Asian pit viper with large crown scales and smooth dorsal scales.

Habitat
Found in Nepal, Thailand, Cambodia, Laos, Vietnam, northern West Malaysia and on the Indonesian island of Java. The type locality is listed as "Java". There are unconfirmed, but credible reports from southern Myanmar (Burma), northern Sumatra and northern Borneo. Prefers coastal forests, bamboo thickets, unused and overgrown farmland, orchards, plantations as well as forests around plantations, where it searches for rats and mice.

Venom
This species has a reputation for being bad-tempered and quick to strike. In northern Malaysia it is responsible for some 700 incidents of snakebite annually with a mortality rate of about 2 percent. Remarkably sedentary, it has often been found in the same spot several hours after an incident involving humans. Its venom causes severe pain and local swelling and sometimes tissue necrosis, but deaths are not common. Unfortunately many victims are left with dysfunctional or amputated limbs due to the lack of antivenom and early treatment.

Sharp-Nosed Pit Viper

Deinagkistrodon is a monotypic genus created for the venomous pit viper species, D. acutus, which is endemic to Southeast Asia. There are no subspecies which are recognized as being valid. Deinagkistrodon acutus is light brown or greyish brown dorsally, with a series of dark brown lateral triangles on each side. The two pointed tops of the two opposite triangles meet each other at the mid-line, forming a series of about 20 light brown, squarish blotches on the back. A row of large black spots extends along each side near the belly.

The top and upper sides of the head are uniformly black, with a black streak from the eye to the angle of the mouth. D. acutus is yellowish ventrally, spotted with dark brown. The young are much lighter than the adults with essentially the same pattern. The head is large, triangular, with an upturned snout. The body is very stout. The tail is short, ending in a compressed, pointed slightly curved cornified scale. The top of the head is covered with nine large shields.

The dorsal scales are strongly and tubercularly keeled. The subcaudals are mostly in pairs, some of the anterior ones are single. This stout snake, usually between 0.8 and 1.0 metre (2.6 and 3.3 ft) in total length (including tail), reaches a maximum total length of 1.57 metres (5.2 ft) in males and 1.41 metres (4.6 ft) in females. The largest specimen on record measured approximately 1.549 metres (5.08 ft).

Habitat
D. acutus is found in southern China (Zhejiang, Fujian, Hunan, Hubei, Guangdong), Taiwan, northern Vietnam, and possibly Laos. The type locality was not included in the original description. The species D. acutus inhabits high, forested mountains up to 1,350 metres (4,430 ft), but has also been found in low coastal regions (100 metres (330 ft)). It prefers lower mountain slopes or rocky hills with small valleys.

Behaviour
D. acutus is a nocturnal species. It is generally discovered by day on rocks or among vegetation along banks of streams, or in firewood near houses, or even in houses. When encountered it may appear sluggish at first, but it is capable of striking vigorously when threatened.

Venom
Dangerous animals often have exaggerated reputations and the species D. acutus is no exception. The popular name "hundred pacer" refers to a local belief that, after being bitten, the victim will only be able to walk 100 steps before dying. In some areas, it has even been called the "fifty pacer." Nevertheless, this species is considered dangerous, and fatalities are not unusual. An antivenom is produced in Taiwan. According to the US Armed Forces Pest Management Board, the venom is a potent hemotoxin that is strongly hemorrhagic. Bite symptoms include severe local pain and bleeding that may begin almost immediately. This is followed by considerable swelling, blistering, necrosis, and ulceration. Systemic symptoms, which often include heart palpitations, may occur suddenly and relatively soon after the bite. Because of its body size and large hinged fangs which permit effective delivery of large quantities of venom, victims bitten by this snake should be treated accordingly.

2 Spiders

Australian Funnel-Web Spider

Atracidae is a family of mygalomorph spiders, commonly known as Australian funnel-web spiders or atracids. It has been included as a subfamily of the Hexathelidae, but is now recognized as a separate family. All members of the family are native to Australia. Atracidae consists of three genera: Atrax, Hadronyche, and Illawarra, comprising 35 species. Some members of the family produce venom, which is dangerous to humans, and bites by spiders of six of the species have caused severe injuries to victims.

The bite of the Sydney funnel-web spider (Atrax robustus) and northern tree funnel-web spider (Hadronyche formidabilis) are potentially deadly, but no fatalities have occurred since the introduction of modern first-aid techniques and antivenom. Spiders in the family Atracidae are medium to large in size, with body lengths ranging from 1 to 5 cm (0.4 to 2.0 in). They have a hairless carapace covering the front part of the body.

Some atracids have relatively long spinnerets; this is especially true of A. robustus. Males have a large mating spur projecting from the middle of their second pair of legs. Like other Mygalomorphae – an infraorder of spiders that includes the tropical tarantulas – these spiders have fangs that point straight down the body and do not point towards each other (cf. Araneomorphae). They have ample venom glands that lie entirely within their chelicerae. Their fangs are large and powerful, capable of penetrating fingernails and soft shoes.

Australian funnel-web spiders make their burrows in moist, cool, sheltered habitats – under rocks, in and under rotting logs, some in rough-barked trees (occasionally metres above ground). They are commonly found in suburban rockeries and shrubberies, rarely in lawns or other open terrain. A burrow characteristically has irregular silk trip-lines radiating from the entrance. Unlike some related trapdoor spiders, they do not build lids to their burrows. The primary range of the Australian funnel-web spiders is the eastern coast of Australia, with specimens found in New South Wales, South Australia, Victoria, and Queensland.

The only Australian states or territories without members of this family are Western Australia and the Northern Territory. Examination of bite records has implicated wandering males in most if not all fatal funnel-web bites to humans. Adult males, recognised by the modified terminal segment of the palp, tend to wander during the warmer months of the year looking for receptive females for mating.

They are attracted to water, hence are often found in swimming pools, into which they often fall while wandering. They are attracted to water, hence are often found in swimming pools, into which they often fall while wandering. The spiders can survive immersion in water for several hours and can deliver a bite when removed from the water. They also show up in garages and yards in suburban Sydney. Contrary to commonly held belief, funnel-web spiders are not able to jump, although they can run quickly. While some very venomous spiders do not always inject venom when they bite, these spiders most often do. The volume of venom delivered to large animals is often small, possibly due to the angle of the fangs, which are not horizontally opposed, and because contact is often brief before the spider is brushed off. About 10 to 25% of bites are claimed to produce significant toxicity, but the likelihood cannot be predicted and all bites should be treated as potentially life-threatening.

Symptoms
Envenomation symptoms observed following bites by these spiders are very similar. The bite is initially very painful, due to the size of the fangs penetrating the skin. Puncture marks and local bleeding are also usually visibles. If substantial envenomation occurs, symptoms generally occur within minutes and progress rapidly. Early symptoms of systemic envenomation include goose bumps, sweating, tingling around the mouth and tongue, twitching (initially facial and intercostal), salivation, watery eyes, elevated heart rate, and elevated blood pressure. As systemic envenomation progresses, symptoms include nausea, vomiting, shortness of breath (caused by airway obstruction), agitation, confusion, writhing, grimacing, muscle spasms, pulmonary oedema (of neurogenic or hypertensive origin), metabolic acidosis, and extreme hypertension. The final stages of severe envenomation include dilation of the pupils (often fixed), uncontrolled generalised muscle twitching, unconsciousness, elevated intracranial pressure, and death. Death generally is a result of progressive hypotension or possibly elevated intracranial pressure consequent on cerebral oedema. The onset of severe envenomation can be rapid. In one prospective study, the median time to onset of envenomation was 28 minutes, with only two cases having onset after 2 hours (both had pressure immobilisation bandages applied). Death may occur within a period ranging from 15 minutes (this occurred when a small child was bitten) to 3 days.

Treatment
Owing to the severity of symptoms, and the speed with which they progress, in areas where these spiders are known to live, all bites from large, black spiders should be treated as though they were caused by Australian funnel-web spiders. First-aid treatment for a suspected funnel-web spider bite consists of immediately applying a pressure immobilization bandage; a technique which consists of wrapping the bitten limb with a crepe bandage, as well as applying a splint to limit movement of the limb. This technique was originally developed for snakebites, but has also been shown to be effective at slowing venom movement and preventing systemic envenomation in case of a funnel-web spider bite.

Some evidence suggests that periods of prolonged localisation may slowly inactivate the venom. Further supportive care may be necessary, but the mainstay of treatment is antivenom. Venom from the male A. robustus is used in producing the antivenom, but it appears to be effective against the venom of all species of atracids. Funnel-web antivenom has also been shown, in vitro, to reverse the effects of eastern mouse spider (Missulena bradleyi) venom.

Prior to the introduction of antivenom, envenomation resulted in significant morbidity and mortality. The purified rabbit IgG antivenom was developed in 1981 through a team effort led by Dr Struan Sutherland, head of immunology at the Australian Commonwealth Serum Laboratories in Melbourne. The antivenom is fast-acting and highly and globally effective. Antivenom therapy has shortened the course of envenomation effects; prior to its availability, the average length of hospital treatment for severe bites was about 14 days. Today, antivenom-treated patients are commonly discharged from hospital within 1 to 3 days. No deaths are known since it became available.

Brazilian Wandering Spiders

Phoneutria fera is a species of spider in the family Ctenidae found in South America (Colombia, Ecuador, Peru, Brazil, Suriname and Guyana). It is commonly known as the Brazilian wandering spider as well as the banana spider, although these names are applied to other species in the genus Phoneutria, particularly Phoneutria nigriventer. P. fera tends to spend a larger amount of time in vegetation during the early period of its life and spends more time on the ground once they become larger. This is more common in females, since they typically tend to be larger in size than males.

Widow Spiders

Latrodectus is a broadly distributed genus of spiders, which is composed of both black widow spiders and brown widow spiders. Species vary widely in size. In most cases, the females are dark-coloured and readily identifiable by reddish markings on the abdomen, which are often hourglass-shaped. These small spiders have an unusually potent venom containing the neurotoxin latrotoxin, which causes the condition latrodectism, both named after the genus. Female widow spiders have unusually large venom glands and their bite can be particularly harmful to large vertebrates, including humans.

Only the bites of the females are dangerous to humans. Despite their notoriety, Latrodectus bites are rarely fatal or even produce serious complications. Female widow spiders are typically dark brown or a shiny black in colour when they are full grown, usually exhibiting a red or orange hourglass on the ventral surface (underside) of the abdomen; some may have a pair of red spots or have no marking at all.

The male widow spiders often exhibit various red or red and white markings on the dorsal surface (upper side) of the abdomen, ranging from a single stripe to bars or spots, and juveniles are often similar to the male pattern. Females of a few species are paler brown and some have no bright markings. The bodies of black widow spiders range from 3–10 mm (0.12–0.39 in) in size; some females can measure 13 mm (0.51 in) in their body length.

Behaviour
The prevalence of sexual cannibalism, a behaviour in which the female eats the male after mating, has inspired the common name "widow spiders". This behaviour may promote the survival odds of the offspring; however, females of some species only rarely show this behaviour, and much of the documented evidence for sexual cannibalism has been observed in laboratory cages where the males could not escape. Male black-widow spiders tend to select their mates by determining if the female has eaten already to avoid being eaten themselves. Like other members of the Theridiidae, widow spiders construct a web of irregular, tangled, sticky silken fibres. Black-widow spiders prefer to nest near the ground in dark and undisturbed areas, usually in small holes produced by animals, or around construction openings or wood piles. Indoor nests are in dark, undisturbed places such as under desks or furniture or in a basement.

The spider frequently hangs upside down near the centre of its web and waits for insects to blunder in and get stuck. Then, before the insect can extricate itself, the spider rushes over to envenomate and wrap it in silk. To feed, the mouth pulses digestive juices over the prey which is liquified and then internalized by capillary action, allowing the slurry to be sucked back up into the mouth. Their prey consists of small insects such as flies, mosquitoes, grasshoppers, beetles, and caterpillars. If the spider perceives a threat, it quickly lets itself down to the ground on a safety line of silk.

As with other web-weavers, these spiders have very poor eyesight and depend on vibrations reaching them through their webs to find trapped prey or warn them of larger threats. When a widow spider is trapped, it is unlikely to bite, preferring to play dead or flick silk at the potential threat; bites occur when they cannot escape. Many injuries to humans are due to defensive bites delivered when a spider gets unintentionally squeezed or pinched.

Distribution
Widow spiders can be found on every continent of the world except Antarctica. In North America, the black widows commonly known as southern (Latrodectus mactans), western (Latrodectus hesperus), and northern (Latrodectus variolus) can be found in the United States, as well as parts of southern Canada – particularly in the Okanagan Valley of British Columbia, as can the "gray" or "brown widow spiders" (Latrodectus geometricus) and the "red widow spiders" (Latrodectus bishopi). The most prevalent species occurring in eastern Asia and Australia is commonly called the redback (Latrodectus hasselti).

Bite
Due to the presence of latrotoxin in their venom, black widow bites are potentially dangerous and may result in systemic effects (latrodectism) including severe muscle pain, abdominal cramps, hyperhidrosis, tachycardia, and muscle spasms. Symptoms usually last for 3–7 days, but may persist for several weeks. In the United States each year, about 2,200 people report being bitten by a black widow, but most do not need medical treatment. Some bites have no venom injected, a "dry" bite. Black widows are not especially aggressive spiders, and they rarely bite humans unless startled or otherwise threatened. Since the venom is not likely to be life-threatening, antivenom has been used as pain relief and not to save lives.

False Black Widows

One common name is cupboard spider, for many species build their webs in dark, sheltered, undisturbed places around the house or garden, in sheds and garages, under garden furniture, compost bins, and the like. Signs of the cupboard spider include small white spots of spider droppings, like small splashes of paint, on the floor underneath the web. Many spiders of the genus Steatoda are often mistaken for widow spiders (Latrodectus), and are known as false black widows.

They are closely related (in the family Theridiidae) but Steatoda are significantly less harmful to humans. Not all Steatoda species resemble black widows – they come in many different colours and sizes, mostly smaller than Latrodectus specimens.

Steatoda paykulliana can grow larger than the black widow, and Steatoda castanea looks more like a brown widow. Like other theridiidae, they often feed on other spiders that get tangled up in their webs, including spiders that are considered hazardous to humans, like wandering male hobo spiders.

Steatoda grossa sometimes preys on black widows. The colour can range from sandy pale brown to reddish plum to satiny black. Like most spiders, its cephalothorax is smaller than its abdomen, which is somewhat egg-shaped, and can have white or beige to orange markings. Although sometimes not or partially visible, these markings usually consists of a frontal crescent, often with a dorsal line or triangular shapes or both. Orange to reddish-marked Steatoda paykulliana can be mistaken for the redback spider). In common with other members of the Theridiidae family, Steatoda spiders construct a tangled web, i.e., an irregular tangle of sticky silken fibres. As with other web-weavers, these spiders have very poor eyesight and depend mostly on vibrations reaching them through their webs to orient themselves to prey or to warn them of larger animals that could injure or kill them.

Recluse Spiders

The recluse spiders or brown spiders, genus Loxosceles, also known as fiddle-backs, violin spiders, or reapers, are a genus of venomous spiders known for their bite, which sometimes produces a characteristic set of symptoms known as loxoscelism. Recluse spiders are now identified as members of the family Sicariidae, having formerly been placed in their own family, the Loxoscelidae. Although recluse spiders have a bad reputation, they are usually not aggressive. Loxosceles is distributed nearly worldwide in warmer areas. All have six eyes arranged in three groups of two (dyads) and some are brownish with a darker brown characteristic violin marking on the cephalothorax.

However, the "violin marking" cannot be used as a reliable way to identify the spider as thousands of species of spider have similar markings. Spiders come with many markings varying greatly within the same species.

Most Loxosceles can live for one and a half to two years. Many species of this genus can live for very long times without food or water. They are about 7–12 mm long. The most common and most famous species in the United States is the brown recluse spider (Loxosceles reclusa). It is found in a large area of the Midwest, west to Colorado and the New Mexico state line and east to northern Georgia.

Sporadic records from other locations only represent incidental introductions, not established populations. The brown recluse feeds on whatever small prey is available, and has been observed to prefer scavenging over actively hunting. Other notable members of this genus include the Chilean recluse spider (L. laeta) and the Mediterranean recluse spider (L. rufescens). Recently, concerns have been raised regarding recluses spreading faster due to warmer air carrying them farther as a result of changing climate. On the contrary, newly hatched recluses do not travel via ballooning and thus the populations are confined to very tight spaces with dense populations.

Venom
Many types of skin wounds are mistaken for or assumed to be the result of a recluse spider bite. Several diseases can mimic the lesions of the bite, including Lyme disease, various fungal and bacterial infections, and the first sore of syphilis. It is important to associate the spider directly with the bite to avoid improper treatment, and to successfully treat common infections or other conditions if no spider was seen. Bites most often occur as a defence when the spider is trapped against the skin, in clothing, for example. Insecticides often fail to kill the spider, instead intoxicating its nervous system and inducing erratic behaviour.

The bite of a recluse spider can generally be categorized into one of the following groups:
● Unremarkable - self-healing minute damage
● Mild reaction - self-healing damage with itchiness, redness, patterns of aggressive behaviour and a mild lesion.
● Dermonecrotic - the uncommon, "classic" recluse bite, producing a necrotic skin lesion. About 66% of necrotic bite lesions heal with no complications. In extreme cases, the lesion may be up to 40 centimetres wide, last for several months, and heal with a permanent scar.
● Systemic or viscerocutaneous - an extremely rare, systemic reaction to envenomation of the bloodstream. It is observed more often in children.
Most bites are unremarkable or mild.

Macrothele spp.

Macrothele is a genus of mygalomorph spiders. It is the only genus in the family Macrothelidae. Most species occur in Asia from India to Japan and Java, with four found in Africa and two in Europe. Spiders of this genus are fairly large, with Chinese species ranging from 1–3 cm (0.4–1.2 in) in female body length. Males are smaller, sometimes only half that length. Macrothelids can be distinguished from other mygalomorph spiders by having larger posterior sigillae on the sternum, and the arrangement of the rows of teeth on the margin of the chelicerae: larger front-facing margin and smaller rear-facing.

These spiders build tube-webs or funnel-webs under rocks or logs, or in crevices in the ground. Macrothele ranges from the western Mediterranean and West Africa to Southeast Asia, mainland China and Taiwan. However, there is some doubt if the western and eastern species should be grouped in the same genus.

Missulena

Missulena is a genus of mygalomorph spiders in the Actinopodidae family, sometimes called mouse spiders. It was first described by Charles Athanase Walckenaer in 1805. M. tussulena is found in Chile, but the rest are indigenous to Australia.

Region
The term "mouse spider" comes from the now disproven belief that they dig deep burrows similar to those of mice. Scotophaeus blackwalli also shares the common name "mouse spider", but is actually quite different. It is in a different family, not a mygalomorph, is much smaller, looks very different, and is not considered dangerous. Mouse spiders are medium-to-large spiders which range in length from 1 cm to 3 cm. Their carapace is glossy, and they have high, broad heads, with eyes spread out across the front of the head. They have short spinnerets, located in the rear of the abdomen. Mouse spiders exhibit sexual dimorphism, with female spiders being all black; and male spiders having species-specific colouration. The male eastern mouse spider (M. bradleyi) has a bluish patch, and the male red-headed mouse spider (M. occatoria) is brownish or blue-black in colour, with bright red-tinged jaws. Mouse spiders prey mainly on insects, though they may consume other small animals as opportunity presents. The primary predators of the mouse spider include wasps, centipedes, and scorpions.

Habitat
The mouse spiders have a Gondwanan distribution, with one species found in Chile and the rest distributed throughout Australia, while the nearest related genera occur in South America. Similar to trapdoor spiders, mouse spiders live in burrows covered with trapdoors, which can extend to nearly 30 cm (1 ft) in depth. Female mouse spiders generally remain in their burrows; the males wander in search of mates.

Symptoms
The bites of several species of mouse spiders in Australia have been found to produce serious symptoms, similar to the Australian funnel-web spider. However, serious envenomations are relatively rare; most mouse spider bites documented in the medical literature did not require use of antivenom or involve serious symptoms. The venom of the eastern mouse spider (M. bradleyi) was found to have toxins similar to the robustoxin found in funnel-web venom; and funnel-web antivenom has been found to be effective in treating severe mouse spider bites. Unlike the funnel-web, however, the mouse spider is far less aggressive towards humans, and may often give "dry" bites. Some evidence suggests that the bite of a mouse spider is potentially as serious as that of an Australasian funnel-web spider; however, recorded bites by this spider are rare, despite the abundance of some species amid human habitation. Funnel-web antivenom has been found to be an effective treatment for serious bites.

Sicarius spp.

Sicarius is a genus of spider in the family Sicariidae. In 2017, the genus Hexophthalma was split off from Sicarius; as currently circumscribed, Sicarius is native to South America with one species found in Central America. Sicarius is one of three genera in the family Sicariidae. The venom of its species appears to be less dangerous than that of species of the other two genera, Hexophthalma and Loxosceles.

Sicarius are desert and dry country spiders that live in the Southern Hemisphere in South America (the single exception is the Central American S. rugosus), known primarily for their self-burying behaviour. All have six eyes arranged in three groups of two (dyads). Sicarius resembles the crab spiders of the family Thomisidae and the members of the family Homalonychidae. However, Sicarius lacks the characteristic violin-shaped marking of the related recluse spiders.

Individual Sicarius can live for as much as 15 years, which makes these among the longest-lived araneomorphae spiders (some tarantulas can live well over 20–30 years), and can live for a very long time without food or water. Sicarius spiders are between one and two inches in length. The females produce egg sacs covered with a mixture of sand and silk.

Venom Components
The spiders of this genus, like those of other species in the family Sicariidae, produce venom containing the necrotic (dermonecrotic) agent, sphingomyelinase D, which is otherwise found only in a few pathogenic bacteria. Species remaining in reduced genus Sicarius appear to have less potent venom than those moved to Hexophthalma. Sicariids are found in barren deserts and are able to bury themselves partially in the sand. Because of this, humans seldom come in contact with them.

Hexophthalma spp.

Hexophthalma is a genus of spiders in the family Sicariidae. Although the genus was originally erected in 1878 (then with the name Hexomma), it was merged into the genus Sicarius in the 1890s, and remained unused until revived in 2017, when it was discovered that the African species then placed in Sicarius were distinct. The English name six-eyed sand spiders is used for members of the genus, particularly Hexophthalma hahni. Species in the genus have necrotic (dermonecrotic) venom, and can potentially cause serious or even life-threatening wounds.

Venom

Species of Hexophthalma produce venom that can have necrotic (dermonecrotic) effects, capable of causing serious or even life-threatening wounds, particularly if the wound becomes infected or the venom spreads in the body. The necrotic effects are caused by a family of proteins related to sphingomyelinase D, present in the venom of all sicariid spiders. In this respect, the genus resembles Loxosceles, the recluse spiders However, most Hexophthalama species have only been studied in vitro, and the detailed effects of their venom in humans and other vertebrates are unknown.

Tarantula

Tarantulas comprise a group of large and often hairy arachnids belonging to the Theraphosidae family of spiders, of which about 900 species have been identified. This article only describes members of the Theraphosidae, although some other members of the same infraorder (Mygalomorphae) are commonly referred to as "tarantulas". Some species have become popular in the exotic pet trade. New World species kept as pets have urticating hairs that can cause irritation to the skin and, in extreme cases, cause damage to eyes.

Like all arthropods, the tarantula is an invertebrate that relies on an exoskeleton for muscular support. Like other Arachnida, a tarantula's body comprises two main parts, the prosoma (or cephalothorax) and the opisthosoma (or abdomen). The prosoma and opisthosoma are connected by the pedicel, or pregenital somite. This waist-like connecting piece is actually part of the prosoma and gives the opisthosoma a wide range of motion relative to the prosoma.

Tarantula sizes range from as small as a fingernail to as large as a dinner plate when the legs are fully extended. Depending on the species, the body length of tarantulas ranges from 2.5 to 10 cm (1 to 4 in), with leg spans of 8–30-centimetre (3–12 in). Leg span is determined by measuring from the tip of the back leg to the tip of the front leg on the opposite side. Some of the largest species of tarantula may weigh over 85 g (3 oz); the largest of all, the goliath birdeater (Theraphosa blondi) from Venezuela and Brazil, has been reported to attain a weight of 170 g (6.0 oz) and a leg-span up to 30 cm (12 in), males being longer and females greater in girth. The fang size of this tarantula reaches a maximum of 3.8 cm (1.5 in).

Theraphosa apophysis (the pinkfoot goliath) was described 187 years after the goliath birdeater, so its characteristics are not as well attested. Theraphosa blondi is generally thought to be the heaviest tarantula, and T. apophysis to have the greatest leg span. Two other species, Lasiodora parahybana (the Brazilian salmon birdeater) and Lasiodora klugi, rival the size of the two goliath spiders. Most species of North American tarantulas are brown.

Elsewhere, species have been found that variously display cobalt blue (Cyriopagopus lividus), black with white stripes (Aphonopelma seemanni), yellow leg markings (Eupalaestrus campestratus), metallic blue legs with vibrant orange abdomen and green prosoma (Chromatopelma cyaneopubescens). Their natural habitats include savannah, grasslands such as the pampas, rainforests, deserts, scrubland, mountains, and cloud forests. They are generally classed among the terrestrial types. They are burrowers that live in the ground.

Distribution

Tarantulas of various species occur throughout the United States, Mexico, in Central America, and throughout South America. Other species occur variously throughout Africa, much of Asia (including Ryukyu Islands in southern Japan), and all of Australia. In Europe, some species occur in Spain, Portugal, Turkey, south Italy, and Cyprus.

Habits

Some genera of tarantulas hunt prey primarily in trees; others hunt on or near the ground. All tarantulas can produce silk – while arboreal species typically reside in a silken "tube tent", terrestrial species line their burrows with silk to stabilize the burrow wall and facilitate climbing up and down. Tarantulas mainly eat large insects and other arthropods such as centipedes, millipedes, and other spiders, using ambush as their primary method of prey capture. Armed with their massive, powerful chelicerae tipped with long chitinous fangs, tarantulas are well-adapted to killing other large arthropods. The biggest tarantulas sometimes kill and consume small vertebrates such as lizards, mice, bats, birds, and small snakes.

Symptoms

All tarantulas are venomous and some bites cause serious discomfort that might persist for several days. In general, the effects of the bites of all kinds of tarantula are not well known. While the bites of many species are known to be no worse than a wasp sting, accounts of bites by some species are reported to be very painful and to produce intense spasms that may recur over a period of several days; the venom of the African tarantula Pelinobius muticus also causes strong hallucinations.

For Poecilotheria species, researchers have described more than 20 bites with the delayed onset of severe and diffuse muscle cramps, lasting for several days, that in most cases resolved completely with the use of benzodiazepines and magnesium. In all cases, seeking medical aid is advised. Because other proteins are included when a toxin is injected, some individuals may suffer severe symptoms due to an allergic reaction rather than to the venom. Such allergic effects can be life-threatening. Additionally, the large fangs of a tarantula can inflict painful puncture wounds which can lead to secondary bacterial infections if not properly treated.

Before biting, tarantulas may signal their intention to attack by rearing up into a "threat posture", which may involve raising their prosoma and lifting their front legs into the air, spreading and extending their fangs, and (in certain species) making a loud hissing by stridulating. Tarantulas often hold this position for longer than the duration of the original threat. Their next step, short of biting, maybe to slap down on the intruder with their raised front legs.

If that response fails to deter the attacker, the tarantulas of the Americas may next turn away and flick urticating bristles toward the pursuing predator. The next response may be to leave the scene entirely, but especially if no line of retreat is available, their final response may also be to whirl suddenly and bite. Some tarantulas are well known to give "dry bites", i.e., they may defensively bite some animal that intrudes on their space and threatens them, but they do not pump venom into the wound. New World tarantulas (those found in North and South America) are equipped with urticating hairs (technically bristles) on their abdomens, and almost always throw these barbed bristles as the first line of defence.

These bristles irritate sensitive areas of the body and especially seem to target curious animals which may sniff these bristles into the mucous membranes of the nose. Some species have more effective urticating bristles than others. The goliath birdeater is known for its particularly irritating urticating bristles. Urticating bristles can penetrate the cornea, so eye protection should be worn when handling such tarantulas. Old World tarantulas (from Europe, Africa, Asia, and Australia) have no urticating bristles and are more likely to attack when disturbed. They often have more potent, medically significant venom, and are faster and much more nervous and defensive than New World species.

Some dangerous spider species are related to tarantulas and are frequently confused with them. A popular urban legend maintains that deadly varieties of tarantula exist somewhere in South America. This claim is often made without identifying a particular spider, although the "banana tarantula" is sometimes named. A likely candidate for the true identity of this spider is the dangerous Brazilian wandering spider Phoneutria fera, of the family Ctenidae, as it is sometimes found hiding in clusters of bananas and is one of several spiders called the "banana spider." It is not technically a tarantula, but it is fairly large (4- to 5-inch legspan), somewhat hairy, and is highly venomous to humans.

Another dangerous type of spider that has been confused with tarantulas is the Australian funnel-web spider. The best known of these is the Sydney funnel-web spider Atrax robustus, a spider that is aggressive, highly venomous, and (prior to the development of antivenom in the 1980s) was responsible for numerous deaths in Australia. These spiders are members of the same suborder as tarantulas, Opisthothelae. Some Australians use the slang term 'triantelope' (a corruption of the incorrect term 'tarantula', which is also used) for large, hairy, and harmless members of the huntsman spider family which are often found on interior household walls and in automobiles.

3 Scorpions

Centruroides spp.

The number of species accepted as valid may vary, depending on the authority. The genus is highly speciose, containing at least 70 species. Centruroides is a genus of scorpions belonging to the family Buthidae. Several North American species are known by the common vernacular name bark scorpion. Numerous species are extensively found throughout the southern United States, Mexico, Central America, the Antilles and northern South America. Some are known for their interesting patterning or large size (among Buthidae); most if not all fluoresce strongly under ultraviolet illumination, except after moulting. They contain several highly venomous species, and fatalities are known to occur. The venom of the Mexican scorpion Centruroides limpidus limpidus contains the neurotoxins CII1 and CII2.

Deathstalker

The deathstalker (Leiurus quinquestriatus) is a species of scorpion, a member of the Buthidae family. It is also known as the Palestinian yellow scorpion, Omdurman scorpion, Naqab desert scorpion and by many other colloquial names, which generally originate from the commercial captive trade of the animal. To eliminate confusion, especially important with potentially dangerous species, the scientific name is normally used to refer to them.

The name Leiurus quinquestriatus roughly translates into English as "five-striped smooth-tail". Other species of the genus Leiurus are also often referred to as "deathstalkers". Leiurus quinquestriatus is yellow, and 30–77 millimetres (1.2–3.0 in) long, with an average of 58 mm (2.3 in).

Distribution
Leiurus quinquestriatus can be found in desert and scrubland habitats ranging from North Africa through to the Middle East. Its range covers a wide sweep of territory in the Sahara, Arabian Desert, Thar Desert, and Central Asia, from Algeria and Mali in the west through to Egypt, Ethiopia, Asia Minor and the Arabian Peninsula, eastwards to Kazakhstan and western India in the northeast and southeast.

Hazards
The deathstalker is one of the most dangerous species of scorpions. Its venom is a powerful mixture of neurotoxins, with a low lethal dose. While a sting from this scorpion is extraordinarily painful, it normally would not kill a healthy adult human. However, young children, the elderly, or infirm (such as those with a heart condition and those who are allergic) are at much greater risk. Any envenomation runs the risk of anaphylaxis, a potentially life-threatening allergic reaction to the venom. A study from Israel shows a high rate of pancreatitis following envenomation. If a sting from Leiurus quinquestriatus does prove deadly, the cause of death is usually pulmonary edema. Antivenom for the treatment of deathstalker envenomations is produced by pharmaceutical companies Twyford (German) and Sanofi Pasteur (French), and by the Antivenom and Vaccine Production Centre in Riyadh. Envenomation by the deathstalker is considered a medical emergency even with antivenom treatment, as its venom is unusually resistant to treatment and typically requires large doses of antivenom.

Uses
A component of the deathstalker's venom, the peptide chlorotoxin, has shown potential for treating human brain tumors. There has also been some evidence to show that other components of the venom may aid in the regulation of insulin and could be used to treat diabetes.

4 Insects

Bees

Wasps

Ants

Lepidopteran Caterpillars

5 Other Arthropods

Centipedes

ANIMALS Other Arthropods Centipedes

Centipedes (from Latin prefix centi-, "hundred", and pes, pedis, "foot") are arthropods belonging to the class Chilopoda of the subphylum Myriapoda, an arthropod group which also includes Millipedes and other multi-legged creatures. Centipedes are elongated metameric creatures with one pair of legs per body segment. Centipedes are highly venomous, and often inject paralysing venom; some species contains neurotoxic venom. Despite the name, centipedes can have a varying number of legs, ranging from 30 to 354. Centipedes always have an odd number of pairs of legs. Therefore, no centipede has exactly 100 legs.

A key trait uniting this group is a pair of venom claws or forcipules formed from a modified first appendage. Centipedes are predominantly carnivorous. Their size can range from a few millimetres in the smaller lithobiomorphs and geophilomorphs to about 30 cm (12 in) in the largest scolopendromorphs.

Centipedes can be found in a wide variety of environments. They normally have a drab coloration combining shades of brown and red. Cavernicolous (cave-dwelling) and subterranean species may lack pigmentation, and many tropical scolopendromorphs have bright aposematic colours. Worldwide, an estimated 8,000 species of centipedes are thought to exist, of which 3,000 have been described. Centipedes have a wide geographical range, where they even reach beyond the Arctic Circle. They are found in an array of terrestrial habitats from tropical rainforests to deserts. Within these habitats, centipedes require a moist microhabitat because they lack the waxy cuticle of insects and arachnids, therefore causing them to rapidly lose water. Accordingly, they are found in soil and leaf litter, under stones and dead wood, and inside logs.

Centipedes are among the largest terrestrial invertebrate predators, and often contribute significantly to the invertebrate predatory biomass in terrestrial ecosystems. Centipedes have a rounded or flattened head, bearing a pair of antennae at the forward margin. They have a pair of elongated mandibles, and two pairs of maxillae. The first pair of maxillae form the lower lip, and bear short palps. The first pair of limbs stretch forward from the body to cover the remainder of the mouth. These limbs, or maxillipeds, end in sharp claws and include venom glands that help the animal to kill or paralyse its prey.

Many species of centipedes lack eyes, but some possess a variable number of ocelli, which are sometimes clustered together to form true compound eyes. However, these eyes are only capable of discerning light and dark, and have no true vision. In some species, the first pair of legs at the head end of the centipede acts as sense organs similar to antennae, but unlike the antennae of most other animals, theirs point backwards. Unusual sense organs found in some groups are the organs of Tömösváry. These are located at the base of the antennae, and consist of a disc-like structure with a central pore surrounded by sensory cells. They are probably used for sensing vibrations, and may even provide a sense of hearing. Forcipules are a unique feature found only in centipedes and in no other arthropods. The forcipules are modifications of the first pair of legs, forming a pincer-like appendage always found just behind the head. Forcipules are not true mouthparts, although they are used in the capture of prey items, injecting venom and holding onto captured prey. Venom glands run through a tube almost to the tip of each forcipule.

Hazards
Some species of centipedes can be hazardous to humans because of their bite. Although a bite to an adult human is usually very painful and may cause severe swelling, chills, fever, and weakness, it is unlikely to be fatal. Bites can be dangerous to small children and those with allergies to bee stings. The venomous bite of larger centipedes can induce anaphylactic shock in such people. Smaller centipedes are generally incapable of piercing human skin. Even nonvenomous centipedes are considered frightening by humans due to their dozens of legs moving at the same time and their tendency to dart swiftly out of the darkness towards one's feet. A 19th-century Tibetan poet warned his fellow Buddhists, "if you enjoy frightening others, you will be reborn as a centipede."

Remipede

Remipedia is a class of blind crustaceans found in coastal aquifers which contain saline groundwater, with populations identified in almost every ocean basin so far explored, including in Australia, the Caribbean Sea, and the Atlantic Ocean. The first described remipede was the fossil Tesnusocaris goldichi (Lower Pennsylvanian), but, since 1979, at least seventeen living species have been identified in subtropical regions around the world. Remipedes are 1–4 centimetres (0.4–1.6 in) long and comprise a head and an elongate trunk of up to thirty-two similar body segments. They lack eyes and pigmentation. The swimming appendages are lateral on each segment, and the animals swim on their backs.

They are generally slow-moving. They are the only known venomous crustaceans, and have fangs connected to secretory glands, which inject a combination of digestive enzymes and venom into their prey. They have a generally primitive body plan in crustacean terms, and have been thought to be a basal, ancestral crustacean group.

However, Fanenbruck et al. showed that at least one species, Godzilliognomus frondosus, has a highly organized and well-differentiated brain, with a particularly large olfactory area which is a common feature for species that live in dark environments.

6 Toxic Birds

Hooded Pitohui

A medium-sized songbird with rich chestnut and black plumage, this species is one of the few known poisonous birds, containing a range of batrachotoxin compounds in its skin, feathers and other tissues. These toxins are thought to be derived from their diet, and may function both to deter predators and protect the bird from parasites. The hooded pitohui (Pitohui dichrous) is a species of bird in the genus Pitohui found in New Guinea. The species was long thought to be a whistler (Pachycephalidae) but is now known to be in the Old World oriole family (Oriolidae). Within the oriole family this species is most closely related to the variable pitohuis in the genus Pitohui, and then the figbirds.

A medium-sized songbird with rich chestnut and black plumage, this species is one of the few known poisonous birds, containing a range of batrachotoxin compounds in its skin, feathers and other tissues. These toxins are thought to be derived from their diet, and may function both to deter predators and protect the bird from parasites.

The close resemblance of this species to other unrelated birds also known as pitohuis which are also poisonous is an example of convergent evolution and Müllerian mimicry. Their appearance is also mimicked by unrelated non-poisonous species, a phenomenon known as Batesian mimicry.

The toxic nature of this species is well known to local hunters, who avoid it. This species is one the most poisonous species of pitohui, but the toxicity of individual birds can vary geographically. The hooded pitohui is found in forests from sea-level up to 2,000 m (6,600 ft), but is most common in hills and low mountains. A social bird, it lives in family groups and frequently joins and even leads mixed-species foraging flocks. The diet is made up of fruits, seeds and invertebrates. This species is apparently a cooperative breeder, with family groups helping to protect the nest and feed the young. The hooded pitohui is common and not at risk of extinction.

Physiology
The hooded pitohui is 22 to 23 cm (8.7–9.1 in) long and weighs 65–76 g (2.3–2.7 oz). The adult has a black upperwing, head, chin, throat and upper breast and a black tail. The rest of the plumage is a rufous chestnut. The bill and legs are black, and the irises are either reddish brown, dark brown or black. Both sexes look alike. Juvenile birds look like adults, except that the rectrices of the tail and remiges of the wing are tinged with brown. The function of the toxins to the hooded pitohui has been the source of debate and research since its discovery. The initial suggestion was that the toxins acted as a chemical deterrent to predators. Some researchers cautioned this suggestion was premature, and others noted that the levels of batrachotoxins were three orders of magnitude lower than in the poison dart frogs that do use it in this way. Another explanation for the purpose of the toxins is to mitigate the effects of parasites. In experimental conditions chewing lice were shown to avoid toxic feathers of hooded pitohui in favour of feathers with lower concentrations of toxin or no toxins at all. Additionally lice that did live in the toxic feathers did not live as long as control lice, suggesting that the toxins could lessen both the incidence of infestation and the severity.

Distribution
The hooded pitohui is endemic to the islands of New Guinea. It is found widely across the main island, and also on the nearby island of Yapen. It inhabits rainforest, forest edge habitats and secondary growth, and sometimes mangrove forests. It is most commonly found in hills and low mountains, between 350–1,700 m (1,150–5,580 ft), but is found locally down to sea-level and up to 2,000 m (6,600 ft). It typically occurs at higher elevations than the lowland variable pitohui and lower than the (unrelated) black pitohui, although there is some overlap.

Little Shrikethrush

The little shrikethrush (Colluricincla megarhyncha) is a species of bird in the family Pachycephalidae.

Habitat
It is found in Australia and New Guinea. Its natural habitats are subtropical or tropical moist lowland forests and subtropical or tropical moist montane forests.

Toxicity
During a study of toxicity in birds, two specimens of this species were tested. One of these specimens contained traces of batrachotoxins (BTXs) similar to those found in the secretions of Central and South American poison dart frogs.

Spur-Winged Goose

The spur-winged goose (Plectropterus gambensis) is a large bird in the family Anatidae, related to the geese and the shelducks, but distinct from both of these in a number of anatomical features, and therefore treated in its own subfamily, the Plectropterinae.

It occurs in wetlands throughout sub-Saharan Africa. Adults are 75–115 cm (30–45 in) long and weigh on average 4–6.8 kg (8.8–15.0 lb), rarely up to 10 kg (22 lb), with males noticeably larger than the females. The wingspan can range from 150 to 200 cm (59 to 79 in). One source claims the average weight of males is around 6 kg (13 lb) and the weight of females is around 4.7 kg (10 lb).

However, 11 geese of this species banded in South Africa were found to average only 3.87 kg (8.5 lb), with a range of 2.4 to 5.4 kg (5.3 to 11.9 lb). Another study in South Africa found that 58 males weighed an average of 5.52 kg (12.2 lb) and measured 98.1 cm (38.6 in) in total length; while 34 females averaged 3.35 kg (7.4 lb) in weight and 84.2 cm (33.1 in) in total length.

Habitat
This species often occurs in open grasslands with lakes, seasonal pools, rivers, swamps and river deltas. Large inland rivers and lakes are perhaps most commonly inhabited, with saline lakes and upland areas generally being avoided, although the species can occur to an elevation of 3,000 m (9,800 ft) in eastern Africa. It is also absent from arid zones.

Common Quail

The common quail (Coturnix coturnix) or European quail is a small ground-nesting game bird in the pheasant family Phasianidae. Coturnix is the Latin for this species. With its characteristic call of "wet my lips", this species of quail is more often heard than seen. It is widespread in Europe and North Africa, and is categorised by the IUCN as "least concern". It should not be confused with the Japanese quail, Coturnix japonica, native to Asia, which, although visually similar, has a very distinct call. Like the Japanese quail, common quails are sometimes kept as poultry. It is a small, round bird, essentially streaked brown with a white eyestripe, and, in the male, a white chin. As befits its migratory nature, it has long wings, unlike the typically short-winged gamebirds. It measures roughly 18.0–21.9 cm (7.1–8.62 in) and weighs 91–131 g (3.2–4.62 oz)

Habits
This is a terrestrial species, feeding on seeds and insects on the ground. It is notoriously difficult to see, keeping hidden in crops, and reluctant to fly, preferring to creep away instead. Even when flushed, it keeps low and soon drops back into cover. Often the only indication of its presence is the distinctive "wet-my-lips" repetitive song of the male. The call is uttered mostly in the mornings, evenings and sometimes at night. It is a strongly migratory bird, unlike most game birds.

Poisoning
If they have eaten certain plants, although which plants is still in debate, the meat from quail can be poisonous, with one in four who consume poisonous flesh becoming ill with coturnism, which is characterized by muscle soreness, and which may lead to kidney failure.

7 Mammals

European Mole

The European mole (Talpa europaea) is a mammal of the order Eulipotyphla. It is also known as the common mole and the northern mole. This mole lives in an underground tunnel system, which it constantly extends. It uses these tunnels to hunt its prey. Under normal conditions the displaced earth is pushed to the surface, resulting in the characteristic molehills. It feeds mainly on earthworms, but also on insects, centipedes and even mice and shrews.

Its saliva contains toxins which paralyse earthworms in particular. The mole has a cylindrical body and is 11 to 16 cm (4.3 to 6.3 in) long, weighing 70 to 130 g (2.5 to 4.6 oz). Females are typically smaller than males. The eyes are small and hidden behind fur, while the ears are just small ridges in the skin.

The fur is usually dark grey, but the actual range of colours is larger, as due to the subterranean habits there is no disadvantage in having off-coloured fur. European moles with white, light grey, tan, taupe, and black fur have all been reported.

Habitat

While moles are typically found in tunnel systems, the European mole is not exclusively an underground dweller. In the spring and early summer when the young moles leave their mothers' burrows they must find new territory. This forces them to leave their burrow and they can either make new tunnel systems or enter existing systems. In the summer time, however, they are likely to burrow much more superficially. The superficial burrowing could be due in part to the soil that is much harder, which makes burrowing a greater challenge. T. europaea have also been found to spend a lot of time at the sides of drainage lines and streams but do not inhabit flooded or dry soils. However, dry areas do become important when their normal habitats become flooded. Factors such as the type of soil, vegetation present, and altitude have no effect on the areas that moles choose to inhabit. The one factor that does greatly influence the mole population in a specific area is the abundance of earthworms. One would expect for the earthworm population to decrease as the moles feed, however no research has shown this to be true.

Platypus

The platypus (Ornithorhynchus anatinus), sometimes referred to as the duck-billed platypus, is a semiaquatic egg-laying mammal endemic to eastern Australia, including Tasmania. Together with the four species of echidna, it is one of the five extant species of monotremes, the only mammals that lay eggs instead of giving birth to live young. The animal is the sole living representative of its family (Ornithorhynchidae) and genus (Ornithorhynchus), though a number of related species appear in the fossil record.

The first scientists to examine a preserved platypus body (in 1799) judged it a fake, made of several animals sewn together. The unusual appearance of this egg-laying, duck-billed, beaver-tailed, otter-footed mammal baffled European naturalists when they first encountered it, with some considering it an elaborate hoax. It is one of the few species of venomous mammals: the male platypus has a spur on the hind foot that delivers a venom capable of causing severe pain to humans.

The unique features of the platypus make it an important subject in the study of evolutionary biology and a recognizable and iconic symbol of Australia; it has appeared as a mascot at national events and features on the reverse of the Australian twenty-cent coin. The platypus is the animal emblem of the state of New South Wales. Until the early 20th century humans hunted the platypus for its fur, but it is now protected throughout its range. Although captive-breeding programs have had only limited success, and the platypus is vulnerable to the effects of pollution, it is not under any immediate threat. The body and the broad, flat tail of the platypus are covered with dense, brown fur that traps a layer of insulating air to keep the animal warm. The fur is waterproof, and the texture is akin to that of a mole.

The platypus uses its tail for storage of fat reserves (an adaptation also found in animals such as the Tasmanian devil). The webbing on the feet is more significant on the front feet and is folded back when walking on land. The elongated snout and lower jaw are covered in soft skin, forming the bill. The nostrils are located on the dorsal surface of the snout, while the eyes and ears are located in a groove set just back from it; this groove is closed when swimming. Platypuses have been heard to emit a low growl when disturbed and a range of other vocalisations have been reported in captive specimens.

Venom

While both male and female platypuses are born with ankle spurs, only the male's spurs deliver venom, composed largely of defensin-like proteins (DLPs), three of which are unique to the platypus. The DLPs are produced by the immune system of the platypus. The function of defensins is to cause lysis in pathogenic bacteria and viruses, but in platypuses they also are formed into venom for defence.

Although powerful enough to kill smaller animals such as dogs, the venom is not lethal to humans, but the pain is so excruciating that the victim may be incapacitated. Oedema rapidly develops around the wound and gradually spreads throughout the affected limb. Information obtained from case histories and anecdotal evidence indicates the pain develops into a long-lasting hyperalgesia (a heightened sensitivity to pain) that persists for days or even months.

Venom is produced in the crural glands of the male, which are kidney-shaped alveolar glands connected by a thin-walled duct to a calcaneus spur on each hind limb. The female platypus, in common with echidnas, has rudimentary spur buds that do not develop (dropping off before the end of their first year) and lack functional crural glands. The venom appears to have a different function from those produced by nonmammalian species; its effects are not life-threatening to humans, but nevertheless powerful enough to seriously impair the victim.

Since only males produce venom and production rises during the breeding season, it may be used as an offensive weapon to assert dominance during this period. Similar spurs are found on many archaic mammal groups, indicating that this is an ancient characteristic for mammals as a whole, and not exclusive to the platypus or other monotremes.

Eurasian Water Shrew

The Eurasian water shrew (Neomys fodiens), known in the United Kingdom as the water shrew, is a relatively large shrew, up to 10 cm (4 in) long, with a tail up to three-quarters as long again. It has short, dark fur, often with a few white tufts, a white belly, and a few stiff hairs around the feet and tail. It lives close to fresh water, hunting aquatic prey in the water and nearby. Its fur traps bubbles of air in the water which greatly aids its buoyancy, but requires it to anchor itself to remain underwater for more than the briefest of dives.

Like many shrews, the water shrew has venomous saliva, making it one of the few venomous mammals, although it is not able to puncture the skin of large animals, nor that of humans. Highly territorial, it lives a solitary life and is found throughout the northern part of Europe and Asia, from Britain to Korea.

The Eurasian water shrew grows to a length of about 10 cm (4 in) long with a tail length of 8 cm (3 in) and weight of 15 to 19 grams (0.53 to 0.67 oz). The dense short fur on the head, back and sides is greyish-black. The underparts are dirty white and are sharply demarcated from the dorsal surface. Sometimes they are tinged with rusty brown or occasionally are entirely dark grey. There is a white spot just behind the eye and often another near the small, rounded ear which is nearly hidden in the fur. The nose is black and the snout long and tapering.

Distribution
The Eurasian water shrew is found throughout Europe with the exception of Iceland, Ireland, certain Mediterranean islands and the Balkans. In Asia, its range extends from western Siberia and Asia Minor to North Korea and the Pacific coast of Siberia. It rarely strays far from water and is found in and around ditches, streams, ponds, watercress beds, fish ponds, damp meadows and rough bushy ground adjoining water.

Mediterranean Water Shrew

The Mediterranean, Southern or Miller's water shrew (Neomys anomalus) is a species of mammal in the family Soricidae.

Distribution
This shrew is found in Albania, Austria, Belgium, Bosnia and Herzegovina, Bulgaria, Croatia, Czech Republic, France, Germany, Greece, Hungary, Iran, Italy, Liechtenstein, Lithuania, North Macedonia, Poland, Portugal, Romania, Serbia and Montenegro, Slovakia, Slovenia, Spain, Switzerland, Turkey, and Ukraine.

Feeding Habits
It feeds mainly on amphibians and small fish, but also take insects and worms. Because of its small size and thus higher surface area to volume ratio, it loses body heat more quickly and must eat two or three times its body mass each day.

Northern Short-Tailed Shrew

The northern short-tailed shrew (Blarina brevicauda) is the largest shrew in the genus Blarina, and occurs in the north-eastern region of North America. It is a semifossorial, highly active, and voracious insectivore and is present in a variety of habitats. It is notable in that it is one of the few venomous mammals. The specific epithet, brevicauda, is a combination of the Latin brevis and cauda, meaning "short tail". This shrew has a total length of 108 to 140 mm (4.3 to 5.5 in), of which 18 to 32 mm (0.71 to 1.26 in) is tail; and weighs 15 to 30 g (0.53 to 1.06 oz).

The species exhibits slight sexual dimorphism in size, with the male being slightly larger than the female. The dorsal fur is thick and velvety, and can be black, brownish black, or silvery gray, with the ventral fur being a bit lighter and grayer. The shrew molts from a summer coat which is shorter and paler than the winter pelage in October and November, and back again sometime in February through July.

Range
This shrew is found throughout central and eastern North America, from southern Saskatchewan to Atlantic Canada and south to northern Arkansas and Georgia. It is probably the most common shrew in the Great Lakes region. Population densities usually range from five to 30 shrews per hectare (two to 12 per acre), but rarely exceed 200/ha (80/ac). The typical home range of a shrew is 2.5 ha, and may overlap slightly with the ranges of other shrews.

Habitat
Both disturbed and undisturbed habitats are used by the northern short-tailed shrew, including grasslands, old fields, fencerows, marshy areas, deciduous and coniferous forests, and household gardens, though the preferred habitats are those which are moist with leaf litter or thick plant cover. Burned-over forests are not quickly recolonized by B. brevicauda, and shrews quickly depart clear-cuts.

Toxin
The saliva of the northern short-tailed shrew contains a kallikrein-like protease, used to paralyse and subdue its prey. The toxin is strong enough to kill small animals, up to sizes somewhat larger than the shrew itself, and results in painful bites to humans who attempt to handle the shrew. The venomous saliva is secreted from submaxillary glands, through a duct which opens at the base of the lower incisors, where the saliva flows along the groove formed by the two incisors, and into the prey. The toxin is very similar in structure to the one produced by the Mexican beaded lizard (Heloderma horridum) which independently developed its toxin from the same precursor protein.

Behaviour
Other shrews spend more time above ground than does the northern short-tailed shrew, which prefers to tunnel along below ground, through the leaf litter, or at the snow/ground interface. Bouts of frenzied activity, lasting around five minutes, are followed by longer periods of resting, with the total active time amounting to only 16% of a 24-hour day. This animal is capable of digging at a rate of 2.5 cm/min, in between resting. The shrew constructs a nest up to 20 cm (8 in) in diameter underground or underneath a log, and lines it with leaves or the fur of the meadow vole (Microtus pennsylvanicus). This nest is kept clean, with wastes deposited outside the nest in a latrine area. Other parts of the burrow system are used for food storage.

Southern Short-Tailed Shrew

The southern short-tailed shrew is a gray, short-tailed shrew that inhabits the eastern United States. The southern short-tailed shrew is the smallest shrew in its genus, measuring 7 to 10 cm (2.8 to 3.9 in) in total length, and weighing less than 14 g (0.49 oz). It has a comparatively heavy body, with short limbs and a thick neck, a long, pointed snout and ears that are nearly concealed by its soft, dense fur. As its name indicates, the hairy tail is relatively short, measuring 1.2 to 2.5 cm (0.47 to 0.98 in). The feet are adapted for digging, with five toes ending in sharp, curved claws. The fur is slate gray, being paler on the underparts.

Distribution
The southern short-tailed shrew is found in the south-eastern United States, from southern Virginia to eastern Texas, and in the Mississippi valley as far as southern Illinois. Within this region, it is found primarily in pine forests. However, these range from dry to wet and even swampy habitats, as well as disturbed forests and abandoned agricultural land.

Elliot's Short-Tailed Shrew

Elliot's short-tailed shrew (Blarina hylophaga) is a small, slate grey, short-tailed species of shrew. Its common name comes from Daniel Giraud Elliot, who first described the species in 1899. Elliot's short-tailed shrew is similar in appearance to the closely related southern short-tailed shrew, although slightly larger on average, and was long thought to belong to the same species. It is a heavily built shrew with short legs and tail, and a long, pointed snout with long whiskers. The ears and eyes are both small, the eyelids being permanently closed in some individuals, a feature otherwise unknown among shrews. The fur is velvety in texture, and uniformly coloured greyish to brown. Adults range from 9 to 12 cm (3.5 to 4.7 in) in total length, including the 2-to-3 cm (0.79-to-1.18 in) tail, and weigh 13 to 16 g (0.46 to 0.56 oz).

Distribution
Elliot's short-tailed shrew is found in lowland environments with heavy vegetation from southern Iowa and Nebraska in the north to parts of Texas and northern Louisiana in the south, including much of the states of Missouri, Kansas, Oklahoma, and Arkansas, and the north-eastern corner of Colorado. The species inhabits a diverse range of habitats, including grasslands, agricultural land, and woodland. Although it generally prefers well watered environments with plenty of ground litter, it is also known from relatively dry and sandy terrain in Texas and Colorado, often with minimal ground cover. Elliot's short-tailed shrew is generally a solitary, nocturnal animal, spending the day sleeping in burrows in soft soil or leaf litter. The burrows may contain nests made from grass or leaves, and are surrounded by a network of trackways that the shrew uses while hunting for prey. They have been reported to travel across home ranges of anything from 0.06 to 0.55 hectares (0.15 to 1.36 acres), and to travel mostly around dawn and sunset. Having poor eyesight, they hunt primarily by means of echolocation. They are active throughout the year, and do not hibernate.

Hispaniolan Solenodon

The Hispaniolan solenodon (Solenodon paradoxus), also known as the Haitian solenodon, or agouta, is a solenodon found only on Hispaniola, the island shared by Haiti and the Dominican Republic. It was first described by Brandt in 1833. A similar but smaller species, Marcano's solenodon (S. marcanoi), once lived on the island, but became extinct after European colonization. The Hispaniolan solenodon looks much like an oversized shrew; males and females are similar in size. Adults measure 49 to 72 cm (19 to 28 in) in total length, including a tail 20 to 25 cm (7.9 to 9.8 in), and weigh about 800 g (28 oz) on average. Although they are somewhat variable in colour, they are typically dusky brown over most of the body, with a paler underside and reddish fur on the sides of the head, throat and upper chest. The tail, legs, snout, and eyelids are hairless.

Distribution
Hispaniolan solenodona are found only on the island of Hispaniola, in the Dominican Republic and parts of southern Haiti. Their habitat is usually undisturbed moist forest below 1,000 m (3,300 ft) elevation, although they are sometimes found at higher altitudes or close to developed agricultural land.

Behaviour
Hispaniolan solenodons are nocturnal; during daylight hours, they stay in their burrows, trees, hollowed-out logs or caves, remaining hidden from view. Their burrows may contain multiple chambers and tunnels and are typically inhabited by an adult pair accompanied by up to six younger family members. When they emerge into the open air, they run on the soles of their feet, following an erratic, zigzag course. Hispaniolan solenodons feed mainly on arthropods, but will also eat worms, snails, mice and small reptiles; they may also feed on a small amount of fruit, grains, and leaf litter. They probe the earth with their snouts and dig or rip open rotten logs with their claws. They have been reported to make a number of vocalisations, including a loud defensive "chirp", an aggressive "squeal", a soft "squeak" when encountering familiar conspecifics, and a high-pitched "clic" when encountering strangers. They have also been reported to make echolocation clicks at 9 to 31 kHz.

Slow Loris

Slow lorises are a group of several species of nocturnal strepsirrhine primates that make up the genus Nycticebus. Found in Southeast Asia and bordering areas, they range from Bangladesh and Northeast India in the west to the Sulu Archipelago in the Philippines in the east, and from Yunnan province in China in the north to the island of Java in the south. Slow lorises have a round head, a narrow snout, large eyes, and a variety of distinctive coloration patterns that are species-dependent. Their arms and legs are nearly equal in length, and their trunk is long and flexible, allowing them to twist and extend to nearby branches. The hands and feet of slow lorises have several adaptations that give them a pincer-like grip and enable them to grasp branches for long periods of time.

Slow lorises move slowly and deliberately, making little or no noise, and when threatened, they stop moving and remain motionless. Their only documented predators—apart from humans—include snakes, changeable hawk-eagles and orangutans, although cats, civets and sun bears are suspected. Little is known about their social structure, but they are known to communicate by scent marking. Males are highly territorial. Slow lorises reproduce slowly, and the infants are initially parked on branches or carried by either parent. They are omnivores, eating small animals, fruit, tree gum, and other vegetation.

Distribution
Slow lorises are found in South and Southeast Asia. Their collective range stretches from Northeast India through Indochina, east to the Sulu Archipelago (the small, southern islands of the Philippines), and south to the island of Java (including Borneo, Sumatra, and many small nearby islands). They are found in India (North-eastern states), China (Yunnan province), Laos, Vietnam, Cambodia, Bangladesh, Burma, Thailand, Malaysia, the Philippines, Indonesia, Brunei, and Singapore.

Toxicity
Slow lorises have a toxic bite, a trait rare among mammals and unique to lorisid primates. The toxin is obtained by licking a gland on their arm, and the secretion is activated by mixing with saliva. Their toxic bite is a deterrent to predators, and the toxin is also applied to the fur during grooming as a form of protection for their infants. The secretion from the arm contains a chemical related to cat allergen, but may be augmented by secondary toxins from the diet in wild individuals. The secretion from the brachial gland of captive slow lorises is similar to the allergen in cat dander, hence the secretions may merely elicit an allergic reaction, not toxicosis. Loris bites cause a painful swelling, and the single case of human death reported in the scientific literature was believed to have resulted from anaphylactic shock.

8 Lizards

Gila Monster

The Gila monster is a species of venomous lizard native to the south-western United States and north-western Mexican state of Sonora. A heavy, typically slow-moving lizard, up to 60 cm (2.0 ft) long, the Gila monster is the only venomous lizard native to the United States and one of only two known species of venomous lizards in North America, the other being its close relative, the Mexican beaded lizard (H. horridum). Although the Gila monster is venomous, its sluggish nature means it represents little threat to humans. However, it has acquired a fearsome reputation, and is sometimes killed despite being protected by state law in Arizona.

Distribution
The Gila monster is found in the South-western United States and Mexico, a range including Sonora, Arizona, parts of California, Nevada, Utah, and New Mexico (potentially including Baja California). They inhabit scrubland, succulent desert, and oak woodland, seeking shelter in burrows, thickets, and under rocks in locations with ready access to moisture. In fact, Gila monsters seem to like water and can be observed immersing themselves in puddles of water after a summer rain. They avoid living in open areas such as flats and farmland.

Mexican Beaded Lizard

The Mexican beaded lizard (Heloderma horridum) is a species of lizard in the family Helodermatidae, one of the two species of venomous beaded lizards found principally in Mexico and southern Guatemala. It and its congener (member of the same genus) the Gila monster (Heloderma suspectum) are the only lizards known to have evolved an overt venom delivery system. The Mexican beaded lizard is larger than the Gila monster, with duller coloration, black with yellowish bands.

As it is a specialized predator that feeds primarily upon eggs, the primary use of its venom is still a source of debate among scientists. However, this venom has been found to contain several enzymes useful for manufacturing drugs in the treatment of diabetes, and research on the pharmacological use of its venom is ongoing.

Adult beaded lizards range from 57 to 91 cm (22 to 36 in) in length. They are substantially larger than the Gila monster, which only reaches lengths of 30 to 56 cm (12 to 22 in). The snout-to-vent length of a beaded lizard averages 33 to 48 cm (13 to 19 in). The average body mass of an adult beaded lizard is 800 g (1.8 lb), about 45% heavier than the average mass of a gila monster, with large specimens exceeding 2,000 g (4.4 lb). Maximum weight known is 4,000 g (8.8 lb) Although males are slightly larger than females, the lizards are not sexually dimorphic.

Habitat
Beaded lizards are found in the Pacific drainages from southern Sonora to south-western Guatemala and two Atlantic drainages, from central Chiapas to south-eastern Guatemala. Their habitats are primarily in the desert, tropical deciduous forests and thorn scrub forests, but are found in pine-oak forests, with elevations from sea level to 1500 m. In the wild, the lizards are only active from April to mid-November, spending about an hour per day above the ground.

Venom
The venom glands of the beaded lizard are modified salivary glands located in the reptile's lower jaw. Each gland has a separate duct leading to the base of its grooved teeth. When biting, the beaded lizard hangs on its victim and chews to get its venomous saliva into the wound. Although its jaw grip is strong, its unsocketed teeth are easily broken off at their bases. The beaded lizard's venom is a weak hemotoxin, and although human deaths are rare, it can cause respiratory failure.

It consists of a number of components, including L-amino acid oxidase, hyaluronidase, phospholipase A, serotonin, and highly active kallikreins that release vasoactive kinins. The venom contains no enzymes that significantly affect coagulation. Almost all documented human bites (eight in the past century) have resulted from prodding captive lizards with a finger or bare foot.

While invertebrates are essentially immune to the effects of this venom, effects on vertebrates are more severe and varied. In mammals such as rats, major effects include a rapid reduction in carotid blood flow followed by a marked fall in blood pressure, respiratory irregularities, tachycardia, and other cardiac anomalies, as well as hypothermia, edema, and internal haemorrhage in the gastrointestinal tract, lungs, eyes, liver, and kidneys.

In humans, the effects of bites are associated with excruciating pain that may extend well beyond the area bitten and persist up to 24 hours. Other common effects of bites on humans include local edema (swelling), weakness, sweating, and a rapid fall in blood pressure. Beaded lizards are immune to the effects of their own venom.

Komodo Dragon

The Komodo dragon (Varanus komodoensis), also known as the Komodo monitor, is a species of lizard found in the Indonesian islands of Komodo, Rinca, Flores, and Gili Motang. A member of the monitor lizard family Varanidae, it is the largest living species of lizard, growing to a maximum length of 3 metres (10 ft) in rare cases and weighing up to approximately 70 kilograms (150 lb). Their unusually large size has been attributed to island gigantism, since no other carnivorous animals fill the niche on the islands where they live.

However, recent research suggests the large size of Komodo dragons may be better understood as representative of a relict population of very large varanid lizards that once lived across Indonesia and Australia, most of which, along with other megafauna, died out after the Pleistocene (as a result of human activity). As a result of their size, these lizards dominate the ecosystems in which they live. Komodo dragons hunt and ambush prey including invertebrates, birds, and mammals.

It has been claimed that they have a venomous bite; there are two glands in the lower jaw which secrete several toxic proteins. The biological significance of these proteins is disputed, but the glands have been shown to secrete an anticoagulant. Komodo dragons' group behaviour in hunting is exceptional in the reptile world. The diet of big Komodo dragons mainly consists of Timor deer, though they also eat considerable amounts of carrion. Komodo dragons also occasionally attack humans.

Behaviour
The Komodo dragon prefers hot and dry places, and typically lives in dry, open grassland, savannah, and tropical forest at low elevations. As an ectotherm, it is most active in the day, although it exhibits some nocturnal activity. Komodo dragons are solitary, coming together only to breed and eat. They are capable of running rapidly in brief sprints up to 20 km/h (12 mph), diving up to 4.5 m (15 ft), and climbing trees proficiently when young through use of their strong claws. To catch out-of-reach prey, the Komodo dragon may stand on its hind legs and use its tail as a support. As it matures, its claws are used primarily as weapons, as its great size makes climbing impractical. For shelter, the Komodo dragon digs holes that can measure from 1 to 3 m (3.3 to 9.8 ft) wide with its powerful forelimbs and claws. Because of its large size and habit of sleeping in these burrows, it is able to conserve body heat throughout the night and minimise its basking period the morning after. The Komodo dragon hunts in the afternoon, but stays in the shade during the hottest part of the day.

Saliva
Although previous studies proposed that Komodo dragon saliva contains a variety of highly septic bacteria that would help to bring down prey, research in 2013 suggested that the bacteria in the mouths of Komodo dragons are ordinary and similar to those found in other carnivores. They actually have surprisingly good mouth hygiene. As Bryan Fry put it: "After they are done feeding, they will spend 10 to 15 minutes lip-licking and rubbing their head in the leaves to clean their mouth... Unlike people have been led to believe, they do not have chunks of rotting flesh from their meals on their teeth, cultivating bacteria."

Venom

In late 2005, researchers at the University of Melbourne speculated the perentie (Varanus giganteus), other species of monitors, and agamids may be somewhat venomous. The team believes the immediate effects of bites from these lizards were caused by mild envenomation. Bites on human digits by a lace monitor (V. varius), a Komodo dragon, and a spotted tree monitor (V. scalaris) all produced similar effects: rapid swelling, localised disruption of blood clotting, and shooting pain up to the elbow, with some symptoms lasting for several hours. In 2009, the same researchers published further evidence demonstrating Komodo dragons possess a venomous bite. MRI scans of a preserved skull showed the presence of two glands in the lower jaw. The researchers extracted one of these glands from the head of a terminally ill dragon in the Singapore Zoological Gardens, and found it secreted several different toxic proteins. The known functions of these proteins include inhibition of blood clotting, lowering of blood pressure, muscle paralysis, and the induction of hypothermia, leading to shock and loss of consciousness in envenomated prey. As a result of the discovery, the previous theory that bacteria were responsible for the deaths of Komodo victims was disputed.

Perentie

The perentie (Varanus giganteus) is the largest monitor lizard or goanna native to Australia, and the fourth-largest living lizard on earth, after the Komodo dragon, Asian water monitor, and the crocodile monitor. Found west of the Great Dividing Range in the arid areas of Australia, it is rarely seen because of its shyness and the remoteness of much of its range from human habitation. The lizard can grow up to 2.5 m (8 ft 2 in) long, although the average length is around 1.75 to 2 m (5 ft 9 in to 6 ft 7 in) and weigh up to 15 kg (33 lb) — maximum weight can be over 20 kg (44 lb).

Its rival for the title of the third-largest lizard is the crocodile monitor, which although often longer, exceeding 2.4 m in length, is lighter and less bulky than the perentie. However, perenties are relatively lean lizards and are less bulky than either the Komodo dragon or the Asian water monitor.

Venom

In late 2005, University of Melbourne researchers discovered that all monitors may be somewhat venomous. Previously, bites inflicted by monitors were thought to be prone to infection because of bacteria in their mouths, but the researchers showed that the immediate effects are caused by mild envenomation. Bites on the hand by Komodo dragons, (V. komodensis), perenties (V. giganteus), lace monitors (V. varius) and spotted tree monitors (V. scalaris) have been observed to cause swelling within minutes, localised disruption of blood clotting, and shooting pain up to the elbow, which can often last for several hours.

Distribution

Perenties are found in the arid desert areas of Western Australia, South Australia, the Northern Territory, and Queensland. Their habitats consist of rocky outcroppings and gorges, with hard-packed soil and loose stones.

Behaviour

Uncommon, perenties generally avoid human contact and will retreat before they are seen. Being able diggers, they can excavate a burrow for shelter in only minutes. Their long claws enable them to easily climb trees. They often stand on their back legs and tail to gain a better view of the surrounding terrain. This behaviour, known as "tripoding", is quite common in monitor species. Perenties are fast sprinters, and can run using either all four legs or just their hind legs. Typical of most goannas, the perentie will either freeze (lying flat on the ground, and remaining very still until the danger has passed) or run if detected. If cornered, this powerful carnivore will stand its ground and use its arsenal of claws, teeth, and whip-like tail to defend itself. They inflate their throats and hiss as a defensive or aggressive display, and strike at opponents with their muscular tails. Perenties will also lunge forward with open mouths, either as a bluff or as an attack. The bite of a perentie can do much damage, not only from the teeth, but also because of the oral secretions from their mouths.

Lace Monitor

The lace monitor or lace goanna (Varanus varius) is a member of the monitor lizard family, Australian members of which are commonly known as goannas. It belongs to the subgenus Varanus. Lace monitors are the second-largest monitor in Australia after the perentie. They can be as long as 2.1 m (over 6.8 ft) with a head-and-body length of up to 76.5 cm (2.5 ft). The tail is long and slender and about 1.5 times the length of the head and body. The maximum weight of lace monitor can be 20 kg (44 lb), but most adults are much smaller.

Distribution

These common terrestrial and often arboreal monitors are found in eastern Australia and range from Cape Bedford on Cape York Peninsula to south-eastern South Australia. They frequent both open and closed forests and forage over long distances (up to 3 km a day).

Venom

In late 2005, University of Melbourne researchers discovered that all monitors may be somewhat venomous. Previously, bites inflicted by monitors were thought to be prone to infection because of bacteria in their mouths, but the researchers showed that the immediate effects may be caused by mild envenomation. Bites on the hand by Komodo dragons (V. komodoensis), perenties (V. giganteus), lace monitors (V. varius) and spotted tree monitors (V. scalaris) have been observed to cause swelling within minutes, localised disruption of blood clotting, and shooting pain up to the elbow, which can often last for several hours.

Washington State University biologist Kenneth V. Kardong and toxicologists Scott A. Weinstein and Tamara L. Smith, have stated that this allegation of venom glands "has had the effect of underestimating the variety of complex roles played by oral secretions in the biology of reptiles, produced a very narrow view of oral secretions and resulted in misinterpretation of reptilian evolution". According to these scientists "reptilian oral secretions contribute to many biological roles other than to quickly dispatch prey". They concluded that, "Calling all in this clade venomous implies an overall potential danger that does not exist, misleads in the assessment of medical risks, and confuses the biological assessment of squamate biochemical systems".

9 Amphibians

American Toad

The American toad (Anaxyrus americanus) is a common species of toad found throughout the eastern United States and Canada. It is divided into three subspecies—the eastern American toad (A. a. americanus), the dwarf American toad, and the rare Hudson Bay toad. Recent taxonomic treatments place this species in the genus Anaxyrus instead of Bufo.

Asiatic Toad

The Asiatic toad or Chusan Island toad (Bufo gargarizans) is a species of toad endemic to East Asia. It is common in China (specifically Anhui, Fujian, Gansu, Guizhou, Hebei, Heilongjiang, Henan, Hubei, Hunan, Inner Mongolia, Jiangsu, Jiangxi, Jilin, Qinghai, Shaanxi, Shandong, Shanxi, Sichuan, and Zhejiang) and portions of the Russian Far East (up north to the Amur River valley and on Sakhalin Island, and east to Transbaikalia in Siberia), but relatively rare on the Korean Peninsula. Asiatic toads are also found on the Miyako Islands of southern Japan, although they have been extirpated from some islands in recent years, possibly including Okinawa.

The Miyako subspecies, Bufo gargarizans miyakonis, is also known as the Miyako toad. The Asiatic toad avoids dense forests, but is found in most other habitats, including grasslands, open forests, meadows, and cultivated areas. It prefers humid areas, and is seldom found at altitudes of more than 800 meters. The Asiatic toad plays an important role in traditional Oriental medicine.

An extract of the toxins secreted by the toad, known as toad venom or chan-su, has long been touted for its medicinal properties. In addition, dried toad skins have been prescribed as remedies for dropsy and other ailments. More recently, Western medical science has also taken an interest in the toad. In 1998, an antimicrobial peptide was extracted from the toad, and patented.

Cane Toad

The cane toad (Rhinella marina), also known as the giant neotropical toad or marine toad, is a large, terrestrial true toad native to South and mainland Central America, but which has been introduced to various islands throughout Oceania and the Caribbean, as well as Northern Australia. It is the world's largest toad. It is a member of the genus Rhinella, but was formerly in the genus Bufo, which includes many different true toad species found throughout Central and South America.

The cane toad is a prolific breeder; females lay single-clump spawns with thousands of eggs. Its reproductive success is partly because of opportunistic feeding: it has a diet, unusual among anurans, of both dead and living matter. Adults average 10–15 cm (3.9–5.9 in) in length; the largest recorded specimen had a snout-vent length of 24 cm (9.4 in). The cane toad is very large; the females are significantly longer than males, reaching a typical length of 10–15 cm (3.9–5.9 in), with a maximum of 24 cm (9.4 in).

Larger toads tend to be found in areas of lower population density. They have a life expectancy of 10 to 15 years in the wild, and can live considerably longer in captivity, with one specimen reportedly surviving for 35 years. The skin of the cane toad is dry and warty. It has distinct ridges above the eyes, which run down the snout. Individual cane toads can be grey, yellowish, red-brown, or olive-brown, with varying patterns. A large parotoid gland lies behind each eye. The ventral surface is cream-coloured and may have blotches in shades of black or brown. The pupils are horizontal and the irises golden. The toes have a fleshy webbing at their base, and the fingers are free of webbing.

Distribution
The cane toad is native to the Americas, and its range stretches from the Rio Grande Valley in South Texas to the central Amazon and south-eastern Peru, and some of the continental islands near Venezuela (such as Trinidad and Tobago). This area encompasses both tropical and semiarid environments. The density of the cane toad is significantly lower within its native distribution than in places where it has been introduced. In South America, the density was recorded to be 20 adults per 100 m (109 yd) of shoreline, 1 to 2% of the density in Australia.

Colorado River Toad

The Colorado River toad (Incilius alvarius), also known as the Sonoran Desert toad, is found in northern Mexico and the south-western United States. Its toxin, as an exudate of glands within the skin, contains 5-MeO-DMT and bufotenin. The Colorado River toad can grow to about 190 millimetres (7.5 in) long and is the largest toad in the United States apart from the non-native cane toad (Rhinella marina). It has a smooth, leathery skin and is olive green or mottled brown in colour. Just behind the large golden eye with horizontal pupil is a bulging kidney-shaped parotoid gland.

Below this is a large circular pale green area which is the tympanum or ear drum. By the corner of the mouth there is a white wart and there are white glands on the legs. All these glands produce toxic secretions. Dogs that have attacked toads have been paralysed or even killed. Raccoons have learned to pull a toad away from a pond by the back leg, turn it on its back and start feeding on its belly, a strategy that keeps the raccoon well away from the poison glands.

Unlike other vertebrates, this amphibian obtains water mostly by osmotic absorption across its abdomen. Toads in the family bufonidae have a region of skin known as "the seat patch", which extends from mid abdomen to the hind legs and is specialized for rapid rehydration. Most of the rehydration is done through absorption of water from small pools or wet objects.

Distribution
The Colorado River toad is found in the lower Colorado River and the Gila River catchment areas, in south-eastern California, New Mexico, Mexico and much of southern Arizona. It lives in both desert and semi-arid areas throughout its range. It is semiaquatic and is often found in streams, near springs, in canals and drainage ditches, and under water troughs. The Colorado River toad is known to breed in artificial water bodies (e.g., flood control impoundments, reservoirs) and as a result, the distributions and breeding habitats of these species may have been recently altered in south central Arizona. It often makes its home in rodent burrows and is nocturnal. Its call is described as, "a weak, low-pitched toot, lasting less than a second."

Common Toad

The common toad, European toad, or in Anglophone parts of Europe, simply the toad (Bufo bufo, from Latin bufo "toad"), is an amphibian found throughout most of Europe (with the exception of Ireland, Iceland, and some Mediterranean islands), in the western part of North Asia, and in a small portion of Northwest Africa. It is one of a group of closely related animals that are descended from a common ancestral line of toads and which form a species complex. The toad is an inconspicuous animal as it usually lies hidden during the day.

It becomes active at dusk and spends the night hunting for the invertebrates on which it feeds. It moves with a slow, ungainly walk or short jumps, and has greyish-brown skin covered with wart-like lumps. Although toads are usually solitary animals, in the breeding season, large numbers of toads converge on certain breeding ponds, where the males compete to mate with the females. Eggs are laid in gelatinous strings in the water and later hatch out into tadpoles.

After several months of growth and development, these sprout limbs and undergo metamorphosis into tiny toads. The juveniles emerge from the water and remain largely terrestrial for the rest of their lives. The common toad can reach about 15 cm (6 in) in length. Females are normally stouter than males and southern specimens tend to be larger than northern ones. The head is broad with a wide mouth below the terminal snout which has two small nostrils.

There are no teeth. The bulbous, protruding eyes have yellow or copper coloured irises and horizontal slit-shaped pupils. Just behind the eyes are two bulging regions, the paratoid glands, which are positioned obliquely. They contain a noxious substance, bufotoxin, which is used to deter potential predators. The head joins the body without a noticeable neck and there is no external vocal sac. The body is broad and squat and positioned close to the ground. The fore limbs are short with the toes of the fore feet turning inwards. At breeding time, the male develops nuptial pads on the first three fingers. He uses these to grasp the female when mating. The hind legs are short relative to other frogs' legs and the hind feet have long, unwebbed toes. There is no tail.

The skin is dry and covered with small wart-like lumps. The colour is a fairly uniform shade of brown, olive-brown or greyish-brown, sometimes partly blotched or banded with a darker shade. The common toad tends to be sexually dimorphic with the females being browner and the males greyer. The underside is a dirty white speckled with grey and black patches.

Distribution
After the common frog (Rana temporaria), the edible frog (Pelophylax esculentus) and the smooth newt (Lissotriton vulgaris), the common toad is the fourth most common amphibian in Europe. It is found throughout the continent with the exception of Iceland, the cold northern parts of Scandinavia, Ireland and a number of Mediterranean islands. These include Malta, Crete, Corsica, Sardinia and the Balearic Islands. Its easterly range extends to Irkutsk in Siberia and its southerly range includes parts of north-western Africa in the northern mountain ranges of Morocco, Algeria and Tunisia.

Corroboree Frog

The corroboree frogs are two species of small, poisonous ground dwelling frogs, native to Southern Tablelands of Australia. The two species are the southern corroboree frog (Pseudophryne corroboree) and the northern corroboree frog (Pseudophryne pengilleyi). They are unique among frogs in that they produce their own poison rather than obtain it from their food source as is the case in every other poisonous frog species.

Distribution
Corroboree frogs have different patterns. The corroboree frog is found only in 400 km2 patches in the sub-alpine regions of the Australian Capital Territory and southern New South Wales.

Toxicity
Corroboree frogs are the first vertebrates discovered that are able to produce their own poisonous alkaloids, as opposed to obtaining it via diet as many other frogs do. The alkaloid is secreted from the skin as a defence against predation, and potentially against skin infections by microbes. It has been described as potentially lethal to mammals if ingested. The unique alkaloid produced has been named pseudo-phrynamine.

Behaviour
Corroborree frogs are quite unusual in their nature. Not only do they not start breeding until four years of age, they also hibernate during winter under whatever shelter they can find. This may be snow gum trees, or bits of bark or fallen leaves. Males stay with the egg nests and may breed with many females over the course of one season.

European Green Toad

The European green toad (Bufo viridis) is a species of toad found in mainland Europe. It lives in many habitats, including steppes, mountainous areas, semi-deserts, and urban areas. The species comprises at least 12 major evolutionary lineages, and there are variations in the colour and pattern of this toad across its range. The spots on the back vary from green to dark brown and sometimes red spots appear, too.

The underside is white or very lightly coloured. The European green toad will change colour in response to heat and light changes. Females are larger than males and can lay 9,000 to 15,000 eggs at a time. It can reach a maximum size (head and body length) of 10 cm (about 4 inches), but growth to this size is rare.

Fowler's Toad

Fowler's toad (Anaxyrus fowleri, formerly Bufo fowleri) is a species of toad in the family Bufonidae. The species is native to North America, where it occurs in much of the eastern United States and parts of adjacent Canada. It was previously considered a subspecies of Woodhouse's toad (Anaxyrus woodhousii, formerly Bufo woodhousii). Fowler's toad is usually brown, grey, olive green and rust red in colour with darkened warty spots. If the toad has a pale stripe on its back it is an adult.

The belly is usually uniformly whitish except for one dark spot. The male may be darker in overall colour than the female. The adult toad is typically 5 to 9.5 cm (2.0 to 3.7 in) in head-body length. The tadpole is oval with a long tail and upper and lower fins, and is 1 to 1.4 cm (0.39 to 0.55 in) long.

Behaviour
Predators of Fowler's toad include snakes, birds, and small mammals. It uses defensive coloration to blend into its surroundings. It also secretes a noxious compound from the warts on its back. The secretion is distasteful to predators and can be lethal to small mammals. The toad is also known to play dead.

Habitat
Fowler's toad lives in open woodlands, sand prairies, meadows, and beaches. It burrows into the ground during hot, dry periods and during the winter.

Mantella

Mantella (also known as golden frogs or Malagasy poison frogs) are a prominent genus of aposematic frogs in the family Mantellidae, endemic to the island of Madagascar. The members of the genus are diurnal and terrestrial in behaviour, exhibiting bright colouration or cryptic markings which are species specific. All the species of the genus are considered small frogs in morphology, typically varying in sizes of 18–31 millimetres (0.71–1.22 in). A common characteristic across most species within the genus is that species are sexually dimorphic in size, with female specimens usually being larger than males.

Mantella are often compared to the neotropical family of Dendrobatidae due to their use of aposematism, a defence mechanism that uses dramatic colourations to deter potential predators. Colourations and markings vary from species to species, with combinations of green, red, orange, yellow, blue, brown, white and black. These colourations are often evidence that the specimen is, to a degree, toxic with pharmacologically active alkaloid secretions.

Distribution
Mantella are endemic to the island of Madagascar and its smaller coastal islands ("Nosy" in Malagasy). They inhabit a wide variety of different habitat types including primary rainforests, secondary rainforests, swamps, bamboo forests, semi-arid streambeds, slow moving forest streams, seasonal streams, montane grassland savannah and in wet canyons.

Panamanian Golden Frog

The Panamanian golden frog (Atelopus zeteki) is a species of toad endemic to Panama. Panamanian golden frogs inhabit the streams along the mountainous slopes of the Cordilleran cloud forests of west-central Panama. While the IUCN lists it as critically endangered, it may in fact have been extinct in the wild since 2007. Individuals have been collected for breeding in captivity in a bid to preserve the species. The alternative common name, Zetek's golden frog, and the epithet zeteki both commemorate the entomologist James Zetek.

Despite its common name, the Panamanian golden frog is a true toad, a member of the family Bufonidae. It was first described as a subspecies of Atelopus varius, but is now classified as a separate species. The Panamanian golden frog is a national symbol and is considered to be one of the most beautiful frogs in Panama.

The skin colour ranges from light yellow-green to bright gold, with some individuals exhibiting black spots on their backs and legs. Females are generally larger than males; females typically range from 45 to 63 mm (1.8 to 2.5 in) in length and 4 to 15 g (0.14 to 0.53 oz) in weight, with males between 35 and 48 millimetres (1.4 and 1.9 in) in length and 3 and 12 grams (0.11 and 0.42 oz) in weight.

Toxicity
The Panamanian golden frog has a variety of toxins, including steroidal bufadienolides and guanidinium alkaloids of the tetrodotoxin class. One of the latter, zetekitoxin AB, has been found to be a blocker of voltage-dependent sodium channels several orders of magnitude more potent than its analog saxitoxin. Their toxin is water-soluble and affects the nerve cells of anyone who comes in contact with it. Panamanian golden frogs use this toxin to protect themselves from most predators. Due to the risk of testing the poison on humans, it has been done with mice. Large doses can be fatal in 20 or 30 minutes. Death is preceded by clonic (grand mal) convulsions until the functions of the circulatory and respiratory systems cease.

Distribution
The Panamanian golden frog is endemic to Panama, living close to mountain streams on the eastern side of the Tabasará mountain range in the Coclé and Panamá provinces. Its geographic range previously extended as far east as the town of El Copé in western Coclé Province before the onset of the fungal disease chytridiomycosis, which caused the El Copé population to rapidly collapse in 2004. Vital habitat is lost each year to small farms, commercialized agriculture, woodlot operations, livestock range, industrial expansion, and real estate development. Individuals are kept in captive-breeding programmes in more than 50 institutions across North America and Panama.

Poison Dart Frog

Poison dart frog (also known as dart-poison frog, poison frog or formerly known as poison arrow frog) is the common name of a group of frogs in the family Dendrobatidae which are native to tropical Central and South America. These species are diurnal and often have brightly coloured bodies. This bright coloration is correlated with the toxicity of the species, making them aposematic. Some species of the family Dendrobatidae exhibit extremely bright coloration along with high toxicity, while others have cryptic coloration with minimal to no amount of observed toxicity. The species that have great toxicity derive this from their diet of ants, mites and termites. Other species however, that exhibit cryptic coloration and low to no amounts of toxicity, eat a much larger variety of prey.

These amphibians are often called "dart frogs" due to the Amerindians' indigenous use of their toxic secretions to poison the tips of blowdarts. However, of over 170 species, only four have been documented as being used for this purpose (curare plants are more commonly used), all of which come from the genus Phyllobates, which is characterized by the relatively large size and high levels of toxicity of its members.

Most species of poison dart frogs are small, sometimes less than 1.5 cm (0.59 in) in adult length, although a few grow up to 6 cm (2.4 in) in length. They weigh 1 oz. on average. Most poison dart frogs are brightly coloured, displaying aposematic patterns to warn potential predators. Their bright coloration is associated with their toxicity and levels of alkaloids.

Habitat
Poison dart frogs are endemic to humid, tropical environments of Central and South America. These frogs are generally found in tropical rainforests, including in Bolivia, Costa Rica, Brazil, Colombia, Ecuador, Venezuela, Suriname, French Guiana, Peru, Panama, Guyana, Nicaragua, and Hawaii (introduced). Natural habitats include subtropical and tropical, moist, lowland forests, subtropical or tropical high-altitude shrubland, subtropical or tropical, moist, montanes and rivers, freshwater marshes, intermittent freshwater marshes, lakes and swamps. Other species can be found in seasonally wet or flooded lowland grassland, arable land, pastureland, rural gardens, plantations, moist savannah and heavily degraded former forest. Premontane forests and rocky areas have also been known to hold frogs. Dendrobatids tend to live on or close to the ground, but also in trees as much as 10 m (33 ft) from the ground.

Toxicity
Many poison dart frogs secrete lipophilic alkaloid toxins such as allopumiliotoxin 267A, batrachotoxin, epibatidine, histrionicotoxin, and pumiliotoxin 251D through their skin. Alkaloids in the skin glands of poison frogs serve as a chemical defence against predation, and they are therefore able to be active alongside potential predators during the day. About 28 structural classes of alkaloids are known in poison frogs. The most toxic of poison dart frog species is Phyllobates terribilis. It is argued that dart frogs do not synthesize their poisons, but sequester the chemicals from arthropod prey items, such as ants, centipedes and mites – the diet-toxicity hypothesis.

Fire Salamander

The fire salamander (Salamandra salamandra) is possibly the best-known salamander species in Europe. It is black with yellow spots or stripes to a varying degree; some specimens can be nearly completely black while on others the yellow is dominant. Shades of red and orange may sometimes appear, either replacing or mixing with the yellow according to subspecies. Fire salamanders can have a very long lifespan; one specimen lived for more than 50 years in Museum Koenig, a German natural history museum.

Habitat
Fire salamanders live in central Europe forests and are more common in hilly areas. They prefer deciduous forests since they like to hide in fallen leaves and around mossy tree trunks. They need small brooks or ponds with clean water in their habitat for the development of the larvae. Whether on land or in water, fire salamanders are inconspicuous. They spend much of their time hidden under wood or other objects. They are active in the evening and the night, but on rainy days they are active in the daytime as well.

Toxicity
The fire salamander's primary alkaloid toxin, samandarin, causes strong muscle convulsions and hypertension combined with hyperventilation in all vertebrates. The poison glands of the fire salamander are concentrated in certain areas of the body, especially around the head and the dorsal skin surface. The coloured portions of the animal's skin usually coincide with these glands. Compounds in the skin secretions may be effective against bacterial and fungal infections of the epidermis; some are potentially dangerous to human life.

Distribution
Fire salamanders are found in most of southern and central Europe. They are most commonly found at altitudes between 250 metres (820 ft) and 1,000 metres (3,300 ft), only rarely below (in Northern Germany sporadically down to 25 metres (82 ft)). However, in the Balkans or Spain they are commonly found in higher altitudes as well.

Iberian Ribbed Newt

The Iberian ribbed newt or Spanish ribbed newt (Pleurodeles waltl) is a newt endemic to the central and southern Iberian Peninsula and Morocco. It is the largest European newt species and it is also known for its sharp ribs which can puncture through its sides, and as such is also called the sharp-ribbed newt. This species should not be confused with the different species with similar common name, the Iberian newt (Lissotriton boscai). The Iberian ribbed newt has tubercles running down each side. Through these, its sharp ribs can puncture. The ribs act as a defence mechanism, causing little harm to the newt.

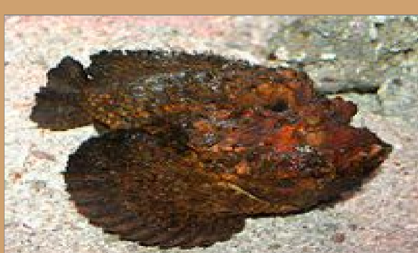
This mechanism could be considered as a primitive and rudimentary system of envenomation, but is completely harmless to humans. At the same time as pushing its ribs out the newt begins to secrete poison from special glands on its body.

The poison coated ribs create a highly effective stinging mechanism, injecting toxins through the thin skin in predator's mouths. The newt's effective immune system and collagen coated ribs mean the pierced skin quickly regrows without infection.

In the wild, this amphibian grows up to 30 cm (12 in), but rarely more than 20 cm (7.9 in) in captivity. Its colour is dark gray dorsally, and lighter gray on its ventral side, with rust-coloured small spots where its ribs can protrude. This newt has a flat, spade-shaped head and a long tail, which is about half its body length. Males are more slender and usually smaller than females. The larvae have bushy external gills and usually paler colour patterns than the adults.

10 Fish

Stonefish



Synanceia is a genus of fish of the family Synanceiidae, the stonefishes, whose members are dangerously venomous and even fatal to humans. It is one of the most venomous fish known. They are found in the coastal regions of the Indo-Pacific.

Habitat
Synanceia are primarily marine, though some species are known to live in rivers. Its species have potent neurotoxins secreted from glands at the base of their needle-like dorsal fin spines which stick up when disturbed or threatened. The vernacular name of the species, the stonefish, derives from its grey and mottled camouflage similar to the colour of a stone. Swimmers may not notice them and inadvertently step on them, triggering a sting. When the stonefish is disturbed, it may inject an amount of venom proportional to the amount of pressure applied to it.
A study published in 2018 reports that stonefish also have the ability to extend a sharp, specialized spine known as a lachrymal saber as an additional defence mechanism.

Treatment
Stonefish stings are extremely painful and potentially lethal. The two most recommended treatments are the application of heat to the affected area, and antivenom. Hot water (at a temperature no higher than 45 °C (113 °F)) applied to the injured area has been found to destroy stonefish venom, and causes minimal discomfort to the victim. Antivenom is used in more extreme cases. Vinegar is found on some Australian beaches as it is said to lessen the pain. The stonefish is one of the most venomous fish in the world and stings can cause death if not treated. Most stonefish stings occur as a result of stepping on the creature which forces venom into the foot, while it is less common for the fish to sting when it is picked up. Stonefish stings can occur on the beach, not just in the water, since stonefish can survive out of the water for up to 24 hours. They are not easily seen as they look similar to rocks or coral. Stonefish antivenom is the second-most administered in Australia.

Lionfishes

Pterois is a genus of venomous marine fish, commonly known as lionfish, native to the Indo-Pacific. Also called zebrafish, firefish, turkeyfish, tastyfish or butterfly-cod, it is characterized by conspicuous warning coloration with red, white, creamy, or black bands, showy pectoral fins, and venomous spiky fin rays. Pterois radiata, Pterois volitans, and Pterois miles are the most commonly studied species in the genus. Pterois species are popular aquarium fish. P. volitans and P. miles are a recent and significant invasive species in the west Atlantic, Caribbean Sea and Mediterranean Sea. Pterois fish in the Atlantic range from 5 to 45 cm (2.0 to 17.7 in) in length, weighing from 0.025 to 1.3 kg (0.055 to 2.866 lb). They are well known for their ornate beauty, venomous spines, and unique tentacles. Juvenile lionfish have a unique tentacle located above their eye sockets that varies in phenotype between species. The evolution of this tentacle is suggested to serve to continually attract new prey; studies also suggest it plays a role in sexual selection.

Interaction
Lionfish are known for their venomous fin rays, an uncommon feature among marine fish in the East Coast coral reefs. The potency of their venom makes them excellent predators and hazardous to fishermen and divers. Pterois venom produced negative inotropic and chronotropic effects when tested in both frog and clam hearts and has a depressing effect on rabbit blood pressure. These results are thought to be due to nitric oxide release. In humans, Pterois venom can cause systemic effects such as extreme pain, nausea, vomiting, fever, breathing difficulties, convulsions, dizziness, redness on the affected area, headache, numbness, paresthesia (pins and needles), heartburn, diarrhoea, and sweating.

Rarely, such stings can cause temporary paralysis of the limbs, heart failure, and even death. Fatalities are common in very young children, the elderly, those with a weak immune system, or those who are allergic to their venom. Their venom is rarely fatal to healthy adults, but some species have enough venom to produce extreme discomfort for a period of several days. However, Pterois venom is a danger to allergic victims as they may experience anaphylaxis, a serious and often life-threatening condition that requires immediate emergency medical treatment. Severe allergic reactions to Pterois venom include chest pain, severe breathing difficulties, a drop in blood pressure, swelling of the tongue, sweating, runny nose, or slurred speech. Such reactions can be fatal if not treated.

Range
The lionfish is a predator native to the Indo-Pacific. It aggressively preys on small fish and invertebrates. They can be found around the seaward edge of reefs and coral, in lagoons, and on rocky surfaces commonly to 50 m deep, although lionfish have on multiple occasions been recorded to 300 m depth. They show a preference for turbid inshore areas and harbours, and have a generally hostile attitude and are territorial towards other reef fish. Many universities in the Indo-Pacific have documented reports of Pterois aggression towards divers and researchers. P. volitans and P. miles are native to subtropical and tropical regions from southern Japan and southern Korea to the east coast of Australia, Indonesia, Micronesia, French Polynesia, and the South Pacific Ocean. P. miles is also found in the Indian Ocean, from Sumatra to Sri Lanka and the Red Sea.

Scorpionfish

Scorpaenidae (also known as the scorpionfish) are a family of mostly marine fish that includes many of the world's most venomous species. As the name suggests, scorpionfish have a type of "sting" in the form of sharp spines coated with venomous mucus. The family is a large one, with hundreds of members. They are widespread in tropical and temperate seas, but mostly found in the Indo-Pacific. They should not be confused with the cabezones, of the genus Scorpaenichthys, which belong to a separate, though related, family, Cottidae. Some types, such as the lionfish, are attractive as well as dangerous, and highly desired for aquaria. In addition to the name scorpionfish, informal names for family members include firefish, turkeyfish, dragonfish, and stingfish, usually with adjectives added. General characteristics of family members include a compressed body, ridges and/or spines on the head, one or two spines on the operculum, and three to five spines on the preopercle. The dorsal fin has 11 to 17 spines, often long and separated from each other, and the pectoral fins are well-developed, with 11 to 25 rays.

The spines of the dorsal, anal, and pelvic fins all have venom glands at their bases. Most species are bottom-dwellers that feed on crustaceans and smaller fish. Many inhabit shallow waters, but a few live as deep as 2,200 m (7,200 ft). Most scorpionfish, such as the stonefish, wait in disguise for prey to pass them by before swallowing, while lionfish often ambush their prey. When not ambushing, lionfish may herd the fish, shrimp, or crab into a corner before swallowing. Like many perciform fishes, scorpionfish are suction feeders that capture prey by rapidly projecting a suction field generated by expansion of the fish's buccal cavity.

Toadfish

Batrachoididae is the only family in the ray-finned fish order Batrachoidiformes. Members of this family are usually called toadfish, or "frogfish": both the English common name and scientific name refer to their toad-like appearance (batrakhos is Greek for frog). Toadfish are benthic ambush predators that favour sandy or muddy substrates where their cryptic coloration helps them avoid detection by their prey. Toadfish are well known for their ability to "sing", males in particular using the swim bladder as a sound-production device used to attract mates. Toadfish are usually scaleless, with eyes set high on large heads.

Their mouths are also large, with both a maxilla and premaxilla, and often decorated with barbels and skin flaps. They are generally drab in colour, although those living on coral reefs may have brighter patterns. They range in size from 7.5 cm (3.0 in) length in Thlassophryne megalops, to 57 cm (22 in) in the Pacuma toadfish.

The gills are small and occur only on the sides of the fish. The pelvic fins are forward of the pectoral fins, usually under the gills, and have one spine with several soft rays. For the two separate dorsal fins, the first is smaller with spines, while the second has from 15 to 25 soft rays. The number of vertebrae range from 25 to 47.

Distribution
Toadfishes are found worldwide. Most toadfish are marine, though some are found in brackish water and one subfamily, the Thalassophryninae, is found exclusively in freshwater habitats in South America. In particular, Daector quadrizonatus and Thalassophryne amazonica are known from the Atrato River in Colombia and the Amazon River, respectively.

Habits
Toadfishes are bottom-dwellers, ranging from near-shore areas to deep waters. They tend to be omnivorous, eating sea worms, crustaceans, mollusks, and other fish. They often hide in rock crevices, among the bottom vegetation, or even dig dens in the bottom sediments, from which they ambush their prey. Toadfish can survive out of water for as long as 24 hours, and some can move across exposed mudflats at low tide using their fins.

Rabbitfishes

Rabbitfishes or spinefoots are perciform fishes in the family Siganidae. The 29 species are in a single genus, Siganus. In some now obsolete classifications, the species having prominent face stripes—colloquially called foxfaces–are in the genus Lo. Other species, such as the masked spinefoot (S. puellus), show a reduced form of the stripe pattern. Rabbitfishes are native to shallow waters in the Indo-Pacific, but S. luridus and S. rivulatus have become established in the eastern Mediterranean via Lessepsian migration.

They are commercially important food fish, and can be used in the preparation of dishes such as bagoong. All rabbitfish have large, dark eyes and small, somewhat rabbit-like mouths, which gives them their name. Most species have either bright colours or a complex pattern. The largest rabbitfish grows to about 53 cm (21 in), but most species only reach between 25 and 35 cm (10 and 14 in).

Another unusual feature among rabbitfishes is their pelvic fins, which are formed from two spines, with three soft rays between them. The dorsal fin bears 13 spines with 10 rays behind, while the anal fin has seven spines and nine rays behind; the fin spines are equipped with well-developed venom glands. The sting is very painful, but it is generally not considered medically significant in healthy adults.

Goblinfish

Glyptauchen panduratus, the goblinfish, is a species of waspfish endemic to the reefs off the southern coast of Australia at depths from 5 to 60 metres (16 to 197 ft). This species grows to a total length of 20 centimetres (7.9 in). This species is the only known member of its genus. The fish has an elongated, compressed body with a distinctive rounded to squarish head, with a 'neck', or notch, between the eyes and dorsal fin.

A large erectile spine occurs on each side below the eyes which are ringed with red, and are the most visible part of the fish. The fins are well developed, the spinous part of dorsal fin is very long and fairly high, and the pectorals are long and wide and may be spread to the sides like fans.

The colouration is cryptic, and is variable from white to grey, reddish-brown, and black. The fish can rapidly adjust its colouration to blend in with the environment. A dark band may be seen across the rear part of the body, with a caudal peduncle and posterior of dorsal and anal fins pale. Whitish patches and small black spots may be scattered on body and fins. The goblinfish has venomous dorsal spines.

Behaviour
The fish is a bottom dweller, generally nocturnal, and does not move around much during the day, so it is not seen very often by divers.

Distribution
It is found in sheltered and moderately exposed coastal reef and rocky areas in estuaries between 3 and 60 m deep near Rottnest Island, Western Australia, to Sydney, New South Wales, and around Tasmania.

Inimicus spp.

Inimicus is a genus of venomous fishes, closely related to the true stonefishes. This genus is a member of the family Synanceiidae (devilfishes, goblinfishes, and stonefishes) of the ray-finned fish order Scorpaeniformes. These benthic fishes are found on sandy or silty substrates of lagoon and seaward reefs, in coastal regions of tropical oceans. The ten described species are collectively known by various common names, including ghoul, goblinfish, sea goblin, spiny devilfish, stinger, and stingfish).

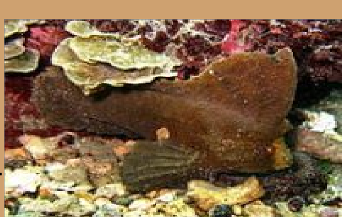
Adults are typically 13-25 centimetres in length, and can weigh up to 480 grams. The body colour can be a dull yellow, gray, brown, or rust in colour with light blotches, and very similar to that of the surrounding sandy or coral seabed in which they are found. This coloration acts as a camouflage which renders them extremely difficult to detect in their natural habitat.

Distribution
Members of the genus Inimicus are distributed mainly in warm tropical waters in the coastal regions of Indo-Pacific oceans. Their range does however extend a little into the subtropical zone. The waters of the Red Sea off the coast of Egypt appear to mark the westernmost limit of their range, while specimens have been reported as far to the east as New Caledonia. The northern coast of New South Wales, Australia marks the southernmost extent of their range, which extends as far to the north as Japan's Aomori, the northernmost prefecture of Japan's main island. Inimicus are benthic fishes, living mainly on the bottom of mangrove swamps and coral reefs, at depths between 5 and 450 meters.

Toxins
Like all known members of the family Synanceiidae, all members of the genus Inimicus possess a complex and extremely potent venom. It is stored in glands at the bases of needle-like spines in their dorsal fins. Upon contact with the dorsal fin, the fish can deliver a very painful, potentially fatal, sting. The venom consists of a mixture of proteolytic enzymes, including stonustoxin (a hemotoxin), trachynilysin (a neurotoxin), and cardioleputin (a cardiotoxin). Envenomation results severe and immediate local pain, sometimes followed by shock, paralysis, tissue necrosis, and even death.

Treatment
Envenomation by Inimicus species is characterized by immediate and severe local pain. Medical aid must be sought at the earliest opportunity after envenomation. Recommended first aid treatment includes immersion of the affected area in hot water. Immersing the injured area in water at a temperature of at least 45 °C (113 °F) can partially denature the proteolytic enzymes in the venom. Some relief can also be obtained by infiltrating the envenomation site with a local anesthetic. For more extreme cases, an intramuscular injection of a specific horse-derived antivenom can be lifesaving. Tetanus toxoid vaccine should also be administered, if indicated. Surviving victims often suffer localized tissue necrosis and nerve damage, leading to atrophy of adjoining muscle tissues.

Cockatoo Waspfish



Ablabys taenianotus, the Cockatoo waspfish, is a small fish species that belongs to the scorpionfishes family Scorpaenidae. This fish can be up to 6 inches (15 cm) in length. The body compressed laterally, endowed with a dorsal fin starting from the top of the head until joining practically the superior base of the caudal fin. When the dorsal fin is spread, it looks like a crest resembling the one on a cockatoo. The thorns of the dorsal fin are venomous. This fish mostly stays on the substratum and moves by means of its pectoral fins. Its colour varies from cream to dark brown, with irregular spots.

Distribution
This species occurs in the tropical West Pacific Ocean, from Malaysia to Japan and from Indonesia to Australia. Ablabys taenianotus lives at depths from 2 to 60 ft (1 to 18 m) on sandy, silty or rubble bottoms, and also in fields of sea grass Zosteraceae.

Behaviour
This species is benthic and nocturnal. It is an opportunistic predator and ambushes passing prey while mimicking a crumpled, dead leaf or a drifting piece of seaweed. It allows itself to drift with the moving water in the way that an inert object would do. It may be found singly or in pairs. The fish feeds on small shrimp and other tiny crustaceans that pass near its mouth.

Striped Blenny

Meiacanthus grammistes the striped blenny, also called the striped fang blenny, grammistes blenny, line-spot harptail blenny or striped poison-fang blenny, is a species of combtooth blenny from the western Pacific Ocean. The fish stays in the open ocean, but travels into shallow saltwater and brackish estuaries. This venomous species occasionally makes its way into the aquarium trade.

Venom
The unusual venom, which targets the body's opioid receptors, is being investigated as a potential new painkiller for human use. The venom consists of a neuropeptide also seen in cone snail venom, a lipase similar to the one used by certain species of scorpions and an opioid peptide. Blennies use it to stun predators. The venom reduces the blood pressure of the predator, relaxing its jaws so the blenny can escape. Administration of the venom was found to not cause pain in mice, which is atypical, as most fish venoms are painful. Administration of the venom also did not result in a drop in heart rate in rats.

Stargazers

The stargazers are a family, Uranoscopidae, of perciform fish that have eyes on top of their heads (hence the name). The family includes about 51 species (one extinct) in eight genera, all marine and found worldwide in shallow and deep saltwaters. In addition to the top-mounted eyes, a stargazer also has a large, upward-facing mouth in a large head. Their usual habit is to bury themselves in sand, and leap upwards to ambush prey (benthic fish and invertebrates) that pass overhead.

Some species have a worm-shaped lure growing out of the floors of their mouths, which they can wiggle to attract prey's attention. Both the dorsal and anal fins are relatively long; some lack dorsal spines. Lengths range from 18 up to 90 cm, for the giant stargazer Kathetostoma giganteum. Stargazers are venomous; they have two large venomous spines situated behind their opercles and above their pectoral fins. The species within the genera Astroscopus and Uranoscopus can also cause electric shocks.

Astroscopus species have a single electric organ consisting of modified eye muscles, while Uranoscopus species have theirs derived from sonic muscles. These two genera within stargazers are out of eight total independent evolutions of bioelectrogenesis. They are also unique among electric fish in not possessing specialized electroreceptors.

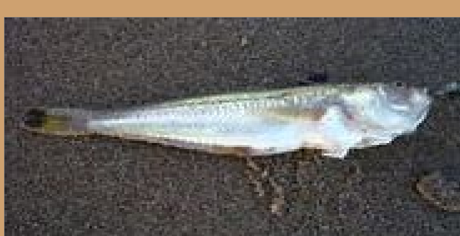
Venom
The unusual venom, which targets the body's opioid receptors, is being investigated as a potential new painkiller for human use. The venom consists of a neuropeptide also seen in cone snail venom, a lipase similar to the one used by certain species of scorpions and an opioid peptide. Blennies use it to stun predators. The venom reduces the blood pressure of the predator, relaxing its jaws so the blenny can escape. Administration of the venom was found to not cause pain in mice, which is atypical, as most fish venoms are painful. Administration of the venom also did not result in a drop in heart rate in rats.

Chimaeras

Chimaeras are cartilaginous fish in the order Chimaeriformes, known informally as ghost sharks, rat fish, spookfish or rabbit fish; the latter three names are not to be confused with rattails, Opisthoproctidae or Siganidae, respectively. At one time a "diverse and abundant" group (based on the fossil record), their closest living relatives are sharks, though their last common ancestor with sharks lived nearly 400 million years ago. Today, they are largely confined to deep water. Chimaeras live in temperate ocean floors down to 2,600 m (8,500 ft) deep, with few occurring at depths shallower than 200 m (660 ft).

Exceptions include the members of the genus Callorhinchus, the rabbit fish and the spotted ratfish, which locally or periodically can be found at relatively shallow depths. Consequently, these are also among the few species from the Chimaera order kept in public aquaria. They have elongated, soft bodies, with a bulky head and a single gill-opening. They grow up to 150 cm (4.9 ft) in length, although this includes the lengthy tail found in some species. In many species, the snout is modified into an elongated sensory organ.

Weevers



Weevers (or weeverfish) are nine extant species of fishes of family Trachinidae, order Trachiniformes, part of the Percomorpha clade. They are long (up to 37 cm), mainly brown in colour, and have venomous spines on their first dorsal fins and gills. During the day, weevers bury themselves in sand, just showing their eyes, and snatch prey as it comes past, which consists of shrimp and small fish.

Weevers are unusual in not having swim bladders, as do most bony fish, and as a result, sink as soon as they stop actively swimming. With the exception of T. cornutus from the southeast Pacific, all species in this family are restricted to the eastern Atlantic (including the Mediterranean). A tenth, extinct species, Callipterus speciosus, is known from the Monte Bolca lagerstätte of the Lutetian epoch.

Distribution
The lesser weever can be found from the southern North Sea to the Mediterranean, and is common around the south coast of the United Kingdom and Ireland, the Atlantic coast of France, Portugal and Spain, and the northern coast of the Mediterranean. The high number of bathers found on popular tourist beaches in these areas means stings are common, although individual chances of being stung are low. The South Wales Evening Post stated (on 8 August 2000) that around 40 weever stings are recorded in the Swansea and Gower area every year, but many victims do not seek medical assistance and go uncounted.

Interaction
Most human stings are inflicted by the lesser weever, which habitually remains buried in sandy areas of shallow water and is thus more likely to come into contact with bathers than other species (such as the greater weever, which prefers deeper water); stings from other species are generally limited to anglers and commercial fishermen. Even very shallow water (sometimes little more than damp sand) may harbour lesser weevers. The vast majority of injuries occur to the foot and are the result of stepping on buried fish; other common sites of injury are the hands and buttocks. Stings are most common in the hours before and after low tide (especially at springs), so one possible precaution is to avoid bathing or paddling at these times. They also increase in frequency during the summer (to a maximum in August), but this is probably the result of the greater number of bathers.

Symptoms
At first, many victims believe they have simply scratched themselves on a sharp stone or shell, although this barely hurts; significant pain begins about 2–3 minutes after being stung. Weever stings cause severe pain; common descriptions from victims are "extremely painful" and "much worse than a wasp (or bee) sting". Common and minor symptoms include severe pain, itching, swelling, heat, redness, numbness, tingling, nausea, vomiting, joint aches, headaches, abdominal cramps, lightheadedness, increased urination, and tremors. Rare and severe symptoms include abnormal heart rhythms, weakness, shortness of breath, seizures, decreased blood pressure, gangrene, tissue degeneration, and unconsciousness.

Treatment
Although extremely unpleasant, weever stings are not generally dangerous and the pain will ease considerably within a few hours even if untreated. Complete recovery may take a week or more; in a few cases, victims have reported swelling and/or stiffness persisting for months after envenomation. First aid treatment consists of immersing the affected area in hot water (as hot as the victim can tolerate without being scalded), which will accelerate denaturation of the protein-based venom. The use of hot water will reduce the pain felt by the victim after a few minutes. Usual experience is that the pain then fades within 10 to 20 minutes, as the water cools. Folklore often suggests the addition of substances to the hot water, including urine, vinegar, and Epsom salts, but this is of limited (if any) value. Heat should be applied for at least 15 minutes, but the longer the delay (before heat is applied), the longer the treatment should be continued. Once the pain has eased, the injury should be checked for the remains of broken spines, and any found need to be removed. Over-the-counter analgesics, such as aspirin or ibuprofen, may be of assistance in management of pain and can also reduce edema.

Dogfish Sharks

The Squalidae, also called dogfish sharks or spiny dogfishes, are a family of sharks in the order Squaliformes. They have two dorsal fins, each with smooth spines, but no anal fin, and their skin is generally rough to the touch. Unlike virtually all other shark species, dogfish sharks possess venom which coats their dorsal spines – this venom is mildly toxic to humans. These sharks are characterized by teeth in upper and lower jaws similar in size; a caudal peduncle with lateral keels; the upper precaudal pit usually is present; and the caudal fin is without a subterminal notch. They are carnivorous, principally preying upon organisms smaller than themselves. The livers and stomachs of the Squalidae contain the compound squalamine, which possesses the property of reduction of small blood vessel growth in humans. Two genera are known: Squalus, which contains numerous species, and Cirrhigaleus, which has three species.

Stingrays

Stingrays are a group of sea rays, which are cartilaginous fish related to sharks. Many species are endangered. They are classified in the suborder Myliobatoidei of the order Myliobatiformes and consist of eight families: Hexatrygonidae (sixgill stingray), Plesiobatidae (deepwater stingray), Urolophidae (stingarees), Urotrygonidae (round rays), Dasyatidae (whiptail stingrays), Potamotrygonidae (river stingrays), Gymnuridae (butterfly rays), and Myliobatidae (eagle rays). Stingrays are common in coastal tropical and subtropical marine waters throughout the world.

Some species, such as Dasyatis thetidis, are found in warmer temperate oceans, and others, such as Plesiobatis daviesi, are found in the deep ocean. The river stingrays, and a number of whiptail stingrays (such as the Niger stingray), are restricted to fresh water. Most myliobatoids are demersal (inhabiting the next-to-lowest zone in the water column), but some, such as the pelagic stingray and the eagle rays, are pelagic.

There are about 220 known stingray species organized into 10 families and 29 genera. Stingray species are progressively becoming threatened or vulnerable to extinction, particularly as the consequence of unregulated fishing. As of 2013, 45 species have been listed as vulnerable or endangered by the IUCN. The status of some other species is poorly known, leading to their being listed as data deficient.

Injuries
Stingrays are not usually aggressive and attack humans only when provoked, as when a ray is accidentally stepped on. Contact with the stinger causes local trauma (from the cut itself), pain, swelling, muscle cramps from the venom, and later may result in infection from bacteria or fungi. The injury is very painful, but seldom life-threatening unless the stinger pierces a vital area. The barb usually breaks off in the wound, and surgery may be required to remove the fragments. Fatal stings are very rare. The death of Steve Irwin in 2006 was only the second recorded in Australian waters since 1945. The stinger penetrated his thoracic wall, causing massive trauma.

Venom
The venom of the stingray has been relatively unstudied due to the mixture of venomous tissue secretions cells and mucous membrane cell products that occurs upon secretion from the spinal blade. Stingrays can have anywhere between one and three blades. The spine is covered with the epidermal skin layer. During secretion, the venom punctures through the epidermis and mixes with the mucus to release the venom on its victim. Typically, other venomous organisms create and store their venom in a gland.

The stingray is notable in that it stores its venom within tissue cells. The toxins that have been confirmed to be within the venom are cystatins, peroxiredoxin, and galectin. Galectin induces cell death in its victims and cystatins inhibit defence enzymes. In humans, these toxins lead to increased blood flow in the superficial capillaries and cell death. Despite the number of cells and toxins that are within the stingray, there is little relative energy required to produce and store the venom. The venom is produced and stored in the secretory cells of the vertebral column at the mid-distal region.

These secretory cells are housed within the ventrolateral grooves of the spine. The cells of both marine and freshwater stingrays are round and contain a great amount of granule-filled cytoplasm. The cells of marine stingrays are located only within these lateral grooves of the stinger. The cells of freshwater stingray branch out beyond the lateral grooves to cover a larger surface area along the entire blade. Due to this large area and an increased number of proteins within the cells, the venom of freshwater stingrays has a greater toxicity than that of marine stingrays.

Estuary Cobbler (Catfish)

Cnidoglanis macrocephalus is a species of catfish (order Siluriformes) of the family Plotosidae, and is the only species of the genus Cnidoglanis. It is commonly known as the cobbler, estuary cobbler, deteira, estuary catfish, South Australian catfish, or Swan River catfish. Like other eeltail catfish, the cobbler resembles a catfish in front, but an eel behind. It can grow up to 91.0 centimetres (35.6 in) SL, 2,500 grams (5.5 lb). They may live up to 13 years. The dorsal and pectoral fins have sharp, venomous spines that can inflict painful wounds.

Distribution
The cobbler is found from Main Beach, Queensland to Jervis Bay, New South Wales, and Kingston SE, South Australia to Houtman Abrolhos Islands, Western Australia and Duck River, Tasmania, in near-shore and reef habitats.

Treatment
Treatment of injuries by submersion of the wound in hot water is suggested though the role of heat in denaturation of toxins is debated. However, despite this study, hot water immersion is still the recommended first aid treatment for envenomation.

Ecology
The estuary cobbler is an inshore marine species which lives in shallow bays and sandy inlets near river mouths. It is found most frequently over sand, rocks and weeds in clear to turbid waters. By day, the estuary cobbler are most often found in holes and on ledges in banks. Estuary cobblers stay in holes and under ledges during the day, then come out at night to feed. They are opportunistic feeders, primarily feed on molluscs, crustaceans (prawns and amphipods), polychaete worms, algae, and organic debris.

Striped Eel Catfish

Plotosus lineatus, common name striped eel catfish, is a species of eeltail catfishes belonging to the family Plotosidae. Plotosus lineatus can reach a maximum length of 32 cm (13 in). The body is brown with cream-colored or white longitudinal bands.

The most striking feature of this species is in the fins, in fact the second dorsal, caudal and anal are fused together as in eels. In the rest of the body is quite similar to a freshwater catfish: the mouth is surrounded by four pairs of barbels, four on the upper jaw and four on the lower jaw. The first dorsal and each of the pectoral fins have a highly venomous spine. They may even be fatal.

Distribution
P. lineatus occurs in the Indian Ocean, in the western Pacific Ocean and sometimes enters freshwaters in East Africa and Madagascar. The species now also occurs in the Mediterranean, having invaded as a Lessepsian migrant through the Suez Canal. P. lineatus is found in coral reefs; it is also found in estuaries, tide pools and open coasts.

11 Cephalopods

Blue-Ringed Octopus

Blue-ringed octopuses, comprising the genus Hapalochlaena, are four highly venomous species of octopus that are found in tide pools and coral reefs in the Pacific and Indian oceans, from Japan to Australia. They can be identified by their yellowish skin and characteristic blue and black rings that change colour dramatically when the animal is threatened. They eat small animals, including crabs, hermit crabs, shrimp, and other crustaceans.

They are recognized as one of the world's most venomous marine animals. Despite their small size—12 to 20 cm (5 to 8 in)—and relatively docile nature, they are dangerous to humans if provoked and handled because of their venom, which contains the powerful neurotoxin tetrodotoxin.

Behaviour
Blue-ringed octopuses spend most of their time hiding in crevices while displaying effective camouflage patterns with their dermal chromatophore cells. Like all octopus, they can change shape easily, which helps them to squeeze into crevices much smaller than themselves. This, along with piling up rocks outside the entrance to its lair, helps safeguard the octopus from predators. If they are provoked, they quickly change colour, becoming bright yellow with each of the 50-60 rings flashing bright iridescent blue within a third of a second as an aposematic warning display. In the greater blue-ringed octopus (Hapalochlaena lunulata), the rings contain multi-layer light reflectors called iridophores. These are arranged to reflect blue–green light in a wide viewing direction. Beneath and around each ring there are dark pigmented chromatophores which can be expanded within 1 second to enhance the contrast of the rings. There are no chromatophores above the ring, which is unusual for cephalopods as they typically use chromatophores to cover or spectrally modify iridescence. The fast flashes of the blue rings are achieved using muscles which are under neural control. Under normal circumstances, each ring is hidden by contraction of muscles above the iridophores. When these relax and muscles outside the ring contract, the iridescence is exposed thereby revealing the blue colour.

Toxicity
The blue-ringed octopus, despite its small size, carries enough venom to kill twenty-six adult humans within minutes. Their bites are tiny and often painless, with many victims not realizing they have been envenomated until respiratory depression and paralysis start to set in. As of 2018 no blue-ringed octopus antivenom is available.

Venom
The octopus produces venom containing tetrodotoxin, histamine, tryptamine, octopamine, taurine, acetylcholine and dopamine. The venom can result in nausea, respiratory arrest, heart failure, severe and sometimes total paralysis, blindness, and can lead to death within minutes if not treated. Death, if it occurs, is usually from suffocation due to paralysis of the diaphragm. The major neurotoxin component of the blue-ringed octopus is a compound that was originally known as maculotoxin but was later found to be identical to tetrodotoxin, a neurotoxin also found in pufferfish, and in some poison dart frogs. Tetrodotoxin is 1,200 times more toxic than cyanide. Tetrodotoxin blocks sodium channels, causing motor paralysis, and respiratory arrest within minutes of exposure. The tetrodotoxin is produced by bacteria in the salivary glands of the octopus. Direct contact is necessary to be envenomated. Faced with danger, the octopus's first instinct is to flee. If the threat persists, the octopus will go into a defensive stance, and show its blue rings. If the octopus is cornered, and touched, the person would be in danger of being bitten and envenomated.

Effects
Tetrodotoxin causes severe and often total body paralysis. Tetrodotoxin envenomation can result in victims being fully aware of their surroundings but unable to move. Because of the paralysis that occurs, they have no way of signalling for help or any way of indicating distress. The victim remains conscious and alert in a manner similar to curare or pancuronium bromide. This effect, however, is temporary and will fade over a period of hours as the tetrodotoxin is metabolized and excreted by the body.

Treatment
First aid treatment is pressure on the wound and artificial respiration once the paralysis has disabled the victim's respiratory muscles, which often occurs within minutes of being bitten. Because the venom primarily kills through paralysis, victims are frequently saved if artificial respiration is started and maintained before marked cyanosis and hypotension develop. Efforts should be continued even if the victim appears not to be responding. Respiratory support until medical assistance arrives will improve the victim's chances of survival. It is essential that rescue breathing be continued without pause until the paralysis subsides and the victim regains the ability to breathe on their own. This is a daunting physical prospect for a single individual, but use of a bag valve mask respirator reduces fatigue to sustainable levels until help can arrive. Definitive hospital treatment involves placing the patient on a medical ventilator until the toxin is removed by the body. Victims who survive the first twenty-four hours usually recover completely.

12 Cnidarians

Jellyfish

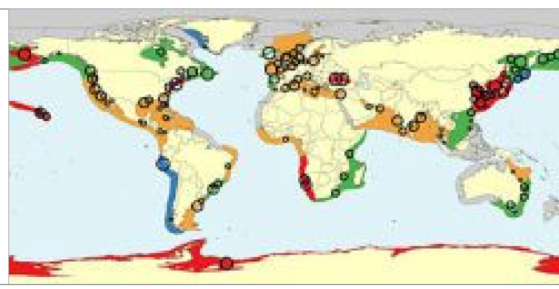
Jellyfish or sea jellies are the informal common names given to the medusa-phase of certain gelatinous members of the subphylum Medusozoa, a major part of the phylum Cnidaria. Jellyfish are mainly free-swimming marine animals with umbrella-shaped bells and trailing tentacles, although a few are not mobile, being anchored to the seabed by stalks. The bell can pulsate to provide propulsion and highly efficient locomotion. The tentacles are armed with stinging cells and may be used to capture prey and defend against predators. Jellyfish have a complex life cycle; the medusa is normally the sexual phase, the planula larva can disperse widely and is followed by a sedentary polyp phase. Jellyfish are found all over the world, from surface waters to the deep sea. Scyphozoans (the "true jellyfish") are exclusively marine, but some hydrozoans with a similar appearance live in freshwater. Large, often colourful, jellyfish are common in coastal zones worldwide. The medusae of most species are fast growing, mature within a few months and die soon after breeding, but the polyp stage, attached to the seabed, may be much more long-lived.

Anatomy
The main feature of a true jellyfish is the umbrella-shaped bell. This is a hollow structure consisting of a mass of transparent jelly-like matter known as mesoglea, which forms the hydrostatic skeleton of the animal. 95% or more of the mesogloea (the tissue that functions as a hydro-static skeleton) consists of water, but it also contains collagen and other fibrous proteins, as well as wandering amoebocytes which can engulf debris and bacteria. The mesogloea is bordered by the epidermis on the outside and the gastrodermis on the inside. The edge of the bell is often divided into rounded lobes known as lappets, which allow the bell to flex. In the gaps or niches between the lappets are dangling rudimentary sense organs known as rhopalia, and the margin of the bell often bears tentacles.

Size
Jellyfish range from about one millimetre in bell height and diameter, to nearly 2 metres (6.6 ft) in bell height and diameter; the tentacles and mouth parts usually extend beyond this bell dimension. The smallest jellyfish are the peculiar creeping jellyfish in the genera Staurocladia and Eleutheria, which have bell disks from 0.5 millimetres (0.02 in) to a few millimetres in diameter, with short tentacles that extend out beyond this, which these jellyfish use to move across the surface of seaweed or the bottoms of rocky pools.

Map of population trends of native and invasive jellyfish. Circles represent data records; larger circles denote higher certainty of findings.

Red - High Certainty
Yellow - Low Certainty
Green - Stable
Blue - Decrease
Grey - No Data



Habitats
Most jellyfish are marine animals, although a few hydromedusae inhabit freshwater. The best known freshwater example is the cosmopolitan hydrozoan jellyfish, Craspedacusta sowerbii. It is less than an inch (2.5 cm) in diameter, colourless and does not sting. Some jellyfish populations have become restricted to coastal saltwater lakes, such as Jellyfish Lake in Palau. Jellyfish Lake is a marine lake where millions of golden jellyfish (Mastigias spp.) migrate horizontally across the lake daily. Although most jellyfish live well off the ocean floor and form part of the plankton, a few species are closely associated with the bottom for much of their lives and can be considered benthic. The upside-down jellyfish in the genus Cassiopea typically lie on the bottom of shallow lagoons where they sometimes pulsate gently with their umbrella top facing down.

Parasites
Jellyfish are hosts to a wide variety of parasitic organisms. They act as intermediate hosts of endoparasitic helminths, with the infection being transferred to the definitive host fish after predation. Some digenean trematodes, especially species in the family Lepocreadiidae, use jellyfish as their second intermediate hosts. Fish become infected by the trematodes when they feed on infected jellyfish.

Stings
Jellyfish are armed with nematocysts. Contact with a jellyfish tentacle can trigger millions of nematocysts to pierce the skin and inject venom, but only some species' venom causes an adverse reaction in humans. The effects of stings range from mild discomfort to extreme pain and death. Most jellyfish stings are not deadly, but stings of some box jellyfish (Irukandji jellyfish), such as the sea wasp, can be deadly. Stings may cause anaphylaxis (a form of shock), which can be fatal. Jellyfish kill 20 to 40 people a year in the Philippines alone. In 2006 the Spanish Red Cross treated 19,000 stung swimmers along the Costa Brava. Vinegar (3–10% aqueous acetic acid) may help with box jellyfish stings, but not the stings of the Portuguese man o' war.

Salt water may help if vinegar is unavailable. Rubbing wounds, or using alcohol, ammonia, fresh water, or urine is not advised as they can encourage the release of more venom. Clearing the area of jelly and tentacles reduces nematocyst firing. Scraping the affected skin, such as with the edge of a credit card, may remove remaining nematocysts. Once the skin has been cleaned of nematocysts, hydrocortisone cream applied locally reduces pain and inflammation. Antihistamines may help to control itching. Immunobased antivenins are used for serious box jellyfish stings.

Hydrozoans

Hydrozoa are a taxonomic class of individually very small, predatory animals, some solitary and some colonial, most living in salt water. The colonies of the colonial species can be large, and in some cases the specialized individual animals cannot survive outside the colony.

A few genera within this class live in fresh water. Hydrozoans are related to jellyfish and corals and belong to the phylum Cnidaria. Some examples of hydrozoans are the freshwater jelly (Craspedacusta sowerbyi), freshwater polyps (Hydra), Obelia, Portuguese man o' war (Physalia physalis), chondrophores (Porpitidae), "air fern" (Sertularia argentea), and pink-hearted hydroids (Tubularia).

Sea Anemones

Sea anemones are a group of marine, predatory animals of the order Actiniaria. As cnidarians, sea anemones are related to corals, jellyfish and Hydra. A typical sea anemone is a single polyp attached to a hard surface by its base, but some species live in soft sediment and a few float near the surface of the water. The polyp has a columnar trunk topped by an oral disc with a ring of tentacles and a central mouth. The tentacles can be retracted inside the body cavity or expanded to catch passing prey. They are armed with cnidocytes (stinging cells).

In many species, additional nourishment comes from a symbiotic relationship with single-celled dinoflagellates, zooxanthellae or with green algae, zoochlorellae, that live within the cells. Some species of sea anemone live in association with hermit crabs, small fish or other animals to their mutual benefit. Sea anemones breed by liberating sperm and eggs through the mouth into the sea.

The resulting fertilized eggs develop into planula larvae which, after being planktonic for a while, settle on the seabed and develop directly into juvenile polyps. Sea anemones also breed asexually, by breaking in half or into smaller pieces which regenerate into polyps. Sea anemones are sometimes kept in reef aquariums; the global trade in marine ornamentals for this purpose is expanding and threatens sea anemone populations in some localities, as the trade depends on collection from the wild.

Habitats
Sea anemones are found in both deep oceans and shallow coastal waters worldwide. The greatest diversity is in the tropics although there are many species adapted to relatively cold waters. The majority of species cling on to rocks, shells or submerged timber, often hiding in cracks or under seaweed, but some burrow into sand and mud, and a few are pelagic.

Coral

Corals are marine invertebrates within the class Anthozoa of the phylum Cnidaria. They typically live in compact colonies of many identical individual polyps. Corals species include the important reef builders that inhabit tropical oceans and secrete calcium carbonate to form a hard skeleton. A coral "group" is a colony of myriad genetically identical polyps. Each polyp is a sac-like animal typically only a few millimetres in diameter and a few centimetres in length. A set of tentacles surround a central mouth opening. An exoskeleton is excreted near the base.

Over many generations, the colony thus creates a large skeleton characteristic of the species. Individual heads grow by asexual reproduction of polyps. Corals also breed sexually by spawning: polyps of the same species release gametes simultaneously over a period of one to several nights around a full moon.

Although some corals are able to catch small fish and plankton using stinging cells on their tentacles, most corals obtain the majority of their energy and nutrients from photosynthetic unicellular dinoflagellates in the genus Symbiodinium that live within their tissues. These are commonly known as zooxanthellae. Such corals require sunlight and grow in clear, shallow water, typically at depths less than 60 metres (200 ft).

Soft Corals
In soft corals, there is no stony skeleton but the tissues are often toughened by the presence of tiny skeletal elements known as sclerites, which are made from calcium carbonate. Soft corals are very variable in form and most are colonial. A few soft corals are stolonate, but the polyps of most are connected by sheets of coenosarc. In some species this is thick and the polyps are deeply embedded. Some soft corals are encrusting or form lobes. Others are tree-like or whip-like and have a central axial skeleton embedded in the tissue matrix. This is composed either of a fibrous protein called gorgonin or of a calcified material. In both stony and soft corals, the polyps can be retracted, with stony corals relying on their hard skeleton and cnidocytes for defence against predators, and soft corals generally relying on chemical defences in the form of toxic substances present in the tissues known as terpenoids.

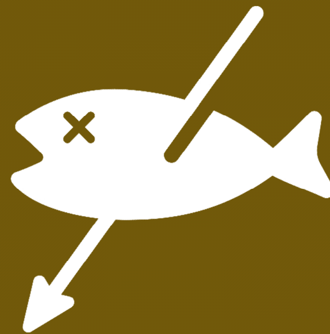
Stony Corals
The polyps of stony corals have six-fold symmetry while those of soft corals have eight. The mouth of each polyp is surrounded by a ring of tentacles. In stony corals these are cylindrical and taper to a point, but in soft corals they are pinnate with side branches known as pinnules. In some tropical species these are reduced to mere stubs and in some they are fused to give a paddle-like appearance. In most corals, the tentacles are retracted by day and spread out at night to catch plankton and other small organisms. Shallow water species of both stony and soft corals can be zooxanthellate, the corals supplementing their plankton diet with the products of photosynthesis produced by these symbionts. The polyps interconnect by a complex and well-developed system of gastrovascular canals, allowing significant sharing of nutrients and symbionts.

3 Dangerous Animals

These are animals which aren't poisonous but can kill you or cause severe damage to you.

Bear

Shark



Hunting

How to track, hunt and trap any type of animal

"The hunter that travels out into the woods is lost to the world, yet finds themself."
Unknown

Introduction

Hunting details the different types of methods you can use to track and capture wild animals.

Purpose	The aim of HUNTING is to expose the reader to a wide range of techniques to catch, collect, trap and kill animals humanely in preparation for field dressing and eventual consumption.
Lost?	• For a list of animal tracks, see the ANIMALS section. • If you want to prepare a captured animal for consumption, head to the FIELD DRESSING section. • For the hunting of fish, see the FISHING section. • If you're injured by a wild animal or insect, head to the INJURY > Animal & Plant section. • For raising tame animals, see the ANIMAL HUSBANDRY section.

Contents

1 Hunting Types

Quickly summarises the different forms of hunting which are discussed in more detail below.

Baiting	The use of decoys, lures, scent or food to attract targeted animals.
Blind or Stand Hunting	Waiting for animals in a concealed or elevated position.

Calling	The use of noises to attract or drive animals.
Camouflage	Concealing oneself visually, or with scent, to blend in with the environment.
Dogs	Used to help flush, herd, drive, track, point at, pursue, or retrieve animals.
Game Drive System	Prehistoric hunting strategy where game were herded into areas where they could be hunted in groups.
Driving	The herding of animals in a particular direction, as over a cliff or to other hunters.
Flushing	The practice of scaring targets from concealed areas.
Spotlighting	The use of artificial light to find or blind targets before capture. Modern lighting also includes IR and other devices.
Scouting	Consists of a variety of tasks and techniques for finding animals to hunt.
Stalking	The practice of walking stealthily, often in pursuit of an identified animal.
Tracking	The practice of interpreting physical evidence to pursue animals.
Trapping	The use of devices (e.g., snares, pits, deadfalls) to capture or kill an animal.

2 Baiting

The use of decoys, lures, scent or food to attract targeted animals. E.g. in a mousetrap.

3 Blind/Stand Hunting

Waiting for animals in a concealed or elevated position.

4 Calling

The use of noises to attract or drive animals.

5 Camouflage

Concealing oneself visually, or with scent, to blend in with the environment.

6 Dogs

Used to help flush, herd, drive, track, point at, pursue, or retrieve animals.

7 Game Drive System

Prehistoric hunting strategy where game were herded into areas where they could be hunted in groups.

8 Driving

The herding of animals in a particular direction, as over a cliff or to other hunters.

9 Flushing

The practice of scaring targets from concealed areas.

10 Spotlighting

The use of artificial light to find or blind targets before capture. Modern lighting also includes IR and other devices.

11 Scouting

Consists of a variety of tasks and techniques for finding animals to hunt.

12 Stalking

The practice of walking stealthily, often in pursuit of an identified animal.

13 Tracking

The practice of interpreting physical evidence to pursue animals.

Animal Tracks

Below are images of different animals tracks in the ground for identification purposes.

	Armadillo	Badger	Black Bear	Beaver	-
Track Identification					

Scat Identification

14 Trapping

The use of devices (e.g., snares, pits, deadfalls) to capture or kill an animal.

Trapping

Leg-hold Traps	
Body Gripping Traps	
Deadfall Traps	
Snares	Use brass wire, fishing wire or string for the best traps.
Trapping Pit	
Cage Traps	
Glue Trap	

Spring Traps

Gin Trap	A Gin Trap is mechanical device designed to catch an animal by the leg using spring operated jaws either with or without a serrated edge or teeth. They come in a variety of shapes and sizes.
Fenn Trap	Fenn Traps are the most popular spring trap used by gamekeepers. Sometimes referred to as Solway Spring Trap, they come in two sizes, MK4 or MK6. It is an offence to set any spring trap in the open.
Body Grip	

Kania Trap 2000	
Scissor Style Mole Trap	

Cage Traps

Fox Cage	

Bird Cage Traps

Larsen Trap	
Multi-Trap	

15 Killing

Techniques for the humane killing of animals while hunting.

Fishing

Fishing tips for any style, weather condition or region

"There is a fine line between fishing and just standing on the shore like an idiot."
Steven Wright

Introduction

This section contains advice on how to fish with different equipment and climates.

Purpose	The aim of FISHING is to provide details into the various ways you can catch sea-life, from rod fishing to spearfishing to netting. It concludes with the various conditions that can affect your ability to catch fish such as the weather or time of day.
Lost?	• If you're injured by a wild fish, head to the INJURY > Animal & Plant section. • For the care of tame fish in an agricultural system, see the GARDENING > Permaculture section. • For the continual harvesting of fish for food at home, see the ANIMAL HUSBANDRY section. • For information on cooking fish, see the COOKING section. • For a list of dangerous sea creatures, see the ANIMALS section. • For information on waves and tides, see the SURVIVAL section.

Contents

1 Fishing Types

These are the different types to catch fish.

Hand-Gathering

It is possible to harvest sea foods with minimal equipment by using the hands. Gathering seafood by hand can be as easy as picking shellfish or kelp up off the beach, or doing some digging for clams or crabs.

Flounder Tramping

Every August, the small Scottish village of Palnackie hosts the world flounder tramping championships where flounder are captured by stepping on them.

Noodling

The noodler places his hand inside a catfish hole. If all goes as planned, the catfish swims forward and latches onto the noodler's hand, and can then be dragged out of the hole.

Pearl Divers

Traditionally harvested oysters by free-diving to depths of thirty metres. Today, free-diving recreational fishers catch lobster and abalone by hand.

Trout Binning

Another method of taking trout. Rocks in a rocky stream are struck with a sledgehammer. The force of the blow stuns the fish.

Trout Tickling

In the British Isles, the practice of catching trout by hand is known as trout tickling.

Spearfishing

Spearfishing is an ancient method of fishing conducted with an ordinary spear or a specialised variant such as a harpoon, trident, arrow or eel spear. Some fishing spears use slings (or rubber loops) to propel the spear.

Bowfishing

Uses a bow and arrow to kill fish in shallow water from above.

Gigging

Uses small trident type spears with long handles for gigging bullfrogs with a bright light at night, or for gigging suckers and other rough fish in shallow water.

Hawaiian Slings

Have a sling separate from the spear, in the manner of an underwater bow and arrow.

Harpoons

Spearfishing with barbed poles was widespread in palaeolithic times.

Pike Pole Fishing

In the past, pike poles were used for ice fishing. Fisherman in large numbers put pike poles into ice holes in places known for big fish to crowd, so that a dense forest is made of pike poles. When drifting fish hits a pole, a fisherman feels this and pulls the catch out.

Polespears

Have a sling attached to the spear.

Modern Spearguns

Traditional spearfishing is restricted to shallow waters, but the development of the speargun has made the method much more efficient. With practice, divers are able to hold their breath for up to four minutes and sometimes longer.

Tridents

Three-pronged spears. They are also called leisters or gigs. They are used for spear fishing and were formerly also a military weapon.

Netting

Fishing nets are meshes usually formed by knotting a relatively thin thread.

Cast Nets

Round nets with small weights distributed around the edge. They are also called throw nets. The net is caste or thrown by hand in such a manner that it spreads out on the water and sinks. Fish are caught as the net is hauled back in.

Drift Nets

Nets which are not anchored. They are usually gillnets, and are commonly used in the coastal waters of many countries.

Gillnets

Catch fish which try to pass through by snagging on the gill covers. Trapped, the fish can neither advance through the net nor retreat.

Hand Nets

Are small nets held open by a hoop. They have been used since antiquity. They are also called scoop nets, and are used for scooping up fish near the surface of the water.

Seine Nets

Are large fishing nets that can be arranged in different ways. In purse seining fishing the net hangs vertically in the water by attaching weights along the bottom edge and floats along the top.

Surrounding Net

A surrounding net is a fishing net which surrounds fish and other aquatic animals on the sides and underneath. It is typically used by commercial fishers, and pulled along the surface of the water. There is typically a purse line at the bottom, which is closed when the net is hauled in.

Tangle Nets

Also known as tooth nets, are similar to gillnets except they have a smaller mesh size designed to catch fish by the teeth or upper jaw bone instead of by the gills.

Trawl Nets

Large nets, conical in shape, designed to be towed in the sea or along the sea bottom. The trawl is pulled through the water by one or more boats, called trawlers. The activity of pulling the trawl through the water is called trawling.

2 Angling

Angling is a method of fishing by means of an "angle" (hook). The hook is usually attached to a line, and is sometimes weighed down by a sinker so it sinks in the water. The hook is usually baited with lures or bait fish.

Angling

Line fishing is fishing with a fishing line. A fishing line is any cord made for fishing. Important parameters of a fishing line are its length, material, and weight (thicker, sturdier lines are more visible to fish).

Droplining

A dropline consists of a long fishing line set vertically down into the water, with a series of baited hooks Droplines have a weight at the bottom and a float at the top. They are not usually as long as longlines and have fewer hooks.

Handlining

Is fishing with a single fishing line, baited with lures or bait fish, which is held in the hands. Handlining can be done from boats or from the shore. It is used mainly to catch groundfish and squid, but smaller pelagic fish can also be caught.

Jiggerpole

A long fishing pole that is used with a short and heavy line, usually a foot (0.3 m) or less of 50 lbf (220 N) test or heavier. Then a large lure or bait is attached and manually worked around the shoreline and cover.

Jigging

Is the practice of fishing with a jig, a type of fishing lure. A jig consists of a lead sinker with a hook moulded into it and usually covered by a soft body to attract fish. Jigs are intended to create a jerky, vertical motion, as opposed to spinnerbaits which move through the water horizontally.

Longlining

FISHING Angling Angling

Is a commercial technique that uses a long heavy fishing line with a series of hundreds or even thousands of baited hooks hanging from the main line by means of branch lines called "snoods". Longlines are usually operated from specialised boats called longliners.

Slabbing

A bass fishing technique, that involves repetitively lifting and dropping a flat lure, usually made of 1 to 2.5 oz of lead painted to look like a baitfish (or heavy slabs of metal), through a school of actively feeding fish that the angler has located on a fishfinder.

Trolling

Is fishing with one or more baited lines which are drawn through the water. This may be done by pulling the line behind a slow moving boat, or by slowly winding the line in when fishing from the land. Trolling is used to catch pelagic fish such as mackerel and kingfish.

Trotlining

A trotline is like a dropline, except that a dropline has a series of hooks suspended vertically in the water, while a trotline has a series of hooks suspended horizontally in the water.

Angling - Rod Fishing

Fishing rods give more control of the fishing line. The rod is usually fitted with a fishing reel which functions as a mechanism for storing, retrieving and paying out the line. Floats may also be used, and can function as bite indicators. The hook can be dressed with lures or bait.

Bank Fishing

Fishing from river banks and similar shorelines. Bank fishing is usually performed with a fishing rod and reel, although nets, traps, and spears can also be used. People who fish from a boat can sometimes access more areas in prime locations with greater ease than bank fishermen.

Casting

The act of throwing the fishing line out over the water using a flexible fishing rod. The usual technique is for the angler to quickly flick the rod from behind toward the water. Casting is also a sport adjunct to fishing, much as shooting is to hunting.

Float Tubes

Small doughnut-shaped boats with an underwater seat in the "hole". Float tubes are used for fly fishing and enable the angler to reach deeper water without splashing and disturbing stillwater fish.

Fly Fishing

The use of artificial flies as lures. These are cast with specially constructed fly rods and fly lines. The fly line (today, almost always coated with plastic) is heavy enough cast in order to send the fly to the target. Artificial flies vary dramatically in size, weight and colour. Fly fishing is a distinct and ancient angling method, most renowned as a method for catching trout and salmon

Tenkara Fishing

Tenkara is a form of fly fishing that originated in Japan over 200 years ago. It was originally done with a bamboo pole between 12' and 20' with the line tied directly on the tip of the rod requiring no reel. Modern tenkara rods are usually made of graphite and are telescopic. Unlike western style fly fishing tenkara uses either a tapered line or a level line and forgoes the PVC coated fly fishing line.

Rock Fishing

Fishing from rocky outcrops into the sea. It is a popular pastime in Australia and New Zealand. It can be a dangerous pastime and claims many lives each year.

Pitch Fishing

A technique designed to deliver the lure quietly and at a distance over the water. The lure will fly high and far out over the water, landing in a loud splash. Pitch fishing involves sending the lure out a lower angle, and thus making a smaller splash which will hopefully not scare the fish.

Surfcasting

Fishing from a shoreline using a rod to cast into the surf. With few exceptions, surf fishing is done in saltwater, often from a beach. The basic idea of most surfcasting is to cast a bait or lure as far out into the water as is necessary to reach the target fish from the shore. This may or may not require long casting distances and muscular techniques.

Angling - Other

Other forms of angling not mentioned above.

Bottom Fishing

Is fishing at the bottom of a body of water. In the United Kingdom it is called "ledgering". A common rig for fishing on the bottom is a weight tied to the end of the line, with a hook about an inch up line from the weight. The method can be used both with hand lines and rods.

Ice Fishing

The practice of catching fish with lines and hooks through an opening in the ice on a frozen body of water. It is practised by hunter-gatherers such as the Inuit and by anglers in other cold or continental climates.

Kayak Fishing

Many of the techniques used are the same as those used on other fishing boats, apart from difference is in the set-up, how each piece of equipment is fitted to the kayak, and how each activity is carried out on such a small craft.

Kite Fishing

Kites can provide the boatless fishermen access to waters that would otherwise be available only to boats. Similarly, for boat owners, kites provide a way to fish in areas where it is not safe to navigate such as shallows or coral reefs where fish may be plentiful. Kites can also be used for trolling a lure through the water.

Kontiki Fishing

Is the practice of using either a Kontiki sailing raft, or a modern motorised torpedo device to pull a longline (up to 25 hooks) from the beach up to two thousand metres offshore. This method of fishing is very popular on the surf beaches of New Zealand. The electric kontikis can also be used to pull surfcasting lines and baits offshore, before releasing them to fish. Modern electric kontikis use electric trolling motors, lithium batteries and GPS controlled autopilots, and electric winches are used to retrieve the line, hooks and kontiki back to shore.

Boat Anglers

Fishing is usually done either from a boat or from a shoreline or river bank. When fishing from a boat, pretty much any fishing technique can be used, from nets to fish traps, but some form of angling is by far the most common.

Remote Control Fishing

Fishing can also be done using a remote controlled boat. This type of fishing is commonly referred to as RC fishing. The boat is usually one to three feet long and runs on a small DC battery. A radio transmitter controls the boat. The fisherman connects the fishing line/bait to the boat; drives it; navigating the water by manipulating the remote controller.

3 Trapping

Traps are culturally almost universal and seem to have been independently invented many times. There are essentially two types of trap, a permanent or semi-permanent structure placed in a river or tidal area and pot-traps that are baited to attract prey and periodically lifted.

Dam Fishing

An artisanal technique called dam fishing is used by the Baka pygmies. This involves the construction of a temporary dam resulting in a drop in the water levels downstream—allowing fish to be easily collected.

Basket Weir Fish Traps

Were widely used in ancient times. They are shown in medieval illustrations and surviving examples have been found. Basket weirs are about 2 m long and comprise two wicker cones, one inside the other—easy to get into and hard to get out.

Fishing Weir

Large fishing weir structures were constructed from wood posts and wattle fences. 'V' shaped structures in rivers could be as long as 60 metres and worked by directing fish towards fish traps or nets. Such fish traps were evidently controversial in medieval England.

Fish Wheels

Operate alongside streams, much as a water-powered mill wheel. A wheel complete with baskets and paddles is attached to a floating dock. The wheel rotates due to the current of the stream. The baskets on the wheel capture fish travelling upstream and transfer them into a holding tank. When the holding tank is full, the fish are removed.

Lobster Traps

Also called lobster pots, are traps used to catch lobsters. They resemble fish traps, yet are usually smaller and consist of several sections. Lobster traps are also used to catch other crustaceans, such as crabs and crayfish. They can be constructed in various shapes, but the design strategy is to make the entry into the trap much easier than exit.

Rod Types

Line Types

4 Conditions

Seasonal Conditions

Summer Conditions

Early Morning (4:30-9am)	Fishing is excellent from before sunup to just before mid-morning. At this time of year there is abundant food and cover for fish, so finding hungry fish can be a challenge.
Late Morning-Early Afternoon (9am-5pm)	Fishing is poor for most of the day. Fish move to deep water to cool off.
Afternoon-Early Evening (5pm-9pm)	Fishing is excellent from early sundown until dark as the waters cool and fish rise up from the depths.

Fall/Autumn Conditions

Early Morning (Daybreak-9am)	Fish aren't biting much from sunup to early morning. The water is cool because the sun is too low to penetrate the water.
Late Morning-Early Afternoon (9am-12pm)	Fish are biting off and on in warmer, shallow water. The water is generally cool due to the season.
Afternoon-Early Evening (12pm-6pm)	Fishing at this point is excellent. Sun is directly overhead for several hours and the water gets more comfortable near the surface. This makes for seasonally good fishing because fish are putting on weight for the winter.

Winter Conditions

Water temperature serves as the most critical element in locating and catching fish. Fish are cold blooded, during colder periods their metabolic rate slows way down and they eat less. On colder days, fish stay in the warmest water they can find, so try to locate deeper dredge holes, canals and pockets adjacent to shallow flats, and slow down your presentation to a crawl. The colder the water, the slower the retrieve. The warmer the water in winter, the more chance you have at catching fish. Deeper water will be the best bet in early mornings and on sunny days the flats can come alive as those temperatures begin to rise. The current which triggers fish feeding can come from the wind and from the tide.

They love to take up a position on the down tide/wind side of a point that has the current sweeping across it. During bouts of cold weather with sunny days, fish the flats late in the afternoon when the water has absorbed maximum radiation. Fish will move to the warmer water to feed. Areas of dark bottom can be especially productive late in the afternoon. Cold water is extremely clear water. Use lighter fishing tackle, less visible in the water. Fish respond to changes in atmospheric pressure. Cold fronts usher in high pressure shut down the fishing action completely.
Don't let cold weather stop you from fishing.

Spring Conditions

Early Morning (6am-9am)	Fish aren't biting. The water is cold and doesn't heat up because the sun is low and the rays bounce off the water. Best to wait until a week or so after thaw, as spring turnover takes time for the water temperature to even out to 39.2°C.
Late Morning-Early Afternoon (9am-1pm)	Fish are biting off and on. The water begins to warm up because rays begin to penetrate the water. Remember to fish the downwind shoreline, as the winds will push the warmer surface water along with surface food into that area.
Afternoon-Early Evening (1pm-5pm)	Fish are eating a lot because their metabolism and digestion are cranked. Water is warm because the sun is directly overhead.

Time Conditions

These are the time conditions which affect when fish are most likely to bite.

Temperature	Too many hot days in the summer can make fish in shallow lakes, ponds and rivers sluggish. The same thing happens in the winter when water temperatures are lower.

FISHING Conditions Time Con

Light	Fish prefer early morning and evening sun to the bright sun of midday. Morning sun warms the shallows, creating more comfortable water temperatures for fish to feed. Late morning is best when the sun has had more of a chance to warm the shallows. This is particularly true during early spring in shallows with dark or mud bottoms because dark areas absorb heat more rapidly than light sandy bottoms. Warm water temperatures make bait fish more active and available to game fish on cool early-spring days. On hot sunny days, fish move to cooler, deeper waters to stay comfortable. High-heat conditions make shallow and top water lures and fishing bait best only in the early morning and late afternoon when cooler temperatures and lower light levels allow fish to cruise the shallows for meals. In midday, hot water surface temperature, decreased surface oxygen and occasional increasing winds cause fish to move deeper. In these conditions, deep fishing baits, rigs and lures are best. Already, you can see how a combination of time of day, light and weather can affect your fishing.

Variables

FISHING Conditions Variables

These are the other variables such as weather which affect when fish are most likely to bite.

Wind	Wind can play a large role in when to fish and your fishing success. Wind pushes water and surface food to the far shore, with bait fish behind it, and with game fish behind the bait fish. So if you're fishing from shore on a windy day, fish where you have to cast into the wind. That way your lure moves with the wind, just like the other food in the lake at the same time. If you're fishing from a boat, cast with the wind on a sheltered shore.
Storms	Storms and changing weather patterns affect fishing success since fish are keenly attuned to changes in barometric conditions. With many fish, feeding increases during the hours immediately before a cold front, but slows during and after a storm or front hits. Fishing after a cold front is poor and continues to be poor for a day or two. Warm fronts cause surface water temperatures to increase, putting fish into a feeding mode. This can be particularly true in the winter, when a warming trend can cause otherwise sluggish fish to start feeding actively. Most of this feeding activity is on or near the warm surface.
Cloudy Days	Cloudy days improve fishing since the clouds prevent light penetration. Overcast skies signal when to fish because they cause fish to cruise for food more than they would during bright days when they tend to hide and stay close to structure. On overcast, cloudy days, fish are less likely to be at specific structure spots or areas and more likely to be scattered throughout a waterway.
Light Rain	A light rain is another good time to fish, especially a warm spring or summer rain. Rain can help you hide from the fish since the rain breaks up the view a fish has through the water surface. This is true for shore, wade or boat fishing. Rain also washes insects and fishing bait into the water, creating a feeding binge for fish.
Hard Rain	Hard rain conditions are a poor time to fish. A hard rain muddies the water, makes it difficult for fish to find bait or lures and causes heavy runoff, which can clog their gills. The increased water flow in rivers from any rain increases current flow and makes it difficult for fish to maintain a comfortable position in the river. High water levels can also create rapids, waves and unsafe fishing conditions.
Tide	The rising or falling time is the best for fishing while water level is not too deep or too low. As a water level decreasing, fish sense the dropping water and will move out with the tide to deeper water. When water level increases, larger fish, such as redfish, flounder, drum and trout will also follow that rising tide. Tides cause bait to move and promote active feeding coastal fish.

FISHING Conditions Variables

Gardening

How to grow any type of food, herbs and flowers

"To plant a garden is to believe in tomorrow."
Audrey Hepburn

Introduction

Gardening is the practice of growing and cultivating plants as part of horticulture. In gardens, ornamental plants are often grown for their flowers, foliage, or overall appearance; useful plants, such as root vegetables, leaf vegetables, fruits, and herbs, are grown for consumption, for use as dyes, or for medicinal or cosmetic use. Gardening is considered by many people to be a relaxing activity. Gardening ranges in scale from fruit orchards, to long boulevard plantings with one or more different types of shrubs, trees, and herbaceous plants, to residential back gardens including lawns and foundation plantings, and to container gardens grown inside or outside.

Gardening may be very specialized, with only one type of plant grown, or involve a large number of different plants in mixed plantings. It involves an active participation in the growing of plants, and tends to be labour-intensive, which differentiates it from farming or forestry. In respect to its food-producing purpose, gardening is distinguished from farming chiefly by scale and intent. Farming occurs on a larger scale, and with the production of salable goods as a major motivation.

Gardens take time so once the crisis is upon you is when you need to begin thinking about a renewable food source. You have to have seeds in the ground while you still have plenty of food on hand. Plants do not develop over night and there are never any guarantees of a good harvest. You should have enough supplies stockpiled so food is not an immediate concern while your garden develops. If the crisis happens in the winter months you need enough food to last until spring and then until your plants begin to bear fruit. You should have at a minimum a 12-month supply of food, to allow for all variables. Some crops can take months before the plants would be ready for harvesting.

In some areas of the country, you may have a shortened growing season so once a plant is ready for harvest you cannot expect to get another crop in and matured before the first frost in the fall. A growing season is typically determined by the number of days between the last frost in the spring and the first frost in the fall. You will never achieve a 100 percent rate in other words a percentage of what you raise will never reach your table. Some of your produce will be eaten by pests or animals and some may even rot prematurely not to mention lack of rain, hailstorms or even excessive rainfall will influence crop yields.

Purpose	The aim of GARDENING is to provide tips and tricks on growing vegetables, fruit, herbs, spices, nuts and other edible plants. There's sections on assisting the growth of plants such as soil quality, pests and diseases. The end of the guide is dedicated to permaculture techniques such as Aeroponics, Aquaponics, Hydroponics and Aquaculture.
Lost?	• For ways to identify wild plants and trees, see the PLANTS section. • For ideas on what to grow for medicinal purposes, see the NATURAL REMEDIES section. • For ideas on what to grow based on dish, see the RECIPE section. • For ideas on what to grow based on nutrition, see the HEALTH section.

1 In-Ground Gardening

In-ground gardening poses one of the best ways to get started gardening, however can be one of the most challenging to maintain. First you must pick a spot, rip up the sod, till the soil, and continue to work in compost and soil amendments until the soil is at your desired level of fertility.	**Advantages** Cost effective, easy to start, easy to change methods if needed.	**Disadvantages** Good soil is hard to come by, weeds will be your number one enemy, slow to start in the spring since it is often muddy, can be wasteful on water, tilling kills worms and soil life, and open soil is left bare to be exposed to solar radiation.

Preparing The Garden	If you decide to plant in the ground directly, you should first complete a soil test to ensure soil quality.	**Tools** ● Garden spades ● A rotary tiller (locate a rental, or hire someone locally to the job) ● Yard waste bags ● Garden stakes and twine (for edged beds) ● A hose (for circular beds) ● Tarp (optional - this is if you would like to start a separate compost pile for grass) ● Compost	For purchased compost, calculate the amount needed using a soil calculator- simply enter the square footage of your bed, and the # of inches of compost that you would like to till into your soil (4-5 inches is recommended). Your will then be given the cubic yardage of compost needed.
Steps	1. Mow the grass as low as possible before removing all of the sod and grass. 2. For an edged bed, use the garden stakes and twine to create an outline on the grass – for a round bed, use the hose to form a circular shape. 3. Using the garden spades, follow the outside of the twine (or hose) to cut straight down into the soil. 4. Put aside the stakes, twine, or hose. Till the entire plot with the roto-tiller. 5. Form a separate compost pile of the patches of grass and sod (they would overwhelm your bin!). Layer them with their roots side facing up, sprinkle with water, and let them decompose. At the end of the day, cover them with the tarp. 6. As you work, remove any pebbles, stones or other debris. Pull out weeds and roots; dispose in yard waste bags. 7. Add your calculated amount of compost (about 4-5 inches across the total square footage of the bed; if purchasing compost, use a soil calculator to determine the total number of cubic yards needed). Rake and dig into the soil. 8. Return the excess soil to the bed, and smooth out with garden hoes and rakes to form an even top layer. 9. You are now ready to plant your garden!		

2 Aquaponics

Aquaponics is the process of growing plants with the use of fish. The fish waste will be broken down by bacteria, turning the nitrates into nitrites that the plant can use as food. It is an organic form of hydroponics and allows for the ability to grow 2 crops at once (fish and plants).	**Advantages** Conserves water, allows for soil-less growing, organic version of hydroponics, grows 2 crops at once.	**Disadvantages** Can be expensive, lots of space needed to house fish tank and plants, dependent on fish food to feed fish.
See the Permaculture section for more.		

3 Hydroponics

The process of growing food using a nutrient solution. Hydroponics uses water soluble nutrients to feed the plants right at the source. This leads to fast growth and the ability to grow without soil.	**Advantages** Grow without soil, grow indoors or outdoors, fastest growth of any gardening method, all nutrients are 100% plant available.	**Disadvantages** Can be expensive to set up, indoor lights are pricey, dependency on synthetic fertilizers costs money, no organic options.
See the Permaculture section for more.		

4 Raised Beds

Garden beds made from wood, timbers, bricks, or mounds that elevates the soil higher than the original level.	**Advantages** Elevates the soil to dry it out faster, allows for better drainage, reduces strain on the back from reducing how far one must bend to weed, plant or harvest, better soil quality, reduces compaction of the soil because you are not stepping in the bed, weeding is easier due to the uncompacted soil.	**Disadvantages** Wood can be expensive, once the beds are in and built it is a commitment to keep them there.

GARDENING Types of Gardening

5 Back To Eden

Back To Eden	Advantages	Disadvantages
Placing 4-6 inches of wood chips on the soil to cover the soil and act as protection for soil bacteria, as well as retain moisture, and mulch weeds. Most often you can get wood chips for free just by contacting your local municipal tree company. They have to pay to throw out the wood chips, so if you call they will usually drop off more than enough for free.	Retains moisture, amends soil over time, protects the soil from solar radiation and weathering, and suppresses weeds.	Wood chips will take nitrogen from the soil if mixed into the soil leaving plants with nitrogen deficiencies, hardy weeds will still find a way to grow, so weeding is still something that has to be done, moving wood chips can be labour intensive and tiring. Planting seeds is also a challenge since mulch does not delineate between weeds and your vegetable plants.

6 Straw Bale Gardening

Straw Bale Gardening	Advantages	Disadvantages
Bales are great raised beds: straw collects/disburses moisture and is compostable, which means over time your plants will gain nutrients as the straw decomposes. Plus, the bales retain heat to extend your gardening season even further.	Cheap gardening method for those who want raised bed gardens, but do not like the weeds and the building of the beds. Straw bales are relatively lightweight and can be moved around, if you change your mind about a gardening method, they are not permanent.	Dries out fast, takes lots of time to break down the centre of the bales (condition them) so that there is something to grow in, many farmers spray hay with weed killer and this can be harmful to consume and may even inhibit plant growth.

7 Core Gardening

Core Gardening	Advantages	Disadvantages
Use this in combination with raised beds to provide the most amazing growing conditions for the plants. The soil holds on to water like a sponge for weeks at a time (once charged), the grass breaks down quickly feeding the soil, the nitrogen prevents any nitrogen from being taken from the soil during the breaking down of the grass, and the organic material adds good drainage, porosity, and loamyness.	Easy to set up, retains water, amends soil quickly, doesn't mound soil like hügelkultur, breaks down faster than hügelkultur, loosens soil, increases drainage, and allows for microbes and fungi to colonize the straw and interact with plant roots.	Takes some water to charge the core initially.

8 Container Gardening

Container Gardening	Advantages	Disadvantages
Growing in pots is a great way to maximize space, increase productivity, or use a spot that normally would not be able to have plants grown. From balcony gardens to patio gardens, this method is popular and fun! All the benefits of gardening can be had in square inches, rather than square feet. Make sure to have a steady watering schedule with your plants, so they will not dry out on you. Also if you are looking to container garden for a long time, invest on good quality pots. Clay pots tend to crack, so look into other alternatives.	Small footprint, great for people that do not have a ton of space (apartments, condos, patios), mobile.	Constant water upkeep since soil tends to dry faster, pots can be expensive, pot size limits growth.

9 Square Foot Gardening

Square Foot Gardening	Advantages	Disadvantages
The basic concept: Create a small garden bed (4 feet by 4 feet or 4 feet by 8 feet are common sizes) and divide it into a grid of 1-foot squares, which you manage individually. Seeds or seedlings of each kind of vegetable are planted in one or more squares, at a density based on plant size (e.g., you'd plant about 16 radish seeds per square, but only one tomato plant). Since there are no paths, there is no wasted space, and the soil in the bed stays loose because you never step on it.	High yields, fast set-up, minimal regular maintenance, less weeding.	High initial cost, cramped beds, insufficient depth, lots of watering, more frequent maintenance.

The Square Foot Gardening method can be started using only a frame and some dividers. Picture a box divided into smaller squares, each measuring 1-foot by 1-foot. The square foot gardening method focuses on the number of seeds that can be planted within each square box based on the size of the plant. For example, one tomato plant might occupy its own square while oregano can be planted 4 times within a square. Carrot seeds, on the other hand, can be planted 16 to a square.

10 Mittleider Method

Mittleider	Advantages	Disadvantages
The Mittleider Gardening method is an easy-to-use method that allows gardeners to raise an abundance of vegetables and other crops on almost any soil, in practically any season, in almost any climate, and virtually at any elevation.	Cheap soil, grow in any climate.	Difficult to build the garden.

11 Keyhole Gardening

Keyhole gardens provide adequate growing conditions in less-than-adequate environments. Keyhole gardens are named after their shape: they are typically round beds with a pie-slice-shaped aisle for easy access, all built around a circular centre compost. These types of garden beds provide the best of several worlds: raised beds allow for regulated soil conditions, the compost centre permits rich nutrients to re-enter the soil through recycling, and soil stays nourished via water poured into the compost pile, essentially drought-proofing your crops.	**Advantages** o	**Disadvantages** o

12 Window Farms

A vertical cascade of hanging vessels–typically halved soda/water bottles–home to soil-less leafy green plants and herbs. The method is simple enough. Plants grow out of the bottle while an air pump (such as those used in fish tanks) circulate liquid nutrients that gently flow down the structure. Sunlight is necessary, but for windows that don't receive enough light, hanging LED lights will work. This method of gardening is ideal for residents with no patch of grass for their own; the method is also dirtless.	**Advantages** o	**Disadvantages** o

2 Soil

Information on the different types of soil, fertilizers and how to prepare soil for use.

Preparing Soil

Soil Testing
Before you start dumping on the lime and fertilizers, your first step should be taking a soil sample to send off for testing. A good soil test will evaluate the basic texture of your soil - sand, silt, or clay—and determine its acidity—the pH level. The available amounts of nutrients including magnesium, calcium, phosphorus, and potassium will be calculated and recommendations will be made for raising each to the correct levels for optimum plant growth. Armed with this knowledge, you can make the proper improvements. Too much of a good thing can be just as harmful as too little so let your soil test be your guide. Home test kits are available but they are not as accurate or thorough as professional testing. Contact your county extension office for soil testing information and instructions. Most have websites; fees for soil testing, along with the proper forms, can be found there.

- To take a representative sample, scrape away any surface litter, plant residues, leaves, etc.
- Avoid sampling in a spot where ashes have been dumped, manure or compost stored, or brush burned.
- Cut straight into the soil with a shovel or trowel 6 to 8 inches deep making a V-shaped hole.
- Cut a 1 inch wide slice of soil the length of the hole from one side. Take a 1 inch strip from the centre of this slice to use in your sample.
- Repeat sampling randomly around the garden and mix the samples together in a clean glass jar or bucket. Since we use raised beds we take a slice from each bed and mix them all together.
- Measure out a cupful of soil, dry it indoors for a few days, and seal in a plastic bag with your information on it.
- Send it in with the proper forms and fees.

Results
When you get your test results the fertilizer recommendations will be quite specific, and speak to three elements: nitrogen, phosphorus, and potassium. Fertilizer terms can be confusing. What is the NPK ratio? What are nitrogen, phosphorous, and potassium? Let us take the guesswork out of fertilizing. It's all about the soil. Most soil doesn't have all the nutrients needed for optimal growth, which means you won't get the harvest or flower bloom desired. There are six primary nutrients that plants require—carbon, hydrogen, oxygen, nitrogen, phosphorus, and potassium. The latter three nutrients come from the soil.

N P K Fertilizer Labels
Every fertilizer label will give information relating to its "N-P-K" content, expressed as a number ratio. On the label, you'll see numbers like 5-10-10, 10-10-10, and 10-6-4. There is valuable information in the labelled numbers: They indicate the amount of nitrogen, phosphorus, and potassium (standardized in that order) in the particular fertilizer blend.

For example, 100-pound bag of 10-10-10 contains ten pounds of each element. The rest is filler, which gives it bulk and makes it easier to spread.

Nitrogen
N stands for nitrogen which helps plants make leafy growth. For nitrogen they will tell you how much manure to use. If you are using fresh manure, spread it on in the fall so it can break down over the winter and be safe for spring planting. If you prefer, dried blood, alfalfa, soybean, or cottonseed meals can be substituted. Nitrogen is released quickly from them so it is best to wait until spring to add it to your soil. 10 pounds of blood meal supplies the same amount of nitrogen as 10-20 bushels of manure but without the added benefit of all the organic matter that manure contains.

Phosphorus
P stands for phosphorus which is necessary for germination, strong root growth, flowers, and fruit. It helps plants absorb minerals, grow strong stems, and withstand disease. Rock phosphate provides phosphorus, magnesium, and trace minerals. Rock powders are wonderful soil enhancements. They are slow acting but long lasting so they need to be applied only every 3-4 years. Bone meal and bone char are more readily available sources of phosphorus.

Potassium
K stands for potassium or potash. It regulates the flow of water in plant cells and is necessary for flowering, fruiting, and disease resistance. A lack of potassium will cause plants to have weak stems and stunted growth. For added potassium you can use granite dust or greensand which is made from glauconite, an ocean mineral high in potassium and iron. Wood ashes are also high in potash.

Amending pH
Achieve the proper soil pH. A very high or very low soil pH may result in plant nutrient deficiency or toxicity. A pH value of 7 is neutral; microbial activity is greatest and plant roots absorb/access nutrients best when the pH is in the 5.5 to 7 range. Add organic matter to your soil. It improves structure, slowly releases nutrients, and increases beneficial microbial activity. (NOTE: It is virtually impossible to know the nutrient content of aged manure.)

Fertilizers

Natural, Organic, Synthetic Fertilizers
Fertilizer providing the N-P-K nutrients mentioned above can come in both organic and synthetic versions. What's the difference?
Organic fertilizers come from sources such as manure, blood meal, cottonseed meal, feather meal, crab meal, etc. (Bear in mind: Not all products labelled "natural" are organic. Greensand—derived from inorganic mineral-based or "rock" matter—is an example of a natural, although inorganic, material.) Organic fertilizers work in concert with soil microbes that break fertilizers down for plant uptake. Because they don't add excess salts and acid to the soil, organic fertilizers are beneficial in encouraging healthy soil biology rich in microbial activity.

Synthetic fertilizers are lab-made and derived from compounds like ammonium nitrate, ammonium phosphate, superphosphate, and potassium sulphate. They expedite plant growth and can contribute to bloom rate in flowering plants. However, they are high in salts and can be detrimental to populations of beneficial microorganisms and also leach into water sources. Applying too much synthetic fertilizer can "burn" foliage and damage your plants. Synthetic fertilizers are great for a boost, but do little to improve your soil's long-term health, texture, or long-term fertility.

Because synthetic fertilizers are highly water-soluble, they can also leach out into streams and ponds. In general, organic fertilizers need time to enrich the soil, so they're best applied in the fall so the nutrients will be available in the spring. For the spring, some fertilizers combine the best of both worlds with an organically-based fertilizer mix that also contains small amounts of synthetic fertilizers to ensure the immediate availability of nutrients.

Note that the N-P-K ratio of organic fertilizers is typically lower than that of a synthetic fertilizer. By law, the ratio label can only list nutrients that are immediately available.

Granular vs Soluble
You may also notice that there are both granular and soluble formulations.
● Granular fertilizers are solids that must be worked into the soil and given time (and water) before they dissolve and become available to plants.
● Slow-release fertilizers are a subset of granular formulations. A portion of the fertilizer is not immediately available to the plant. Nutrients are metered out over several weeks. Therefore, they are applied less frequently.
● Sometimes called "liquid feed," soluble fertilizers are sold as either ready-to-use solutions or packaged dry-milled materials that need to be dissolved in water. These tend to be quick-release fertilizers high in nitrogen that result in fast green growth. (Miracle-Gro is a good example of a soluble fertilizer.)
To build the long-term health and fertility of your soil, we recommend using granular organic fertilizers. Supplementing with an additional water-soluble fertilizer is a way to ensure that your plants have the nutrients they need when they need a boast (during active growth).

Buying Fertilizer
Shopping for fertilizer can be confusing because plants have individual nutrient requirements.
If you don't have any specific soil needs, a 5-5-5 fertilizer is an all-purpose fertilizer that provide plants with what they need for healthy growth.
Evergreens — holly, rhododendron, yew, and others — not only need high nitrogen to keep them green, but several trace elements as well. Evergreen food may have an analysis of 30-10-10, plus a dose of copper, molybdenum, and iron. Flowering annuals, on the other hand, burst into bloom when nitrogen is held back. The tonic they need is 5-10-10..
Good-quality bonemeal worked into the soil around newly planted bulbs keeps them springing up for several years.

Compost Tea
Before buying bags or bottles of fertilizers, consider how you might add nutrients to the soil by improving its biology. Try compost tea, a liquid produced by extracting beneficial microbes (bacteria, fungi, protozoa, and nematodes) from compost. Applying compost tea to both soil and plant foliage adds those beneficial microorganisms to the growing medium, which boosts plant health and encourages growth. Compost tea is made using a brewing process similar to that used for making beer. Active compost, a brewing kit, and a little information can go a long way toward turning your landscape into a thriving ecosystem. See information on how to make compost tea.

Soil Fixes
If you have clay soil, add coarse sand (not beach sand), compost, and peat moss. If you have sandy soil, add humus or aged manure, peat moss, or sawdust with some extra nitrogen. Heavy, clay-rich soil can also be added to improve the soil. If you have silt soil, add coarse sand (not beach sand) or gravel and compost, or well-rotted horse manure mixed with fresh straw.

Soil Amendments

Let your soil test be your guide when adding fertilizers and amendments to your soil. Too much of a good thing is worse than not enough so don't overdo it. The idea is to feed the soil not the plants. Healthy soil results in healthy growth.

Minerals

The minerals used in soil correction.

Aragonite	A source of calcium found in mollusc shells. Since it is low in magnesium it is good to use if your soil needs calcium but does not need any extra magnesium. Too much magnesium can "tie up" other nutrients, making them unavailable for plants to use. If your pH is low, aragonite has almost as much sweetening power as limestone.
Azomite	A trademarked acronym for A to Z Minerals Including Trace Elements. Mined in Utah, it is ancient volcanic dust that merged with sea water 30 million years ago. It has over 60 minerals that are good for plant growth.
Bone Char	Burned bone meal that provides a readily used source of phosphorus.
Calphos Colloidal Phosphate	A good choice if your soil is low in calcium and phosphorus.
Dolomitic Limestone	Will not only sweeten your soil better than pure limestone it also provides calcium and magnesium.
Granite Meal	A rock powder that provides slow release potassium and trace minerals without changing the pH of your soil.
Greensand	Also called glauconite. It is high in potassium and iron and has small amounts of magnesium and other trace elements. It is good for loosening clay soils and improving sandy soil.
Gypsum	23% calcium and 17% sulphur so it provides calcium without raising pH levels. It helps improve drainage by aerating the soil. It neutralizes plant toxins and removes sodium from the soil. The sulphur reacts with water and forms a weak sulphuric acid that frees up calcium in your soil.
Hi-Cal Lime	Used to raise the pH and add calcium at the same time.
Sulphate of Potash	Contains 51% potassium and 18% sulphur along with trace amounts of calcium and magnesium. It is mined in the Great Salt Lake Desert in Utah.

Sul-Po-Mag	Also called langbeinite, is used if you need magnesium and potassium but not more calcium. It does not raise pH.
Zeolites	Found in volcanic ash and can improve water and mineral retention in sandy soils.

Fertilizers

Alfalfa Meal	A source of readily available nitrogen for plant growth and also feeds soil organisms. It contains vitamins, folic acid, and trace minerals.
Blood Meal	Very high in fast-release nitrogen. It also repels deer.
Fish Meal	An excellent source of nitrogen and potassium. It is a by-product of fish farming.
Kelp Meal	Dried, ground up seaweed. It provides trace minerals, amino acids, and enzymes that stimulate plant and root growth and are beneficial to soil life. By improving soil structure it can help your soil hold moisture and reduce the effects of drought and frost.
Soybean Meal	Contains high amounts of nitrogen and potassium that are released slowly as it breaks down. Look for organic sources since most commercially grown soybeans are genetically modified.

Composting

Compost is organic matter that has been decomposed in a process called composting. This process recycles various organic materials otherwise regarded as waste products and produces a soil conditioner (the compost). Compost is rich in nutrients. It is used, for example, in gardens, landscaping, horticulture, urban agriculture and organic farming. The compost itself is beneficial for the land in many ways, including as a soil conditioner, a fertilizer, addition of vital humus or humic acids, and as a natural pesticide for soil. In ecosystems, compost is useful for erosion control, land and stream reclamation, wetland construction, and as landfill cover. At the simplest level, the process of composting requires making a heap of wet organic matter (also called green waste), such as leaves, grass, and food scraps, and waiting for the materials to break down into humus after a period of months.

However, composting also can take place as a multi-step, closely monitored process with measured inputs of water, air, and carbon- and nitrogen-rich materials. The decomposition process is aided by shredding the plant matter, adding water and ensuring proper aeration by regularly turning the mixture when open piles or "windrows" are used. fungi, earthworms and other detritivores further break up the material. Bacteria requiring oxygen to function (aerobic bacteria) and fungi manage the chemical process by converting the inputs into heat, carbon dioxide, and ammonium.

Fundamentals
Composting is an aerobic method (meaning that it requires the presence of air) of decomposing organic solid wastes. It can therefore be used to recycle organic material. The process involves decomposition of organic material into a humus-like material, known as compost, which is a good fertilizer for plants. Composting requires the following three components: human management, aerobic conditions, development of internal biological heat.

Composting organisms require four equally important ingredients to work effectively:
- **Carbon** - for energy; the microbial oxidation of carbon produces the heat, if included at suggested levels. High carbon materials tend to be brown and dry.
- **Nitrogen** - to grow and reproduce more organisms to oxidize the carbon. High nitrogen materials tend to be green (or colourful, such as fruits and vegetables) and wet.
- **Oxygen** - for oxidizing the carbon, the decomposition process.
- **Water** - in the right amounts to maintain activity without causing anaerobic conditions.

Certain ratios of these materials will provide microorganisms to work at a rate that will heat up the pile. Active management of the pile (e.g. turning) is needed to maintain sufficient supply of oxygen and the right moisture level. The air/water balance is critical to maintaining high temperatures 130–160 °F (54–71 °C) until the materials are broken down.

The most efficient composting occurs with an optimal carbon: nitrogen ratio of about 25:1. Hot container composting focuses on retaining the heat to increase decomposition rate and produce compost more quickly. Rapid composting is favoured by having a C/N ratio of ~30 or less. Above 30 the substrate is nitrogen starved, below 15 it is likely to outgas a portion of nitrogen as ammonia.

Nearly all plant and animal materials have both carbon and nitrogen, but amounts vary widely, with characteristics noted above (dry/wet, brown/green). Fresh grass clippings have an average ratio of about 15:1 and dry autumn leaves about 50:1 depending on species. Mixing equal parts by volume approximates the ideal C:N range. Few individual situations will provide the ideal mix of materials at any point. Observation of amounts, and consideration of different materials as a pile is built over time, can quickly achieve a workable technique for the individual situation.

Aerobic Composting

Anaerobic Composting

Vermicomposting

3 Seed Bank

A seed bank stores seeds to preserve genetic diversity; hence it is a type of gene bank. There are many reasons to store seeds. The genes that plant breeders need to increase yield, disease resistance, drought tolerance, nutritional quality, taste, etc. of crops. A seed bank is recommended regardless of whether you currently have the outdoor space or not for a garden because vegetables and certain fruits can be raised indoors, in a garage, basement or any room as long as you have adequate sunlight or artificial lighting. Additionally you may have to evacuate to a safe haven and you must always consider the possibility of never returning. You may have to rebuild your life essentially in another location and this means you would need a renewable and sustainable food source.

Seed Types

Hybrid Seeds
A hybrid seed is seed produced by cross-pollinated plants. The best plants are selected to improve the characteristics of the resulting plants, to increase yields, uniformity of the fruit, improve the colour, and for disease and drought resistance and so on. Many believe that taste does suffer when cross-pollinating however. While, the hybrid seeds you plant will produce the same plant, the seeds from the hybrid plant will not have any consistency nor have the desired characteristics of the plants from which the seeds were developed. In other words, you cannot harvest the seeds from a plant grown from a hybrid seed and expect to get an identical plant or even a plant at all in some cases.

The seeds may not germinate and if they do, the plant may not blossom, nor bear fruit because they generally will not pollinate. This means for you the Prepper you would have to purchase or have enough seeds stockpiled to plant every season. This means that hybrid seeds and the resulting plants would not be a renewable nor sustainable food source. If you only had enough seeds for one season and did not have a way of obtaining more seeds, you would not have a food source. You would have to have enough hybrid seeds stockpiled to last indefinably. There is another option however and that is heirloom seeds.

Heirloom Seeds
An heirloom plant or often called an heirloom variety and even called heritage fruit is considered an old cultivar. It is quite common for a plants' heritage to be well over 100 years old. The heritage is maintained by open-pollination of the plant to produce a seed that carries the plant's heritage forward. The good and bad traits of the plant are carried forward in the seed.

Note: Harvest your seeds from the plants that produce the most fruit and appear to be the strongest/healthiest. Gather seeds from more than just one tomato plant, for example, to ensure you are not always carrying the worst traits of the plants forward. What you need to be concerned about is the fact that an heirloom plant will produce seeds that once planted will replicate the plant exactly and will produce a plant that bears fruit. The seeds inside the fruit can then be harvested for the next growing season.

You can do this year after year. However, the seeds must be harvested and stored in a specific way to ensure the seeds will germinate. You can stockpile hybrid seeds as well as heirloom seeds in your seed bank. Use the hybrid seeds when growing conditions are not ideal because the seeds are developed using the best traits of the plant so they are more likely to produce fruit under less than ideal conditions.

If you know, you will only be in a location for one growing season, do not have the time or resources to properly prepare the garden plot, and do not have time to compost for fertilization then you should consider planting hybrids, because of their hardiness. Always have heirloom plants in the ground when possible as well, so you can be continually harvesting seeds for your seed bank to establish a long-term food source.

Seed List

A recommended collection of seeds to keep on hand for disasters. These foods will cover your nutritional requirements. You should choose foods based on your location and what grows best there.

Vegetable Seeds	Bean	Broccoli	Capsicum (Green Pepper)	Carrot	Corn	Cucumber	Lettuce	Potato	Pea	Pumpkin	Tomato
Fruit Seeds	Apple	Blackberry	Fig	Grapes	Lemon	Mango	Orange	Pear	Pineapple	Strawberry	Watermelon
Herb Seeds	Bay Leaf	Basil	Black Pepper	Chives	Coriander	Garlic	Lavender	Mint	Oregano	Parsley	Rosemary
Nut Seeds	Almond	Cashew	Hazelnuts	Macadamia	Peanut	Pistachio	Pine Nut	Walnut			
Other Seeds	Wheat	Sugar	Oat	Barley	Couscous	Rice	Rye	Olive	Cocoa Bean	Tea	Coffee Bean

4 Vegetables

How to grow a variety of vegetables from either a seed or cutting. Avacados can be found in the fruit section and tomatos are in the vegetable section.

Subheadings

1 Artichoke

The globe artichoke is a variety of a species of thistle cultivated as a food. The edible portion of the plant consists of the flower buds before the flowers come into bloom. The budding artichoke flower-head is a cluster of many budding small flowers (an inflorescence), together with many bracts, on an edible base. Once the buds bloom, the structure changes to a coarse, barely edible form. This vegetable grows to 1.4–2 m (4.6–6.6 ft) tall, with arching, deeply lobed, silvery, glaucous-green leaves 50–82 cm (20–32 in) long. The flowers develop in a large head from an edible bud about 8–15 cm (3–6 in) diameter with numerous triangular scales; the individual florets are purple. The edible portions of the buds consist primarily of the fleshy lower portions of the involucral bracts and the base, known as the "heart"; the mass of immature florets in the centre of the bud is called the "choke" or beard. These are inedible in older, larger flowers.

Introduction											

Planting

Begin by starting seeds indoors, ideally 8-12 weeks before your region's last expected frost date. Use individual pots or modules, approximately 10-15 cm (4-6 inches) deep, filled with a high-quality seed-starting mix. Sow seeds about 1 cm (½ inch) deep, as they need a bit of darkness to germinate.

Maintain consistent moisture in the soil, ensuring it's damp but not waterlogged. Optimal germination occurs with soil temperatures between 21-26°C (70-80°F), usually taking 10-20 days. Once seedlings emerge and develop a few true leaves, they'll need a period of "vernalization" if you're growing them as annuals in cooler climates. This involves exposing them to temperatures between 0-10°C (32-50°F) for 10-14 days, which helps trigger flower bud formation later in the season. After this, or once the danger of frost has passed, harden off the seedlings by gradually exposing them to outdoor conditions over 1-2 weeks before transplanting them into their final garden spot.

Care

- Watering: Keep soil consistently moist, especially during establishment and bud formation. Deep watering is preferred.
- Mulching: Apply a thick layer of organic mulch around plants to retain moisture, suppress weeds, and regulate soil temperature.
- Fertilizing: Artichokes are heavy feeders. Supplement with balanced fertilizer in spring; established plants may benefit from additional feeding during bud development.
- Support: Stake tall plants if necessary to prevent them from falling over in strong winds or due to heavy buds.
- Pest/Disease: Monitor for aphids, slugs, and snails. Ensure good drainage to prevent crown rot.
- First-Year Buds (Perennials): Consider removing any first-year flower stalks to encourage stronger root development for future seasons.
- Overwintering (Cold Climates): After harvest or frost, cut back plants to 15-30 cm (6-12 inches) and mulch heavily over the crown to protect from severe cold.

Pests / Diseases

Common Pests & Mitigation
- Aphids: Small, soft-bodied insects that cluster on new growth and undersides of leaves, causing curling and stunted growth. They also excrete "honeydew," which can lead to sooty mold.
Mitigation/Treatment: Blast with a strong stream of water, especially under leaves. Use insecticidal soap or neem oil for heavier infestations. Encourage natural predators like ladybugs and lacewings.
- Slugs and Snails: Chew holes in leaves and can damage young plants.
Mitigation/Treatment: Hand-pick them, especially at night. Use barriers like copper tape or diatomaceous earth around plants. Employ organic slug/snail baits.
- Artichoke Plume Moth (larvae): Considered a serious pest, larvae tunnel into leaves, stems, and buds, causing significant damage and deformity.
Mitigation/Treatment: Primarily affects perennial artichokes. Monitor with pheromone traps. Remove and destroy infested plant parts. Bacillus thuringiensis (Bt) is an organic spray that targets caterpillars. Proper garden sanitation, including removing old plant debris, helps.

Common Diseases & Mitigation
- Crown Rot (e.g., Bacterial Crown Rot): Caused by fungi or bacteria, leading to wilting, dark discoloration of stems, and softening/rotting of the crown. Often exacerbated by poor drainage.
Mitigation/Treatment: Ensure excellent soil drainage and avoid overwatering. Plant in raised beds if soil is heavy. Use healthy propagation material and sanitize tools between plants. Remove and destroy infected plants promptly.
- Powdery Mildew: White, powdery fungal growth on leaves, typically in warm, humid conditions.
Mitigation/Treatment: Ensure good air circulation by proper plant spacing. Avoid overhead watering, especially late in the day. Remove affected leaves. Horticultural oils or sulfur-based fungicides can treat outbreaks.
- Botrytis (Gray Mold): A fungal disease causing fuzzy gray mold on leaves and buds, especially in cool, moist, and poorly ventilated conditions.
Mitigation/Treatment: Improve air circulation by spacing plants adequately. Avoid overhead watering. Remove infected plant material. Sanitation and good hygiene are crucial.

General Proactive Measures
- Healthy Soil: Vigorous plants are more resistant to pests and diseases. Maintain rich, well-drained soil with plenty of organic matter.
- Proper Watering: Water at the base of the plant to avoid wetting foliage, reducing fungal disease risk.
- Air Circulation: Space plants adequately to promote airflow.
- Sanitation: Remove and dispose of diseased or heavily infested plant material promptly.
- Crop Rotation: If growing artichokes as annuals, rotate their location to prevent soil-borne disease buildup.

Harvest / Storage

Harvesting Artichokes
Harvest artichoke buds when they are fully formed, firm, and tightly closed, typically about 7-10 cm (3-4 inches) in diameter (for main buds). The lower scales should still be tight against the bud. If the scales begin to open or separate, the artichoke is past its prime for eating and will become tough and fibrous, though you can let it flower for ornamental value or seed collection. Use sharp pruning shears or a knife to cut the stem 2-5 cm (1-2 inches) below the base of the bud, leaving a bit of stem attached. This encourages the plant to produce smaller side buds for a continuous harvest.

Storing Artichokes
For short-term storage (up to a week), lightly sprinkle unwashed artichokes with water and place them in a plastic bag (perforated or with a few holes for air circulation). Store in the crisper drawer of your refrigerator. Do not wash them before storing, as excess moisture can encourage mold. For longer storage (several months), artichokes must be cooked or blanched first. Trim and clean them, then boil for about 20 minutes in lemon water. Drain, cool in ice water, pat dry thoroughly, and then freeze in airtight freezer bags or containers.

Variants

- Green Globe (and 'Green Globe Improved'): The most common and widely cultivated variety, large and round with thick, fleshy green leaves.
- Imperial Star: Bred for annual production from seed, often yielding buds in the first year without cold vernalization.
- Violet de Provence (or 'French Artichoke'): Smaller, more compact, with dark purple leaves, often eaten raw or lightly cooked.
- Romanesco (or 'Purple Romanesco'): Italian variety with a distinctive slightly conical or spiral shape and a violet hue, known for a tender, sweet flavor.
- Big Heart: Known for its large, meaty heart and often thornless bracts, making it easier to prepare.
- Purple Sicilian: Features small, deep purple buds, sometimes eaten raw when young.
- Emerald: A hybrid variety known for being earlier to mature than some others, and tolerant of various conditions.
- Opal F1 / Concerto F1 / Tempo F1: Modern F1 hybrid varieties, often chosen for specific traits like color, yield, or disease resistance.

Other Tips

- Choose Wisely: Select varieties suited to your climate (perennial types for mild winters, annual types like 'Imperial Star' for colder areas).
- Deep, Rich Soil: Artichokes are heavy feeders; ensure soil is well-amended with compost and drains excellent.
- Full Sun: They need at least 6-8 hours of direct sunlight daily for optimal growth and bud production.
- Ample Space: Give plants 90-150 cm (3-5 feet) of space; they grow large.
- Consistent Water: Maintain steady moisture, especially when buds are forming, to prevent toughness.
- Mulch Heavily: A thick layer of organic mulch conserves moisture, suppresses weeds, and regulates soil temperature.
- Fertilize: Feed established plants regularly with a balanced fertilizer, particularly in spring.
- Vernalization (for Annuals): If growing from seed in colder climates, a period of cold exposure (vernalization) is crucial for bud production.
- First-Year Sacrifices: Consider removing any buds in the first year of perennial plants to encourage stronger root development.
- Harvest Promptly: Pick buds when firm and tightly closed; waiting too long makes them tough and fibrous.
- Overwintering Prep: In cold regions, cut back foliage and mulch crowns heavily for winter protection.
- Good Drainage is Key: Avoid waterlogging, which can lead to fatal crown rot.

2 Asparagus

Asparagus, or garden asparagus, folk name sparrow grass, scientific name Asparagus officinalis, is a spring vegetable, a flowering perennial plant species in the genus Asparagus. It was once classified in the lily family, like the related Allium species, onions and garlic, but the Liliaceae have been split and the onion-like plants are now in the family Amaryllidaceae and asparagus in the Asparagaceae. Asparagus is a herbaceous, perennial plant growing to 100–150 cm (39–59 in) tall, with stout stems with much-branched, feathery foliage. The "leaves" are in fact needle-like cladodes (modified stems) in the axils of scale leaves; they are 6–32 mm (0.24–1.26 in) long and 1 mm (0.039 in) broad, and clustered four to 15 together, in a rose-like shape. The root system is adventitious and the root type is fasciculated. The flowers are bell-shaped, greenish-white to yellowish, 4.5–6.5 mm (0.18–0.26 in) long, with six tepals partially fused together at the base; they are produced singly or in clusters of two or three in the junctions of the branchlets.

It is usually dioecious, with male and female flowers on separate plants, but sometimes hermaphrodite flowers are found. The fruit is a small red berry 6–10 mm diameter, which is poisonous to humans. Plants native to the western coasts of Europe are treated as Asparagus officinalis subsp. prostratus, distinguished by its low-growing, often prostrate stems growing to only 30–70 cm (12–28 in) high, and shorter cladodes 2–18 mm (0.079–0.709 in) long.

Introduction	Asparagus is one of the first plants that greets us in springtime! It's a perennial, which means that once it gets established, asparagus will return year after year. Here's how to grow asparagus in your garden. Asparagus plants may take 2 to 3 years to truly get started and produce, so patience is needed! But then again, the plant can be productive for up to 25 years, so we think it's worth the wait. Asparagus are dioecious, which means that there are male and female plants. The key to the sex of the plant appears in the fall: Red berries form on female ferns. Inside the berries are tiny seeds—about 19,200 to a pound—and, yes, you can plant them—although it will take at least 3 years before you have a harvestable crop. Because male plants do not need to expend energy in producing berries, they have stronger root systems and can be up to three times more productive than female plants. Regions with cool winters are best for this cool-season crop, which is planted in early spring.										

Planting

Asparagus is planted in early spring as soon as the soil can be worked.
The plant is normally grown from "crowns" (1-year-old plants). Before you do anything, check the pH of your soil. Asparagus likes a pH of 6.0 to 8.0. Asparagus does not like to have its feet "wet," so be sure that your garden bed has good drainage. (For that reason, raised beds can be a good place to plant asparagus. Eliminate all weeds from the bed, digging it over and working in a 2- to 4-inch layer of compost, manure or soil mix.

Plant crowns deeply to protect them from the deep cultivation needed for annual weed control.
Dig a trench of about 12 to 18 inches wide and 6 to 8 inches deep. If digging more than one trench, space the trenches at least 3 feet apart. Within the trench, space asparagus crowns 12 to 18 inches apart (measured from root tip to root tip).

The traditional method of planting asparagus goes as follows:
1. Add a 2-inch-high mound of rich soil to the bottom of the trench and place the asparagus crowns on top of the mound, spreading their roots out evenly.
2. Add about 2 inches of soil over top of the crowns.
3. As the season progresses and spears grow to be 2–3 inches tall, add 2 more inches of soil, being careful not to bury the spears completely.
4. Once the spears again grow through the layer of soil, add an additional 2-inch layer of soil. Repeat this process until the trench has been filled to ground level. Depending on how deep you dug your trench, you may need to add soil one or two more times throughout the season.
5. After you've filled the trench completely, mound the soil slightly to prevent water from pooling around the emerging spears.

Rather than fill in the trench little by little, some gardeners prefer to fill it in all at once. While it's thought that the traditional method results in stronger plants overall, gardeners don't typically have any issues result from the "all-at-once" method, either. As long as the soil is fairly loose, the spears won't have a problem pushing through to the surface.

Care

When the trench is filled, add a 4- to 6-inch layer of mulch and water regularly. Do not harvest the spears in the first year (the plant needs time to grow out its root system), but cut down dead foliage in late fall and side-dress with compost. During the second year, harvest for only 3 to 4 weeks, side-dressing in spring and early fall and cutting down dead foliage in late fall. During the third year, the bed should be in full production, so you can start to harvest asparagus sparingly throughout the season.

Pests / Diseases

- Asparagus Beetles (Common and Spotted): These are the primary pest. Adults (shiny, often metallic blue-black with red/yellow markings or orange with black spots) and their greyish larvae feed on spears, causing scarring and browning, and can defoliate ferns, weakening the plant. Eggs are laid on spears and ferns.
- Asparagus Aphids: Tiny, pale green, powdery insects that suck sap from ferns, leading to stunted or distorted growth.
- Slugs and Snails: They can chew holes in emerging spears and foliage, especially in damp conditions.
- Asparagus Miner: Small maggots that tunnel within the stems, making plants vulnerable to diseases.
- Cutworms: Larvae that can sever young spears at the soil line, or feed on roots.

Harvest / Storage

If you have young plants, the season may last 2 to 3 weeks. However, established plants produce longer—up to 8 weeks. Asparagus can take three growing seasons to harvest, though you may be able to lightly harvest during the second year. Check your plant every other day for harvest-ready spears. Spears grow quickly and may become too woody before you know it! Once an asparagus spear starts to open and have foliage, it's too tough for eating. Harvest spears at 6 to 8 inches tall and at least ½ inch thick, cutting the spears off with a knife or scissors at the soil line. Stop harvesting spears when the diameter of the spears decreases to the size of a pencil. After harvest, allow the ferns to grow; this replenishes the nutrients for next year's spear production. Always leave one or two spears. Cut back asparagus AFTER the foliage has died back and turned brown or yellow. This is usually in the fall after frost. Cut back to the ground.

Asparagus does not keep for very long after it's picked, so be sure to eat it within two or three days from harvest. Brush off any visible dirt or give the spears a light washing with cold water before storing. It's very important to dry washed spears thoroughly; moisture can lead to mould. To store, bundle the spears together, wrap the stem ends of the spears in a moist paper towel, and place the bundle in a plastic bag. Store in the crisper drawer of your refrigerator. If you have enough space in your fridge, you can also store asparagus by placing the spears in a cup of water. Keep about an inch of clean water in the cup.

Variants

For highest yields, plant male hybrids such as 'Jersey Giant', 'Jersey King', and 'Jersey Knight'. Older varieties 'Mary Washington' and 'Martha Washington' may produce female plants, which are not as productive as the males. White asparagus is not a variety, but simply asparagus grown in the absence of sunlight to prevent chlorophyll from developing. White asparagus is slightly sweeter, but has less fibre than green asparagus. Purple asparagus is bred to be purple in colour, but turns green when it is cooked. Purple varieties tend to have thicker spears, but fewer of them.

Other Tips

A pinch of baking soda in the cooking water keeps beans, spinach, and asparagus greener. At only 40 calories per cup, asparagus is amazingly healthy. For more planting tips, see our page on growing asparagus from seed.

3 Bean (Climbing)

A bean is a seed of one of several genera of the flowering plant family Fabaceae, which are used for human or animal food. Seeds called "beans" are often included among the crops called "pulses" (legumes), although a narrower prescribed sense of "pulses" reserves the word for leguminous crops harvested for their dry grain. They are distinguished from the many other varieties of beans in that green beans are harvested and consumed with their enclosing pods, before the bean seeds inside have fully matured. An analogous practice is the harvest and consumption of unripened pea pods, as is done with snow peas or sugar snap peas.

Introduction

Pole and bush beans (more commonly called green beans) are a tender vegetable and a great addition to any garden!
Green beans are delicious when incorporated into any recipe. The main difference between bush and pole beans is the plants' growing styles: bush beans tend to grow more compactly and do not require support, while pole beans will vine and need to be grown up stakes or trellises. Bush beans generally require less maintenance and are easier to grow, but pole beans typically yield more beans and are very disease resistant. Green beans (also called string beans) are a tender annual that can grow anywhere with 6 to 8 hours of sun. Though most green beans are indeed green, they also come in purple, red, yellow and streaked varieties.

Introduction

The main difference between bush and pole beans is the plants' growing styles.
- Bush beans tend to grow more compactly (about two-feet tall) and do not require support. Pole beans will vine (a good ten feet) and need to be grown up stakes or trellises.
- Bush beans generally require less maintenance and are easier to grow, but pole beans typically yield more beans and are very disease-resistant.
- Bush beans produce before pole beans in about 50 to 55 days; pole beans will take 55 to 65 days.
- Bush beans often come in all at once, so stagger your planting every two weeks. Pole beans need their vines to grow and will produce for a month or two if you keep harvesting.

Planting

Pole beans will grow as a climbing vine that will grow 10 to 15 feet tall. Therefore, pole beans require a trellis or staking. Bush beans will spread up to 2 feet, but do not require support. Do not start seeds indoors; they may not survive transplanting. Normal, moderately-rich soil is fine for beans. Beans don't need supplemental fertilizer as they fix their own nitrogen, but you should still amend the soil with organic matter. Seeds can be sown outdoors anytime after the last spring frost; minimum soil temperature is 48 degrees F. Don't plant too early or the seeds can rot.

Plant all bean seeds 1 to 2 inches deep in normal soil, and a little deeper for sandier soils. Cover soil to warm if necessary. Bush beans: Plant about 4 inches apart. Pole beans: Set up trellises or teepees first for support. Then plant seeds about 6 to 8 seeds per teepee or every 6 inches apart. If you like pole beans, an easy support for them is a "cattle panel"—a portable section of wire fence—16 feet long and 5 feet tall. The beans will climb with ease and you won't have to get into contorted positions to pick them. For a harvest that lasts all summer, sow beans every 2 weeks. If you're going to be away, skip a planting. Beans do not wait for anyone. Rotate crops each year.

Care

Mulch soil to retain moisture; make sure that it is well-drained. Beans have shallow roots so mulch keep them cool. Water regularly, from start of pod to set. If you do not keep beans well watered, they will stop flowering. Water on sunny days so foliage will not remain soaked. Avoid a high-nitrogen fertilizer or you will get lush foliage and few beans. Just add a side dressing of compost or composted mature halfway through their growing season. Weed diligently and use shallow cultivation to prevent disturbing the root systems.

Pests / Diseases

- Mexican Bean Beetles (These beetles eat the flowers, beans and especially leaves of beans.)
- Japanese Beetles
- Aphids
- Slugs (These pests are attracted to damp conditions.)
- Cucumber Beetles
- White Mould (Avoid damp conditions)
- Mosaic Viruses (Try to keep vines dry by not crowding plants and providing ample air circulation)
- Woodchucks
- Cutworms
- Bean blossoms will drop from the plant if the weather is too hot, and too much nitrogen in the soil will prevent pods from setting.

Harvest / Storage

Green beans are picked young and tender before the seeds inside have fully developed. Look for firm, sizable that are firm and can be snapped, generally as thick as a pencil. Snap or cut off the plant, do not tear the plant. Fresh beans should snap easily when broken. Once you see the seeds inside bulging, green beans are past their peak and will taste tough. Pick green beans every day; the more you pick, the more beans grow. Store beans in a moisture-proof, airtight container in the refrigerator. Beans will toughen over time even when stored properly. Beans can be kept fresh for about 4 days, or blanched and frozen immediately after harvesting. Beans can also be canned or pickled.

Variants

- 'Kentucky Wonder' (pole): Will produce a bountiful harvest.
- 'Bountiful' (bush): Early producer. Stringless heirloom.
- 'Bush Blue Lake' (bush): Keeps flavour well after harvest.
- 'Bean Mascotte' (bush): Compact, ideal for container gardens.
- 'Fortex' (pole): French variety, large beans.
- 'Royal Burgundy' (bush): Purple pods that turn green when cooked. Early producing. Not popular with the bean beetle.

Other Tips

Beans are commonly used in everyday expressions to indicate something of little value. Consequently, someone who isn't worth a hill of beans is seen as being worth very little, although one could argue that today a hill of beans actually costs a pretty penny.

4 Beetroot

The beetroot is the taproot portion of the beet plant, usually known in North America as the beet, also table beet, garden beet, red beet, or golden beet. It is one of several of the cultivated varieties of Beta vulgaris grown for their edible taproots and their leaves (called beet greens). Usually the deep purple roots of beetroot are eaten boiled, roasted or raw, and either alone or combined with any salad vegetable. A large proportion of the commercial production is processed into boiled and sterilized beets or into pickles. In Eastern Europe, beet soup, such as borscht, is a popular dish. In Indian cuisine, chopped, cooked, spiced beet is a common side dish. Yellow-coloured beetroots are grown on a very small scale for home consumption.

Sowing Season	**Northern Hemisphere (Cold Climate)** Mar-Aug	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Sep-Apr	**Southern Hemisphere (Temperate Climate)** Jul-Apr	**Southern Hemisphere (Subtropical Climate)** Feb-Oct	**Southern Hemisphere (Tropical Climate)** Mar-Jun			
Sowing Guide	**Sowing Depth** 20-30mm	**Row Spacing** 30-40cm	**Plant Spacing** 5-10cm	**Frost Tender / Hardy** H	**Direct Sow / Raise Seeds** D	**Germination Time** 15-25 Days	**Maturity Time** 55-85 Days				
Introduction	Beets are a cool-season vegetable crop. This root veggie grows quickly and has many different varieties, which showcase deep red, yellow, or white bulbs of different shapes. Beets can survive frost and almost freezing temperatures, which makes them a great choice for northern gardeners and an excellent long-season crop.										

Planting

A soil pH between 6.0 and 7.0 is best, but slightly alkaline soils are tolerated in some areas. Till in aged manure before planting. Beets require especially good nutrition and a high phosphorus level to germinate. Go easy on nitrogen however, an excess will cause sprawling greens and tiny bulbs beneath the soil. (Learn more about soil amendments and preparing soil for planting.) Wait until soil reaches 50°F before planting. Plant seeds ½ inch deep and 1-2 inches apart. Make sure soil remains moist for germination. In zones with low moisture and rainfall, soak the seeds for 24 hours before planting. Early crop can be planted in March/April, and late crop anytime from June to September. Successive plantings are also possible as long as the weather doesn't exceed 75°F. Space plantings about 20 days apart. Winter crops are a definite possibility in Zone 9 and above.

Care

Thinning is necessary, as you may get more than one seedling out of each seed. Thin when they reach about 2 inches high by pinching them off. Pulling them out of the ground may disturb the roots of nearby seedlings. Established plants should be thinned to 3–4 inches between plants. Mulch and water well. Beets need to maintain plenty of moisture. Any necessary cultivation should be gentle, beets have shallow roots that are easily disturbed.

Pests / Diseases

● Flea Beetles
● Leaf Hoppers
● Mexican Bean Beetles

Harvest / Storage

Days to maturity tend to be between 50 and 70 for most varieties, although they can be harvested at any time you see fit. If you like larger bulbs, wait longer, but understand they will be tougher and woody. Don't let greens grow above 6 inches before harvesting. Don't forget about the tops! Beet greens have a delicious and distinctive flavour, and hold more nutrition than the roots. Fresh beets can be stored in the refrigerator for 5–7 days. Clipping the tops off beets will keep them fresher for longer. Leave about one inch of stem on each beet, and store the greens separately. For root cellar type storage, make sure you brush off any soil clinging to these crops, then store them in a cool, dry place. An unheated closet might do, or put them in a cooler in your basement. Beets can be frozen, canned, and pickled. Read more about a new way to store beets in the root cellar.

Variants

● 'Detroit Dark Red' - Sturdy, traditional red variety, round.
● 'Formanova' - Long, cylindrical beets that grow in the same fashion as carrots. Excellent for canning.

Other Tips

The humble beet, steamed, boiled, roasted, pickled, borscht'ed—but especially served raw—has emerged as a nutrient-dense food considered especially beneficial for health.

5 Broccoli

Broccoli is an edible green plant in the cabbage family whose large flowering head is eaten as a vegetable.
The word broccoli comes from the Italian plural of broccolo, which means "the flowering crest of a cabbage", and is the diminutive form of brocco, meaning "small nail" or "sprout". Broccoli is often boiled or steamed but may be eaten raw. Broccoli is a cool-weather crop that does poorly in hot summer weather. Broccoli grows best when exposed to an average daily temperature between 18-23°C (64-73°F). When the cluster of flowers, also referred to as a "head" of broccoli, appear in the centre of the plant, the cluster is green. Garden pruners or shears are used to cut the head about an inch from the tip. Broccoli should be harvested before the flowers on the head bloom bright yellow. While the heading broccoli variety performs poorly in hot weather, mainly due to insect infestation, the sprouting variety is more resistant, though attention must be paid to sucking insects (such as aphids), caterpillars and whiteflies

Sowing Season	**Northern Hemisphere (Cold Climate)** May-Aug	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Nov-Mar	**Southern Hemisphere (Temperate Climate)** Sep-Apr	**Southern Hemisphere (Subtropical Climate)** Feb-Jun	**Southern Hemisphere (Tropical Climate)** Mar-Jun			
Sowing Guide	**Sowing Depth** 6mm	**Row Spacing** 40-60cm	**Plant Spacing** 35-45cm	**Frost Tender / Hardy** H	**Direct Sow / Raise Seeds** R/D	**Germination Time** 15-25 Days	**Maturity Time** 60-120 Days				
Introduction	Broccoli is a cool-season crop that, like spinach, can be grown in the spring or fall. Here's how to grow broccoli in your garden. With broccoli, you may even be able to get a continual harvest throughout the summer and fall if you practice succession gardening and your summers don't get excessively hot. A member of the cabbage family, broccoli is rich in vitamins.										

Planting

As a cool-season crop, broccoli can germinate in soil with temperatures as low as 40°F (5°C), though most gardeners start broccoli indoors if growing it from seed. See our free online Planting Calendar for local seed-starting dates. For outdoor spring plantings, sow seeds or set transplants into the garden 2 to 3 weeks before your last spring frost date. (See local frost dates here.) If you transplant, assume 10 less days for growth or the "days to maturity" given on the seed packet. You may need to make use of a cold frame to protect young plants from frost. For fall plantings, seed 85 to 100 days before your average first fall frost. If you live in a warm climate, a fall planting is best, as broccoli thrives in cool weather.

Plant seeds in mid- to late-summer in most places. Broccoli requires full sun and moist, fertile soil that's slightly acidic. Work in 2 to 4 inches of rich compost or a thin layer of manure before planting. (Learn more about soil amendments and preparing soil for planting.) Plant seeds ½ inch deep, or set transplants slightly deeper than they were grown originally. Within a row, space your plants 12 to 24 inches apart with 36 inches between each row. Space plants 12 to 24 inches apart, depending on the side heads you want to harvest. If you overseed, you will need to thin seedlings to 12 inches apart to give room for the broccoli to grow.

Care

Fertilize broccoli three weeks after transplanting seedlings into the garden. Provide consistent soil moisture with regular watering, especially in drought conditions. Some varieties of broccoli are heat tolerant, but all need adequate moisture. Do not get developing broccoli heads wet when watering. Roots are very shallow, so try not to disturb the plants. Suffocate weeds with mulch. Mulch will also help to keep soil temperatures down.

Pests / Diseases

● Flea Beetles
● Aphids: Curling leaves may mean that the plant's sap is being sucked by insects. Apply soapy water to all sides of leaves whenever you see aphids.
● Downy mildew: Yellow patches on leaves are usually caused by moist weather. Keep leaves as dry as possible with good air circulation. Buy resistant varieties.
● Cabbage loopers: Small holes on the leaves between the veins mean small green caterpillars are present. Look at the undersides of the leaves. Hand pick if the problem is small or control with Bacillus thuringiensis, a natural, bacterial pesticide. Use a floating row cover just after planting through harvest to prevent caterpillars.
● Cabbageworms and other worm pests: Treat same as loopers.
● Cabbage root maggots
● Whiteflies
● Nitrogen deficiency: If the bottom leaves turn yellow and the problem continues toward the top of the plant, the plants need a high nitrogen (but low phosphorus) fertilizer or blood meal. Blood meal is a quick nitrogen fix for yellowing leaves.

● Clubroot: Quickly wilting plants may be due to this fungus in the soil. The entire plant, including all roots and root tendrils, must be gently dug up and removed. If the roots are gnarled and misshapen, then clubroot is the problem. Act quickly to remove the plants so that the fungus doesn't continue to live in the soil. Do not compost the plants. Raise the pH of your soil to above 7.2. You may need to sterilize your soil, too.
● Woodchucks

Harvest / Storage

In terms of timing: Harvest broccoli when the buds of the head are firm and tight, right before the heads flower. If you do see yellow petals, harvest immediately. For best taste, harvest in the morning before the soil heats up. Cut heads from the plant, taking at least 6 inches of stem. Cut the stalk of the main head at an angle, about 5 to 8 inches below the head. Most varieties have side-shoots that will continue to develop after the main head is harvested. You can harvest from one plant for many weeks, in some cases, from spring to fall, if your summer isn't too hot. Learn more tips on harvesting broccoli.

Store broccoli in the refrigerator for up to 5 days. If you wash before storing, make sure to dry it thoroughly. Broccoli can be blanched and frozen for up to one year.

Variants

● 'Green Goliath' is heat-tolerant and sprouts side shoots that will mature for harvesting.
● 'Green Duke' is heat tolerant and an early variety that's especially good for Southern gardeners.
● 'Calabrese' is a prolific Italian heirloom that sprouts side shoots that will mature for harvesting. Great for fall planting, too.
● 'Flash' is a fast-growing, heat-resistant hybrid with good side-shoot production once the central head is cut. Great for fall planting, too.
● 'Paragon' is a popular variety in Canada.

Other Tips

One ounce of broccoli has an equal amount of calcium as one ounce of milk. Learn more about the amazing health benefits of broccoli. Once you've gotten broccoli down pat, why not try growing one of its relatives? See our Growing Guides for cauliflower, cabbage, Brussels sprouts, rutabaga, kale, and turnips!

6 Brussels Sprouts

The Brussels sprout is a member of the Gemmifera Group of cabbages (Brassica oleracea), grown for its edible buds. The leafy green vegetables are typically 2.5–4 cm (0.98–1.6 in) in diameter and look like miniature cabbages. The Brussels sprout has long been popular in Brussels, Belgium, and may have originated and gained its name there. Brussels sprouts grow in temperature ranges of 7–24°C (45–75°F), with highest yields at 15–18°C (59–64°F). Fields are ready for harvest 90 to 180 days after planting. The edible sprouts grow like buds in helical patterns along the side of long, thick stalks of about 60 to 120 cm (24 to 47 in) in height, maturing over several weeks from the lower to the upper part of the stalk.

Sprouts may be picked by hand into baskets, in which case several harvests are made of five to 15 sprouts at a time, or by cutting the entire stalk at once for processing, or by mechanical harvester, depending on variety. Each stalk can produce 1.1 to 1.4 kg (2.4 to 3.1 lb), although the commercial yield is about 900 g (2.0 lb) per stalk. Harvest season in temperate zones of the northern latitudes is September to March, making Brussels sprout a traditional winter stock vegetable. In the home garden, harvest can be delayed as quality does not suffer from freezing. Sprouts are considered to be sweetest after a frost. Brussels sprouts are a cultivar group of the same species as cabbage, collard greens, broccoli, kale, and kohlrabi; they are cruciferous (they belong to the Brassicaceae family; old name Cruciferae). Many cultivars are available, some being purple in colour, such as Ruby Crunch or Red Bull.

Sowing Season	**Northern Hemisphere (Cold Climate)** May-Aug	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Oct-Feb	**Southern Hemisphere (Temperate Climate)** Dec-Apr	**Southern Hemisphere (Subtropical Climate)** Feb-Jun	**Southern Hemisphere (Tropical Climate)** Feb-Apr		
Sowing Guide	**Sowing Depth** 6mm	**Row Spacing** 90cm	**Plant Spacing** 50-75cm	**Frost Tender / Hardy** H	**Direct Sow / Raise Seeds** R/D	**Germination Time** 6-12 Days	**Maturity Time** 80-140 Days			
Introduction	Brussels sprouts are a member of the cabbage family, and an excellent source of protein and vitamins. Here's how to plant and grow Brussels sprouts in your garden! They have a long growing season (80+ days to harvest), and are generally more successful when grown for a fall harvest, as they only increase in flavour after a light frost or two.									

Planting

Due to Brussels sprouts' need for a long growing season, plant them with a fall or winter harvest in mind. In regions with cold winters, where temperatures are regularly below freezing, start seeds indoors about 2–3 weeks before the last spring frost date for an early fall harvest. In regions with mild winters, where temperatures are occasionally below freezing, start seeds outdoors in early to mid-summer for a mid-fall or early winter harvest. In regions with warm winters, where temperatures are rarely or never below freezing, start seeds outdoors in late summer for a mid- to late winter harvest. Another way to determine planting time is to count backwards from your first fall frost date.

Direct sow seeds into the garden about 4 months before the first fall frost. Raised beds are especially recommended for cold-season vegetables, especially when seasons are changing and temps are not consistent. Work fertilizer into soil a few days before planting or transplanting. Plant transplanted seedlings 12–24 inches apart. If direct sowing seeds, plant ½ inch deep and 2–3 inches apart. Thin plants to 12–24 inches apart when they reach 6 inches tall. Water well at time of planting/transplanting.

Care

Fertilize three weeks after transplanting. Mulch to retain moisture and keep the soil temperature cool. If growing during hot weather, be sure to keep the plants well watered. Do not disturb the soil around the plants; roots are shallow and susceptible to damage.

Pests / Diseases

● Aphids
● Cabbage Root Maggots
● Flea Beetles
● Clubroot
● Downy Mildew
● White mould

Harvest / Storage

Harvest sprouts from the bottom of the stalk when they reach about 1 inch in diameter. Do not wash the sprouts before storing them, only right before use. Keep in plastic for up to 5 days, in the refrigerator. Protect the plant by mulching with straw or providing a cover if you plan to harvest into the winter.

Variants

- 'Jade Cross' is resistant to some diseases and known for its tolerance for hotter weather.
- 'Oliver' and 'Long Island Improved' are early varieties with shorter growing season requirements (80–90 days).
- 'Valiant' produces consistent, uniform sprouts.

Other Tips

7 Cabbage

Cabbage or headed cabbage is a leafy green, red (purple), or white (pale green) biennial plant grown as an annual vegetable crop for its dense-leaved heads. It is closely related to broccoli and cauliflower; Brussels sprouts; and savoy cabbage. Brassica rapa is commonly named Chinese, celery or napa cabbage and has many of the same uses. Cabbage is high in nutritional value. Cabbage heads generally range from 0.5 to 4 kilograms (1 to 9 lb), and can be green, purple or white. Smooth-leafed, firm-headed green cabbages are the most common. Smooth-leafed purple cabbages and crinkle-leafed savoy cabbages of both colours are rarer. It is a multi-layered vegetable. Under conditions of long sunny days, such as those found at high northern latitudes in summer, cabbages can grow quite large. As of 2012, the heaviest cabbage was 62.71 kilograms (138.25 lb). Cabbage seedlings have a thin taproot and cordate (heart-shaped) cotyledon. The first leaves produced are ovate (egg-shaped) with a lobed petiole. Plants are 40–60 cm (16–24 in) tall in their first year at the mature vegetative stage, and 1.5–2.0 m (4.9–6.6 ft) tall when flowering in the second year. Heads average between 0.5 and 4 kg (1 and 8 lb), with fast-growing, earlier-maturing varieties producing smaller heads.

Most cabbages have thick, alternating leaves, with margins that range from wavy or lobed to highly dissected; some varieties have a waxy bloom on the leaves. Plants have root systems that are fibrous and shallow. About 90 percent of the root mass is in the upper 20–30 cm (8–12 in) of soil; some lateral roots can penetrate up to 2 m (6.6 ft) deep. The inflorescence is an unbranched and indeterminate terminal raceme measuring 50–100 cm (20–40 in) tall, with flowers that are yellow or white. Each flower has four petals set in a perpendicular pattern, as well as four sepals, six stamens, and a superior ovary that is two-celled and contains a single stigma and style. Two of the six stamens have shorter filaments. The fruit is a silique that opens at maturity through dehiscence to reveal brown or black seeds that are small and round in shape. Self-pollination is impossible, and plants are cross-pollinated by insects. The initial leaves form a rosette shape comprising 7 to 15 leaves, each measuring 25–35 cm (10–14 in) by 20–30 cm (8–12 in); after this, leaves with shorter petioles develop and heads form through the leaves cupping inward.

Sowing Season	**Northern Hemisphere (Cold Climate)** Feb-Sep	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Aug-Apr	**Southern Hemisphere (Temperate Climate)** Jun-Apr	**Southern Hemisphere (Subtropical Climate)** All Year	**Southern Hemisphere (Tropical Climate)** Feb-Nov			
Sowing Guide	**Sowing Depth** 6mm	**Row Spacing** 50-70cm	**Plant Spacing** 40-50cm	**Frost Tender / Hardy** H	**Direct Sow / Raise Seeds** R/D	**Germination Time** 6-12 Days	**Maturity Time** 60-120 Days				
Introduction	Cabbage is a hardy, leafy vegetable full of vitamins. It can be difficult to grow; it only likes cool temperatures and it can be a magnet for some types of garden pests. Here are some tips for growing cabbage in your garden! By planning your growing season and providing diligent care, you may have two successful crops in one year, in both spring and fall. Many varieties are available to suit both your growing conditions and taste preferences.										

Planting

To prepare soil, till in aged manure or compost. Start cabbage seeds indoors 6 to 8 weeks before the last spring frost in your area. Consult our Planting Calendar for suggested dates. Before planting the seedlings outdoors, harden off the plants over the course of a week. Transplant outdoors 2 to 3 weeks before the last expected frost date. If possible, plant on a cloudy day so that the seedlings aren't subjected to intense sunlight right away. Plant 12 to 24 inches apart in rows, depending on the size of head desired. The closer you plant, the smaller the cabbages. Because cabbage, broccoli, and cauliflower are closely related, and require similar nutrients, it's best not to plant them together. They are all heavy feeders, depleting the soil faster of required nutrients; plus, they will attract the same pests and diseases. For cabbage, also avoid proximity to strawberries and tomatoes. Cabbages can be grown near beans and cucumbers. Check out our chart of plant companions for an expanded list of friends and foes.

Care

When seedlings reach about 5 inches tall, thin to make sure that they are still the desired length apart. (The plants you remove can be transplanted elsewhere in your garden.) Mulch thickly around the area to retain moisture and regulate soil temperature. Fertilize 3 weeks after transplanting with an all-purpose fertilizer. Practice crop rotation with cabbages to avoid a build-up of soil borne diseases.

Pests / Diseases

- Imported Cabbageworms: Dill protects all members of the cabbage family by attracting beneficial wasps that kill cabbageworms and other pests.
- Aphids
- Cabbage Root Maggots
- Flea Beetles
- Cutworms
- Splitting

Harvest / Storage

Harvest when heads reach desired size and are firm. This will take around 70 days for most green cabbage varieties. Most early varieties will produce 1- to 3-pound heads. Cut each cabbage head at its base with a sharp knife. After harvesting, bring inside or put in shade immediately. To get two crops from early cabbage plants, cut the cabbage head out of the plant, leaving the outer leaves and root in the garden. The plant will send up new heads—pinch them off until only four or so smaller heads remain. When these grow to tennis-ball size, they'll be perfect for salad. After harvesting, remove the entire stem and root system from the soil to prevent disease build-up. Only compost healthy plants; destroy those with maggot infestation. Cabbage can be stored in the refrigerator for no more than two weeks, wrapped lightly in plastic. Make sure it is dry before storing. In proper root cellar conditions, cabbage will keep for up to 3 months.

Variants

● If you are planting for a fall harvest, try red or Chinese cabbage. Good varieties include 'Ruby Perfection' and 'Lei-Choy'.
● For a quick harvest time, try 'Golden Acre', 'Primo', or 'Stonehead'.
● 'Early Jersey Wakefield' resists splitting.
● Disease-resistant varieties include 'Blue Vantage' and 'Cheers'.

Other Tips

Cabbage is a hardy vegetable, is an antioxidant- and nutrient-rich, and a great addition to any garden!

8 Peppers (Capsicum)

Peppers (also known as Capsicum) is a genus of flowering plants in the nightshade family Solanaceae. In addition to use as spices and food vegetables, Capsicum species have also been used as medicines and lachrymatory agents.

Sowing Season	**Northern Hemisphere (Cold Climate)** Apr-Jun	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Sep-Nov	**Southern Hemisphere (Temperate Climate)** Aug-Dec	**Southern Hemisphere (Subtropical Climate)** Aug-Mar	**Southern Hemisphere (Tropical Climate)** All Year			
Sowing Guide	**Sowing Depth** 4mm	**Row Spacing** 80-100cm	**Plant Spacing** 40-60cm	**Frost Tender / Hardy** FT	**Direct Sow / Raise Seeds** R/D	**Germination Time** 10-20 Days	**Maturity Time** 70-110 Days				
Introduction	Peppers are a tender, warm-season crop. Here's how to grow peppers in your garden! Peppers resist most garden pests and offer something for everyone: spicy, sweet, or hot; and a variety of colours, shapes, and sizes. For this page, we will focus on sweet bell peppers.										

Planting

Start seeds indoors 8-10 weeks before last spring frost date. The temperature must be at least 70° F for seed germination, so keep them in a warm area for the best and fastest results. Start pepper seeds three to a pot, and thin out the weakest seedling. Let the remaining two pepper plants spend their entire lives together as one plant. The leaves of two plants help protect peppers against sunscald and the yield is often twice as good as two segregated plants. Begin to harden off plants about 10 days before transplanting. A week before transplanting, introduce fertilizer or aged compost into your garden soil. After the danger of frost has passed, transplant seedlings outdoors, 18 to 24 inches apart (but keep paired plants close to touching.) Soil should be at least 65° F, as peppers will not survive transplanting at temps any colder. Northern gardeners can warm up the soil by covering it with black plastic. Put two or three match sticks in the hole with each plant, along with about a teaspoon of fertilizer. These give the plants a bit of sulphur, which they like.

Care

Soil should be well drained, but be sure to maintain adequate moisture either with mulch or plastic covering. Water one to two inches per week, but remember that peppers are extremely heat sensitive. If you live in a warm or desert climate, watering everyday may be necessary. Fertilize after the first fruit set. Weed carefully around plants. If necessary, support plants with cages or stakes to prevent bending. Try commercially available cone-shaped wire tomato cages. They may not be ideal for tomatoes, but they are just the thing for peppers. Or, build your own garden supports. For larger fruit, spray the plants with a solution of one tablespoon of Epsom salts in a gallon of water, once when it begins to bloom, and once ten days later.

Pests / Diseases

● Aphids
● Flea Beetles
● Cucumber Mosaic Virus
● Blossom-End Rot appears as a soft, sunken area which turns darker in colour.
● Pollination can be reduced in temperatures below 60° F and above 90° F.
● Too much nitrogen will reduce fruit from setting.

Harvest / Storage

Harvest as soon as peppers reach desired size. The longer bell peppers stay on the plant, the more sweet they become and the greater their Vitamin C content. Use a sharp knife or scissors to cut peppers clean off the plant for the least damage. Peppers can be refrigerated in plastic bags for up to 10 days after harvesting. Bell peppers can be dried, and we would recommend a conventional oven for the task. Wash, core, and seed the peppers. Cut into one-half-inch strips. Steam for about ten minutes, then spread on a baking sheet. Dry in the oven at 140° F (or the lowest possible temperature) until brittle, stirring occasionally and switching tray positions. When the peppers are cool, put them in bags or storage containers.

Variants

● Green to Red: 'Lady Bell,' 'Gypsy,' 'Bell Boy,' 'Lipstick'
● Yellow: 'Golden California Wonder'

Other Tips

The popular green and red bell peppers that we see in supermarkets are actually the same thing; the red peppers have just been allowed to mature on the plant longer, changing colour and also gaining a higher content of Vitamin C.

9 Carrot

The carrot (Daucus carota) is a root vegetable, usually orange in colour, though purple, black, red, white, and yellow cultivars exist. Carrots are a domesticated form of the wild carrot, Daucus carota, native to Europe and south-western Asia. The plant probably originated in Persia and was originally cultivated for its leaves and seeds. The most commonly eaten part of the plant is the taproot, although the stems and leaves are eaten as well.

Sowing Season	Northern Hemisphere (Cold Climate) Mar-Aug	Northern Hemisphere (Temperate Climate) o	Northern Hemisphere (Subtropical Climate) o	Northern Hemisphere (Tropical Climate) o	Southern Hemisphere (Cold Climate) Aug-Mar	Southern Hemisphere (Temperate Climate) Sep-May	Southern Hemisphere (Subtropical Climate) Feb-Nov	Southern Hemisphere (Tropical Climate) Feb-Sep			
Sowing Guide	Sowing Depth 4mm	Row Spacing 25-30cm	Plant Spacing 3-8cm	Frost Tender / Hardy Half Hardy	Direct Sow / Raise Seeds D	Germination Time 10-20 Days	Maturity Time 70-120 Days				
Introduction	Carrots are a popular root vegetable that's easy to grow as long as it's planted in loose, sandy soil. Here's what you need to know about planting, growing, and harvesting carrots in your garden! Most varieties of carrots are resistant to pests and diseases, and they are also a good late-season crop that can tolerate frost. In fact, they prefer to be grown during the cooler ends of the growing season—spring and fall. Carrots' root is rich in sugar, and a great source of vitamins and carotene. Not all carrots are orange; varieties vary in colour from purple to white! If there is a challenge to growing carrots, it's just having soil that's not too heavy—otherwise, you'll end up with stunted, round carrots! Most carrot varieties need deep, loose soil that lets them grow without difficulty. Carrots are grown from seed and take between two and four months to mature, depending on the variety. Depending on the variety and local growing conditions, carrots may take anywhere from 2 to 4 months to mature.										

Planting

Prepare the seedbed for carrots well before sowing seed! See more about preparing the soil below. Wait until the soil has dried out before digging it. Plan to plant seeds outdoors 3 to 5 weeks before the last spring frost date. Find your local frost dates here. Tip: Plant additional seeds every 3 weeks or so for multiple harvests. Plant carrot seeds 3 to 4 inches apart in rows. Rows should be at least a foot apart. Cover the newly sown seeds with sand or fine soil that will not crust over when dry. Keep the soil moist with frequent shallow waterings. The soil can't crust for small carrot seeds to germinate. (If you put your finger in the ground, it should be moist, but not wet, to the middle knuckle.) Carrots are sometimes slow to germinate. They may take 2 to 3 weeks to show any signs of life, so don't panic if your carrots don't appear right away! Carrots are best grown in full sunlight, but can tolerate a moderate amount of shade. Carrots grown in shade won't be as robust as those in full sun, however. Provide shade for seeds planted in mid-summer so that the soil does not heat up. Garden fleece will do this job.

One of the most important things to consider when growing carrots (and other root vegetables) is the condition of your soil. Follow these guidelines to ensure a healthy carrot harvest: Make sure your soil is free of stones. Stones obstruct the path of carrot roots, which can result in a stunted and misshapen crop. Till your soil before planting. Carrots need deeply-tilled, loose soil that they can easily push through. Use the right type of soil. Carrots grow best in sandy or loamy soil (as opposed clayey or silty soil), so add sand if necessary! Avoid using manure or too much fertilizer. Have you ever seen a carrot that has grown "legs" or has forked? Fresh manure, or even recently-applied rotted manure, can cause carrots to fork and send out little side roots. Don't use it before you plant your carrot seeds.

Care

After planting, gently mulch to retain moisture, speed germination, and block the sun from hitting the roots directly. Once plants are an inch tall, thin so that they stand 3 inches apart. Snip them with scissors instead of pulling them out to prevent damage to the fragile roots of the remaining plants. Water at least one inch per week. Weed diligently, but be careful not to disturb the carrots' roots while doing so. Fertilize with a balanced fertilizer 5-6 weeks after sowing.

Pests / Diseases

● Wireworms
● Flea Beetles
● Aster Yellow Disease will cause shortened and discoloured carrot tops and hairy roots. This disease is spread by pests as they feed from plant to plant. Keep weeds down and invest in a control plan for pests such as leafhoppers. This disease has the ability to overwinter.

Harvest / Storage

Carrots should be mature and ready for harvest in about 2–4 months, or when they reach at least ½ inch in diameter. You may harvest whenever desired maturity is reached. If you're growing carrots in the spring and early summer, harvest before daily temperatures get too hot, as the heat can cause carrot roots to grow fibrous. Carrots taste much better after a couple of frosts. (A frost encourages the plant to start storing energy—sugars—in its root for later use.) Following the first hard frost in the fall, cover carrot rows with an 18-inch layer of shredded leaves to preserve them for harvesting later.

To store freshly-harvested carrots, twist off the green tops, scrub off the dirt under cold running water, let dry and seal in airtight plastic bags, and refrigerate. If you simply put fresh carrots in the refrigerator, they'll go limp in a few hours. You may leave mature carrots in the soil for temporary storage if the ground will not freeze and pests aren't a problem. Carrots can be stored in tubs of moist sand for winter use.

Variants

Nantes varieties are 6 to 7 inches long, cylindrical (not tapered), and entirely edible. They are medium-sized, sweet and mild, and have a crisp texture. Danvers carrots are a classic heirloom carrot, 6 to 8 inches long, that tapers at the end and has a rich, dark orange colour. This variety can handle heavy soil better than most varieties.
● 'Little Finger' is a small Nantes type of carrot only 4 inches long and one inch thick. Great for containers.
● 'Bolero': resists most leaf pests.
● 'Thumberline': round carrot, good for clumpy or clay soil.

Other Tips

Don't expect the perfect shape of grocery store carrots. Your carrots will still taste better, whatever their shape! Carrots' root is rich in sugar, and a great source of vitamins and carotene. Not all carrots are orange; varieties vary in colour from purple to white. Carrots are biennial plants. If you leave them in the ground, the tops will flower and produce seeds the second year. Carrots have a long list of health benefits, not just those from Vitamin A.

Do your carrots look round, short, fat, and/or more like a potato?	Carrots need loose, light, airy soil. Most of us need to add sand. We use 100% sand mixed with ⅓ peat moss.
Do your carrots look round, short, fat, and/or more like a potato?	Till deeper! Carrots usually give up if they grow down a foot and hit any soil clumps. While we're not normally big fans of tilling, you must prepare a carrot bed. Till down 18 inches and make sure there are no rocks, weeds, or even soil clumps to impede your carrots' growth.
Do you carrots look as if they have legs or do they split?	Do not amend the soil. You have too much heavy compost or manure and too many nutrients. Not enough sand. Do not baby carrots.
Do you carrots look as if they have legs or do they split?	Seed directly in the ground. Don't transplant. Try to distribute seed in an even fashion so seeds don't grow together or use a seed-sower or thin vigorously to the right space.

Do you carrots look as if they have legs or do they split?	Main soil moisture with frequent shallow waterings during germination. The soil can't crust over.

10 Cauliflower

Cauliflower is one of several vegetables in the species Brassica oleracea in the genus Brassica, which is in the family Brassicaceae. It is an annual plant that reproduces by seed. Typically, only the head is eaten – the edible white flesh sometimes called "curd" (with a similar appearance to cheese curd).

Sowing Season	Northern Hemisphere (Cold Climate) May-Jul	Northern Hemisphere (Temperate Climate) o	Northern Hemisphere (Subtropical Climate) o	Northern Hemisphere (Tropical Climate) o	Southern Hemisphere (Cold Climate) Nov-Apr	Southern Hemisphere (Temperate Climate) Dec-Apr	Southern Hemisphere (Subtropical Climate) Jan-May	Southern Hemisphere (Tropical Climate) Jan-Apr			
Sowing Guide	Sowing Depth 6mm	Row Spacing 75-90cm	Plant Spacing 45-70cm	Frost Tender / Hardy H	Direct Sow / Raise Seeds R/D	Germination Time 6-12 Days	Maturity Time 100-160 Days				
Introduction	Cauliflower is a cool-season crop and a descendant of the common cabbage. It is more difficult to grow than its relatives because it does not tolerate the heat or cold as well. If you plant to attempt growing cauliflower in the home garden, it requires consistently cool temperatures with temperatures in the 60s. Otherwise, it may prematurely "button"—form small, button-size heads—rather than forming a single, large, white head. Given that cauliflower enjoys cool temperature, it's a good autumn crop in many regions. Because of its temperature requirements, however, cauliflower is usually grown commercially and not the best crop for the beginner gardener. Are you up for the challenge?										

Planting

Select a site with at least 6 hours of full sun. Soil needs to be very rich in organic matter; add composted mature to the soil before planting. Fertile soil holds in moisture to prevent heads from "buttoning." Test your soil! (Get a comprehensive soil test through your local cooperative extension office.) The soil pH should be between 6.5 and 6.8. It is best to start cauliflower from transplants rather than seeds. Transplant 2 to 4 weeks before the average frost date in the spring, no sooner and not much later. Space the transplants 18 to 24 inches apart with 30 inches between rows. Use starter fertilizer when transplanting. Plant fall cauliflower about the same time as fall cabbage. This is usually 6 to 8 weeks before the first fall frost, but after the daytime temperature is below 75 degrees F. If you really want to try starting cauliflower from seeds, start the seeds 4 to 5 weeks before the plants are needed. Plant the seeds in rows 3 to 6 inches apart and up to half an inch deep. Do not forget to water the seeds during their germination and growth. Once they become seedlings, transplant them to their permanent place in the garden. In early spring, be ready to cover your plants with old milk jugs for protection if needed. For fall crops, shade them if they need protection from the heat. Add mulch to conserve moisture.

Care

Make sure that the plants have uninterrupted growth. Any interruption can cause the plants to develop a head prematurely or ruin the edible part completely. Cauliflower requires consistent soil moisture. They need 2 inches of water each week; with normal rainfall, this usually requires supplemental watering. For best growth, side-dress the plants with a nitrogen fertilizer. Note that the cauliflower will start out as a loose head and that it takes time for the head to fully form. Many varieties take at least 75 to 85 days from transplant. Be patient! When the curd (the white head) is about 2 to 3 inches in diameter, tie the outer leaves together over the head with a rubber band, tape, or twine. This is called blanching, and it protects the head from the sun and helps you get that pretty white colour. The plants are usually ready for harvest 7 to 12 days after blanching.

Pests / Diseases

- Cabbageworm: Nectar from dwarf zinnias lures in ladybugs and other predators that help to protect cauliflower from cabbageworms.
- Cabbage root maggots
- Aphids
- Harlequin bugs
- Clubroot
- Black Rot

Harvest / Storage

When the heads are compact, white, and firm, then it is time to harvest them. Ideally, the heads will grow to 6 to 8 inches in diameter. Cut the heads off the plant with a large knife. Be sure to leave some of the leaves around the head to keep it protected. If the heads are too small, but have already started to open up, they will not improve and should be harvested. If the cauliflower has a coarse appearance, it is too mature and should be tossed. If you want to store cauliflower, you can put the head in a plastic bag and store it in the refrigerator. It should last for about a week. For long-term storage, you can also freeze or pickle the heads.

Variants

- 'Snowball', which produces medium heads and a good yield throughout the growing season.
- 'Orange', which has a similar taste to the white cauliflower, but has more vitamin A.

Other Tips

11 Celery

Celery (Apium graveolens) is a marshland plant in the family Apiaceae that has been cultivated as a vegetable since antiquity. Celery has a long fibrous stalk tapering into leaves. Depending on location and cultivar, either its stalks, leaves, or hypocotyl are eaten and used in cooking. Celery seed is also used as a spice and its extracts have been used in herbal medicine.

Sowing Season	**Northern Hemisphere (Cold Climate)** Mar-Jun	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Sep-Dec	**Southern Hemisphere (Temperate Climate)** Sep-Feb	**Southern Hemisphere (Subtropical Climate)** Mar-Oct	**Southern Hemisphere (Tropical Climate)** Apr-Sep			
Sowing Guide	**Sowing Depth** 4mm	**Row Spacing** 30-55cm	**Plant Spacing** 15-30cm	**Frost Tender / Hardy** H	**Direct Sow / Raise Seeds** R	**Germination Time** 15-25cm	**Maturity Time** 120-140 Days				

Introduction

Celery is a long-season vegetable grown in the spring or fall. It has the reputation of being fussy; however, it's really quite easy if you understand its specific needs. Here are tips from the pros on sowing, growing, and harvesting celery. We enjoy growing celery because it's not only crunchy, but also more flavourful than what you typically find in grocery stores. Plus, commercial celery is one of the most pesticide-laden crops so why not grow your own! Celery has three critical needs:
1. A long growing season (130 to 140 days of mostly cool weather). Celery will not tolerate high heat.
2. A constant, unfailing water supply. The soil must stay watered at all times. If celery has a spell without water, it will be problematic (stringy, tough, and/or hollow stalks).
3. Rich, fertile soil with plenty of organic matter mixed in. The crop is a big feeder and also needs to be fertilized during its growth period, too. Because celery roots are shallow (just a few inches deep), make sure nutrients are in the top of the soil.

Celery is often grown as a winter crop in the South, a summer crop in the far North, and a fall crop in most other areas Transplants are hard to find, so be prepared to start plants from seed.

Planting

Because the season is so long, celery seeds should always be started indoors for the best success rate. For a spring crop, sow seeds indoors 10 to 12 weeks before the average last frost date for your area. For a fall crop, sow in summer, timing so that you can set out transplants 10 to 12 weeks before the first autumn frost. Soak seeds in warm water overnight prior to planting to reduce germination time. To get good germination, don't cover the seeds with soil. Simply press the seeds into potting soil that's formulated for seed-starting and cover the trays or pots with plastic covers to hold the moisture. Germination should take place in about a week. When the plants are two inches tall, transplant them to individual peat pots or to another, deeper, flat with new potting soil. If you use flats, put the plants at least two inches apart.

Plant celery outdoors when the soil temperature reaches 50 degrees F. or more, and when the nights don't dip down below 40 degrees F. Work organic compost into the soil prior to planting. (Learn more about soil amendments and preparing soil for planting.) Or mix in fertilizer (about one pound of 5-10-10 per 30 square feet). Harden off seedlings before transplanting by reducing water slightly, and keeping them outdoors for a couple hours a day. Transplant seedlings 8 to 10 inches apart. Direct sow seeds ¼ inch deep. These will need to be thinned to 12 inches apart when they reach about six inches high. Mulch the plants after they are 6 inches tall to keep the soil moist and the roots cool. Water directly after planting.

Care

Celery requires lots of water. Make sure to provide plenty of water during the entire growing season, especially during hot, dry weather. If celery does not get enough water, the stalks will be dry and small. Add plenty of compost and mulch around the plants to retain moisture. Sidedress with a 5-10-10 fertilizer in the second and third month of growth (one tablespoon per plant and sprinkle it in a shallow furrow three to four inches from the plant and cover it with soil). Keep celery weeded but be careful when weeding as celery has shallow roots and could easily get disturbed. Tie growing celery stalks together to keep them from sprawling.

Pests / Diseases

- Flea beetles
- Slugs and Snails
- Earwigs

To control pests, cover the plants with garden fabric (row covers) during the first four to six weeks of the growing season.

Harvest / Storage

The parts of celery that are harvested are mainly the stalks, which will be above ground. Pick the stalks whenever you want. Young celery is as good as the mature product. Harvest stalks from the outside in. You may begin harvesting when stalks are about 8 inches tall. Celery can be kept in the garden for up to a month if soil is built up around it to maintain an ideal temperature. Celery will tolerate a light frost, but not consecutive frosts. Tip: The darker the stalks become, the more nutrients they will contain. Texture changes with colour; dark green stalks will be tougher. Keep celery in a plastic bag in the refrigerator. Celery stores really well; you can keep it for many weeks with no trouble.

Variants

- 'Utah 52-70R Improved' is good for gardeners with limited space. Will only reach 18 inches tall.
- 'Alfina' has slender stalks and is a dark green, quick-growing variety (60 days to maturity).
- 'Conquistador' is tolerant of higher temps and watering shortage.

Other Tips

Keep in mind the grocery store celery is lighter in colour and bigger than home-grown celery because the commercial varieties are grown in greenhouses and/or protected from the sun; they often carries a lot of pesticides, too. Celery stalks can be frozen. Cut the stalks into half-inch pieces and store in freezer-grade bags. The ancient Romans believed that celery had healing powers, especially when it came to headaches.

12 Chilli

The chilli pepper (also chile pepper, chilli pepper, or simply chilli) is the fruit of plants from the genus Capsicum, members of the nightshade family, Solanaceae. Chilli peppers are widely used in many cuisines to add spiciness to dishes.

Sowing Season	**Northern Hemisphere (Cold Climate)** o	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Sep-Nov	**Southern Hemisphere (Temperate Climate)** Aug-Dec	**Southern Hemisphere (Subtropical Climate)** Jul-Mar	**Southern Hemisphere (Tropical Climate)** All Year			

GARDENING Vegetables Chilli

Sowing Guide	Sowing Depth	Row Spacing	Plant Spacing	Frost Tender / Hardy	Direct Sow / Raise Seeds	Germination Time	Maturity Time				
	4mm	80-100cm	40-60cm	FT	R/D	10-20 Days	60-110 Days				
Introduction											

Planting

To plant chili pepper seeds, begin by starting them indoors about 8-12 weeks before your region's last expected frost date. This gives the plants a crucial head start, as they require a long, warm growing season. Use small seed-starting trays or individual pots filled with a high-quality, well-draining seed-starting mix. Sow the seeds shallowly, about 0.5 cm (¼ inch) deep, and lightly cover them with soil.

Chili pepper seeds need warmth to germinate, ideally a consistent soil temperature between 26-32°C (80-90°F), with hotter varieties often preferring the higher end of this range. You can achieve this by placing trays on a heat mat, on top of a refrigerator, or in a warm, sunny spot. Keep the soil consistently moist but not waterlogged, as excessive wetness can lead to rot. Germination times vary widely by variety, from about 7-10 days for common types to several weeks for super-hots. Once seedlings emerge and have their first true leaves, provide them with plenty of light and prepare to harden them off before transplanting outdoors after all danger of frost has passed.

Care

Once established, chili pepper plants thrive with consistent care focused on warmth, moisture, and nutrition. Ensure they receive at least 6-8 hours of direct sunlight daily; they are sun-loving plants. Maintain consistently moist soil, especially as flowers and fruits begin to develop, but avoid overwatering, which can lead to root rot. Good drainage is paramount, so consider planting in raised beds or containers if your native soil is heavy. Regularly check the soil moisture and water deeply when the top inch or two feels dry.

Chili peppers are heavy feeders and benefit from a regular fertilization schedule. Begin with a balanced fertilizer during their initial growth phase to encourage strong foliage. Once flowering starts and fruits begin to set, switch to a fertilizer higher in phosphorus and potassium to promote blooming and fruiting rather than just leafy growth. Providing adequate air circulation by spacing plants appropriately helps prevent fungal diseases. For taller varieties or those with heavy fruit loads, staking or caging the plants will offer essential support, preventing stems from breaking and keeping the peppers off the ground. Regularly inspect plants for pests like aphids or spider mites and treat promptly with organic solutions like insecticidal soap if necessary.

Pests / Diseases

● Aphids: Small, soft-bodied insects clustering on new growth, causing stunted, curled leaves.
Mitigation: Blast with water, use insecticidal soap, neem oil, or introduce natural predators (ladybugs).
● Spider Mites: Tiny, often reddish mites causing stippling (tiny dots) on leaves and fine webbing, especially in dry conditions.
Mitigation: Increase humidity, spray with insecticidal soap or neem oil, introduce predatory mites.
● Whiteflies: Small, white, winged insects found on leaf undersides, causing yellowing and stunted growth.
Mitigation: Use sticky traps, insecticidal soap, or neem oil.
● Thrips: Tiny, slender insects causing silvery streaks on leaves and distorted growth.
Mitigation: Blue sticky traps, neem oil, or insecticidal soap.
● Fungus Gnats: Small, dark flies usually indicating overwatering; their larvae can feed on roots.
Mitigation: Allow soil to dry out between waterings, use sticky traps, or beneficial nematodes.
● Cutworms: Larvae that sever young seedlings at the soil line.
Mitigation: Use cardboard collars around seedling stems, remove garden debris, or apply Bt (Bacillus thuringiensis).

● Powdery Mildew: White, powdery fungal growth on leaves.
Mitigation: Ensure good air circulation, avoid overhead watering, apply neem oil or horticultural oils.
● Bacterial Leaf Spot: Dark, water-soaked spots on leaves that turn brown/black, causing defoliation.
Mitigation: Use disease-free seeds/starts, avoid overhead watering, ensure good air circulation, remove affected leaves.
● Anthracnose: Fungal disease causing sunken, circular lesions on ripe fruit, sometimes with pinkish spores.
Mitigation: Use disease-free seeds, rotate crops, improve air circulation, harvest promptly, remove infected fruit/debris. Use fungicides in severe cases.
● Phytophthora Blight/Root Rot: Causes wilting, stem lesions, and root rot, especially in waterlogged conditions.
Mitigation: Ensure excellent drainage, avoid overwatering, plant in raised beds if soil is heavy. Remove infected plants.
● Mosaic Viruses (e.g., Tobacco Mosaic Virus): Causes mottled, yellowing, or distorted leaves and stunted growth.
Mitigation: Plant resistant varieties, sanitize tools, control insect vectors (aphids), avoid tobacco use near plants, remove and destroy infected plants.
● Blossom End Rot: Not a disease, but a calcium deficiency causing black, sunken spots on the blossom end of fruits.
Mitigation: Ensure consistent watering (avoiding dry/wet cycles), maintain proper soil pH (6.0-7.0), and ensure adequate soil calcium (amend with gypsum or

Harvest / Storage

Chili peppers are ready for harvest when they have reached their mature size and their desired color, which can vary from green to vibrant reds, yellows, oranges, or even purples, depending on the variety. For most common uses, like fresh consumption or cooking, pick them when they are fully colored. If you're aiming for maximum heat, especially with super-hot varieties, allow the peppers to remain on the plant a bit longer after they've colored up, as this can increase their capsaicin content. Always use sharp scissors or pruning shears to cut the stem about 2-5 cm (1-2 inches) above the cap of the pepper to avoid damaging the plant, and pick regularly to encourage further production. For hotter varieties, wearing gloves is highly recommended to prevent skin irritation.

For short-term storage, fresh chili peppers can be kept unwashed in the crisper drawer of your refrigerator for two to three weeks. It's best to store them loosely or in a perforated plastic bag to allow for some air circulation, as excess moisture can lead to mold. Do not wash them before refrigerating.

For longer-term preservation, freezing is an excellent option. Wash and thoroughly dry the peppers before freezing. You can freeze them whole by spreading them in a single layer on a baking sheet until solid, then transferring them to airtight freezer bags. Alternatively, you can chop them (removing stems and seeds if desired) before freezing in freezer bags or containers. Drying is another effective method, particularly for thinner-walled varieties; peppers can be air-dried in ristras or using a dehydrator, then stored whole or ground into powder or flakes. Pickling in a vinegar-based brine is also a popular way to preserve chili peppers for extended periods.

Variants

• Bell Pepper (Capsicum annuum): No heat (0 SHU), commonly green, red, yellow, orange, or purple.
• Jalapeño (Capsicum annuum): Mild to medium heat (2,500-8,000 SHU), typically green, turning red when mature. Often pickled or used in salsas.
• Serrano (Capsicum annuum): Hotter than jalapeños (10,000-23,000 SHU), small, slender, and bright green.
• Poblano (Capsicum annuum): Mild heat (1,000-2,000 SHU), dark green, broad, and often used for stuffing. When dried, it's called an Ancho.
• Cayenne (Capsicum annuum): Medium to hot heat (30,000-50,000 SHU), long, thin, and red. Often dried and ground into powder.
• Habanero (Capsicum chinense): Very hot (100,000-350,000 SHU), fruity flavor, typically orange or red, but can be other colors.
• Scotch Bonnet (Capsicum chinense): Similar heat and fruity flavor to habaneros (80,000-400,000 SHU), but with a distinctive squat, "bonnet" shape.
• Bird's Eye Chili (Thai Chili) (Capsicum annuum or Capsicum frutescens): Hot (50,000-100,000 SHU), small, pointed, and widely used in Asian cuisine.
• Tabasco (Capsicum frutescens): Medium-hot (30,000-50,000 SHU), primarily known for making Tabasco sauce.
• Anaheim (Capsicum annuum): Mild (500-2,500 SHU), long, often used for roasting or stuffing.
• Banana Pepper (Hungarian Wax) (Capsicum annuum): Mild to medium heat (0-15,000 SHU), yellow, long, and often pickled.
• Ghost Pepper (Bhut Jolokia) (Capsicum chinense): Extremely hot (800,000-1,041,427 SHU), one of the former world record holders.
• Carolina Reaper (Capsicum chinense): World's hottest (1,400,000-2,200,000+ SHU), extremely pungent with a distinctive pointed tail.

Other Tips

• Sunlight is Key: Chillies need at least 6-8 hours of direct sunlight daily for best growth and fruit production.
• Warmth Lovers: They thrive in warm conditions; protect from frost. Start seeds indoors in cooler climates.
• Well-Drained Soil: Use rich, well-draining soil with a pH between 6.0-7.0. Raised beds or containers are excellent for drainage.
• Consistent Watering: Keep the soil consistently moist but never waterlogged. Overwatering can lead to root rot.
• Fertilize Regularly: Chillies are heavy feeders. Use a balanced fertilizer during vegetative growth, then switch to one higher in phosphorus and potassium once flowering begins.
• Good Air Circulation: Space plants adequately to ensure airflow, reducing fungal disease risk.
• Pinch for Bushiness: Pinch off the top few leaves of young plants to encourage bushier growth and more fruit.
• Support Tall Varieties: Stake or cage taller plants to support heavy fruit loads and prevent breakage.
• Patience for Heat: For hotter varieties, allowing fruit to stay on the plant longer (until fully colored) often increases capsaicin (heat) levels.
• Pest Vigilance: Regularly check for aphids, spider mites, and whiteflies. Treat promptly with insecticidal soap or neem oil.
• Harvesting: Pick chillies as they ripen to encourage more production. Use sharp snips to avoid damaging the plant.

13 Corn / Maize

Maize, also known as corn, is a cereal grain first domesticated by indigenous peoples in southern Mexico about 10,000 years ago. The leafy stalk of the plant produces pollen inflorescences and separate ovuliferous inflorescences called ears that yield kernels or seeds, which are fruits.

Sowing Season	**Northern Hemisphere (Cold Climate)** o	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Oct-Jan	**Southern Hemisphere (Temperate Climate)** Sep-Jan	**Southern Hemisphere (Subtropical Climate)** Aug-Feb	**Southern Hemisphere (Tropical Climate)** All Year			
Sowing Guide	**Sowing Depth** 15-25mm	**Row Spacing** 50-90cm	**Plant Spacing** 20-30cm	**Frost Tender / Hardy** FT	**Direct Sow / Raise Seeds** D	**Germination Time** 6-12 Days	**Maturity Time** 80-120 Days				
Introduction	Sweet corn is an annual with yellow, white, and bi-collared ears. A long, frost-free growing season is necessary. Here's how to plant, grow, and harvest corn in your garden. Sweet corn is wind-pollinated, so it should be planted in blocks, rather than in single rows. Early, mid, and late-season varieties extend the harvest. If you miss the optimal harvest time, the corn's flavour will go downhill fast, as sugars convert to starch.										

Planting

Corn plants are picky about their soil. Work in aged manure or compost the fall before planting and let it overwinter in the soil. Starting corn seeds indoors is not recommended. Plant seeds outdoors two weeks after the last spring frost date. Make sure the soil temperature is above 60°F (16°C) for successful germination. (Up to 65°F/18°C for super sweet varieties.) In colder zones, the ground can be warmed by a black plastic cover if necessary. Plant seeds through holes in the plastic. Plant seeds 1.5 to 2 inches deep and 4 to 6 inches apart. Rows 30 to 36 inches apart. For sufficient pollination, plan your plot right. Don't plant two long rows, rather, plant corn blocks of at least four rows. You may choose to fertilize at planting time; corn is meant to grow rapidly. If you are confident that the soil is adequate, this can be skipped. Water well at planting time.

Care

When your plants are 3 to 4 inches tall, thin them so they are 8 to 12 inches apart. Be careful not to damage the roots when weeding. Soil must be well drained and able to keep consistent moisture. In dry conditions, be sure to keep corn well watered due to its shallow roots. Water at a rate of 5 gallons per sq yard. Mulch helps reduce evaporation.

Pests / Diseases

• Raccoons
• Deer
• Spotted Cucumber Beetles
• Flea Beetles
• Cutworms

Harvest / Storage

Harvest when tassels begin to turn brown and cobs start to swell. Kernels should be full and milky. Pull ears downward and twist to take off stalk. Sweet corn varieties lose their sweetness soon after harvesting. Prepare for eating or preserving immediately after picking. Sweet corn freezes well, especially if removed from ears before freezing. Learn how to properly freeze corn. Corn kernels can also be harvested for other purposes, like corn-filled therapy packs.

Variants

There are three types of sweet corn: Normal, sugar-enhanced, and super sweet. Each one contains a different level of sucrose, changing the flavour and texture of the corn. Sweeter varieties will stay sweeter for longer after harvest.
• 'Iochief': Midseason, normal-sugar variety. Yellow.
• 'Silver Queen': normal sugar-variety. Resistant to some bacterial diseases. White.
• 'Sweet Sunshine': supersweet variety, disease resistant, high yield. Yellow.
• 'Argent': sugar-enhanced variety, good taste. White.

Other Tips

Baby corn is produced from regular corn plants that are harvested early, while the ears are immature. Regular sweet corn, sugar-enhanced sweet corn, and supersweet corn varieties can be used, along with a few varieties that are specific for baby corn. If your corn shucks harder than usual, prepare for a cold winter. Corn is one of the Three Sisters; its growing style pairs perfectly with beans and squash. Corn is great for eating but also has so many other uses including medicinal.

14 Cucumber

The cucumber (Cucumis sativus), or less formally cuke, is a widely cultivated plant in the gourd family, Cucurbitaceae. It is a creeping vine that bears cucumiform fruits that are used as vegetables. There are three main varieties of cucumber: slicing, pickling, and seedless.

Sowing Season	Northern Hemisphere (Cold Climate) Apr-Jun	Northern Hemisphere (Temperate Climate) o	Northern Hemisphere (Subtropical Climate) o	Northern Hemisphere (Tropical Climate) o	Southern Hemisphere (Cold Climate) Oct-Dec	Southern Hemisphere (Temperate Climate) Sep-Feb	Southern Hemisphere (Subtropical Climate) Jul-Mar	Southern Hemisphere (Tropical Climate) Feb-Sep			
Sowing Guide	Sowing Depth 10mm	Row Spacing 100-120cm	Plant Spacing 40-60cm	Frost Tender / Hardy FT	Direct Sow / Raise Seeds D	Germination Time 10-15 Days	Maturity Time 60-90 Days				
Introduction	An easy-care vegetable that loves sun and water, cucumbers grow quickly as long as they receive consistent watering. Most varieties will grow in any amount of space, thanks to the plant's ability to climb. Of course, these prolific veggies are perfect for pickling! There are two types of cucumber plants: vining cucumbers and bush cucumbers. The most common varieties grow on vigorous vines shaded by large leaves. The growth of these plants is fast, and the crop yield is abundant if you care for them properly. Vining varieties grow up a trellis or fence. They will be cleaner—versus those that grow atop soil—often more prolific, and easier to pick. Bush cucumbers are, however, nicely suited to containers and small gardens. Make successive plantings (every two weeks for continued harvests). In already-warm summer soil, cucumbers will grow quickly and ripen in about six weeks! If you're interested in making pickles, we recommend several prolific varieties below that are bred especially for pickling, such as heirloom 'Boston Pickling'. For crispy pickles, be sure to prepare them within a few hours of harvesting!										

Planting

Cucumber plants are seeded or transplanted outside in the ground no earlier than 2 weeks after last frost date. Cucumbers are extremely susceptible to frost damage; the soil must be at least 70°F for germination. Do not plant outside too soon. Before you plant outside, select a site with full sun. Soil should be neutral or slightly alkaline with a pH of 7.0. Cucumbers require fertile soil. Mix in compost and/or aged manure before planting to a depth of 2 inches and work into the soil 6 to 8 inches deep. Make sure that soil is moist and well-drained, not soggy.

Improve clay soil by adding organic matter. Improve dense, heavy soil by adding peat, compost or rotted manure. (Get a soil test if you are unsure of your soil type; contact your local county cooperative extension.) Light, sandy soils are preferred for northern gardens, as they warm quickly in the spring.

Plant seedlings one inch deep and about 36 to 60 inches apart, depending on variety. For vines trained on a trellis, space plants 1 foot apart. For an early crop, start cucumber seeds indoors about 3 weeks before you transplant them in the ground. They like bottom heat of about 70°F (21°C). If you don't have a heat mat, put the seeds flat on top of the refrigerator or perch a few on top of the water heater. If you live in the cooler climates, you can help warm the soil by covering the hill or row with black plastic.

Once the ground is warm, mulch with pine straw, chopped leaves, or another organic mulch to keep pests at bay, and also keep bush types off the ground to avoid disease. A trellis is a good idea if you want the vine to climb, or if you have limited space. Trellising also protects the fruit from damage from lying on the moist ground.

Care

The main plant care requirement for cucumbers is water—consistent watering! They need one inch of water per week (more if temperatures are sky high). Put your finger in the soil and when it is dry past the first joint of your finger, it is time to water. Inconsistent watering leads to bitter-tasting fruit. Water slowly in the morning or early afternoon, avoiding the leaves so that you don't get leaf diseases which will ruin the plant. If possible, water your cucumbers with a soaker hose or drip irrigation to keep the foliage dry. Mulch to hold in soil moisture. Cover seeds with netting or a berry basket if you have pests; this will keep them from digging out the seeds. When seedlings emerge, begin to water frequently, and increase to a gallon per week after fruit forms. When seedlings reach 4 inches tall, thin plants so that they are 1½ feet apart.

If you've worked organic matter into the soil before planting, you may only need to side-dress your plants with compost or well-rotted manure. If you wish, use a liquid fertilizer from your garden store such as vegetable plant food which is low nitrogen/high potassium and phosphorus formula. Apply at planting, 1 week after bloom, and every 3 weeks, directly to the soil around the plants. Or, you can work a granular fertilizer into the soil. Do not over-fertilize or the fruits will get stunted. If you have limited space or would prefer vertical vines, set up trellises early to avoid damage to seedlings and vines. Spray vines with sugar water to attract bees and set more fruit.

Pests / Diseases

If your cucumber plants do not set fruit, it's not usually a disease. There is probably a pollination issue. The first flowers were all male. Both female and male flowers must be blooming at the same time. This may not happen early in the plant's life, so be patient. (Female flowers are the ones with a small cucumber-shaped swelling at the base that will become the fruit.) Lack of fruit may also be due to poor pollination by bees, especially due to rain or cold temperatures, or insecticides. To rest assured, you could always hand pollinate. (Dip a Q-tip into the male pollen and transfer it to the centre of the female flower.) Remember, gynoecious hybrids require pollinator plants. Squash bugs may attack seedlings. Aphids are always a nuisance for any vegetable plant but easily managed. Powdery mildew can be a problem if the leaves get wet (water at the soil level). Apply fungicides at the first sign of its presence. Cucumber Beetles may attack the vines and can cause disease.

Harvest / Storage

Don't let cucumbers get too large or they will taste bitter. At peak harvesting time, you should be picking cucumbers every couple of days. They'll grow quickly! Harvest regular slicing cucumbers when they about 6 to 8 inches long (slicing varieties). Harvest dills at 4 to 6 inches long and pickles at 2 inches long for pickles. The large burpless cucumbers can be up to 10 inches long and some types are even larger. Cucumbers are best picked before their seeds become hard and are eaten when immature. Do not let them get yellow. A cucumber is of highest quality when it is uniformly green, firm, and crisp.

Any cucumbers left on the vine too long will also get tough skins and lower plant productivity. How to pick? Using a knife or clippers, cut the stem above the fruit. Pulling the fruit may damage the vine. Keep them picked. If you don't, as plants mature, they will stop producing. Cucumbers are over 90 percent water. Store wrapped tightly in plastic wrap to retain moisture. They will keep for a week to 10 days when stored properly in the refrigerator.

Variants

- Burpless Bush Hybrid is a popular bush form of cucumber.
- ‘Boston Pickling’ is our favourite heirloom variety bred especially for pickling.
- We also recommend disease-resistant ‘Sassy’ or ‘Calypso’ for early yields.
- Long, thin ‘Parisian Pickling’ is great for making gherkins or cornichons.
- Lemon cucumber is a smaller cucumber many folks find reliable.

Other Tips

Plant cucumbers while you are wearing your pajamas, on the first day of May, before sunrise, and no bugs will eat them. If you’re pickling, consider growing dill, the favourite pickling herb! Plant every few weeks into midsummer to ensure a constant supply. Don’t forget that cucumbers aren’t just for eating. When puréed in the blender, cucumbers make a great summer facial for toning the skin. With special moulds, you can grow cucumbers in different shapes like hearts and stars!

15 Eggplant

Eggplant (Solanum melongena) is a species in the nightshade family (Solanaceae) grown for its edible fruit. Although eggplant is the common name in many countries, in British English, it is called aubergine, and in South Asia and South Africa, brinjal.

Sowing Season	**Northern Hemisphere (Cold Climate)** Apr-May	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Oct-Dec	**Southern Hemisphere (Temperate Climate)** Sep-Feb	**Southern Hemisphere (Subtropical Climate)** Aug-Mar	**Southern Hemisphere (Tropical Climate)** All Year			
Sowing Guide	**Sowing Depth** 4mm	**Row Spacing** 80-90cm	**Plant Spacing** 50-75cm	**Frost Tender / Hardy** FT	**Direct Sow / Raise Seeds** R/D	**Germination Time** 10-20 Days	**Maturity Time** 90-120 Days				

Introduction

Eggplants—also known as aubergine—are warm-weather vegetables that are harvested in mid- to late summer. See how to plant, grow, harvest, and cook these lovely deep purple crops—one of our favourite grilling vegetables! Eggplants are actually perennials though they are treated by most gardeners as annuals. Given their tropical and subtropical heritage, eggplants do require relatively high temperatures, similar to tomatoes and peppers (which are also in the nightshade family of vegetables). Like tomatoes, eggplants grow hanging from the vines of a plant that grows several feet in height. Because they need warm soil, eggplants are usually purchased as transplants (or, started indoors about two months in advance). Raised beds enriched with composted manure are an ideal growing place for eggplants because the soil warms more quickly. Eggplants are also great for containers and make lovely ornamental borders. Though eggplants are usually a beautiful dark purple colour, their colour can vary, and so can the size and shape—from small- to large-fruited. Explore eggplants!

Planting

Start plants indoors in flats or peat pots 2 months before the soil warms up or buy nursery transplants just before planting. Plant outdoors in a very sunny spot with well-draining, fertile soil (with a pH from 6.3 to 6.8). Mix 1 inch or so of well-rotted manure or a general fertilizer such as 5-10-5 throughout the planting bed about a week before planting. (Apply 2 to 3 pounds per 100 square feet.) Use a covering of black plastic mulch to warm heavy clay soils before setting out transplants. If transplanting, set 3- to 4-inch tall seedlings 24 to 30 inches apart in well-prepared beds. Mix 1 tablespoon of 5-10-5 or a shovelful of rotted manure or good compost with the soil in the bottom of each planting hole and cover with more soil.

If you’re growing eggplant in pots, use a dark-coloured container. Each plant needs five-gallon (or, larger) pots and should be placed in full sun and outdoors so it can be pollinated. Use a premium potting mix to avoid disease. Stake the plants right away (just an inch or two from the plant) to provide support as they climb and to avoid disturbing the soil later. If you live in a cold climate, consider using row covers to keep the eggplants warm and sheltered. Open the ends of the row covers on warm days so that the bees may pollinate. After planting, water well. Add a layer of mulch to retain moisture and suppress weeds.

Care

Eggplant will fall over once loaded with fruit. Be sure to stake plants 24 inches tall or use a cage to keep the plants upright. If growing eggplant in containers, stake the stems before the fruit forms. Water well without letting the soil get soggy. Consistent watering is best, and a soaker hose or drip system at ground level is ideal. Apply a balanced fertilizer every two weeks during the growing season. For bigger fruits, restrict to five or six per plant. Pinch out the terminal growing points for a bushier plant.

Pests / Diseases

Flea beetles are probably the most common pest, but a healthy eggplant should be able to withstand damage from their tiny holes. Verticillium wilt and Powdery Mildew can affect eggplant. Tomato Hornworms are sometimes an issue. Eggplant fruit may not ripen properly due to cold temperatures, pest damage, or infertile soils. Strangely-shaped eggplant are the result of inconsistent watering or low moisture.

Harvest / Storage

Harvest 16 to 24 weeks after sowing when the skin of the fruit is shiny and unwrinkled. Don’t wait too long to harvest! As soon as the skin does not rebound to gentle pressure from your finger, it’s ripe. When harvesting, do not pull the fruit (as it won’t come off). Cut the fruit with a sharp knife or pruning shears close to the stem, leaving about an inch of it attached. Eggplants can be stored for up to two weeks in humid conditions no lower than 50 degrees Fahrenheit. Store in the refrigerator where it will keep for several days. Do not wash or cut in advance to avoid damaging the skin, which will quickly perish if exposed.

Variants

- ‘Black Beauty’ is the traditional eggplant size. One plant produces 4 to 6 large rounded fruit.
- ‘Ichiban’ eggplant is a slim, long hybrid with thin skin. Expect a dozen or more fruit from one plant.
- ‘Little Fingers’ are small, finger-sized eggplant. Small-fruited varieties tend to be especially heavy bearers.
- ‘Easter Egg’ is an ornamental eggplant, usually white in colour. (It’s not edible.)

Other Tips

16 Leek

The leek is a vegetable, a cultivar of Allium ampeloprasum, the broadleaf wild leek. The edible part of the plant is a bundle of leaf sheaths that is sometimes erroneously called a stem or stalk. The genus Allium also contains the onion, garlic, shallot, scallion, chive, and Chinese onion.

17 Lettuce

Lettuce (Lactuca sativa) is an annual plant of the daisy family, Asteraceae. It is most often grown as a leaf vegetable, but sometimes for its stem and seeds. Lettuce is most often used for salads, although it is also seen in other kinds of food, such as soups, sandwiches and wraps; it can also be grilled.

Sowing Season	**Northern Hemisphere (Cold Climate)** Jan-Dec	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Sep-May	**Southern Hemisphere (Temperate Climate)** All Year	**Southern Hemisphere (Subtropical Climate)** All Year	**Southern Hemisphere (Tropical Climate)** Apr-Nov			
Sowing Guide	**Sowing Depth** 5mm	**Row Spacing** 20-30cm	**Plant Spacing** 20-30cm	**Frost Tender / Hardy** H	**Direct Sow / Raise Seeds** R/D	**Germination Time** 6-12 Days	**Maturity Time** 60-90 Days				
Introduction	Home-grown lettuce is far superior—in both taste and vitamin A content—to the store-bought alternative! Here's how to plant, grow, and harvest lettuce in your garden. Lettuce is cool-season crop that grows well in the spring and fall in most regions. Lettuce seedlings will even tolerate a light frost. Temperatures between 7.2-18.3°C (45-65°F) are ideal. Because lettuce grows quickly, the best approach is to plant a small amount at a time, staggering your plantings.										

Planting

Before you plant your lettuce seeds, make sure the soil is prepared. It should be loose and drain well so it's moist without staying soggy. To keep the soil fertile, feed it with composted organic matter about one week before you seed or transplant. Since the seed is so small, a well-tilled seedbed is essential. Stones and large clods of dirt will inhibit germination. Direct sowing is recommended as soon as the ground can be worked. Plant seeds ½ inch deep. Snow won't hurt them, but a desiccating cold wind will. If you want an earlier crop, however, you may start seeds indoors 4 to 6 weeks before your last spring frost date for an earlier crop. Harden off seedlings for about one week, and transplant outside between 2 weeks before and 2 weeks after last spring frost.

Seed may be sown in single rows or broadcast for wide row planting. When broadcasting, you'll need to "thin" for the proper spacing.
- Leaf lettuce: Plant 4 inches apart.
- Cos and loose-headed types: Plant 8 inches apart.
- Firm-headed types: Plant 16 inches apart.

Your rows of plants should be 12 to 15 inches apart. Cover the seeds with ¼ to ½ inch of soil. Water thoroughly at time of transplanting. Consider planting rows of chives or garlic between your lettuce to control aphids. They act as "barrier plants" for the lettuce. If you'd like to grow your lettuce inside your home, check out these tips for growing lettuce indoors. In some regions, it's possible to plant a second crop of lettuce in the fall or even early winter.

Care

Care

Fertilize 3 weeks after transplanting. Lettuce prefers soil that is high in organic material, with plenty of compost and a steady supply of nitrogen to keep if growing fast. Use organic alfalfa meal or a slow-release fertilizer. Make sure the soil remains moist but is well drained. Lettuce will tell you when it needs water. Just look at it. If the leaves are wilting, sprinkle them anytime—even in the heat of the day—to cool them off and slow down the transpiration rate. An organic mulch will help conserve moisture, suppress weeds, and keep soil temperatures cool throughout the warmer months.

Weed by hand if necessary, but be careful of damaging your lettuce plants' roots; they are shallow. Planning your garden so that lettuce will be in the shade of taller plants, such as tomatoes or sweet corn, may reduce bolting in the heat of the summer. You should be able to sow additional lettuce seeds every two weeks for a continuous harvest throughout the growing season. To plant a fall crop, create cool soil in August by moistening the ground and covering it with a bale of straw. A week later, the soil under the bale will be about 10°F (6°C) cooler than the rest of the garden. Sow a three-foot row of lettuce seeds every couple of weeks—just rotate the straw bale around the garden.

Pests / Diseases

- Aphids
- Earwigs
- Cutworms
- White Mould
- Woodchucks
- Rabbits

Harvest / Storage

Lettuce should be harvested when full size, but just before maturity. The leaves taste best when they're still young and tender. Before maturity, you can harvest leaf lettuce by simply removing outer leaves so that the centre leaves can continue to grow. Butterhead or romaine types can be harvested by removing the outer leaves, digging up the whole plant, or cutting the plant about an inch above the soil surface. A second harvest is often possible when using the first or third methods. Crisphead lettuce is picked when the centre is firm. Mature lettuce gets bitter and woody and will go bad quickly, so check your garden everyday for ready-to-harvest leaves. It's best to harvest lettuce in the morning before leaves have been exposed to sun. As time passes and the plant loses vigour, you may be better off planting a second round of seeds than waiting for new leaves. Keep lettuce in the refrigerator for up to 10 days in a loose plastic bag.

Variants

- Crisphead: 'King Crown', 'Mission'
- Cos (Romaine): 'Wallop', 'Paris White Cos'
- Loose Heads: 'Burpee Bibb'
- Red Leaf: 'Red Sail' (Not recommended for hot weather; the red pigment absorbs more heat.)

Other Tips

Did you know that lettuce and sunflowers are relatives? They both belong to the Asteraceae (or "daisy") family. Your lettuce has wilted? Put the leaves in a bowl of cold water with ice cubes and soak for about 15 minutes. Eating lettuce for dinner can be calming and help to reduce stress.

18 Mushroom

Edible mushrooms are the fleshy and edible fruit bodies of several species of macrofungi (fungi which bear fruiting structures that are large enough to be seen with the naked eye). They can appear either below ground (hypogeous) or above ground (epigeous) where they may be picked by hand.

Introduction

Onions are a cold-season crop, easy to grow because of their hardiness. Here's how to grow an endless supply of onions in your garden! Typically, onions are planted early in the spring and harvested in the fall after their tops begin to die back. In the southern U.S., some onion varieties can be planting in the fall. We recommend using onion sets, which can be planted without worry of frost damage and have a higher success rate than direct seed or transplants. Onion plants grow well on raised beds or raised rows at least 4 inches high. If you'd prefer to start your onions from seeds, check out our tips for growing onions from seed indoors.

Planting

Plant onions as soon as the ground can be worked in the spring, usually late March or April. Make sure outdoor temperatures don't dip below 20°F (-6°C). Select a location with full sun, where your onions won't be shaded by other plants. Soil needs to be well-drained, loose, and rich in nitrogen; compact soil affects bulb development. Add aged manure or compost to the soil in early spring, before planting. Onion plants are heavy feeders and need constant nourishment to produce big bulbs. At planting time, mix in some nitrogen fertilizer. Onion seeds are short-lived. If planting seeds indoors, start with fresh seeds each year. Start seeds indoors about 6 weeks before transplanting to the garden. Think of onions as a leaf crop, not a root crop. When planting onion sets, don't bury them more than 1 inch under the soil. For sets or transplants, space plants 4 to 5 inches apart in rows 12 to 18 inches apart. Practice crop rotation with onions. Add mulch between the rows of onions. This will help retain moisture and stifle weeds.

Care

Fertilize every few weeks with nitrogen to get big bulbs. Cease fertilizing when the onions push the soil away and the bulbing process has started. Do not put the soil back around the onions; the bulb needs to emerge above the soil. Generally, onion plants do not need consistent watering if mulch is used. About one inch of water per week (including rain water) is sufficient. If you want sweeter onions, water more. Onions will look healthy even if they are bone dry, so be sure to water during drought conditions.

Pests / Diseases

● Thrips: To control thrips—tiny insects about as fat as a sewing needle—take a dark piece of paper into the garden and knock the onion tops against it; if thrips are present, you will spot their tan-coloured bodies on the paper. A couple of treatments with insecticidal soap kills them. Follow the package directions. Spray the plants twice, three days apart, and the thrips should disappear.
● Onion Maggots: Cover your emerging onion crop with a fine mesh netting. Seal it by mounding soil around the edges. The onion maggot likes to lay its eggs at the base of plants, so the netting should prevent that. You should also keep mulch away because the insects like decaying organic matter, and make sure you completely harvest your onions as the season progresses. Onion maggots are usually a problem in very rainy periods, so these precautions may be unnecessary if you have a dry season.

Harvest / Storage

Pull any onions that send up flower stalks; this means that the onions have stopped growing. These onions will not store well but can be used in recipes within a few days. When onions start to mature, the tops (foliage) become yellow and begin to fall over. At that point, bend the tops down or even stomp on them to speed the final ripening process. Loosen the soil around the bulbs to encourage drying. When tops are brown, pull the onions. Be sure to harvest in late summer, before cool weather. Mature onions may spoil in fall weather. Clip the roots and cut the tops back to 1 inch (but leave the tops on if you are planning to braid the onions). Let the onions cure on dry ground for a few days, weather permitting. Always handle them very carefully—the slightest bruise will encourage rot to set in.

Allow onions to dry for several weeks before you store them in a root cellar or any other storage area. Spread them out on an open screen off the ground to dry. Store at 40 to 50°F (4 to 10°C) in braids or with the stems removed in a mesh bag or nylon stocking. Mature, dry-skinned bulbs like it cool and dry. Don't store onions with apples or pears, as the ethylene gas produced by the fruits will interrupt the onions' dormancy. Onions may also spoil the flavour of these fruits (as well as potatoes). A pungent onion will store longer than a sweet onion. Eat the sweet varieties first and save the more pungent onions for later.

Variants

Long-day Varieties
● 'Yellow Sweet Spanish': large, round shape; yellow-white.
● 'First Edition': high-yielding, stores well, flavourful, creamy-yellow
● 'Red Wethersfield': flat bulbs that store well, white flesh, red-skinned
Short-day Varieties
● 'Stuttgarter': sold in sets, early maturity with slightly flat shape, yellow
● 'White Bermuda': extremely mild, with thick, flat bulbs; white
● 'Burgundy': good table onion with mild, sweet white flesh, red-skinned

Other Tips

Yes, you can plant a sprouted onion, though you won't get more onions from it. You will get lots of tasty green sprouts, however! Here's how to do it: Fill a pot with potting soil and make a hole in the middle that is about the depth and width of the onion. Place the onion in the hole and cover with soil. Water and put the pot in a sunny spot. Harvest the green sprouts as needed for cooking. If you get a sprout with a flower, wait until the flower goes to seed. Save the seeds for planting in the spring. Practice crop rotation with onions. To make onions taste milder, soak them in milk or pour boiling water over the slices and let stand for 20 minutes. Rinse with cold water.

20 Onions (Spring)

Scallions (also known as green onions, spring onions or salad onions) are vegetables of various Allium onion species. Scallions have a milder taste than most onions. Their close relatives include garlic, shallot, leek, chive, spring onion and Chinese onion.

21 Parsnip

The parsnip is a root vegetable closely related to the carrot and parsley. It is a biennial plant usually grown as an annual. Its long, tuberous root has cream-colored skin and flesh; and left in the ground to mature, it becomes sweeter in flavour after winter frosts. In its first growing season, the plant has a rosette of pinnate, mid-green leaves.

Sowing Guide	Sowing Depth 5mm	Row Spacing 35-50cm	Plant Spacing 5-10cm	Frost Tender / Hardy H	Direct Sow / Raise Seeds D	Germination Time 20-30 Days	Maturity Time 120-140 Days			
Introduction	Parsnips, popular with ancient Greeks and Romans, were brought over to the Americas with the first colonists. Although parsnips are biennials, they are usually grown as an annual vegetable. Here's how to plant and grow parsnips in your garden! Parsnips are a hardy, cool-season crop that is best harvested after a hard frost. Parsnips are not only tasty in soups and stews, but can also be enjoyed by themselves.									

Planting

Always sow fresh seed. Parsnips need a long growing season, so sow as soon as the soil is workable. Loosen the soil to a depth of 12-15 inches and mix in a 2- to 4-inch layer of compost. Sow 2 seeds per inch ½ an inch deep. Seedlings will emerge in 2-3 weeks.

Care

Thin the seedlings to stand 3-6 inches apart. Water during the summer if rainfall is less than 1 inch per week. Always keep the beds free of weeds.

Pests / Diseases

Pests

- Aphids
- Leaf Miners
- Carrot Rust Flies
- Parsnip Canker (all cultivars but 'Tender and True' are resistant to this)

Harvest / Storage

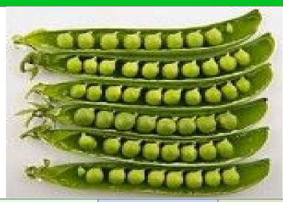
Parsnips mature in about 16 weeks. Leave your parsnips in the ground for a few frosts but harvest before the ground freezes. If you leave them in the ground for the winter, cover them with a thick layer of mulch and harvest immediately after the ground thaws in the spring.

Variants

- 'Avonresister' (short)
- 'Cobham Improved Marrow' (medium)
- 'Gladiator' (long)

Other Tips

22 Pea



The pea is most commonly the small spherical seed or the seed-pod of the pod fruit Pisum sativum. Each pod contains several peas, which can be green or yellow. Pea pods are botanically fruit, since they contain seeds and develop from the ovary of a (pea) flower.

Sowing Season	**Northern Hemisphere (Cold Climate)** Feb-May	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Jan-Oct	**Southern Hemisphere (Temperate Climate)** Feb-Sep	**Southern Hemisphere (Subtropical Climate)** Mar-Jul	**Southern Hemisphere (Tropical Climate)** Mar-Jun			
Sowing Guide	**Sowing Depth** 20-30mm	**Row Spacing** 40-60cm	**Plant Spacing** 5-10cm	**Frost Tender / Hardy** H	**Direct Sow / Raise Seeds** D	**Germination Time** 8-16 Days	**Maturity Time** 65-90 Days				
Introduction	Peas are one of the first crops we plant. Plant as soon as the ground can be worked—even if snow falls after you plant them! Here's our guide on how to plant, grow, and harvest peas. There are three varieties of peas that will suit your garden and cooking needs: ● Pisum savitum, which includes both types of garden peas: sweet peas (inedible pods) and snow peas (edible flat pods with small peas inside). ● Pisum macrocarpon, snap peas (edible pods with full-size peas). Pea plants are easy to grow, but have a very limited growing season. Furthermore, peas do not stay fresh long after harvest, so enjoy them while you can!										

Planting

Preparation
To give your plants the best head start, turn over your pea planting beds and add compost or manure to the soil in the fall. Add wood ashes and bonemeal to the soil before planting. Peas need phosphorus and potassium, but excess nitrogen will encourage foliage growth instead of flowers or pods. For tall and vining pea varieties, set up poles or a trellis at the time of planting. Learn how to build supports here.

Planting
Sow seeds outdoors 4 to 6 weeks before your last spring frost date, when soil temperatures reach at least 45°F (7°C). Here are some more tips on when to start planting peas. Plant seeds 1 inch deep (slightly deeper if soil tends to dry out quickly) and about 2 inches apart. Plant in rows spaced 12–24 inches apart. Get peas in the ground while the soil is still cool, but beware of excessive moisture caused by snowmelt or spring rain, as you don't want the seeds to sit in wet soil. It's a delicate balance of proper timing and weather conditions. If your garden tends to stay too wet, consider investing in raised garden beds. Poke in any seeds that get washed out of the soil. (A chopstick is an ideal tool for this.) A blanket of snow won't hurt emerging pea plants, but several days with temperatures in the teens could. Be prepared to plant again if the first peas don't make it. Alternatively, try starting your peas in a cold frame. A second round of peas can be planted in the late summer or early fall, approximately 6–8 weeks before your first fall frost date. Fall plantings are typically not as productive as spring-grown peas, but make for a nice fall snack nonetheless!

Care

Water sparsely unless the plants are wilting. Do not let plants dry out, or no pods will be produced. To avoid disturbing fragile roots, gently remove intrusive weeds by hand. It's best to rotate pea crops every year or two to avoid a build-up of soil-borne diseases. In between pea plantings, plant other vegetables to take advantage of the nitrogen-rich soil. Peas are best grown in temperatures below 70°F (21°C). Once temperatures get above 80°F (27°C), peas tend to stop producing pods or the pods become tough.

Pests / Diseases

- Aphids
- Mexican Bean Beetles
- Woodchucks
- Fusarium Wilt

Harvest / Storage

Keep your peas well picked to encourage more pods to develop. Pick peas in the morning after the dew has dried. They are crispiest then. Always use two hands when you pick peas. Secure the vine with one hand and pull the peas off with your other hand to avoid damaging the plant. Peas can be frozen or kept in the refrigerator for about 5 days. Place in paper bags, then wrap in plastic. If you missed your peas' peak period, you can still pick, dry, and shell them for use in winter soups.

Variants

- 'Snowbird' (snow pea), resistant to fusarium wilt
- 'Sugar Ann' (snap pea), early variety, short vine
- 'Green Arrow' (garden pea), mid-season variety, high yields, resistant to fusarium wilt

Other Tips

23 Potato

The potato is a starchy, tuberous crop from the perennial nightshade Solanum tuberosum. In many contexts, potato refers to the edible tuber, but it can also refer to the plant itself. Common or slang terms include tater and spud.

Sowing Season	Northern Hemisphere (Cold Climate) Feb-Jun	Northern Hemisphere (Temperate Climate) o	Northern Hemisphere (Subtropical Climate) o	Northern Hemisphere (Tropical Climate) o	Southern Hemisphere (Cold Climate) Aug-Sep	Southern Hemisphere (Temperate Climate) Jan-Feb, Jul-Sep	Southern Hemisphere (Subtropical Climate) Feb-Sep	Southern Hemisphere (Tropical Climate) Feb-Sep			
Sowing Guide	Sowing Depth o	Row Spacing o	Plant Spacing o	Frost Tender / Hardy o	Direct Sow / Raise Seeds o	Germination Time o	Maturity Time o				
Introduction	Wondering how to grow potatoes? We're here to help! The taste and the texture of home-grown potatoes are far superior to those of store-bought spuds, especially the early varieties. Here's how to plant, grow, and harvest potatoes in your garden. Potatoes like cool weather and well-drained, loose soil that is about 45-55°F (7-13°C). In warmer climates, potatoes can be grown as a winter crop.										

Planting

Planting - Time
Potatoes can be started 0 to 2 weeks after last spring frost. You may plant earlier, as soon as soil can be worked, but be aware that some crops may be ruined by a frost or wet soil. However, if have a "late" spring, it's not too late to plant potatoes through April (depending on where you're located). Some folks even plant through June, especially in containers or potato towers.

Planting
With a hoe or round-point shovel, dig a trench about 6 inches wide and 8 inches deep, tapering the bottom to about 3 inches wide. Potatoes are best grown in rows. Space rows about 3 feet apart. Spread and mix in rotted manure or organic compost in the bottom of the trench before planting. (Learn more about soil amendments and preparing soil for planting.) In the trench, place a seed potato piece, cut side down, every 12 to 14 inches and cover with 3 to 4 inches of soil. The best starters are seed potatoes from which eyes (buds) protrude.

(Do not confuse seed potatoes with potato seeds or grocery produce.) Use a clean, sharp paring knife to cut large potatoes into pieces that are roughly the size of a golf ball, making sure that there are at least 2 eyes on each piece. (Potatoes that are smaller than a hen's egg should be planted whole.)

If you are cutting up potato pieces for planting, do so 1 to 2 days ahead of planting. This will give them the chance to "heal" and form a protective layer over the cut surface, improving both moisture retention and rot resistance. 12 to 16 days after planting, when sprouts appear, use a hoe to gently fill in the trench with another 3 to 4 inches of soil, leaving a few inches of the plants exposed. Repeat in several weeks, leaving the soil mounded up 4 to 5 inches above ground level (this is called "hilling"). After the potato plants have emerged, add organic mulch between the rows to conserve moisture, help with weed control, and cool the soil.

Care

Do not allow sunlight to fall on the tubers, which develop under the surface of the soil, or they will turn green. Do the hilling in the morning, when plants are at their tallest. During the heat of the day, plants start drooping. Maintain even moisture, especially from the time when sprouts appear until several weeks after they blossom. The plants need 1 to 2 inches of water per week. If you water too much right after planting and not enough as the potatoes begin to form, the tubers can become misshapen. The last hilling should be done before the potato plants bloom, when the plant is about 6 inches tall. Hoe the dirt up around the base of the plant in order to cover the tubers as well as to support the plant. Hilling keeps the potatoes from getting sunburned, which can cause them to turn green and produce a chemical called solanine. Solanine gives off a bitter taste and is toxic.

Pests / Diseases

- Potato Scab: Most likely caused by a high soil pH. Remember: Potatoes like acidic soil (do not plant in soil with a pH higher than 5.2). Dust seed potatoes with sulphur before planting. Some readers suggest adding pine straw on top of the potatoes when planting for natural anti-bacterial elements.
- Colorado potato beetles need to be hand-picked and predatory birds will often eat them. While they're in the nymph state, they can be controlled with Diatomaceous Earth (food grade) which is a non-toxic way to control pests in the garden. If they continue to be a problem, a few sprays of Spinosad, an organic pesticide, will get rid of the beetles. Always use products at dawn or dusk to avoid harming beneficial insects.
- Aphids
- Flea Beetles
- Early/Late Blight

Harvest / Storage

"New potatoes," which are potatoes that are purposefully harvested early for their smaller size and tender skin, will be ready for harvest 2 to 3 weeks after the plants stop flowering. For mature potatoes, wait 2 to 3 weeks after the foliage has died. New potatoes should not be cured and should be eaten within a few days of harvest, as they will not keep for much longer. Dig potatoes on a dry day. Dig up gently, being careful not to puncture the tubers. Avoid cutting or bruising potato skin. The soil should not be compact, so digging should be easy. If the soil is very wet, let the potatoes air-dry as much as possible before putting them in bags or baskets. For the biggest and best potatoes, harvest only after the plant's foliage has died back. Cut browning foliage to the ground and wait 10 to 14 days before harvesting to allow the potatoes to develop a thick enough skin. Don't wait too long, though, or the potatoes may rot.

Allow freshly dug potatoes to sit in a dry, cool place (45–60°F/7–15°C) for up to two weeks. This allows their skins to cure, which will help them keep for longer. After curing, make sure you brush off any soil clinging to the potatoes, then store them in a cool, somewhat humid, dark place. The ideal temperature for storage is 38 to 40°F (3 to 4°C). Do not store potatoes with apples; the apples' ethylene gas will cause potatoes to spoil. Never store potatoes in the refrigerator. Whether you dig your own potatoes or buy them at a store, don't wash them until right before you use them. Washing potatoes shortens their storage life.

Variants

There are more than 100 varieties of potatoes. Tan-skinned and red-skinned varieties with white flesh are the most common in home gardens.

Early Varieties
- ‘Irish Cobbler’: tan skin, irregular shape
- ‘Norland’: red skin, resistant to potato scab
- ‘Mountain Rose’: red skin and pink flesh, resistant to some viruses

Mid-Season Varieties
- ‘Red Pontiac’: red skin, deep eyes
- ‘Viking’: red skin, very productive
- ‘Chieftan’: red skin, resistant to potato scab, stores well

Late Varieties
- ‘Katahdin’: tan skin, resistant to some viruses
- ‘Kennebec’: tan skin, resistant to some viruses and late blight
- ‘Elba’: tan skin, large round tubers, resistant to blight and potato scab

Other Tips

If your garden soil is very rocky, put the seed potato pieces directly on the ground. Sprinkle with a mix of soil and compost. Cover them with straw or leaves, hilling the material up as the potatoes grow.

24 Pumpkin

A pumpkin is a cultivar of a squash plant, most commonly of Cucurbita pepo, that is round, with smooth, slightly ribbed skin, and deep yellow to orange coloration. The thick shell contains the seeds and pulp.

Sowing Season	**Northern Hemisphere (Cold Climate)** Apr-Jun	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Oct-Dec	**Southern Hemisphere (Temperate Climate)** Sep-Dec	**Southern Hemisphere (Subtropical Climate)** Aug-Mar	**Southern Hemisphere (Tropical Climate)** Feb-Nov			
Sowing Guide	**Sowing Depth** 15-20mm	**Row Spacing** 100-200cm	**Plant Spacing** 100-150cm	**Frost Tender / Hardy** FT	**Direct Sow / Raise Seeds** D	**Germination Time** 8-16 Days	**Maturity Time** 100-140 Days				
Introduction	Note that pumpkins do require a lot of food and a long growing season (generally from 75 to 100 frost-free days) so you need to plant them by late May in northern locations to early July in extremely southern states. Do not plant this tender vegetable until all danger of frost has passed and the soil is warmed, as the seedlings will be injured or rot. Find your local frost dates here. Pumpkins are easy to maintain if you have the space.										

Planting

Site Selection
Pick a site with full sun (to light shade) and lots of space for sprawling vines. Vine varieties need 50 to 100 square feet per hill. However, if your garden space is limited, no worries! Plant pumpkins at the edge of the garden and direct vine growth across the lawn or sidewalk. The vines will only be bothersome for a few weeks. You can also grow pumpkins in big 5 to 10 gallon buckets! Or, try miniature varieties. Pumpkins are big, greedy feeders. They prefer very rich soil that is well-drained and not too soggy. Mix lots of compost and aged mature into the planting site before you sow seeds or transplant.

Planting
Pumpkins do best when the seeds are planted directly in the ground. If your growing season is very short, seed indoors in peat pots about 2 to 4 weeks before last spring frost. Be sure to harden off before transplanting. Wait until the plant soil is 70°F or more before sowing seeds. Optimum soil temperature is 95°F. Pumpkins are very sensitive to the cold. Plant seeds in rows or “pumpkin hills,” which are the size of small pitcher mounds. With hills, the soil will warm more quickly and the seeds will germinate faster. This also helps with drainage and pest control. Prepare the hills in advance with an abundance of old manure dug deep into the ground (12 to 15 inches). If you don’t have manure, loosen the soil and mix in a 2- to 4-inch layer of compost. Plant the seeds 1 inch deep into the hills (4 to 5 seeds per hill). Space hills 4 to 8 feet apart. Your plants should germinate in less than a week with the right soil temperature (70 degrees F) and emerge in 5 to 10 days. When the plants are 2 to 3 inches tall, thin to 2 to 3 plants per hill by snipping off unwanted plants without disturbing the roots of the remaining ones. In rows, sow seeds 6 to 12 inches apart in rows 6 to 10 feet apart. Snip off plants to thin to one plant every 18 to 36 inches.

Care

Use row covers to protect plants early in the season and to prevent insect problems. However, remember to remove covers before flowering to allow pollination by insects! Pumpkins are very thirsty plants and need lots of water. Water one inch per week. Water deeply, especially during fruit set. When watering: Try to keep foliage and fruit dry unless it’s a sunny day. Dampness will make rot and other diseases more likely. Add mulch around your pumpkins to keep in moisture, suppress weeks, and discourage pests. Remember that pumpkins are tender from planting to harvest. Control weeds with mulch. Do not overcultivate, or their very shallow roots may be damaged. Most small vine varieties can be trained up a trellis.

Larger varieties can be trained upward on a trellis, too—though it is an engineering challenge to support the fruit—usually with netting or old stockings. If your first flowers aren’t forming fruits, that’s normal. Both male and female blossoms need to open. Be patient. Bees are essential for pollination, so be mindful when using insecticides to kill pests. If you must use, apply only in the late afternoon or early evening, when blossoms are closed for the day. To attract more bees, try placing a bee house in your garden. Pumpkin vines, though obstinate, are very delicate. Take care not to damage vines, which reduces the quality of fruit.

Pumpkins are HEAVY feeders. Regular treatments of manure or compost mixed with water will sustain good growth. Fertilize on a regular basis. Use a high nitrogen formula in early plant growth. Fertilize when plants are about one foot tall, just before vines begin to run. Switch over to a fertilizer high in phosphorous just before the blooming period. Pinch off the fuzzy ends of each vine after a few pumpkins have formed. This will stop vine growth so that the plant’s energies are focused on the fruit. Pruning the vines may help with space, as well as allow the plant’s energy to be concentrated on the remaining vines and fruit. Gardeners who are looking for a “prize for size” pumpkin might select the two or three prime candidates and remove all other fruit and vines. As the fruit develops, they should be turned (with great care not to hurt the vine or stem) to encourage an even shape. Place a thin board or heavy cardboard under ripening melons and pumpkins to avoid decay and insect damage.

Pests / Diseases

- Squash bugs and cucumber beetles are common, especially later in summer.
- Aphids
- Squash Vine Borer
- Powdery Mildew
- Anthracnose

Poor light, too much fertilizer, poor weather at bloom time, and reduced pollinating insect activity can negatively impact fruit set.

Harvest / Storage

Your best bet is to harvest pumpkins when they are mature. They will keep best this way. Do not pick pumpkins off the vine because they have reached your desired size. If you want small pumpkins, buy a small variety. A pumpkin is ripening when its skin turns a deep, solid colour (orange for most varieties). When you thumb the pumpkin, the rind will feel hard and it will sound hollow. Press your nail into the pumpkin's skin; if it resists puncture, it is ripe. Harvest pumpkins and winter squashes on a dry day after the plants have died back and the skins are hard. To slow decay, leave an inch or two of stem on pumpkins and winter squash when harvesting them. To harvest the pumpkin, cut the fruit off the vine carefully with a sharp knife or pruners; do not tear. Be sure not to cut too close to the pumpkin; a liberal amount of stem (3 to 4 inches) will increase the pumpkin's keeping time.

Handle pumpkins very gently or they may bruise. Pumpkins should be cured in the sun for about a week to toughen the skin and then stored in a cool, dry bedroom, cellar, or root cellar—anywhere around 55°F. If you get a lot of vines and flowers, but no pumpkins, you need more bees in your garden to pollinate the flowers. Grow some colourful flowers next to your pumpkin patch this year and you may get more bees and butterflies! The yellowish pumpkins will soon come handy to give the cows. They help out the fall feed, and if there is anything better for cows in milk we should like to know it. If you're saving seeds, they should last for 6 years.

Variants

- Miniature pumpkins: 'Jack Be Little' miniature pumpkin variety, perfect for a holiday table. Vine variety. Days to maturity: 90 to 100 days. 'We-B-Little' is an All-America Selection winner, and 'Munchkin' is another great miniature pumpkin. Miniature pumpkins are very productive and easy to grow, sometimes producing up to a dozen fruits per plant.
- Pumpkins for carving: 'Autumn Gold' great for carving, decorating. All-America Selection winner. Vine variety. Excellent for Jack-o-Lanterns. Days to maturity are generally 100 to 120 days.
- Giant pumpkins: 'Dill's Atlantic Giant' jumbo variety can grow to 200 pounds. Great for those who want to grow a giant pumpkin. Vine will spread to 25 feet, so space is a must. Days to maturity are 130 to 160 days, so plant early! Thin to the best one or two plants. Feed heavily but keep cultivation shallow. Remove first 2 or 3 female flowers after the plants start to bloom so that the plants grow larger with more leaf surface before setting fruit. Allow a single fruit to develop and pick off all female flowers that develop after this fruit has set on the plant. Take care that the vine doesn't root down near the joints to avoid breakage.

- Perfect pumpkins for pies: 'Sugar Treat' semi-bush hybrid. Ideal for cooking and baking. Days to maturity are generally 100 to 120 days. 'Hijinks' and 'Baby Bear' are both All-America Selection winners and have sweet flesh for pumpkin pie. 'Cinderella's Carriage' is also perfect for pies or soups. 'Peanut Pumpkin' also produces very sweet flesh and can be great in pumpkin pie or pumpkin puree.
- Colourful pumpkins: 'Jarrahdale' has blue-green skin and makes for great decorations. 'Pepitas Pumpkin' is orange and green, and 'Super Moon' is a large white pumpkin.

Other Tips

Pumpkins have been grown in North America for almost 5,000 years.

25 Radish

The radish (Raphanus raphanistrum subsp. sativus) is an edible root vegetable of the Brassicaceae family that was domesticated in Europe in pre-Roman times. Radishes are grown and consumed throughout the world, being mostly eaten raw as a crunchy salad vegetable. They have numerous varieties, varying in size, flavour, colour, and length of time they take to mature.

Sowing Season	Northern Hemisphere (Cold Climate)	Northern Hemisphere (Temperate Climate)	Northern Hemisphere (Subtropical Climate)	Northern Hemisphere (Tropical Climate)	Southern Hemisphere (Cold Climate)	Southern Hemisphere (Temperate Climate)	Southern Hemisphere (Subtropical Climate)	Southern Hemisphere (Tropical Climate)			
	Mar-Oct	o	o	o	Aug-Jun	All Year	All Year	All Year			

Sowing Guide	Sowing Depth	Row Spacing	Plant Spacing	Frost Tender / Hardy	Direct Sow / Raise Seeds	Germination Time	Maturity Time				
	15mm	20-30cm	3-7cm	H	D	5-10 Days	40-60 Days				

Introduction

Radishes are a hardy, easy-to-grow root vegetable that can be planted multiple times in a growing season. Here's how to plant and grow radishes in your garden! Radish seeds can be planted in both the spring and the fall, but growing should be suspended in the height of summer, when temperatures are typically too hot. Hot temperatures may cause radishes to bolt, making them essentially useless. Otherwise, radishes are one of the easiest vegetables to grow.

Planting

Site Selection

Plant in a sunny spot. If radishes are planted in too much shade—or even where neighbouring vegetable plants shade them—they will put all their energy into producing larger leaves. Like carrots, radish plants are primarily grown for their roots. Though the soil needs to be rich in organic matter, it should not be compacted. If your soil is more clay-like, mix in some sand to loosen it and improve drainage. If your soil isn't rich in organic matter, incorporate a few inches of aged compost or all-purpose fertilizer (see packaging for amount) into the planting site as soon as the soil is workable. Till your garden bed to remove any rocks or dirt clods before planting. Practice three-year crop rotation. In other words, only plant radishes in the same spot every third year. This will help prevent diseases from affecting your crop.

Planting

For a spring planting, sow seeds 4–6 weeks before the average date of last frost. It's best to plant radish seeds directly in the garden so as not to disturb their roots. Directly sow seeds outdoors ½ to 1 inch deep and 1 inch apart in rows 12 inches apart. Plant another round of seeds every 10 days or so—while weather is still cool—for a continuous harvest of radishes in the late spring and early summer. Plan on a fall planting. You can plant radishes later than any other root crop in late summer or early fall and still get a harvest. Sow seeds 4–6 weeks before the first fall frost.

Care

Thin radishes to about 2 inches apart when the plants are a week old. Crowded plants do not grow well. Consistent, even moisture is key. Keep soil evenly moist but not waterlogged. A drip irrigation system is a great way to achieve this. Putting a thin layer of mulch around the radishes can help retain moisture in dry conditions.

Pests / Diseases

- Cabbage Root Maggot
- Clubroot
- Weeds: Weeds will quickly crowd out radishes, so keep the bed weed-free.

Harvest / Storage

Radishes will be ready to harvest quite rapidly, as soon as three weeks after planting for some varieties. For most varieties, harvest when roots are approximately 1 inch in diameter at the soil surface. Pull one out and test it before harvesting the rest! Do not leave radishes in the ground long after their mature stage; their condition will deteriorate quickly. Cut the tops and the thin root tail off, wash the radishes, and dry them thoroughly. Store in plastic bags in the refrigerator. Radish greens can be stored separately for up to three days.

Variants

- ‘French Breakfast’: a late-maturing variety that does OK in moderate heat.
- ‘Watermelon’: a mild, sweet radish with white skin and a pinkish centre.
- ‘Burpee White’: spring variety, white skin.
- ‘Daikon’: A white, Japanese, “winter radish” that gets large (up to 16 inches long). Best grown in cooler climates or during the cooler ends of the growing season.
- ‘Rat’s Tail’: These radishes are grown for their seedpods rather than their root. The pods offer a tangy, spicy flavour stronger than your usual radish.
- ‘Dragon’s Tail’: Like ‘Rat’s Tail’, these radishes are grown for their seedpods. The pods of this variety are thinner and turn a lovely purple colour.

Other Tips

Radish seeds have a fairly long shelf life. Don’t be afraid to plant radish seeds that are up to five years old. All may not germinate, but you’ll have plenty that will.

26 Spinach

Spinach (Spinacia oleracea) is an edible flowering plant in the family Amaranthaceae native to central and western Asia. Its leaves are commonly eaten as a vegetable, either fresh, frozen, canned, chipped, or dehydrated.
It is an annual plant (rarely biennial) growing as tall as 30 cm (1 ft). Spinach may overwinter in temperate regions.

Sowing Season	Northern Hemisphere (Cold Climate) Aug-Feb	Northern Hemisphere (Temperate Climate) o	Northern Hemisphere (Subtropical Climate) o	Northern Hemisphere (Tropical Climate) o	Southern Hemisphere (Cold Climate) Feb-Nov	Southern Hemisphere (Temperate Climate) Feb-Sep	Southern Hemisphere (Subtropical Climate) Mar-Jul	Southern Hemisphere (Tropical Climate) Apr-Jun			
Sowing Guide	Sowing Depth 8mm	Row Spacing 40-50cm	Plant Spacing 25-35cm	Frost Tender / Hardy H	Direct Sow / Raise Seeds D	Germination Time 10-25 Days	Maturity Time 50-70 Days				
Introduction	Spinach, a super–cold-hardy vegetable, is a tender-leafed crop that can be planted in very early spring, as well as in fall and winter. Spinach has similar growing conditions and requirements as lettuce, but it is more versatile in both its nutrition and its ability to be eaten raw or cooked. It is higher in iron, calcium, and vitamins than most cultivated greens, and one of the best sources of vitamins A, B, and C.										

Planting

When to Plant
Spring plantings can be made as soon as the soil can be properly worked. In order to give spinach the required six weeks of cool weather from seeding to harvest, it’s important to seed as soon as you can. For proper germination, soil should not be warmer than 70°F (21°C). Successive plantings should be made every two weeks during early spring. Gardeners in northern climates can harvest early-spring spinach if it’s planted just before the cold weather arrives in fall. Protect the young plants with a cold frame or thick mulch through the winter, then remove the protection when soil temperature in your area reaches 40°F (5°F). Common spinach cannot grow in midsummer. (For a summer harvest, try New Zealand Spinach or Malabar Spinach, two similar leafy greens that are more heat tolerant.) If you live in a place with mild winters, you can also plant in the fall. Wait to plant until soil temps are cool enough.

Planting
Select a planting site with full sun to light shade and well-drained soil. Prepare the garden soil with aged manure about a week before planting, or, you may wish to prepare your spot in the fall so that you can sow the seeds outdoors in early spring as soon as the ground thaws. Although seeds can be started indoors, it is not recommended, as seedlings are difficult to transplant. Sow seeds ½-inch to 1-inch deep, covering lightly with soil. Sow about 12 seeds per foot of row, or sprinkle over a wide row or bed. Water the new plants well in the spring.

Care

Fertilize only if necessary due to slow growth, or use as a supplement if your soil pH is inadequate. When seedlings sprout to about two inches, thin them to 3-4 inches apart. Beyond thinning, no cultivation is necessary. Roots are shallow and easily damaged. Keep soil moist with mulching. Water regularly. Spinach can tolerate the cold; it can survive a frost and temps down to 15°F (-9°C).

Pests / Diseases

- Leaf Miners: Radishes attract leaf miners away from spinach. The damage that the leaf miners do to radish leaves doesn’t prevent the radishes from growing underground.
- Bolting
- Mosaic Virus/Blight
- Downy Mildew

Harvest / Storage

Keep an eye on your plants. Harvest when leaves reach the desired size. Don’t wait too long to harvest or wait for larger leaves; bitterness will set in quickly after maturity. The whole plant can be harvested at once, and cut at the base, or leaves may be picked off plants one layer at a time, giving inner layers more time to develop.

Variants

- ‘Giant Nobel’ is a plain leaf variety.
- ‘Winter Bloomsdale’ is a crinkled-leaf, fall variety, tolerant to mosaic viruses.
- ‘Tyee’ can be planted in spring or fall, and is resistant to downy mildew.
- Malabar Spinach (Basella alba) and New Zealand Spinach (Tetragonia tetragonoides) are two heat-tolerant leafy greens that are similar to common spinach. Grow them in the summer, when common spinach can’t take the heat.

Other Tips

Scatter spinach or lettuce seeds around emerging bulb foliage to make wise use of your garden space, and have a leafy green crop at the ready to cover the bare spots left by deadheaded spring flowers. A pinch of baking soda in the cooking water keeps spinach greener. Spinach boosts your brainpower, but it can hinder iron absorption. For better absorption of iron, eat spinach with orange slices.

27 Squash / Zucchini

Cucurbita (Latin for gourd) is a genus of herbaceous vines in the gourd family, Cucurbitaceae, also known as cucurbits, native to the Andes and Mesoamerica. Five species are grown worldwide for their edible fruit, variously known as squash, pumpkin, or gourd depending on species, variety, and local parlance, and for their seeds.

Sowing Season	Northern Hemisphere (Cold Climate) Mar-Jun	Northern Hemisphere (Temperate Climate) o	Northern Hemisphere (Subtropical Climate) o	Northern Hemisphere (Tropical Climate) o	Southern Hemisphere (Cold Climate) Sep-Dec	Southern Hemisphere (Temperate Climate) Sep-Jan	Southern Hemisphere (Subtropical Climate) Aug-Feb	Southern Hemisphere (Tropical Climate) Feb-Nov			
Sowing Guide	Sowing Depth 15-25mm	Row Spacing 90-100cm	Plant Spacing 60-100cm	Frost Tender / Hardy FT	Direct Sow / Raise Seeds D	Germination Time 6-18 Days	Maturity Time 50-90 Days				
Introduction	Squash, especially zucchini, are very prolific producers! Easy to grow, each plant will produce several squash a day during peak season. Make sure you harvest summer squash when tender and still immature! Squash are generally divided into two categories based on when they’re harvested and how they’re used: Summer squash are harvested in the summer before they reach full maturity. Because they’re harvested early, their skin is edible and they have a relatively short shelf life. Summer squash varieties include zucchini, straightneck squash (a.k.a. “yellow summer squash”), and crookneck squash. Winter squash are harvested in autumn after or just before they reach full maturity. This leaves their skin inedible, but gives them a longer shelf life (some varieties are capable of keeping through the winter—hence the name “winter squash”). Winter squash varieties include pumpkins, butternut squash, spaghetti squash, and acorn squash.										

Planting

Planting Timing
We generally recommend direct-seeding for squash because they do not always transplant well. The soil needs to be warm (at least 60°F/16°C at a two-inch depth), so plant summer squash after spring (cool-season) crops, like peas, lettuce, and spinach—from about one week after the last spring frost to midsummer. If you wish to start seeds indoors due to a short gardening season, sow 2 to 4 weeks before your last spring frost in peat pots. If you do transplant, be very gentle with the roots. To get an early start when soil temperatures are not yet ideal, warm the soil with black plastic mulch once the soil has been prepared in early spring. In fact, waiting to plant a few seeds in midsummer will help avoid problems from squash vine borers and other pests and diseases common earlier in the season.

Planting Site
The planting site needs to receive full sun; the soil should be moist and well-drained, but not soggy. Squash plants are heavy feeders. Work compost and plenty of organic matter into the soil before planting for a rich soil base. Most summer squash now come in bush varieties, which take up less space, but winter squash are vining plants that need more space. Bush varieties will need to be thinned in early stages of development to about 8 to 12 inches apart.

Planting
To germinate outside, use a cloche, row cover, or frame protection in cold climates for the first few weeks. Plant seeds about 1-inch deep and 2 to 3 feet apart in a traditional garden bed. Alternatively, plant as a “hill” of 3 or 4 seeds sown close together on a small mound; this is helpful in northern climates, as the soil is warmer off the ground. Allow 5 to 6 feet between hills.

Care

Mulch around plants to protect shallow roots, discourage weeds, and retain moisture. When the first blooms appear, apply a small amount of fertilizer as a side dress application. If your squash blooms flowers but never bears actual fruit, or it bears fruit that stops growing when it’s very small, then it’s a pollination issue. For all types of squash, frequent and consistent watering is important for good fruit development. Water most diligently when fruits form and throughout their growth period. Water deeply once a week, applying at least one inch of water. Do not water shallowly; the soil needs to be moist 4 inches down. After harvest begins, fertilize occasionally for vigorous growth and lots of fruits. If your fruits are misshapen, they might not have received enough water or fertilization.

Pests / Diseases

There are a couple of challenging pests, especially the squash vine borer and the squash bug. The best solution is to get ahead of them before they arrive.
- Cucumber Beetle
- Blossom-End Rot: If the blossom ends of your squash turn black and rot, then your squash have blossom-end rot. This condition is caused by uneven soil moisture levels, often wide fluctuations between wet and dry soil. It can also be caused by calcium levels. To correct the problem, water deeply and apply a thick mulch over the soil surface to keep evaporation at a minimum. Keep the soil evenly moist like a wrung out sponge, not wet and not completely dried out.
- Stink Bug: If your squash looks distorted with a dimpled area, the stink bugs overwintered in your yard. You need to spray or dust with approved insecticides and hand pick in the morning. Clean up nearby weeds and garden debris at the end of the season to avoid this problem.
- Aphids

Harvest / Storage

Harvesting Summer Squash
Harvest summer squash when small and tender for best flavour. You may harvest as "baby squash" or when mature (6 to 8 inches long). Large squash have very little taste. Most varieties average 60 days to maturity, and are ready as soon as a week after flowering. Check plants everyday for new produce. Once squash starts producing, you'll be picking every day! Cut the fruit off the vine rather than breaking them off. Leave at least an inch of stem on the fruit. Use a sharp knife. Should you miss a picking or two, remove the overripe squash as soon as possible to reduce demands on the plants for moisture and nutrients. Summer squash is very susceptible to frost and heat damage, so you do want to pick them all before the first fall frosts arrive. Fresh summer squash can be stored in the refrigerator for up to ten days.

Harvesting Winter Squash
Harvest winter squash when the rind is hard and deep in colour, usually late September through October. Winter squash can be stored in a cool, dark place until needed. Many varieties will last for most of the winter (except for acorn squash, which do not keep for more than a few weeks). If you have a cool bedroom, stashing them under the bed works well. They like a temperature of about 50 to 65°F (10 to 18°C). Pull up the vines and compost them after you've picked everything or after a frost has killed them. Then till the soil to stir up the insects a bit.

Variants

- 'Goldbar' (yellow summer squash)
- 'Cocozelle' (zucchini, summer) dark green, slender
- 'Butterbush' (butternut, winter)
- 'Cream of the Crop' (acorn hybrid, winter)

Other Tips

Squash flowers are edible and make a tasty treat when fried in a light batter. Pumpkins and other squashes are nutritional powerhouses.

28 Tomato

The tomato is the edible, often red, berry of the nightshade Solanum lycopersicum, commonly known as a tomato plant. The tomato is consumed in diverse ways, raw or cooked, as an ingredient in many dishes, sauces, salads, and drinks. While tomatoes are fruits botanically classified as berries, they are considered culinarily as vegetables, to be utilized as an ingredient or side dish for savoury meals.

Sowing Season	Northern Hemisphere (Cold Climate) Mar-May	Northern Hemisphere (Temperate Climate) o	Northern Hemisphere (Subtropical Climate) o	Northern Hemisphere (Tropical Climate) o	Southern Hemisphere (Cold Climate) Sep-Dec	Southern Hemisphere (Temperate Climate) Aug-Dec	Southern Hemisphere (Subtropical Climate) Aug-Mar	Southern Hemisphere (Tropical Climate) Feb-Jul			
Sowing Guide	Sowing Depth 5mm	Row Spacing 50-70cm	Plant Spacing 40-60cm	Frost Tender / Hardy FT	Direct Sow / Raise Seeds R/D	Germination Time 10-20 Days	Maturity Time 80-120 Days				
Introduction	America's favourite vegetable is fairly easy to grow and will produce a bumper crop with proper care. Its uses are numerous, however, tomato plants are susceptible to pests and diseases so proper plant care is important. Though we technically eat the fruit of the tomato plant, the tomato is typically treated as a vegetable in eating and cooking and, thus, commonly categorized as such.										

Planting

If you're starting tomatoes from seed (versus transplants), you'll want to start your seeds indoors 6 to 8 weeks before the average last spring frost date. Transplant seedlings after the last spring frost when the soil has warmed. Select a site with full sun and well-drained soil. For northern regions, it is VERY important that your site receives at least 6 hours of daily sunlight. For southern regions, light afternoon shade will help tomatoes survive and thrive. Two weeks before transplanting tomato plants outdoors, dig soil to about 1 foot deep and mix in aged manure or compost. Some sort of support system is recommended, but sprawling plants can also produce fine crops if you have the space and if the weather cooperates.

Harden off seedlings or transplants for a week before planting in the garden. Set young plants outdoors in the shade for a couple of hours the first day, gradually increasing the amount of time the plants are outside each day to include some direct sunlight. Plant transplants about 2 feet apart. Place tomato stakes or cages in the soil at the time of planting to avoid damaging roots later on. Staking keeps developing tomato fruit off the ground, while caging lets the plant hold itself upright. Pinch off a few of the lower branches on transplants, and plant the root ball deep enough so that the remaining lowest leaves are just above the surface of the soil. If your transplants are leggy, you can remedy this by burying up to ⅔ of the plant, including the lower sets of leaves. Tomato stems have the ability to grow roots from the buried stems. Water well to reduce shock to the roots.

Growing in Containers
Use a large pot or container with drainage holes in the bottom. Use loose, well-draining soil. We recommend a good potting mix with added organic matter. Plant one tomato plant per pot. Choose from bush or dwarf varieties; many cherry tomatoes grow well in pots. Taller varieties may need to be staked. Place the pot in a sunny spot with 6 to 8 hours of full sun a day. Keep soil moist. Containers will dry out more quickly than the garden soil, so check daily and provide extra water during a heat wave.

Care

Water generously the first few days. Water well throughout the growing season, about 2 inches per week during the summer. Water deeply for a strong root system. Water in the early morning. This gives plant the moisture it needs to make it through a hot day. Avoid watering late afternoon or evening. Mulch five weeks after transplanting to retain moisture and to control weeds. Mulch also keeps soil from splashing the lower tomato leaves. To help tomatoes through periods of drought, find some flat rocks and place one next to each plant. The rocks prevent water from evaporating from the soil. Side dress plants with fertilizer or compost every two weeks starting when the tomato fruits are about 1 inch in diameter.

If using stakes, prune plants by pinching off suckers (side stems) so that only a couple of branches are growing from each plant. The suckers grow between the branch and the main stem. Tie growing stems to stakes with twine or soft string. As the plants grow, trim all the lower leaves off the bottom 12 inches of the stem. This helps to keep diseases from spreading from the soil to foliage. Practice crop rotation from year to year to prevent diseases that may have overwintered.

Pests / Diseases

● Aphids
● Flea Beetles
● Tomato Hornworm
● Whiteflies
● Blossom-End Rot
● Late Blight is a fungal disease that can strike during any part of the growing season. It will cause grey, mouldy spots on leaves and fruit which later turn brown. The disease is spread and supported by persistent damp weather. This disease will overwinter, so all infected plants should be destroyed.
● Mosaic Virus creates distorted leaves and causes young growth to be narrow and twisted, and the leaves become mottled with yellow. Unfortunately, infected plants should be destroyed (but don't put them in your compost pile).
● Cracking: When fruit growth is too rapid, the skin will crack. This usually occurs due to uneven watering or uneven moisture from weather conditions (very rainy periods mixed with dry periods). Keep moisture levels constant with consistent watering and mulching.

Harvest / Storage

Leave your tomatoes on the vine as long as possible. If any fall off before they appear ripe, place them in a paper bag with the stem up and store them in a cool, dark place. Never place tomatoes on a sunny windowsill to ripen; they may rot before they are ripe! The perfect tomato for picking will be firm and very red in colour, regardless of size, with perhaps some yellow remaining around the stem. If you grow orange, yellow or any other colour tomato, wait for the tomato to turn the correct colour.

If your tomato plant still has fruit when the first hard frost threatens, pull up the entire plant and hang it upside down in the basement or garage. Pick tomatoes as they ripen. If temperatures start to drop and your tomatoes aren't ripening, watch this video for tips. Never refrigerate fresh tomatoes. Doing so spoils the flavour and texture that make up that garden tomato taste. To freeze, core fresh unblemished tomatoes and place them whole in freezer bags or containers. Seal, label, and freeze. The skins will slip off when they defrost. You can harvest seeds from some tomato varieties.

Variants

Tomatoes grow in all sizes, from tiny "currant" to "cherry" to large "beefsteak." There are thousands of tomato varieties to suit different climates and tastes.
Early Varieties (60 or fewer days to harvest)
● 'Early Cascade': trailing plant, large fruit clusters
● 'Early Girl': one of the earliest tomatoes, produces through the summer
Mid-season Varieties (70 to 80 days to harvest)
● 'Floramerica': firm, deep red flesh, strong plant
● 'Fantastic': meaty rich flavour, heavy yields, crack resistant
Late-season Varieties (80 days or more to harvest)
● 'Amish Paste': Large paste tomatoes, good slicers, heavy yields
● 'Brandywine': A beefsteak with perfect acid-sweet combination, many variants are available

Cherry Tomatoes
● 'Matt's Wild Cherry': bright red tomatoes, foolproof in any climate, bears abundant fruit in high or low temps and in rain or drought
● 'Sun Gold': golden orange tomatoes, very sweet yet tart flavour, huge clusters

Other Tips

29 Turnip

The turnip or white turnip is a root vegetable commonly grown in temperate climates worldwide for its white, bulbous taproot. Small, tender varieties are grown for human consumption, while larger varieties are grown as feed for livestock.

Sowing Season	**Northern Hemisphere (Cold Climate)** Jan-Mar, Jul-Aug	**Northern Hemisphere (Temperate Climate)** o	**Northern Hemisphere (Subtropical Climate)** o	**Northern Hemisphere (Tropical Climate)** o	**Southern Hemisphere (Cold Climate)** Sep-May	**Southern Hemisphere (Temperate Climate)** Sep-May	**Southern Hemisphere (Subtropical Climate)** Aug-May	**Southern Hemisphere (Tropical Climate)** Mar-Jun		
Sowing Guide	**Sowing Depth** 10mm	**Row Spacing** 20-40cm	**Plant Spacing** 7-15cm	**Frost Tender / Hardy** H	**Direct Sow / Raise Seeds** D	**Germination Time** 6-12 Days	**Maturity Time** 50-90 Days			
Introduction	Turnips are cool-weather vegetables that can be grown both in spring and fall, avoiding the hot summer months. They mature very rapidly and you can enjoy both the greens and the roots. Try this ancient root vegetable that's been grown for over 3,000 years. Turnips are hardy biennials usually grown as annuals by the home gardener. We enjoy them most as an autumn crop, seeded in late summer, because they are usually sweeter and more tender than spring crops—and pests are less problematic. What's wonderful about turnips is that they germinate in only a few days. Within a month, you can enjoy their bright greens, and within a second month, you can eat the swollen roots. Try them as a substitute for potatoes.									

Planting

When to Plant
For a late spring harvest, sow turnip seeds directly in the garden as soon as the ground is workable, usually 2 to 3 weeks before the average last frost date. For an autumn harvest, sow turnips in late summer. Sow after summer crops of onions, squash, beans or sweet corn. You can also sow seeds in early autumn for a late autumn harvest.

Planting
Turnips are seeded directly into the garden; they do not transplant well. Select a site that gets full sun. Soil should be well-draining and loosened to a depth of 12 to 15 inches. In advance, mix in a 2- to 4-inch layer of compost or aged manure. Add sand to heavy, clay soil. Scatter turnip seed. Do not cover the seeds with more than ½ an inch of soil. Once seedlings are 4 inches high, thin them to 4 to 6 inches apart. Space wide rows 12 inches apart. Thin turnips grown for greens from 2 to 3 inches apart (or, some of us don't bother thinning for greens at all).

Care

Keep the beds weed free. Mulch heavily. Turnips do not need much care, but consistent soil moisture is important. Keep soil lightly moist, watering at a rate of 1 inch per week to prevent the roots from becoming tough and bitter.

Pests / Diseases

- Root Maggots
- Flea Beetles
- Powdery Mildew
- Downy Mildew
- Aphids

Harvest / Storage

Harvest some turnips very early as turnip greens. The leaves taste best when young and tender. Harvest early types after about 5 weeks; maincrop types after 6 to 10 weeks. Harvest turnips at any size you wish, however, the small, young turnips are nicer and more tender. For fall turnips, consider harvesting just after a light frost (but before a hard freeze) for a sweeter taste. Store for up to 3 or 4 months in a cool outdoor place covered with straw.

Variants

- 'Just Right'
- 'Yellow Globe' have wonderful golden turnip roots, great for roasting.
- 'Purple Top White Globe' are great for an extended production of greens.

Recommended for the Upper Midwest and Canada are cold hardy varieties 'Green Globe' and 'York Globe.' If you are growing turnips primarily for their greens, most any turnip variety will do.

Other Tips

Young turnips are so tender that you can peel and eat them just as you would an apple. Turnips are often confused with rutabagas because they are similar, and people like to plant them together. The two root vegetables grow well under the same conditions, but rutabagas take about four weeks longer to mature. Many turnips are grown not for the root itself but for the turnip greens, which can be cooked or used raw in salads. Younger turnip greens will not be as bitter as mature leaves. If you're wondering how to cook turnips, you're not alone. Both the turnip greens and roots are very nutritious. Turnip roots should generally be peeled and sliced before using them. Both turnip roots and turnip greens are usually cooked, but can also be enjoyed raw.

1 Apple

An apple is a sweet, edible fruit produced by an apple tree (Malus pumila). Apple trees are cultivated worldwide, and are the most widely grown species in the genus Malus. The tree originated in Central Asia, where its wild ancestor, Malus sieversii, is still found today. The apple is a deciduous tree, generally standing 6 to 15 ft (1.8 to 4.6 m) tall in cultivation and up to 30 ft (9.1 m) in the wild. When cultivated, the size, shape and branch density are determined by rootstock selection and trimming method. The leaves are alternately arranged dark green-collared simple ovals with serrated margins and slightly downy undersides. Blossoms are produced in spring simultaneously with the budding of the leaves, and are produced on spurs and some long shoots. The 3 to 4 cm (1.2 to 1.6 in) flowers are white with a pink tinge that gradually fades, five petaled, with an inflorescence consisting of a cyme with 4–6 flowers.

The central flower of the inflorescence is called the "king bloom"; it opens first, and can develop a larger fruit. The fruit matures in late summer or autumn, and cultivars exist with a wide range of sizes. Commercial growers aim to produce an apple that is 2 3⁄4 to 3 1/4 in (7.0 to 8.3 cm) in diameter, due to market preference. Some consumers, especially those in Japan, prefer a larger apple, while apples below 2 1/4 in (5.7 cm) are generally used for making juice and have little fresh market value. The skin of ripe apples is generally red, yellow, green, pink, or russetted although many bi- or tri-collared cultivars may be found. The skin may also be wholly or partly russeted i.e. rough and brown. The skin is covered in a protective layer of epicuticular wax. The exocarp (flesh) is generally pale yellowish-white, though pink or yellow exocarps also occur.

Introduction	How are your apple trees growing? Don't forget to water young trees as they establish their root systems! Here's more advice on planting, growing, and harvesting apples. Apples trees aren't just for people with acres upon acres of land. Even in a small space, you can plant a hedge of dwarf apple trees or an apple espalier and yield a successful crop.										

Planting

Climate Consideration

Not every apple grows everywhere. Each variety has a specific number of days needed for fruit maturity. Tree tags don't always tell you where the variety grows best, but many catalogues do. Also check with your local Cooperative Extension Service for a recommendation specific to your area. As a general rule, if a tree is termed hardy, it grows best in Hardiness Zones 3 to 5. If termed long-season, apple quality will be best in Zones 5 to 8. Check your zone here. Each variety has a number of chill hours needed to set fruit (i.e., the amount of time temperatures are between 32-45°F). The farther north you go, the more chill hours an apple variety needs to avoid late spring freeze problems. Check tree tags for chill hour information or ask the seller.

Site & Soil
Take a soil test prior to planting your apple trees. Your local Cooperative Extension Service can instruct you in collecting the soil sample, help you interpret the results, and provide valuable information about the soil in your county. Results from the soil test will determine the soil amendments necessary to correct nutrient deficiencies and adjust soil pH. The amendments should be worked into the soil to a depth of 12 to 18 inches where the tree will root, not just the planting hole. Apple trees need well-drained soil, nothing too wet. Soil needs to be moderately rich and retain moisture as well as air; mulch with straw, hay, or some other organic material to keep soil moist and provide nutrients as they decompose. Choose a sunny site. For best fruiting, an apple tree needs "full sunlight," which means six or more hours of direct summer sun daily. The best exposure for apples is a north- or east-facing slope. Tree spacing is influenced by the rootstock, soil fertility, and pruning. Seedlings or full-size trees should be planted about 15 to 18 feet apart in a row. A dwarfing rootstock might be 4 to 8 feet apart in a row. Dwarf apple trees are notoriously prone to uprooting under the weight of a heavy crop, so you should provide a support system for your hedge. You can grow your trees against a fence, or you can provide free-standing support in the form of a trellis. Make sure the tree will not be planted in a "frost pocket" where cold air settles in low-lying areas. Choose a higher site with a slip if possible so that cold air will flow away from the trees. Do not plant trees near wooded areas or trees.

Planting
Before planting, remove all weeds and the grass in a 4-foot diameter circle. After you purchase the tree, protect it from injury, drying out, freezing, or overheating. If the roots have dried out, soak them in water about 24 hours before planting. Dig a hole approximately twice the diameter of the root system and 2 feet deep. Place some of the loose soil back into the hole and loosen the soil on the walls of the planting hole so the roots can easily penetrate the soil. Spread the tree roots on the loose soil, making sure they are not twisted or crowded in the hole. Continue to replace soil around the roots. As you begin to cover the roots, firm the soil to be sure it surrounds the roots and to remove air pockets. Do not add fertilizer at planting time, as the roots can be "burned". Fill the remainder of the hole with the loose soil, and press the soil down well. Most apple trees are grafted. The graft union must be at least 2 inches above the soil line so that roots do not emerge from the scion. The graft union (where the scion is attached to the rootstock) can be recognized by the swelling at the junction.

Care

Water young trees regularly, especially those on semidwarfing or dwarfing rootstocks, to ensure that the root system becomes well established. Renew mulch periodically, but pull it away from the tree in the fall so mice don't nest over the winter and eat the bark.

Training Young Trees
When trees are young, it's important to nurture a strong frame of branches so the trees can carry heavy apple crops. Dwarf apple trees are trained to a central leader system. Standard (and sem-dwarf) trees should also be trained to a modified leader.

Minimize Pruning of Trees
Pruning slows a young tree's overall growth and can delay fruiting, so don't be in a hurry to prune, other than removing misplaced, broken, or dead branches. There are several techniques to direct growth without heavy pruning. For example:

Minimize Pruning of Trees
- Rub off misplaced buds before they grow into misplaced branches.
- Bend a stem down almost horizontally for a few weeks to slow growth and promote branches and fruiting. Tie down with strings to stakes in the ground or to lower branches.

Pruning
Prune your mature tree when it is dormant. Completely cut away overly vigorous, upright stems (most common high up in the tree). Remove weak twigs (which often hang from the undersides of limbs. Shorten stems that become too droopy, especially those low in the tree. After about ten years, fruiting spurs (stubby branches that elongate only about a half-inch per year) become overcrowded and decrepit. Cut away some of them and shorten others. When a whole limb of fruiting spurs declines with age, cut it back to make room for a younger replacement.

Thinning Apples
Apples are often grown without any thinning other than what nature provides in the annual spring drop. However, to avoid potential disease and insect problems, it's helpful to thin after the natural fruit drop (about 4 to 6 weeks after bloom) to one fruit per cluster, or about 6 to 8 inches between fruit. This seems hard but this practice evens out production, prevents a heavy crop from breaking limbs, and ensures better-tasting, larger fruit crop. Soon after fruit-set, remove the smallest fruits or damaged ones, leaving about four inches between those that remain.

Pests / Diseases

Apples are prone to insect and diseases—including apple maggots, plum curculios, green fruit worms, and codling moths. Many gardeners who swear off pesticides find they need to find, at minimum, an acceptual annual spray treatment for a decent crop. One idea to avoid pesticides is to select disease-resistant varieties such as 'Prima', 'Priscilla', 'Liberty', and 'Freedom'. They do not require spraying for apple scab, cedar-apple rust, and other common diseases, while most other varieties require periodic spraying every spring and summer after planting. Check with your extension service to find approved pest prevention programs for your area. You can also try an anti-insect oil, found at garden stores.

Spray it in the spring when your apple trees are in the tight cluster stage: after the leaves have unfolded from the fruiting cluster, but before the buds begin to show pink. Other pests such as scales, mites, and aphids should be controlled by natural parasite and predator populations if you haven't used a lot of sprays. The apple maggot can be trapped simply enough by hanging one or two round, softball-size balls—painted red and coated with sticky "Tangle-Trap"—from a branch in June through the summer.

Reapply the sticky goo a time or two, as necessary. Keep deer at bay with repellents, fencing, or deer-resistant plants; deter mice and rabbits with wire-mesh cylinders around the base of the tree. To keep insects away from apple trees, make a solution of 1 cup of vinegar, 1 cup of sugar, and 1 quart of water. Pour this mixture into a wide mouthed plastic jug. Hang the jug, uncovered, in your apple tree. Fend off diseases by raking apple leaves, burying them beneath mulch, or grinding them with a lawnmower at season's end.

Harvest / Storage

Harvest patiently. After all this pruning and caring, be sure to harvest your apples at their peak of perfection. Pluck your apples when their background colour is no longer green. The stem should part readily from the branch when the fruit is cupped in the palm of your hand and given a slight twist around, then up (do not yank on the apple). Different apple varieties mature at different times, so the harvest season can stretch from August to October. If the apple is overripe and soft, use for cooking.

Storing Apples
Only store mid or late season apples. Early season varieties don't keep and are best eaten soon after picking. Mid season varieties should keep for a few weeks, while late season varieties will stay in good condition for anywhere up to five months in a root cellar. Apples destined for storage must be perfect, with no bruises or blemishes that could provide entry points for rot. Store apples by wrapping up individual fruits in newspaper or tissue paper. Place the wrapped apples onto trays that allow air to circulate. You can also store them unwrapped, but the fruits should not touch. Different varieties store for different lengths of time, so keep them separate and eat those that won't store as long first. The ideal store is somewhere cool, dark, and well-ventilated. Most garages and sheds are ideal, while attics and basements should be avoided due to either excessive heat, lack of ventilation or low humidity. Check stored apples regularly and remove any that are going soft, brown or rotting.

Variants

Look for disease-resistant trees, such as 'Liberty', 'Jonafree', 'Macfree', and 'Williams Pride', which will give you the ability to grow organic fruit or to use fewer chemicals. Maintenance is easier, too. You need to choose a rootstock. All apple trees sold have 2 parts: a "rootstock" or foundation and a "scion" or top portion which determines the fruit variety. A rootstock can be "seeding" (which produces a full-size tree) or it can be "dwarfing" or "size-controlling" (which produces a smaller tree for easier care and harvest). For dwarf trees, make sure that the rootstock is specified. A Bud 9 is a common, hardy tree that's easy to train for USDA Climate Zones 3 to 5. The M9 is probably the most widely planted rootstock, though it could die in frigid winters. Buy dormant, bare-root, 1-year-old nursery trees with good root systems. Dwarfs and semi-dwarfs will bear in 3 to 4 years, yielding 1 to 2 bushels per year. Standard-size trees will bear in 5 to 8 years, yielding 4 to 5 bushels of apples per year.

The variety of apple selected should be based on fruit characteristics, bloom time, and pollen compatibility. Consult a local nursery to see which trees are potential cross-pollinators in your area. For best results, include a 'Grimes Golden', 'Golden Delicious', 'Red Delicious', or 'Winter Banana' in your planting. These varieties are known pollinators. Crab-apple trees can also be used as pollinators if they bloom at the same time as the desired variety. Nursery catalogues will provide pollination charts. Most apple varieties do not pollinate themselves or any flowers of the same apple variety; this requires planting at least two different apple tree varieties close to one another so that the bees can pollinate. (There are actually some self-pollinating apple tree varieties if you are really short on space. However, even these apple trees will bear more fruit if cross-pollinated.) Also consider how you will use your apples: Do you love to bake apple pies? Or, perhaps you just want apples that taste far better than what you could buy in a grocery store. See Best Apples for Baking for more information.

A young dwarf tree produces about 1 ½ bushels of fruit—and even less when the tree is part of an apple hedge. So, if you're interested in baking lots of 'Cox's Orange Pippin' apple pies, you'll need to plant several trees of that variety to get enough fruit. If you have no particular culinary goal, try planting one each of different varieties that ripen over the entire harvest season. Then you can enjoy regular apple tastings and still have enough fruit on hand for a "mess" of cooked apples. Seek out the advice of local orchardists about the varieties that will do well in your area. Do the bulk of your planning from an easy chair, with a half-dozen nursery catalogues in your lap!

Other Tips

Most apples are grown from grafted trees and will not come true from seed. The seeds might germinate, and they could develop into productive trees, but the fruit might not be similar to the fruit you purchased. Fruit breeders plant thousands of apple seeds every year from controlled crosses they make. Of these seedlings, no more than one or two are expected to make it into commercial production. If you want an apple tree that develops tasty fruit, you should buy a known variety from a nursery or mail-order source. You can find almost any variety of tree available, and trees you purchase will fruit in a much shorter time. A seed-started tree could take 8-10 years to fruit. Also, apple trees started from seed will have no dwarfing characteristics. Unless you have a large yard, they may be too big for your site.

2 Avocado

The avocado (Persea americana) is a tree, long thought to have originated in South Central Mexico, classified as a member of the flowering plant family Lauraceae. The fruit of the plant, also called an avocado (or avocado pear or alligator pear), is botanically a large berry containing a single large seed known as a "pit" or a "stone". The tree grows to 20 m (66 ft), with alternately arranged leaves 12–25 cm (4.7–9.8 in) long. The flowers are inconspicuous, greenish-yellow, 5–10 mm (0.2–0.4 in) wide. The pear-shaped fruit is 7–20 cm (2.8–7.9 in) long, weighs between 100 and 1,000 g (3.5 and 35.3 oz), and has a large central seed, 5–6.4 cm (2.0–2.5 in) long. Botanically, the avocado fruit is a single-seeded berry, due to the imperceptible endocarp covering the seed, rather than a drupe. The subtropical species needs a climate without frost and with little wind. High winds reduce the humidity, dehydrate the flowers, and affect pollination. When even a mild frost occurs, premature fruit drop may occur, although the 'Hass' cultivar can tolerate temperatures down to −1°C (30.2°F). The trees also need well-aerated soils, ideally more than 1 m deep. Yield is reduced when the irrigation water is highly saline.

Sowing Season	Northern Hemisphere (Cold Climate) ○	Northern Hemisphere (Temperate Climate) ○	Northern Hemisphere (Subtropical Climate) ○	Northern Hemisphere (Tropical Climate) ○	Southern Hemisphere (Cold Climate) ○	Southern Hemisphere (Temperate Climate) ○	Southern Hemisphere (Subtropical Climate) ○	Southern Hemisphere (Tropical Climate) ○			
Growing	Sun Exposure Full Sun	Soil Type Loamy, Well-drained	Soil pH 6.0-7.0	Bloom Time Spring	Flower Colour Green-Yellow	Hardiness Zones 9-11					

Sprouting

Step 1
You'll need to start by removing the pit from the avocado carefully (without cutting it), and then washing it clean of all the avocado fruit (often it helps to soak the pit in some water for a few minutes and then scrub all the remaining fruit off). Be careful not to remove the brown skin on the pit – that is the seed cover.

Step 2
Some avocado pits are slightly oblong, whereas others are shaped almost like perfect spheres – but all avocado pits have a 'bottom' (from where the roots will grow), and a 'top' (from which the sprout will grow). The slightly pointier end is the top, and the flat end is the bottom. In order to get your pit to sprout, you will need to place the bottom root end in water, so it's very important to figure out which end is the 'top' and which is the 'bottom' before you go piercing it with toothpicks.

Step 3
Take four toothpicks and stick them at a slight downward angle into the avocado seed, spaced evenly around the circumference of the avocado. These toothpicks are your avocado scaffolding, which will allow you to rest the bottom half of the avocado in water, so therefore the toothpicks need to be wedged in there firmly. I recommend sticking them in at a slight angle (pointing down), so that more of your avocado base rests in the water when you set this over a glass.

Step 4
And set on a quiet windowsill with sunlight. It's helpful to use a clear glass so you can easily see when roots start to grow, and also when the water needs to be changed. Many guides recommend to change the water every day, but I found, through trial and error, that it is better to change the water every five days to a week or so. You do want to make sure you change the water regularly, to prevent mould, bacteria and fungus growth, which can doom your little avocado sprout.

Step 5
Many online guides I have read say that sprouting can take anywhere from 2-4 weeks, but in my experience, it usually takes at least 8 weeks to get a sprout, so be patient. Here is the process you will witness:
1. The top of the avocado pit will dry out and form a crack, and the outer brown seed skin will slough off.
2. The crack will extend all the way to the bottom of the avocado pit, and through the crack at the bottom, a tiny taproot will begin to emerge.
3. The taproot will grow longer and longer (and may branch), and eventually a small sprout will peek through the top of the avocado pit.
4. Do not allow your taproot to dry out unsubmerged EVER – doing so will be the death of your plant.

Step 6
When the stem is 6-7 inches long, cut it back to about 3 inches, this will encourage new growth. When it hits 6-7 inches again, pot it up in a rich humus soil in an 8-10" diameter pot, leaving the top half of the seed exposed. Place on a sunny windowsill. Avocados love sun – the more sun the better.

Step 7
Give it frequent waterings with an occasional deep soak. The soil should always be moist, but not saturated. Yellowing leaves are a sign of over-watering; let the plant dry out for a few days.

Step 8
When the stem reaches 12 inches tall, pinch out the top two sets of leaves. This will encourage the plant to grow side shoots and more leaves, making it bushy. Each time the plant grows another 6 inches pinch out the 2 newest sets of leaves on top.

Step 9
My avocado trees seem to collect aphids – the nasty critters can't get enough of the delicious avocado leaves. If you get them, here's how to get rid of them: Wash all of the aphids off the plant by spraying your plant down with a hose outside or in the sink/shower. Once the little pests are off, spray your plant with a mixture of water with a small squirt of dishwashing liquid and a teaspoon of neem oil. This will keep aphids from returning. Check your plant every 4-5 days and re-clean and spray when necessary.

Step 10
Baby avocado trees can kick it outdoors in summer, but if you live anywhere where it gets cooler than 7°C (45°F), you'll need to bring them back indoors in the fall/winter, before the temperatures fall.

Planting

You can start with an avocado seed. Wash it. Use three toothpicks to suspend it broad end down over a water-filled glass to cover about an inch of the seed. Put the glass in a warm place out of direct sunlight and replenish water as needed. You should see the roots and stem start to sprout in about two to six weeks. (If you've followed this process so far and have not seen roots or a stem sprout in more than six to eight weeks, try another seed.) When the stem is 6 to 7 inches long, cut it back to about 3 inches. When the roots are thick and the stem has leaves again, plant it in a rich humus soil in a 10½-inch-diameter pot, leaving the seed half exposed. Water it frequently, with an occasional deep soak. The soil should be moist but not saturated. And don't forget: the more sunlight, the better. If the plant turns yellow, you may be over-watering; let it dry out for a few days. If the leaves turn brown and fry at the tips, too much salt has accumulated in the soil. Let water run freely into the pot, and drain it for several minutes. When the stem is 12 inches high, cut it back to 6 inches to encourage the growth of new shoots.

Planting: Young Tree
Remember that avocado trees do best at moderately warm temperatures (60 F to 85 F) with moderate humidity. They can tolerate temperatures, once established, of around 28 F to 32 F with minimal damage. Avoid freezing temperatures. Plant your tree in March through June. If you plant during the summer, there is always the risk of sun damage, because avocado trees don't absorb water very well when they're young. Plant it in a non-lawn area and away from sidewalks and, if you can, plant it in a spot protected from wind and frost. Remember, full sun is best. Dig a hole as deep as the current root ball and just as wide as the width plus a little extra so you can get your hands into the hole to plant it. The avocado is a shallow-rooted tree with most of its feeder roots in the top 6 inches of soil, so give it good aeration. Its root system is very sensitive, and great care should be taken not to disturb it when transplanting. If the tree is root-bound, however, loosen up the soil around the edges and clip the roots that are going in circles.

Soil
Avocado trees like the soil's pH around 6 to 6.5. If you have a heavy clay soil, elevate the tree in a mound for better drainage. Make the mound 1 to 2 feet high and 3 to 5 feet around. Don't put gravel or anything else like planting media in the hole. The sooner the roots get into the bulk soil, the better the tree will do.

Care

Watering
Trees typically need to be watered two to three times a week. As the roots reach out into the bulk soil, more water can be applied and the frequency of watering can diminish to about once a week after a year. When watering the tree, soak the soil well, and then allow it to dry out somewhat before watering again. As with most plants, you don't want the tree to get too dry. The rule of thumb for mature trees is about 20 gallons of water a day during the irrigation season. Seedlings will require quite a bit less water, of course. Check the soil before watering each time to make sure it has dried somewhat. If the soil from around the roots can hold the impression of a hand when squeezed, it has enough water.

Mulching and Fertilizing
Mulch with coarse yard mulch. Redwood bark or cocoa bean husks and shredded tree bark will work. Choose something that is woody and about 2 inches in diameter. Coarse yard mulch is available at some garden-supply centres and through tree-trimming operations. Tree-trimming operations sometimes have material that has been pruned from the tops of trees and doesn't contain any diseased roots. Use online search engines to find a local tree service. Put 20 pounds of gypsum spread around the tree base, and mulch the area with 6 inches of mulch, keeping the material about 6 to 8 inches away from the tree trunk. Fertilize your young avocado trees with ½ to 1 pound of actual nitrogen per tree per year. You can spread it out over several applications as long as it totals ½ to 1 pound of nitrogen. The other important nutrient for avocado trees is zinc. Ordinary home fertilizer for houseplants will normally work.

Other Growing Tips
Be patient about seeing fruit. If you have purchased and planted a tree, you can probably expect to see your first fruit three to four years after planting. If you are growing from a seed, it can take anywhere from five to 13 years before the tree is mature enough to set fruit. When the tree does flower, expect a lot of flowers to fall without setting fruit. This is natural.

Should I plant a "B" type avocado with an "A" type avocado to help with good pollination?	Avocado flowering patterns fall into two groups: "A" type and "B" type flowers. A-type flowers open female in the morning and male in the afternoon, B-type are male in the morning and female in the afternoon. It is widely accepted that fruit production can be helped with the presence of another avocado variety, but it isn't always required.
How does temperature influence pollination and fruit set?	Optimum fruit set occurs at temperatures between about 65 - 75 F. Cooler or warmer temperatures are less ideal. Under some conditions, you may get a fruit from a flower that did not pollinate properly. These small, elongated fruit will often fall from the tree on their own, but if they "hang on" you can pick them and eat them. These fruit are called "cukes" but are sometimes marketed in stores as "Cocktail" or "Finger" avocados.
What can I do about my avocado tree dropping fruit?	This is called fruit drop. An avocado tree typically produces about one million flowers, but only 100-200 pieces of fruit per tree. In other words, 1 fruit in 10,000 will set and mature. Sometimes the tree will set fruit but drop them when they are pea to walnut size. This is typical. To minimize fruit drop of good "fertilized" fruit, avoid stressing the tree. Don't under or overwater it. Research suggests that fruit retention is also better when there are other avocado varieties present to provide cross-pollination, and that these crossed fruit have a higher tendency to stay on the tree. There is also some indication that over-fertilizing with Nitrogen during the early fruit stages can also somewhat influence fruit drop.
How can I tell when my avocados are ripe and ready to pick?	Avocados do not "ripen" on the tree, that is, they do not get soft while on the tree. They mature on the tree. Once you pick an avocado, it can take from 7-21 days for it to soften when left at room temperature. You can speed the process up slightly by placing the avocado in a bag with some other ripe fruit (like an apple or banana) or slow the process down by keeping the fruit in the refrigerator. More on how to ripen avocados.
So, when should I pick my avocados?	Pick a couple of avocados and try to ripen them. If they shrivel up or seem rubbery instead of soft, they are not mature yet. Keep picking fruit every few weeks. Note on the calendar when they soften instead of turning rubbery. Also, note the taste of the fruit. The oil content of the fruit usually increases through the season, and there will be a certain point when it tastes "just right." That date will usually vary somewhat due to climate conditions, and some years will be better than others. Some varieties can also reach a point where they have too much oil and some will turn rancid (although many types fall from the tree before reaching that point).
How many fruit will a mature tree produce in one year?	It is possible for an avocado tree to produce 200 to 300 fruit per tree once it is about 5-7 years of age. The avocado tree, however, alternates bearing. This means that the tree may produce a large crop one year, and then produce a small crop the following year. There are lots of variables that influence this.
How many years will a normal avocado tree produce fruit?	Typically, an avocado tree will continue to grow and produce fruit until something kills the tree.

When is the best time to prune avocado trees?	Avocados can be pruned any time of the year, but there tends to be less vigorous regrowth if it is done after cold weather in the winter, sometime around February.
How large will my avocado tree get?	Growth is reflected in rootstock, variety, soil depth and texture, windiness, irrigation and pruning. Reed, Bacon and Hass trees can ultimately grow to 35 feet in 30 years. Pruning can keep the trees to a manageable size, under 15 feet, but it must be done on a regular basis.
What's the creamy-white foamy looking stuff that grows out of the bark where there are cuts, or small branches have died and dropped off?	It is just sap coming from a wound. It dries into that sugary white, fluffy stuff.

3 Blackberry

The blackberry is an edible fruit produced by many species in the genus Rubus in the family Rosaceae, hybrids among these species within the subgenus Rubus, and hybrids between the subgenera Rubus and Idaeobatus. The taxonomy of the blackberries has historically been confused because of hybridization and apomixis, so that species have often been grouped together and called species aggregates. What distinguishes the blackberry from its raspberry relatives is whether or not the torus (receptacle or stem) "picks with" (i.e., stays with) the fruit. When one picks a blackberry fruit, the torus does stay with the fruit. With a raspberry, the torus remains on the plant, leaving a hollow core in the raspberry fruit.

The term bramble, a word meaning any impenetrable thicket, has traditionally been applied specifically to the blackberry or its products, though in the United States it applies to all members of the genus Rubus. In the western US, the term caneberry is used to refer to blackberries and raspberries as a group rather than the term bramble. The usually black fruit is not a berry in the botanical sense of the word. Botanically it is termed an aggregate fruit, composed of small drupelets. It is a widespread and well-known group of over 375 species, many of which are closely related apomictic microspecies native throughout Europe, north-western Africa, temperate western and central Asia and North and South America.

In its first year, a new stem, the primocane, grows vigorously to its full length of 3–6 m (in some cases, up to 9 m), arching or trailing along the ground and bearing large palmately compound leaves with five or seven leaflets; it does not produce any flowers. In its second year, the cane becomes a floricane and the stem does not grow longer, but the lateral buds break to produce flowering laterals (which have smaller leaves with three or five leaflets). First- and second-year shoots usually have numerous short-curved, very sharp prickles that are often erroneously called thorns. The flowers are produced in late spring and early summer on short racemes on the tips of the flowering laterals. Each flower is about 2–3 cm in diameter with five white or pale pink petals.

Introduction	Blackberries, like raspberries, are a very easy fruit to grow. Once this native berry is ripe, get ready for an abundant harvest, picking every couple of days! Here's how to grow and harvest blackberries in your backyard. Basically, there are three types of blackberries: 1. erect thorny blackberries, 2. erect thornless blackberries, 3. trailing thornless blackberries. The erect blackberries are bushes that support themselves. The trailing blackberries have long canes that must be trellised for support. All blackberries are perennials; the roots come back year after year. However, the top of the plant above the soil is what we call biennial. This means that the canes grow vegetatively for a year, bear fruit the next year, and then die. However, every year the plant sends up new canes to replace those that died! For a great fruit harvest and to avoid a messy plant, pruning is important.										

Planting

Blackberries and hybrids are all self-fertile, so multiple plants are not needed for fruit production. Select a site that receives full sun for the best berry yields. Soil needs to be fertile with good drainage. Add organic content to enrichen your soil. Make sure you plant your blackberries far away from wild blackberries that may carry viruses. For semi-erect cultivars, space plants 5 to 6 feet apart. Space erect cultivars 3 feet apart. Space trailing varieties 5 to 8 feet apart. Space rows about 8 feet apart. Plant shallowly: about one inch deeper than they were grown in the nursery. Planting may be done in late fall, however, it should be delayed until early spring in very cold areas as low temperatures could kill some hybrids.

Care

Mulching is important throughout the season to conserve moisture and suffocate weeds. Keep a thick layer of mulch surrounding plants at all times. Blackberries require plenty of moisture, especially when growing and ripening. Ensure plants receive one inch of water per week and more in hot temperatures. Blackberries benefit from fertilizing in early spring with an all-purpose fertilizer such as 10-10-10, or a 16-16-8. Trellis Trailing Blackberries: Trailing blackberries need a trellis or support. Explore a two-wire system, running a top wire at five to six feet with a second line 18 inches below the top wire. After the first year, there will be fruiting floricanes along the wires. Train the new primocanes into a narrow row below the fruiting canes. Directing all canes in one direction may make it simpler.

Pruning
The main idea is to simply remove the old canes that already bore fruit and let new ones take their place. Trailing blackberries: After the fruit harvest period, the old fruiting (floricanes) are removed to the ground. However, unless there is a lot of disease, it's best to delay removing the old fruiting canes until they have died back considerably. This allows the dying canes to move nutrients back into the crown and roots. After old fruiting canes are removed, train the primocanes up on the wires. Work with one or two canes at a time in a spiral around the trellis wires. Canes from adjacent plants may overlap a little. No pruning of primocanes is necessary. In areas with low winter temperatures, leave the primocanes on the ground for the winter where they could be mulched for winter protection. In the spring, after danger of extreme cold has passed, train the old primocanes (now considered floricanes) up on the wires. Avoid working with the canes in cold weather, as they are more prone to breaking. Erect blackberries produce stiff, shorter canes that come from the crown and from root suckering (often forming a hedgerow).

Erect blackberries benefit from summer pruning. Remove the top one to two inches of new primocanes when they are four feet tall. This causes the canes to branch, increasing next year's yields. Plants will require several pruning sessions to tip each cane as it reaches the four foot height. Primocanes (suckers) that grow outside the hedgerow should be regularly removed. In the winter, remove the dead floricanes (old fruiting canes) from the hedgerow. Also shorten the lateral branches to about 1½ to 2½ feet. If you have primocane-fruiting erect blackberries, cut all canes off just above the ground in the late winter for the best fruit. In the summer, when the primocanes are 3½ feet tall, removed the top 6 inches. The primocanes will branch, thereby producing larger yields in the fall. If you have semi-erect blackberries, they are easier to manage on a Double T Trellis.

Install four-foot cross arms at the top of a six-foot post. Install a three-foot cross arm about two feet below the top line. String high-tensile wire down the rows, connecting to the cross arms. Semi-erect berries need to be pruned in the summer. When the primocanes are five feet tall, remove the top two inches to encourage branching. Several pruning sessions will be required as canes reach the appropriate height. In the winter, remove the dead floricanes (old fruiting canes). Spread the primocanes (new floricanes) out along the trellis. Canes do not need to be shortened. However, they can be if they are difficult to train.

Pests / Diseases

- Raspberry Borers
- Fruit Worms
- Gray Mould
- Viruses

If your plant is suffering from the blackberry disease known as Raspberry Bushy Dwarf virus, the leaves will be have some bright yellow on them, and the leaves of the fruiting vines may have a bleached look in the summer. The disease known as Blackberry Calico will cause faint yellow blotches on the leaves of the plant.

Harvest / Storage

Pick only berries that are fully black. Mature berries are plump yet firm, a deep black colour, and pull freely from the plant without a yank. Berries do no ripen after being picked. Once blackberries start to ripen, they must be picked often—every couple of days. When picking, keep the central plug within the fruit (unlike raspberries). Harvest during the cooler parts of the day. Once picked, place berries in the shade and refrigerate as soon as possible. Blackberries are highly perishable and will only last a few days once harvested, even with refrigeration. Although fresh fruit is always best, blackberries can be stored by canning, preserving, or freezing. Techniques used for freezing blueberries can also be used on blackberries.

Variants

- Erect Thornless: 'Navaho,' 'Arapaho'
- Erect Thorny: 'Cherokee,' 'Brazos,' 'Shawnee,' and 'Cheyenne'
- Semi-erect Thornless: 'Black Satin'
- Trailing: Olallie

Other Tips

Blackberries, raspberries, and strawberries are very high in ellagic acid, which is an antioxidant that acts as a scavenger, helping to make potential cancer-causing chemicals inactive. Ellagic acid reduces the genetic damage caused by carcinogens like tobacco smoke and air pollution. Blackberries also contain other antioxidants that can help lower cholesterol and ward off cardiovascular disease.

4 Blueberry

Blueberries are perennial flowering plants with blue– or purple–collared berries. They are classified in the section Cyanococcus within the genus Vaccinium. Vaccinium also includes cranberries, bilberries, and huckleberries. Commercial "blueberries" – including both wild ('lowbush') and cultivated ('highbush') blueberries – are native to North America. The highbush blueberry varieties were introduced into Europe during the 1930s. Blueberries are usually prostrate shrubs that can vary in size from 10 centimetres (3.9 in) to 4 meters (13 ft) in height. In commercial production of blueberries, the species with small, pea–size berries growing on low–level bushes are known as "lowbush blueberries" (synonymous with "wild"), while the species with larger berries growing on taller cultivated bushes are known as "highbush blueberries".

The leaves can be either deciduous or evergreen, ovate to lanceolate, and 1–8 cm (0.39–3.15 in) long and 0.5–3.5 cm (0.20–1.38 in) broad. The flowers are bell-shaped, white, pale pink or red, sometimes tinged greenish. The fruit is a berry 5–16 millimetres (0.20–0.63 in) in diameter with a flared crown at the end; they are pale greenish at first, then reddish-purple, and finally dark purple when ripe. They are covered in a protective coating of powdery epicuticular wax, colloquially known as the "bloom". They have a sweet taste when mature, with variable acidity. Blueberry bushes typically bear fruit in the middle of the growing season: fruiting times are affected by local conditions such as altitude and latitude, so the peak of the crop, in the northern hemisphere, can vary from May to August.

Sowing Season	Northern Hemisphere (Cold Climate) ○	Northern Hemisphere (Temperate Climate) ○	Northern Hemisphere (Subtropical Climate) ○	Northern Hemisphere (Tropical Climate) ○	Southern Hemisphere (Cold Climate) ○	Southern Hemisphere (Temperate Climate) ○	Southern Hemisphere (Subtropical Climate) ○	Southern Hemisphere (Tropical Climate) ○			
Growing	Sun Exposure Full Sun	Soil Type Loamy, Acidic	Soil pH 4.5-5.5	Bloom Time Spring	Flower Colour White-Pink	Hardiness Zones 3-9					
Introduction	The modern blueberry is a 20th-century invention. Before the 1900s, the only way to enjoy these North American natives was to find them in the wild. Then, scientists started to unlock the secrets of cultivating blueberries, and we're glad they did! Plump, juicy berries are now easy to grow in your backyard on bushes that are resistant to most pests and diseases, and can produce for up to 20 years. A relative of rhododendron and azalea, blueberry bushes aren't just a great edible plant but also an attractive addition to your overall landscape, offering scarlet fall foliage and creamy-white, bell-shaped spring flowers. Learn more about why you should grow blueberries in your home garden. Note: Blueberries are a favourite snack of hungry birds, so it's recommended that you protect blueberry bushes ahead of time with netting or other methods. There are four types of blueberries: highbush, lowbush, hybrid half-high and rabbiteye. The most commonly planted blueberry is the highbush. Most blueberry breeding has focused on this species, so there are many varieties that range widely in cold hardiness and fruit season, size, and flavour. Read more about blueberry varieties below.										

Planting

Fruit Blueberry Planting

Select a sunny, sheltered spot. While blueberries are tolerant of shade, better crops are obtained in the sun. Blueberries thrive in soil that is acidic. The soil pH should ideally be between 4 and 5. Soil can be acidified by mixing a small amount of granulated sulphur into the soil several months before planting. Peat moss, as well as pine bark or needles, are also good additions that will help acidify your soil. The blueberry is a shallow-rooted plant. Therefore, it requires a soil that holds moisture, but also drains well and doesn't stay wet. Mix organic matter into the soil before you set your blueberry bushes. Bushes should be planted as early in the spring as possible. If available, 1- to 3-year-old plants are a good choice. Be sure to go to a reputable nursery.

Dig holes about 20 inches deep and 18 inches wide (about twice as wide and twice as deep as the roots of the plant). Space bushes about 5 feet apart in a row, with at least 8 feet between rows. Prepare a planting mixture of 2 parts loam and one part oak leaf mould, peat moss, aged sawdust, or compost, and place a layer of this mixture in the bottom of the hole. Set the bush in the hole with its roots spread out. Don't plant the bush any deeper than it grew in the pot. Pack the hole tightly with soil. Apply fertilizer one month after planting, not at the time of planting. Apply ½ ounce of a 10-10-10 fertilizer in a band around the plant 6 to 12 inches from the crown.

GARDENING Fruit Blueberry Planting

Growing in a Container Blueberries grown in containers are easier to protect from birds and other critters, more disease resistant, easy to harvest, and easy to move if needed.	● Use a large container with drainage holes. ● Use a potting mix designed for acid-loving plants such as azaleas or rhododendrons, or mix sandy soil with peat moss and compost. ● Plant the bush in the container and water well. ● Add mulch on top of the soil. ● Place the pot in a sunny spot. ● Keep soil moist. ● In northern regions, overwinter the blueberry container in a protected area or cover the container with straw or wrap it in burlap.

Care

GARDENING Blueberry Care

Mulch to keep shallow blueberry root systems moist, which is essential. Apply a 2- to 4-inch layer of woodchips, saw dust, or pine needles around the bush after planting. Blueberries need 1 to 2 inches of water per week. Drape netting over ripening blueberries, so that the birds won't make away with the entire crop. One year after planting, apply 1 ounce of 10-10-10 fertilizer per bush in the spring at blooming time, and increase the rate by 1 ounce each year thereafter to a maximum of 8 ounces for mature bushes. Do not allow the bush to produce fruit for the first year or two after planting. Pinch back any blossoms developing on newly set plants to allow the energy to go to growth.

Pruning
For the first 4 years after planting, there is no need to prune blueberry bushes. From then on, pruning is needed to stimulate growth of the new shoots that will bear fruit the following season. Prune plants in late winter or early spring before new growth begins. Cut out dead, broken, short, weak, and spindly shoots. On highbush varieties, begin with large cuts, removing wood that is more than 6 years old, drooping to the ground, or crowding the centre of the bush. Also remove low-growing branches whose fruit will touch the ground, as well as spindly twigs. Prune lowbush blueberries by cutting all stems to ground level. Pruned plants will not bear the season following pruning, so prune a different half of a blueberry patch every two years (or a different third of a patch every three years).

Pests / Diseases

Fruit Blueberry

- Birds
- Blueberry Maggot
- Powdery Mildew

Harvest / Storage

GARDENING

Blueberries will be ready for picking in late July to mid August. Don't rush to pick the berries as soon as they turn blue. Wait a couple days. When they are ready, they should fall off right into your hand. If you plant 2-year-old blueberry bushes, they should start to bear within a year or two. (Pick off any flowers that form the first year or two after planting, to allow the bush to become established.) Be aware that full production is reached after about 6 years. Blueberries are one of the easiest fruits to freeze. Learn how to properly freeze blueberries so you can have them all winter long.

Variants

Blueberry Fruit Variants GARDENING Blueberry

Highbush
Blueberries are partially self-fertile, so you will harvest more and larger berries by planting two or more varieties. Planting more than one variety can also extend the harvest season. Highbush (Vaccinium corymbosum): A six-foot shrub hardy from Zone 4 to Zone 7. For withstanding cold winters, choose 'Bluecrop', 'Blueray', 'Herbert', 'Jersey', or 'Meader'. For big berries, choose 'Berkeley', 'Bluecrop', 'Blueray', 'Coville', 'Darrow', or 'Herbert'. For flavour, usually the main reason for growing your own fruit, choose 'Blueray', 'Darrow', 'Herbert', 'Ivanhoe', 'Pioneer', 'Stanley', or 'Wareham'. For something different, try 'Pink Lemonade', which produces bright pink blueberries!

Lowbush
Lowbush (Vaccinium angustifolium): For the coldest climates, lowbush varieties are your best bet, hardy from Zone 3 to Zone 7. These are the blueberries you find in cans on supermarket shelves. When fresh, the fruits are sweet and covered with a waxy bloom so thick that the berries appear sky blue or gray. The creeping plants, a foot or so high, are spread by underground stems, or rhizomes. They blanket the rocky upland soils of the Northeast and adjacent portions of Canada. Lowbush blueberries make a nice ornamental fruiting ground cover. Plants sold by nurseries are usually seedlings or unnamed wild plants, rather than named varieties.

Half-High
● Half-High: Breeders have combined qualities of highbush and lowbush blueberries into hybrids known as half-high blueberries. University of Minnesota introductions include 'Northcountry', a variety that grows 18 to 24 inches high and has excellent, mild-flavoured, slightly aromatic sky-blue fruits; and 'Northblue', which grows 20 to 30 inches high and produces an abundance of dark-blue, nickel-size, somewhat tart fruits-just right for pies. 'Northland' is a half-high that grows 3 to 4 feet tall. From Michigan, it has relatively bland, average-quality fruit.

Variants Fruit GARDENING Blueberry

Rabbiteye
Rabbiteye (Vaccinium ashei): Grown in the south-eastern United States, Rabbiteye varieties are extremely adaptable, productive, and pest-tolerant. They do, however, have a high degree of self-incompatibility and require two or more varieties be planted together to ensure pollination.

Container Varieties
- 'Top Hat': Bred by the University of Michigan for small spaces and containers.
- 'Pink Lemonade': Pink blueberries contain genetics from rabbiteye blueberries (a standard in the hot South). These pink berries can be planted in nearly every climate.
- 'Pink Champagne': Another pink variety full of antioxidants and sweeter than blue blueberries.

Other Tips

Blueberries are one of the few truly blue foods on earth. Dried berries were crushed into a powder and rubbed into meat for flavour. Blueberry juice was also used as a purple dye for cloth and baskets. A tea made from the leaves of the blueberry plant was believed to be good for the blood.

5 Cherry

A cherry is the fruit of many plants of the genus Prunus, and is a fleshy drupe (stone fruit). The cherry fruits of commerce usually are obtained from cultivars of a limited number of species such as the sweet cherry (Prunus avium) and the sour cherry (Prunus cerasus). The name 'cherry' also refers to the cherry tree and its wood, and is sometimes applied to almonds and visually similar flowering trees in the genus Prunus, as in "ornamental cherry" or "cherry blossom". Like most temperate-latitude trees, cherry seeds require exposure to cold to germinate (an adaptation which prevents germination during the autumn, which would then result in the seedling being killed by winter temperatures). The pits are planted in the autumn (after first being chilled) and seedlings emerge in the spring. A cherry tree will take three to four years in the field to produce its first crop of fruit, and seven years to attain full maturity. Because of the cold-weather requirement, no members of the genus Prunus can grow in tropical climates.

Cherries have a short growing season and can grow in most temperate latitudes. Cherries blossom in April (in the Northern Hemisphere) and the peak season for the cherry harvest is in the summer. In southern Europe in June, in North America in June, in England in mid-July, and in southern British Columbia (Canada) in June to mid-August. In many parts of North America, they are among the first tree fruits to flower and ripen in mid-Spring. In the Southern Hemisphere, cherries are usually at their peak in late December and are widely associated with Christmas. 'Burlat' is an early variety which ripens during the beginning of December, 'Lapins' ripens near the end of December, and 'Sweetheart' finish slightly later.

Sowing Season	Northern Hemisphere (Cold Climate) ○	Northern Hemisphere (Temperate Climate) ○	Northern Hemisphere (Subtropical Climate) ○	Northern Hemisphere (Tropical Climate) ○	Southern Hemisphere (Cold Climate) ○	Southern Hemisphere (Temperate Climate) ○	Southern Hemisphere (Subtropical Climate) ○	Southern Hemisphere (Tropical Climate) ○			
Growing	Sun Exposure Full Sun	Soil Type Loamy, Well-drained	Soil pH 6.0-7.0	Bloom Time Early Spring	Flower Colour White	Hardiness Zones 4-8					
Introduction	Cherry trees are a sight to behold in the spring, when they're covered in white or pink blossoms. After that, they produce the delicious cherries most people know and love. Here's how to grow cherry trees in your own garden! Sweet cherries are the variety most often found in markets. They have a thick, rich, and almost plumb-like texture. Sweet cherries grow in hardiness zones 5 to 7; they are self-sterile and best for an orchard or a large garden. You'll need at least two or three trees, as they'll need to pollinate each other. However, a recent and exciting development in sweet cherries is the dwarf, self-pollinating cultivar, 'Stella'. Sour cherries are not usually eaten raw, but are widely used for preserves and other cooking uses. Sour cherries are much smaller than sweet cherries and all varieties are self-fertile. They grow in zones 4 to 6. Cherry trees generally start bearing fruit in their fourth year; dwarf trees bear fruit a year earlier. One mature, standard-size tart or sweet cherry tree will produce 30 to 50 quarts of cherries each year; a dwarf tree, about 10 to 15 quarts.										

Planting

Plant cherries in the late fall or early spring (when the ground is soft and has a higher moisture content). For sweet cherries, make sure the different varieties will pollinate each other. Plant in a sunny site with good air circulation; avoid planting near trees or buildings that shade. Cherry trees need deep, well-drained soil. Space sweet cherries 35 to 40 feet apart; dwarfs, 5 to 10 feet apart. Space tart cherries 20 to 25 feet apart; dwarfs, 8 to 10 feet apart. Set trees on standard rootstocks with the graft union a few inches below the soil level. Set trees on dwarf rootstock with the graft union several inches above the soil level.

When planting fan-trained trees, construct the necessary supports before planting. Plant fans only 12 to 15 feet apart. For bareroot trees, place the rootstock on a small mound of soil in the centre of the planting hole, and spread the roots down and away, trying not to bend the roots. Backfiill with soil. For container-grown trees, first remove the rootball and on its side; cut through the roots with shears. Don't cover the top of the root-ball.

Care

There is no difference in care between sour and sweet cherries. Apply mulch to retain moisture. Drape netting over trees to protect the fruit from birds. Water routinely in dry areas. Thinning the fruit is not necessary for cherry trees, as they typically thin naturally in early summer. Prune trees every year in late winter to encourage the growth of new fruiting wood. Don't prune in the fall. Fertilize each spring until trees start to bear, then fertilize only after harvest each season.

Pests / Diseases

- Aphids
- Japanese Beetles
- Caterpillars
- Brown Rot
- Black Knot
- Bacterial Canker: Cut out any branches with signs of black knot or bacterial canker as soon as possible
- Birds

Harvest / Storage

Pick fruits only when FULLY ripe (dark red, black, yellow); the sugar content rises the few days before fully ripened. Be ready to harvest within a week's time. Eat or cook immediately. Pick fruits when firm if they are to be frozen. Be sure top pick with the cherry stem so you do not tear into the fruit, however, take care to lead the fruit spur to produce fruit next year. Hand-picking may injure the shoots and cause infection; Cut the stalks with scissors. Remember that cherry trees do not bear fruit until their fourth year. Thereafter, they should produce about 30 to 50 quarts of cherries each year.

Variants

- Sweet Cherry - Early - 'Black Tartarian'
- Sweet Cherry - Midseason - 'Bing'
- Sweet Cherry - Late - 'Stella'
- Sour Cherry- Early - 'Early Richmond'
- Sour Cherry- Midseason - 'Montmorency'
- Sour Cherry- Late - 'Meteor'

Other Tips

6 Fig

Ficus carica is an Asian species of flowering plant in the mulberry family, known as the common fig. It is the source of the fruit also called the fig and as such is an important crop in those areas where it is grown commercially. Native to the Middle East and western Asia, it has been sought out and cultivated since ancient times and is now widely grown throughout the world, both for its fruit and as an ornamental plant. Ficus carica is a gynodioecious (functionally dioecious), deciduous tree or large shrub, growing to a height of 7–10 metres (23–33 ft), with smooth white bark. Its fragrant leaves are 12–25 centimetres (4.7–9.8 in) long and 10–18 centimetres (3.9–7.1 in) across, and deeply lobed with three or five lobes. The complex inflorescence consists of a hollow fleshy structure called the syconium, which is lined with numerous unisexual flowers.

The flowers themselves are not visible from outside the syconium, as they bloom inside the infructescence. Although commonly referred to as a fruit, the fig is actually the infructescence or scion of the tree, known as a false fruit or multiple fruit, in which the flowers and seeds are borne. It is a hollow-ended stem containing many flowers. The small orifice (ostiole) visible on the middle of the fruit is a narrow passage, which allows the specialized fig wasp Blastophaga psenes to enter the fruit and pollinate the flower, where after the fruit grows seeds.

Introduction

Figs are a delicious treat that thrive in warm climates, but can also be grown in more temperate regions with a bit of extra care. Here's how to grow a fig tree in your garden! Figs thrive in areas with long and hot summers (Zones 8 and warmer), though they can also be grown in colder zones if grown in containers and properly insulated from freezing temperatures or brought indoors. The common fig tree (Ficus carica) is the most popular species of fig for home gardeners because its flowers do not require pollination to yield figs. Many varieties of the common fig tree exist, including hardy cultivars that can be grown outdoors in slightly cooler climates (Zones 6 and 7). Other species of figs either do not produce edible fruit or have very specific pollination requirements (such as needing to be pollinated by a certain type of wasp), making them too much trouble for home gardeners to grow. Figs can be eaten fresh from the tree, preserved, or used in cooking.

Planting

Figs can be planted outdoors in Zone 8 and warmer. In zones where winter temperatures get colder than -12°C (10°F) for periods of time, figs are best grown in containers and kept inside for the winter. Plant fig trees outdoors in the early spring or late fall, when the tree is dormant. For container fig trees, grow them in a soil-based potting mix and add fine bark chips to improve drainage. Keep the tree in full sun in the summer. Be sure to add a high-nitrogen fertilizer every 4 weeks in the spring and summer and water the tree moderately. In the winter, move the tree indoors and keep the soil moist. For outdoor fig trees, plant the tree in the spring or early fall in full sun. Fig trees can grow in most types of soil as long as the soil is well-drained and contains plenty of organic material. Space fig trees at least 20 feet away from any buildings or other trees. Fig trees put down deep roots if given the chance, so bear that in mind when choosing a planting spot.

To plant container-grown trees in the ground:
1. Remove the plant from its pot and remove any circling roots by laying the root ball on its side and using shears to cut through the roots.
2. Dig a hole that is a few inches deeper and wider than the spread of the roots. Set the tree on top of a small mound of soil in the middle of the hole. Be sure to spread the roots away from the trunk without excessively bending them.
3. Plant the tree 2 to 4 inches deeper than it was originally in the pot (check the colour of the trunk to see the original soil line).

Care

Water young fig trees regularly to help them become established. In areas with dry climates, water fig trees deeply at least once a week. Unless grown in containers, most fig trees do not require regular fertilization. However, if your fig tree is not growing much (less than 12 inches in one growing season), you can add ½ to 1 pound of nitrogen supplement. Divide up the nitrogen into 3 to 4 feedings. Start applying the nitrogen in late winter and end in midsummer. You can also apply a layer of mulch around the tree to help prevent weeds and keep in moisture for the roots. Fig trees require little pruning.

During the dormant season, be sure to remove all dead, diseased, or weak branches to encourage growth. If you have an abundant growth of figs, you can thin the fruit to encourage larger figs. In colder regions, bring container-grown fig trees indoors for the winter. Keep the soil moist. If your area experiences a particularly cold winter, fig trees planted outdoors may die back to the ground. If the tree is of a hardy variety, the below-ground part of the tree will likely be unaffected. Remove all dead wood while the tree is still dormant and watch for new growth in the spring.

Pests / Diseases

- Root-Knot Nematodes
- Leaf Spots
- Rust
- Thrips
- Twig Dieback

Harvest / Storage

You should harvest figs only when they are fully ripe, as they will not continue to ripen off the tree. The figs should be fully collared and slightly soft to the touch. You may need to invest in bird netting to protect your crop; figs are a favourite of birds and squirrels. When picking figs, wear gloves or long sleeves because the sap from the fig tree can irritate your skin. Figs are very perishable. Store figs in the refrigerator; they will keep for 2 to 3 days. For long-term storage, you can freeze figs whole for later use. Another storage method is to dry the figs. You can also can your own figs.

Variants

- 'Brown Turkey', which produces abundant medium to large figs. This type works best in warm climates, but is fairly tolerant of cooler temperatures, too.
- 'Celeste' produces small, sweet, purplish figs. It is one of the more winter-hardy varieties.
- 'Hardy Chicago' is a winter-hardy variety that produces purple, medium-size figs.
- 'King' is well adapted for the cooler conditions found in the northwest. It produces medium figs that are sweet and rich in flavour.
- 'Kadota', which vigorously produces small to medium fruit. Its figs are rich and sweet, and it is the most commonly canned fig.

Other Tips

Figs are an excellent source of potassium, dietary fibre, and calcium.

7 Grapefruit

The grapefruit (Citrus × paradisi) is a subtropical citrus tree known for its sour to semi-sweet, somewhat bitter fruit. Grapefruit is a hybrid originating in Barbados as an accidental cross between two introduced species, sweet orange and pomelo or shaddock. The evergreen grapefruit trees usually grow to around 5–6 meters (16–20 ft) tall, although they may reach 13–15 m (43–49 ft). The leaves are glossy, dark green, long (up to 15 centimetres (5.9 in)), and thin. It produces 5 cm (2 in) white four-petaled flowers. The fruit is yellow-orange skinned and generally, an oblate spheroid in shape; it ranges in diameter from 10–15 cm (3.9–5.9 in). The flesh is segmented and acidic, varying in colour depending on the cultivars, which include white, pink, and red pulps of varying sweetness (generally, the redder varieties are the sweetest).

Sowing Season	**Northern Hemisphere (Cold Climate)** ○	**Northern Hemisphere (Temperate Climate)** ○	**Northern Hemisphere (Subtropical Climate)** ○	**Northern Hemisphere (Tropical Climate)** ○	**Southern Hemisphere (Cold Climate)** ○	**Southern Hemisphere (Temperate Climate)** ○	**Southern Hemisphere (Subtropical Climate)** ○	**Southern Hemisphere (Tropical Climate)** ○			
Growing	**Sun Exposure** Full Sun	**Soil Type** Loamy, Well-drained	**Soil pH** 6.0-7.0	**Bloom Time** Spring	**Flower Colour** White	**Hardiness Zones** 9-11					
Introduction	Although Citrus is a subtropical genus, northern gardeners can grow lemons, oranges, and other citrus trees in containers to enjoy fresh citrus fruit. Standard-size grapefruit and orange trees can grow 18 to 22 feet tall, whereas dwarf varieties only grow 8 to 12 feet tall. Most citrus varieties are self-fertile, so only one tree is needed for fruit production. On average, fruit bearing begins when the trees are between 3 and 6 years old; however, exact timing will depend on the type of citrus (lemons, oranges, grapefruit, etc.), the cultivar, your climate, the health of the plant and its care, and other factors. Flowering is not seasonal, but occurs during warm weather and regular rainfall. Flowers and fruits may coincide.										

Planting

Citrus trees should be planted in a sunny and wind-protected area. In the citrus belt (a loosely defined area stretching from southern California to Florida), trees can be planted at any time, however, spring is the best time for container-grown plants. Standard-size citrus trees should be spaced 12 to 25 feet apart and dwarf citrus trees should be set 6 to 10 feet apart. The exact distance depends on the variety. The bigger the fruit, the farther the distance. If the soil is not well-drained, plant the trees on a slight mound to prevent waterlogging. To plant citrus trees inside from seeds, remove the seeds from the desired fruit. Soak the seeds overnight in water and plant them ½ inch deep in moist potting soil. Cover the pot with a plastic bag or wrap and let it sit in a warm and sunny spot for a few weeks until the seeds start to grow. Then, remove the plastic but keep the pot near a warm and sunny window.

Care

A few weeks after planting, and for the first few years (before bearing age), feed the tree a balanced (such as 6-6-6) fertilizer. Learn more about soil amendments and preparing soil for planting. For newly bearing trees, provide nutrients to continue branch and leaf growth, but also to replace nutrients lost by fruit forming. A citrus blend is ideal. Check manufacturer's directions, ask a garden nursery, or consult your local cooperative extension as to how often and how much fertilizer to apply during each year of a tree's growth. Mulches are not recommended for citrus trees, but if trees are located in a cultivated plant bed where mulch is used, keep at least 12 inches of bare ground between the tree trunk and the mulch. Pre-emergent herbicides may be used to prevent weed seeds from germinating. Fruit thinning is unnecessary for citrus trees, as they typically experience something called the "June drop." In late spring or early summer (May or June for most of the country), citrus trees naturally drop a number of their immature fruit.

Pests / Diseases

- Aphids
- Spider Mites
- Root and Crown Rots
- Fungal Leaf Spots
- Fruit Flies
- Tristeza Virus spread by Aphids

Harvest / Storage

Depending on the climate, citrus fruits may take 6 to 8 months to ripen. Citrus fruits will not ripen off the tree, so refrain from picking them too early. The best indicator of ripeness is taste. Harvest the fruit by cutting them off with pruning shears or by pulling the fruit stalk from the tree. Undamaged citrus fruits can be stored for several weeks at cool temperatures.

Variants

- 'Red Blush' (pink flesh)
- 'Marsh Seedless' (white flesh)
- 'Star Ruby' (red flesh)

Other Tips

8 Grapes

A grape is a fruit, botanically a berry, of the deciduous woody vines of the flowering plant genus Vitis.
Grapes can be eaten fresh as table grapes or they can be used for making wine, jam, juice, jelly, grape seed extract, raisins, vinegar, and grape seed oil. Grapes are a non-climacteric type of fruit, generally occurring in clusters. Grapes are a type of fruit that grow in clusters of 15 to 300, and can be crimson, black, dark blue, yellow, green, orange, and pink. "White" grapes are actually green in colour, and are evolutionarily derived from the purple grape. Mutations in two regulatory genes of white grapes turn off production of anthocyanins, which are responsible for the colour of purple grapes. Anthocyanins and other pigment chemicals of the larger family of polyphenols in purple grapes are responsible for the varying shades of purple in red wines. Grapes are typically an ellipsoid shape resembling a prolate spheroid.

Sowing Season	Northern Hemisphere (Cold Climate) ○	Northern Hemisphere (Temperate Climate) ○	Northern Hemisphere (Subtropical Climate) ○	Northern Hemisphere (Tropical Climate) ○	Southern Hemisphere (Cold Climate) ○	Southern Hemisphere (Temperate Climate) ○	Southern Hemisphere (Subtropical Climate) ○	Southern Hemisphere (Tropical Climate) ○			
Growing	Sun Exposure Full Sun	Soil Type Loamy, Well-drained	Soil pH 6.0-7.0	Bloom Time Late Spring	Flower Colour Green-White	Hardiness Zones 4-10					
Introduction	Grapes are often ignored in home gardens, and yet are one of the most widely produced fruit in the world—as well as beautifully ornamental plants. We have plenty of tips for growing grapes in your own backyard. Grape vines not only produce sweet and versatile fruits, they add an element of drama to a garden or landscape. They are vigorous growers, and with the proper pruning, they will produce fruit with ease and can last longer than 30 years. There are three different types of grapes: American (V. labrusca), European (V. viniferia), and North American native Muscadine (V. rotundifolia). American grapes are the most cold-hardy, while European grapes, usually more for wine than the table, do well in warm, dry, Mediterranean type zones. Hybrids are available. Thick skinned Muscadines thrive in the South. Make sure you purchase grape vines from a reputable nursery. Vigorous, 1-year-old plants are best. Smaller, sometimes weaker, 1-year-old plants are often held over by the nursery to grow another year and are then sold as 2-year-old stock. Obtain certified virus-free stock when possible.										

Planting

Plant dormant, bare-root grape vines in the early spring. Construct a trellis or arbor before planting. Grape vines will need to be trained to some sort of support to grow upward. This will also cut the risk of disease. Most grape varieties are self-fertile. To be sure, ask when you are buying vines if you will need more than one plant for pollination. Before planting grapevines, soak their roots in water for two or three hours. Select a site with full sun. If you don't have a spot with full sun, make sure it at least gets morning sun. A small amount of afternoon shade won't hurt. Your soil needs to be deep, well-drained, and loose. You also need good air circulation. Space vines 6 to 10 feet apart (16 feet for muscadines). For each vine, dig a planting hole 12 inches deep and 12 inches wide. Fill with 4 inches of topsoil. Trim off broken roots and set the vine into the hole slightly deeper than it grew in the nursery. Cover the roots with 6 inches of soil and tamp down. Fill with the remaining soil, but don't tamp this down. Prune the top back to two or three buds at planting time. Water at time of planting.

Care

In the first couple of years, the vine should not be allowed to produce fruit. It needs to strengthen its root system before it can support the extra weight of fruit. Pruning is important. Not only would vines run rampant without control, but canes will only produce fruit once. Prune annually when vines are dormant, in March or April. This is before the buds start to swell, but when winter damage is apparent. Don't be afraid to remove at least 90 percent of the previous season's growth. This will ensure a higher quality product. Remember, the more you prune, the more grapes you will have. In the first year, cut back all buds except for 2 or 3. Then, select a couple of strong canes and cut back the rest. Make sure the remaining canes are fastened to the support. In the second year, prune back all canes. Leave a couple of buds on each of the arms. Remove flower clusters as they form. Do not fertilize in the first year unless you have problem soil. Fertilize lightly in the second year of growth. Use mulch to keep an even amount of moisture around the vines. A mesh net is useful in keeping birds away from budding fruit.

Pests / Diseases

- Aphids
- Japanese Beetles
- Powdery Mildew
- Black Rot

Harvest / Storage

If grapes aren't ripening, pinch back some of the foliage to let in more sunlight. Grapes will not continue ripening once picked from the vine. Test a few to see if they are to your liking before harvesting, usually in late summer or early fall. Grapes are ripe and ready to harvest when they are rich in colour, juicy, full-flavoured, easily crushed but not shriveled, and plump. They should be tightly attached to the stems. Sample different grapes from different clusters, and the taste should be between sweet and tart. Check our ripeness guide for more tips on colour. Grapes can be stored for up to six weeks in the cellar, but grapes can absorb the odours of other fruits and vegetables, so keep them separate. Use cardboard boxes or crates lined with clean, dry straw. Separate bunches with straw or sawdust. Check often for spoilage.

Variants

- 'Edelweiss': Hardy in zones 4–7 -28.9°C (–20°F), early white variety. Table and wine.
- 'Reliance': Hardy in zones 4–8, seedless, pink table grape.
- 'Seibel': Hybrid, wine grape. Cold hardy.
- 'Swenson Red': Hardy in zones 4–8, red table grape.
- 'Magnolia': White Muscadine wine grape. Sweet. Best in zones 7–9.
- 'Valiant': Eating grape hardy to Zone 2.

Other Tips

Grapefruit (Citrus paradisi) resemble grapes only in that they grow in clusters, but that was sufficient reason for early European explorers in Barbados to bestow this name on them.

9 Lemon

The lemon, Citrus limon (L.) Osbeck, is a species of small evergreen tree in the flowering plant family Rutaceae, native to South Asia, primarily North eastern India. The tree's ellipsoidal yellow fruit is used for culinary and non-culinary purposes throughout the world, primarily for its juice, which has both culinary and cleaning uses. The pulp and rind (zest) are also used in cooking and baking. The juice of the lemon is about 5% to 6% citric acid, with a pH of around 2.2, giving it a sour taste. The distinctive sour taste of lemon juice makes it a key ingredient in drinks and foods such as lemonade and lemon meringue pie.

10 Lime

A lime (from French lime, "lemon") is a hybrid citrus fruit, which is typically round, green in colour, 3–6 centimetres (1.2–2.4 in) in diameter, and contains acidic juice vesicles. There are several species of citrus trees whose fruits are called limes, including the Key lime, Persian lime, kaffir lime, and desert lime. Limes are a rich source of vitamin C, sour and are often used to accent the flavours of foods and beverages. They are grown year-round. Plants with fruit called "limes" have diverse genetic origins; limes do not form a monophyletic group.

11 Mango

Mangoes are juicy stone fruit (drupe) from numerous species of tropical trees belonging to the flowering plant genus Mangifera, cultivated mostly for their edible fruit. Mango trees grow to 35–40 m (115–131 ft) tall, with a crown radius of 10 m (33 ft). The trees are long-lived, as some specimens still fruit after 300 years. In deep soil, the taproot descends to a depth of 6 m (20 ft), with profuse, wide-spreading feeder roots and anchor roots penetrating deeply into the soil. 'The leaves are evergreen, alternate, simple, 15–35 cm (5.9–13.8 in) long, and 6–16 cm (2.4–6.3 in) broad; when the leaves are young they are orange-pink, rapidly changing to a dark, glossy red, then dark green as they mature. The flowers are produced in terminal panicles 10–40 cm (3.9–15.7 in) long; each flower is small and white with five petals 5–10 mm (0.20–0.39 in) long, with a mild, sweet fragrance. Over 500 varieties of mangoes are known, many of which ripen in summer, while some give a double crop. The fruit takes four to five months from flowering to ripen. The ripe fruit varies in size, shape, colour, sweetness, and eating quality.

Cultivars are variously yellow, orange, red, or green, and carry a single flat, oblong pit that can be fibrous or hairy on the surface, and which does not separate easily from the pulp. The fruits may be somewhat round, oval, or kidney-shaped, ranging from 5–25 centimetres (2–10 in) in length and from 140 grams (5 oz) to 2 kilograms (5 lb) in weight per individual fruit. The skin is leather-like, waxy, smooth, and fragrant, with colour ranging from green to yellow, yellow-orange, yellow-red, or blushed with various shades of red, purple, pink or yellow when fully ripe. Ripe intact mangoes give off a distinctive resinous, sweet smell. Inside the pit 1–2 mm (0.039–0.079 in) thick is a thin lining covering a single seed, 4–7 cm (1.6–2.8 in) long. Mangoes have recalcitrant seeds which do not survive freezing and drying. Mango trees grow readily from seeds, with germination success highest when seeds are obtained from mature fruits.

12 Orange

The orange is the fruit of the citrus species Citrus × sinensis in the family Rutaceae. It is also called sweet orange, to distinguish it from the related Citrus × aurantium, referred to as bitter orange. The sweet orange reproduces asexually (apomixis through nucellar embryony); varieties of sweet orange arise through mutations. The orange tree is an evergreen, flowering tree, with an average height of 9 to 10 m (30 to 33 ft), although some very old specimens can reach 15 m (49 ft). Its oval leaves, alternately arranged, are 4 to 10 cm (1.6 to 3.9 in) long and have crenulate margins.

Sweet oranges grow in a range of different sizes, and shapes varying from spherical to oblong. Inside and attached to the rind is a porous white tissue, the white, bitter mesocarp or albedo (pith). The orange contains a number of distinct carpels (segments) inside, typically about ten, each delimited by a membrane, and containing many juice-filled vesicles and usually a few seeds (pips). When unripe, the fruit is green.

The grainy irregular rind of the ripe fruit can range from bright orange to yellow-orange, but frequently retains green patches or, under warm climate conditions, remains entirely green. Like all other citrus fruits, the sweet orange is non-climacteric. The Citrus sinensis group is subdivided into four classes with distinct characteristics: common oranges, blood or pigmented oranges, navel oranges, and acidless oranges.

Sowing Season	Northern Hemisphere (Cold Climate) ○	Northern Hemisphere (Temperate Climate) ○	Northern Hemisphere (Subtropical Climate) ○	Northern Hemisphere (Tropical Climate) ○	Southern Hemisphere (Cold Climate) ○	Southern Hemisphere (Temperate Climate) ○	Southern Hemisphere (Subtropical Climate) ○	Southern Hemisphere (Tropical Climate) ○			
Growing	Sun Exposure Full Sun	Soil Type Loamy, Well-drained	Soil pH 6.0-7.0	Bloom Time Spring	Flower Colour White	Hardiness Zones 9-11					
Introduction	Although Citrus is a subtropical genus, northern gardeners can grow lemons, oranges, and other citrus trees in containers to enjoy fresh citrus fruit. Standard-size grapefruit and orange trees can grow 18 to 22 feet tall, whereas dwarf varieties only grow 8 to 12 feet tall. Most citrus varieties are self-fertile, so only one tree is needed for fruit production. On average, fruit bearing begins when the trees are between 3 and 6 years old; however, exact timing will depend on the type of citrus (lemons, oranges, grapefruit, etc.), the cultivar, your climate, the health of the plant and its care, and other factors. Flowering is not seasonal, but occurs during warm weather and regular rainfall. Flowers and fruits may coincide.										

Planting

Citrus trees should be planted in a sunny and wind-protected area. In the citrus belt (a loosely defined area stretching from southern California to Florida), trees can be planted at any time, however, spring is the best time for container-grown plants. Standard-size citrus trees should be spaced 12 to 25 feet apart and dwarf citrus trees should be set 6 to 10 feet apart. The exact distance depends on the variety. The bigger the fruit, the farther the distance. If the soil is not well-drained, plant the trees on a slight mound to prevent waterlogging. To plant citrus trees inside from seeds, remove the seeds from the desired fruit. Soak the seeds overnight in water and plant them ½ inch deep in moist potting soil. Cover the pot with a plastic bag or wrap and let it sit in a warm and sunny spot for a few weeks until the seeds start to grow. Then, remove the plastic but keep the pot near a warm and sunny window.

Care

A few weeks after planting, and for the first few years (before bearing age), feed the tree a balanced (such as 6-6-6) fertilizer. Learn more about soil amendments and preparing soil for planting. For newly bearing trees, provide nutrients to continue branch and leaf growth, but also to replace nutrients lost by fruit forming. A citrus blend is ideal. Check manufacturer's directions, ask a garden nursery, or consult your local cooperative extension as to how often and how much fertilizer to apply during each year of a tree's growth. Mulches are not recommended for citrus trees, but if trees are located in a cultivated plant bed where mulch is used, keep at least 12 inches of bare ground between the tree trunk and the mulch. Pre-emergent herbicides may be used to prevent weed seeds from germinating. Fruit thinning is unnecessary for citrus trees, as they typically experience something called the "June drop." In late spring or early summer (May or June for most of the country), citrus trees naturally drop a number of their immature fruit.

Pests / Diseases

- Aphids
- Spider Mites
- Root and Crown Rots
- Fungal Leaf Spots
- Fruit Flies
- Tristeza Virus spread by Aphids

Harvest / Storage

Depending on the climate, citrus fruits may take 6 to 8 months to ripen. Citrus fruits will not ripen off the tree, so refrain from picking them too early. The best indicator of ripeness is taste. Harvest the fruit by cutting them off with pruning shears or by pulling the fruit stalk from the tree. Undamaged citrus fruits can be stored for several weeks at cool temperatures.

Variants

- Sour Oranges - 'Bouquet de Fleurs'
- Sour Oranges - 'Seville'
- Sweet Oranges - 'Valencia' (Valencia)
- Sweet Oranges - 'Ruby' (Blood)
- Sweet Oranges - 'Washington' (Navel)

Other Tips

13 Peach

The peach (Prunus persica) is a deciduous tree native to the region of Northwest China where it was first domesticated and cultivated. It bears an edible juicy fruit called a peach or a nectarine. Prunus persica grows to 4–10 m (13–33 ft) tall and 6 in. in diameter. The leaves are lanceolate, 7–16 cm (2.8–6.3 in) long, 2–3 cm (0.79–1.18 in) broad, pinnately veined. The flowers are produced in early spring before the leaves; they are solitary or paired, 2.5–3 cm diameter, pink, with five petals. The fruit has yellow or whitish flesh, a delicate aroma, and a skin that is either velvety (peaches) or smooth (nectarines) in different cultivars. he flesh is very delicate and easily bruised in some cultivars, but is fairly firm in some commercial varieties, especially when green. The single, large seed is red-brown, oval shaped, approximately 1.3–2 cm long, and is surrounded by a wood-like husk. Peaches, along with cherries, plums and apricots, are stone fruits (drupes). There are various heirloom varieties, including the Indian Peach, or Indian Blood Peach, which arrives in the latter part of the summer, and can have colour ranging from red and white, to purple.

Introduction

Peaches picked at their peak are perfection. Here's how to plant, grow, and harvest peaches at the right time! Plus, we have some delicious peach recipes to try with your bounty! To grow peaches, the trick to choose a type that will fit with your specific climate. Peach trees can grow in USDA Zones 5 to 8, but do especially well in Zones 6 and 7. If you live in one of these zones, you can focus on choosing a variety based on its flavour and harvest-time. If you live in colder regions, there are some varieties that are more cold tolerant that you can choose.

Planting

Before planting peaches, choose a site with well-drained, moderately fertile soil in full sun. Be sure to avoid low areas because frost can more easily settle there and destroy your peaches. Plant the trees in spring. It is best to plant the trees the day you get them (if possible). Pick a tree that is about 1 year old. For container-grown trees, remove the plant from its pot and remove any circling roots by laying the root ball on its side and using shears to cut through the roots. For grafted trees, position the inside of the curve of the graft union away from the sun when planting. Dig a hole that is a few inches deeper and wider than the spread of the roots. Set the tree on top of a small mound of soil in the middle of the hole. Be sure to spread the roots away from the trunk without excessively bending them. If you are planting standard-size trees, space them 15 to 20 feet apart. Space dwarf trees 10 to 12 feet apart. However, most types of peach trees are self-fertile, so planting one tree at a time is fine.

Alternative Planting

If your circumstances are suitable, you might want to try a technique practiced in England. It involves planting a peach tree—ideally a dwarf variety—on the south side of the home or other building, under the eaves of the it. Over time, the gardener prunes and trains the peach tree to espalier in a fan-shape against or very near to the wall of the house. Plastic sheeting is attached to the eaves and draped to cover but not touch the tree, similar to a lean-to. This keeps the tree dry in winter, and the tree enjoys the warms of the sun, directly and as reflected off the house, year round. The plastic should be opened or lifted during bloom time to welcome pollinating insects and on hot, sunny days to ventilate the tree and prevent foliage burn.

Care

Thin the fruits so that they are 6 to 8 inches apart on the branch after the tree blooms (about 4 to 6 weeks). This ensures that the fruits will be larger. Prune and fertilize to accomplish 10 to 18 inches of new growth each season.

Fertilizer

About 6 weeks after planting, fertilize the young trees with 1 pound of a nitrogen fertilizer. During the second year, add ¾ pound of nitrogen fertilizer once in the spring and once in the early summer. After the third year, add about 1 pound of actual nitrogen per year to the mature trees in the spring. To help make the tree hardier, do not fertilize it within 2 months of the first fall frost date or when the fruits are maturing.

Pruning

Each pruning should NOT be avoided. If left unpruned, peach trees weaken, get diseased, and bear less fruit every year. Peaches bloom and bear fruit on second-year wood; therefore, the trees need to make good growth each spring and summer to insure a crop for the next year. Each winter, a large number of red 18- to 24-inch shoots need to be present as fruiting wood. If the trees are not pruned annually, the fruiting shoots move higher and higher, becoming out of reach. Alternate-year pruning results in excessive growth the year following heavy pruning, so annual, moderate pruning is essential for the long-term control of tree vigour and fruiting wood. Be sure to prune the tree to an open centre shape. In the summer of the first year, cut the vigorous shoots that form on the top of the tree by two or three buds. After about a month, check the tree. As soon as you have three wide-angled branches, spaced equally apart, cut back any other branches so that these three are the main branches. In the early summer of the second year, cut back the branches in the middle of the tree to short stubs and prune any shoots developing below the three main branches. After the third year, remove any shoots in the centre of the tree to keep its shape. Be sure to prune the tree annually to encourage production. Pruning is usually done mid to late April. Pinching the trees in the summer is also helpful.

Pests / Diseases

- Borers
- Aphids
- Japanese Beetles
- Leaf Hoppers
- Brown Rot
- Powdery Mildew
- Leaf Curl
- Mosaic Viruses

Harvest / Storage

Peaches are harvested when they are fully ripe from late June through July and August. With peaches, it's especially important to harvest at the RIGHT time. Though this timing depends on what type of peach variety, you can generally go by the colour of the fruit. When peaches are fully ripe, the ground colour of the fruit changes from green to completely yellow. No green should be left on the fruit. They should come off the tree with only a slight twist. The fruits found on the top and outside of the tree usually ripen first. Be careful when picking your peaches because some varieties bruise very easily.

Storage

You can store peaches in the refrigerator in a plastic bag. They should keep for about 5 days. You can also store peaches by making jam or by making pickled peaches. Peaches can also be canned or kept frozen for storage.

Variants

● 'Redhaven', which is the standard and most popular choice. These peaches are medium-size, but can be small if the tree is not properly thinned. Its skin is tough and firm and red in colour.
● 'Reliance', which is a hardy variety. It produces small and soft fruits.
● 'Harmony' ('Canadian Harmony'), which is winter hardy and moderately resistant to bacterial leaf spot. It produces medium to large fruit and freezes well.
● Hale
● Madison
● Saturn
● Contender
● Frost
● Topaz
● Florida Beauty

Other Tips

Although peaches are native to the Chinese countryside, the peach was brought to the western world from Iran. Peaches ripen faster in a closed paper bag at room temperature. Test buds of peaches and other sensitive fruits for freeze damage. Bring in a few twigs cut from the trees and place them in a vase of water. If the twigs bloom in a week or two, expect blossoms in the spring and a crop the following fall.

14 Pear

The pear is any of several tree and shrub species of genus Pyrus, in the family Rosaceae.
It is also the name of the pomaceous fruit of the various trees. Several species of pear are valued for their edible fruit and juices, while others are cultivated as trees.

Sowing Season	Northern Hemisphere (Cold Climate) ○	Northern Hemisphere (Temperate Climate) ○	Northern Hemisphere (Subtropical Climate) ○	Northern Hemisphere (Tropical Climate) ○	Southern Hemisphere (Cold Climate) ○	Southern Hemisphere (Temperate Climate) ○	Southern Hemisphere (Subtropical Climate) ○	Southern Hemisphere (Tropical Climate) ○			
Growing	Sun Exposure Full Sun	Soil Type Loamy, Well-drained	Soil pH 6.0-7.0	Bloom Time Early Spring	Flower Colour White	Hardiness Zones 3-9					
Introduction	Biting into a juicy pear is one of the joys of the season. See how to plant, grow, and harvest pears in your own backyard. They are easy to fit into small yard spaces, and attractive, and require very little care once established. Growing pears is generally easier than growing apples, as they have less pest and disease issues. Two cultivars are generally needed for successful pollination and fruit set. Most pear trees are not self-pollinating. There are many different types of pears; some are best eaten raw and some are best for cooking. You can also grow pears in containers—and plant at any time of the year. Make sure you purchase pears specifically bred for containers. Be aware that pears can take from 3 to 10 years to begin flowering and bear fruit. Once they start producing, pear trees are prolific and long-lasting!										

Planting

● Plant pear trees in late winter or early spring.
● You'll need full sun for best fruit set and fertile, well-drained soil as well as good air circulation.
● If you live outside of the dry western regions, you should choose fire blight–resistant types and rootstocks.
● Plan to plant at least two varieties of pear trees, as they will need to be cross-pollinated to produce fruit. Make sure the varieties are compatible with each other.
● Space standard-size trees 20 to 25 feet apart. Space dwarf trees 12 to 15 feet apart.
● For container-grown trees, remove the plant from its pot and remove any circling roots by laying the root ball on its side and using shears to cut through the roots.
● For grafted trees, position the inside of the curve of the graft union away from the sun when planting.
● Dig a hole that is a few inches deeper and wider than the spread of the roots. Set the tree on top of a small mound of soil in the middle of the hole. Be sure to spread the roots away from the trunk without excessively bending them. Do not add fertilizer or topsoil to the hole.

Care

● Water the young trees well during dry spells to help establish the roots.
● Apply a small amount of fertilizer early in the year. Add ⅛ pound of ammonium nitrate per tree multiplied by the number of years the tree has been set in moderately fertile soil. If you have highly fertile soil, use less fertilizer.
● If the leaves are pale green or yellowish during the summer, use a little more fertilizer the next year.
● If the tree grows more than 12 inches in one season, use less fertilizer the next year.
● Be very careful when applying fertilizer! If you give your trees too much nitrogen, they will become more susceptible to fire blight and also may focus too much energy on producing foliage instead of flowers and fruit.

Pruning
● Prune annually to keep the tree healthy. Generally, prune lightly to keep the trees looking their best and productive.
● For dwarf trees, prune them to a central leader system.
● Standard-size trees can be pruned to either a central leader system or a modified leader system, which is easier to maintain.
● The central leader system features a central trunk with branches that spiral out every 5 to 8 inches, making sure that no branch is directly above another. The training for such a system begins in the early summer of the first year, during which time you should remove any shoots that form within 18 inches of the ground. The end result should resemble a Christmas tree.
● Use spreaders to help shape the branches of the trees. These help the branches to spread outward rather than upward. When the branches are small, you can use clothespins to push the branches away from the main trunk. For bigger branches, use wooden slats with a "V" shape notched into each end.
● Remember to thin the fruit as well, leaving about 6 inches between each cluster of fruit per branch.
● After your trees are established, water them regularly.

Pests / Diseases

● Fire Blight
● Pear Psylla
● Aphids
● Mites
● Powdery Mildew

Harvest / Storage

Harvest / Storage

- Harvest pears when they are mature but still hard. Ripen the pears at room temperature for the best quality fruits.
- Mature pear trees produce a lot of fruit in a short window of time. Be prepared!
- To store pears, pick them when they are fully grown but still very hard. You can keep them in the refrigerator; they should last for about 1 week. You can also keep them in containers in a cool 4.4°C (40°F), dark place; they should keep for 1 to 2 months.
- You can also can the pears for longer storage.

Variants

- ‘Bartlett’, which is the standard choice for pear trees. This tree type is average-size and produces medium to large fruits. These pears ripen to a yellow colour. However, this variety is very vulnerable to fire blight.
- ‘Kieffer’, which is resistant to fire blight. This type produces medium fruit and can be used in canning.
- ‘Anjou’, which produces light-green fruit with a sweet flavour. This type is a good choice for late-blooming pears. Good for canning and fresh use. This type can store for up to 6 months with little loss in quality.

Other Tips

Pick pears when the fruit has a faint yellow blush but is still green. Drop peeled pears in cold, lightly salted water, and they won’t turn brown.

15 Pineapple

The pineapple (Ananas comosus) is a tropical plant with an edible multiple fruit consisting of coalesced berries, also called pineapples, and the most economically significant plant in the family Bromeliaceae.
Pineapples may be cultivated from the offset produced at the top of the fruit, possibly flowering in five to ten months and fruiting in the following six months. The pineapple is a herbaceous perennial, which grows to 1.0 to 1.5 m (3.3 to 4.9 ft) tall, although sometimes it can be taller. In appearance, the plant has a short, stocky stem with tough, waxy leaves. When creating its fruit, it usually produces up to 200 flowers, although some large-fruited cultivars can exceed this. Once it flowers, the individual fruits of the flowers join together to create what is commonly referred to as a pineapple. After the first fruit is produced, side shoots (called 'suckers' by commercial growers) are produced in the leaf axils of the main stem. These may be removed for propagation, or left to produce additional fruits on the original plant.

Commercially, suckers that appear around the base are cultivated. It has 30 or more long, narrow, fleshy, trough-shaped leaves with sharp spines along the margins that are 30 to 100 cm (1.0 to 3.3 ft) long, surrounding a thick stem. In the first year of growth, the axis lengthens and thickens, bearing numerous leaves in close spirals. After 12 to 20 months, the stem grows into a spike-like inflorescence up to 15 cm (6 in) long with over 100 spirally arranged, trimerous flowers, each subtended by a bract. The ovaries develop into berries, which coalesce into a large, compact, multiple fruit. The fruit of a pineapple is arranged in two interlocking helices, eight in one direction, 13 in the other, each being a Fibonacci number.

16 Plum

A plum is a fruit of the subgenus Prunus of the genus Prunus. The subgenus is distinguished from other subgenera (peaches, cherries, bird cherries, etc.) in the shoots having terminal bud and solitary side buds (not clustered), the flowers in groups of one to five together on short stems, and the fruit having a groove running down one side and a smooth stone (or pit). Mature plum fruit may have a dusty-white waxy coating that gives them a glaucous appearance. This is an epicuticular wax coating and is known as "wax bloom".

Dried plum fruits are called "dried plums" or prunes, although, in many countries, prunes are a distinct type of dried plum having a wrinkled appearance. Plums are a diverse group of species. The commercially important plum trees are medium-sized, usually pruned to 5–6 metres height. The tree is of medium hardiness. Without pruning, the trees can reach 12 metres in height and spread across 10 metres.

They blossom in different months in different parts of the world; for example, in about January in Taiwan and early April in the United Kingdom. Fruits are usually of medium size, between 2 and 7 centimetres in diameter, globose to oval. The flesh is firm and juicy. The fruit's peel is smooth, with a natural waxy surface that adheres to the flesh. The plum is a drupe, meaning its fleshy fruit surrounds a single hard seed.

GARDENING Fruit Plum

Sowing Season	Northern Hemisphere (Cold Climate) ○	Northern Hemisphere (Temperate Climate) ○	Northern Hemisphere (Subtropical Climate) ○	Northern Hemisphere (Tropical Climate) ○	Southern Hemisphere (Cold Climate) ○	Southern Hemisphere (Temperate Climate) ○	Southern Hemisphere (Subtropical Climate) ○	Southern Hemisphere (Tropical Climate) ○			
Growing	Sun Exposure Full Sun	Soil Type Loamy, Well-drained	Soil pH 6.0-7.0	Bloom Time Early Spring	Flower Colour White	Hardiness Zones 4-9					
Introduction	Plums! They're ready to pick from late August to early September in most regions. Ever thought about growing plums? Less demanding than most fruit trees, plums are a great choice for beginner gardeners. They're compact and prolific producers and add beauty to your backyard. Plus, plums are delicious cooked in jams and cakes or eaten right out of hand! Plums are a type of stone fruit, which also includes peaches, nectarines, apricots, and cherries.										

Choosing a Variety
● It's important to choose a type of plum that will work with your location. There are three major categories of plum trees: European, Japanese, and American hybrids. The hardy European types work in most regions across the U.S., whereas the Japanese types flourish where peach trees thrive (warmer regions, generally). American hybrids are typically the hardiest of the plums, with some varieties being able to survive as far north as Zone 3.
● European plums are generally self-fertile, but Japanese and American hybrid plums typically need to cross-pollinate with a second variety for cross-pollination. So, if you have space for only one tree, go with a European plum.
● Order bare-root, rather than potted trees, if possible. A well-established tree will yield up to 2 bushels of plums.

Planting

● Plant plum trees in loamy, well-drained soil. Plums do not do well when planted in clay-heavy soils or in locations where their roots will be constantly wet.
● Choose a planting location that receives full sun—at least 6 to 8 hours of direct sunlight.
● Avoid planting in pockets where frost may settle, as the frost may damage your trees.
● If possible, find a sheltered location, such as a south- or west-facing spot out of the wind. This will help the plum tree set fruit.

Planting the Tree
● Space standard-size trees 20 to 25 feet apart and dwarf trees 10 to 15 feet apart.
● Set bare-root trees atop a small mound of soil in the centre of the planting hole, and spread the roots down and away without unduly bending them. Keep the graft union an inch above the soil line.
● For container-grown tree for planting, remove the tree from its pot and get rid of any tightly circling roots by laying the root ball on its side and using shears to trim off these roots. Do your best to untangle roots without damaging roots, but if the root ball is particularly pot-bound, you can loosen it by scraping up and down the sides with a knife or hand fork.
● When planting grafted trees, it's important to keep the graft union 1 to 2 inches above the soil line. This is especially true for dwarf varieties, as roots may start to grow from above the graft if the tree is planted too deep, bypassing the rootstock that keeps the tree dwarf-size.
● Dig a hole that's a few inches deeper and wider than the spread of the roots. For bare-root trees, set the tree on top of a small mound of soil in the middle of the hole and spread the roots away from the trunk without excessively bending them.
For container-grown trees, simply place the root ball in the middle of the hole.

Fill in the hole, stopping periodically to make sure that the roots are thoroughly covered and no air pockets remain around the tree.
● Water the tree thoroughly; this helps the soil to settle around the roots. Keep the tree well watered for the first few weeks after planting.
● For bare-root trees, it's often recommended to stake the tree for at least one year, until the tree is stable enough to stand on its own.

Care

Thinning plum trees is important to prevent branches from breaking under the weight of the fruit. If branches do break, prune them back to undamaged wood, ideally cutting back to a natural fork to avoid leaving stubs. Be sure to water the young trees heavily every week during the first growing season to help promote growth. Then, water regularly. It's best to water the plant deeply at the soil line, then let the soil dry out (though not completely) and water again. Water your tree well into mid-October to give it plenty of moisture through the winter months.

Do not fertilize young fruit trees until they have set a crop. Once established, fruit production requires regular fertilizing all year long. If there's good fruit set, fertilize with one pound calcium nitrate per tree or 1½ lb. 10-10-10. Cut back the nitrogen in fall and winter to avoid encouraging new growth in those seasons. In the fall, rake away all debris and fallen trees.

Prune in early spring or mid-summer to avoid infection. The best time for pruning is usually spring for young trees and mid-summer for established ones. Do NOT prune in the fall or winter injury and infection may occur. To prevent winter injury: Consider a tree wrap or guard around the lower trunk, especially for a young plum tree. To help control pests and diseases, remember to prune your trees to keep them open. You can also mulch around the trees in the spring to help control weeds, but be sure to remove the mulch in the late fall so that no pests use it over the winter.

You can also lightly cultivate the soil around your trees in late spring to eliminate any pests in the soil. Keep an eye on the lower bark and branches for mouse or rabbit damage; if this could be a problem, you may need to install tree guards or fence in young trees with chicken wire for the winter.

Pruning Japanese Plum Trees
If you have a Japanese variety, the best pruning method is to create an "open centre" shape, where the central trunk is cut short and several large branches radiate outwards from it's tip. In the summer of the first year, cut the vigorous shoots that form on the top of the tree by two or three buds. After about a month, check the tree. As soon as you have three wide-angled branches, spaced equally apart, cut back any other branches so that these three are the main branches. In the early summer of the second year, cut back the branches in the middle of the tree to short stubs and prune any shoots developing below the three main branches. After the third year, remove any shoots in the centre of the tree to keep its shape. Japanese types require heavy pruning to help keep them in shape and to produce better fruit. It is also good to thin out the fruit on these types of trees. You should space the plums about 3 to 4 inches apart on each branch.

Pruning European Plum Trees
If you have a European variety, the best pruning method is to create a central leader. This shape features a central trunk with branches that spiral out every 5 to 8 inches, making sure that no branch is directly above another. The training for such a system begins in the early summer of the first year, during which time you should remove any shoots that form within 18 inches of the ground. The end result should resemble a Christmas tree. European types do not require fruit thinning because they do not produce as much fruit as Japanese types. However, the fruit on these types should be spaced about 2 inches apart on each branch.

Pests / Diseases

- Silver Leaf Disease
- Honey Fungus
- Bacterial Canker
- Pocket Plum
- Japanese Beetles
- Plum Aphids
- Plum Moth

Harvest / Storage

European plums have the best flavour when left to ripen on the tree. You can tell when plums are ripe by applying gentle pressure with your fingers. If the skin of the fruit feels soft, then it is ready to be picked. Plums should come off the tree easily with just a slight twist of the fruit. Japanese plums are picked slightly early and allow them to ripen in a cool place. Unfortunately, the fruit does not store for long, so must be eaten or preserved. Alternatively, you can pick the fruits when they are still slightly firm and store them in a cool place to fully ripen. The best place to store plums is in the refrigerator. The best temperature for storing plums is about -0.5-0°C (31-32°F) with relative humidity around 90–95%; if kept at this temperature, plums may last for 2 to 4 weeks.

Variants

For a European type, try the ‘Stanley’. This semi-freestone type is works great for the eastern, midwestern, and some of the northwest regions of the U.S. It is self-fertile, meaning no cross-pollination is necessary. It’s harvested in late August, producing medium to large plums with dark blue skin and greenish-yellow flesh and is great for cooking, canning, or eating fresh. For a Japanese type, try the ‘Satsuma’, which produces large, dark-red plums. This kind is good for eating fresh and canning because of its sweet taste. American hybrid trees, such as ‘Alderman’, ‘Superior’, and ‘Underwood’, are all popular choices. These trees combine the taste of the Japanese variety with the hardiness of the European variety. These types work well for regional extremes.

Other Tips

17 Raspberry

The raspberry is the edible fruit of a multitude of plant species in the genus Rubus of the rose family, most of which are in the subgenus Idaeobatus; the name also applies to these plants themselves. Raspberries are perennial with woody stems. Various kinds of raspberries can be cultivated from hardiness zones 3 to 9. Raspberries are traditionally planted in the winter as dormant canes, although planting of tender, plug plants produced by tissue culture has become much more common. Plants are typically planted 2-6 per m in fertile, well drained soil; raspberries are usually planted in raised beds/ridges, if there is any question about root rot problems. All cultivars of raspberries have perennial roots but, many do not have perennial shoots. In fact, most raspberries have shoots that are biennial (meaning shoots grow in the first growing season and fruits grow off of those shoots during the second growing season). The flowers can be a major nectar source for honeybees and other pollinators.

Raspberries are vigorous and can be locally invasive. They propagate using basal shoots (also known as suckers), extended underground shoots that develop roots and individual plants. They can sucker new canes some distance from the main plant. For this reason, raspberries spread well, and can take over gardens if left unchecked. Raspberries are often propagated using cuttings, and will root readily in moist soil conditions. The fruit is harvested when it comes off the receptacle easily and has turned a deep colour (red, black, purple, or golden yellow, depending on the species and cultivar). This is when the fruits are ripest and sweetest. Excess fruit can be made into raspberry jam or frozen. High tunnel bramble production offers the opportunity to bridge gaps in availability during late fall and late spring. Furthermore, high tunnels allow less hardy floricane-fruiting raspberries to overwinter in climates where they wouldn't otherwise survive. In the tunnel plants are established at close spacing usually prior to tunnel construction.

Introduction

Raspberries are relatively easy to grow and can bear fruit indefinitely with proper care. Here’s how to grow raspberries in your garden—from planting to harvest! There are two types of raspberries, both with their own specific requirements for growing:
- Summer-fruiting raspberries bear one crop per season, in summertime (often June or July).
- Ever-bearing raspberries (also called fall-bearing or primocane-fruiting) bear a fall crop and can also produce fruit the following summer.

Most raspberries are summer-bearing varieties and all are self-fertile, meaning you’ll get fruit with only one variety. They’re best pollinated by bees, and will start producing fruit a year after planting. Though raspberry bushes are naturally inclined to grow in cooler climates, the plants now come in many varieties suited to a range of planting zones. All raspberries will need pruning annually! Raspberries are perennials, however it’s important to realize that their branches (or canes) which bear the fruit live for only two summers. During the first year, the new green cane (primocane) grows vegetatively. The cane develops a brown bark, is dormant in winter, and during the second growing season is called a floricane. The floricane produces fruit in early to mid summer and then dies. New primocanes are produced each year, so fruit production continues year after year. It’s your job to prune out those dead canes each year.

Planting

When to Plant
Raspberry plants can be purchased as dormant, bare-root plants or as potted plants. Plant bare-root transplants in the early spring as soon as the soil can be worked. Plant potted transplants in the spring after threat of frost has passed.

How to Plant
Pick a site with full sun to produce the most fruit. The plant will grow in part shade, but harvests will be meager. Your site needs rich and well-drained soil, great air circulation, and shelter from wind. Avoid a wet area, as well as a windy spot, as raspberries do not like to stand in water nor dry out. Prepare soil with a couple inches of compost or aged manure a couple weeks before planting. (A good rate is about 3 ½ cubic feet of compost per 100 square feet.) Till the soil well before planting. Plant far from wild growing berries, otherwise risk the spread of pests and diseases to your garden. Before planting, soak the roots for an hour or two. Dig a hole that is roomy enough for the roots to spread. Whether you’re planting bare-root or potted plants, keep the crown of the plant 1 or 2 inches above the ground. Space red and yellow raspberry plants from 2 to 3 feet apart, in rows 8 feet apart. Space black and purple types 4 feet apart. Depending on the variety you plant, you may need to fashion a support. A trellis or a fence are good options. If you chose to use one of these, establish them at or before time of planting so the plants are not disturbed when maturing.

Care

Mulching is important throughout the season to conserve moisture and suffocate weeds. Keep a thick layer of mulch surrounding plants at all times. Water one inch per week from spring until after harvest. Regular watering is better than infrequent deep soaking. The roots send up an abundant amount of shoots, called canes. Keep order by pruning away the majority of them, so that the survivors can produce lots of berries.

Pruning
Summer-Bearers produce berries on two year old canes while one year old canes grow right beside them. You shouldn't have trouble telling which is which: the older canes have brown stems, and the young ones are still green. Prune only the older ones, the ones that have finished their fruitful year.

Red Raspberries: Prune any time after the last harvest and before growth begins in the spring. Cut all canes that produced fruit to the ground. Thin to 6 sturdy canes per hill (per foot of row). In areas where winter injury is common, you may delay thinning the primocanes (new growth) until the following spring, when you will be able to tell which canes have survived. Before growth starts in spring, cut the canes to about 12 inches above the support. Don't cut back more than 25% of each cane, to avoid reducing yield.
Black and Purple Raspberries: When primocanes are between 24 to 30 inches in height, pinch out the tip of each shoot to induce branching. This will make the fruit easier to pick and increase production. After harvest, cut down all canes that bore fruit to ground level. Before growth begins the following spring, cut back all side branches so they are 12 to 18 inches long. Select 6 canes per hill, and prune out the rest. Tie these canes to the support system.
Ever-bearing or fall-bearing raspberries: This is easy. Just cut all canes to the ground any time after harvest and before growth begins in the spring. They give fruit on canes which are in their first year of growth, after which there is no reason to keep them. Mow them to the ground or use pruning shears for a small patch.
Ever-bearing or fall-bearing raspberries: Clean up all debris—diseases and pests overwinter. Pruning is not required during the growing season unless you want to keep a uniform order.

Note: This assumes you are harvesting a fall crop. To get both fall and following summer crop, do not remove the primocanes that produced the fall crop. Prune them back in spring to about 12 inches above the support, or to the last visible node that had fruit, cutting off the dead tips.

Pests / Diseases

Raspberries are one of the few fruits that are hardly bothered by pests and diseases. (Black raspberries are more susceptible to this type of damage than red or purple.)

- Keep an eye out for spider mites and Japanese beetles from June through August.
- Rabbits love to eat the canes in winter. A chicken wire fence will help prevent rabbit damage.
- Powdery Mildew
- Cane Borers

Harvest / Storage

All varieties will begin to produce fruit in their second season. In some cases, ever-bearers may bear small berries in their first autumn. In early summer, berries will ripen over a time of about 2 weeks. You will need to pick berries every couple of days. Try to harvest berries on a sunny day, when they are dry. Don't tug too hard on your raspberries when picking. A ripe raspberry will leave the vine willingly. Raspberries can be kept refrigerated for about 5 days. If possible, don't wash the berries after picking, unless you're going to eat them straight away. They will grow mouldy and mushy if not kept dry in storage. If you do need to wash them, let them air dry completely before storing. If the fruit is to be made into preserves, it should be done straight off the plant. Raspberries can be frozen. As with freezing blueberries, make a single layer of berries on a cookie sheet. When frozen, place into airtight bags.

Variants

There are many, many raspberry varieties available today—and each one is unique! Here are a few to get you started. Ask your local garden centre or cooperative extension service which raspberry varieties are best-suited for your area.

- 'Canby': red berries; summer-bearing; nearly thornless; recommended for New England, Upper Great Lakes, and Northwest
- 'Heritage': red berries; ever-bearing; recommended for the Mid-Atlantic and Ohio Valley
- 'Plainsman': red berries; ever-bearing; does well in higher altitudes (the Rockies and High Plains)
- 'Fallgold': yellow berries; ever-bearing; recommended for the Upper Midwest and Canada
- 'Double Gold': yellow berries tinged with peach; ever-bearing; better for warmer areas, as the fall crop can be quite late
- 'Royalty': purple berries; summer-bearing; better for warmer areas
- 'Jewel': black berries; summer-bearing; disease-resistant and great for warmer areas
- 'Black Hawk': black berries; summer-bearing; heat and drought tolerant

Other Tips

Raspberries are a great source of dietary fibre and Vitamin C and they may help to protect against disease.

18 Strawberry

The garden strawberry (or simply strawberry; Fragaria × ananassa) is a widely grown hybrid species of the genus Fragaria, collectively known as the strawberries. It is cultivated worldwide for its fruit. The fruit is widely appreciated for its characteristic aroma, bright red colour, juicy texture, and sweetness. Strawberry cultivars vary widely in size, colour, flavour, shape, degree of fertility, season of ripening, liability to disease and constitution of plant. On average, a strawberry has about 200 seeds on its external membrane.

Some vary in foliage, and some vary materially in the relative development of their sexual organs. Strawberries may also be propagated by seed, though this is primarily a hobby activity, and is not widely practiced commercially. A few seed-propagated cultivars have been developed for home use, and research into growing from seed commercially is ongoing.

Seeds (achenes) are acquired either via commercial seed suppliers, or by collecting and saving them from the fruit. Strawberries can also be grown indoors in strawberry pots. Although the plant may not naturally grow indoors in the winter, use of LED lighting in combination of blue and red light can allow the plant to grow during the winter. Additionally, in certain areas like the state of Florida, winter is the natural growing season where harvesting starts in mid-November.

GARDENING | Fruit | Strawberry

Introduction	Sweet, juicy strawberries are treats when right off the plant. Supermarket berries tend to be tart with grainy texture; this is because the natural sugar in the berries begins converting to starch as soon as it is plucked from the plant. It's definitely worth your while to try growing strawberries, and the good news is that they are relatively easy to grow if you have full sun. Strawberry plants come in three types. For the home garden, we recommend Junebearers. Although you will have to wait a year for fruit harvesting, it will be well worth it.
Day-Neutral	Insensitive to day length, these varieties produce buds, fruits and runners continuously if temperature remains between 35 and 85. Production is less than that of Junebearers.
Everbearer	These varieties form buds during the long days of summer and the short days of autumn. The summer-formed buds flower and fruit in autumn, and the autumn-formed buds fruit the following spring.
Junebearer	Length-of-day sensitive, these varieties produce buds in the autumn, flowers and fruits the following spring, and runners during the long days of summer.

Planting

- Buy disease-resistant plants from a reputable nursery, of a variety recommended in your area.
- Plan to plant as soon as the ground can be worked in the Spring. See your local frost dates.
- Establish new plants each year to keep berry quality high each season.
- Strawberries are sprawling plants. Seedlings will send out runners, or 'daughter' plants, which in turn will send out their own runners.
- Make planting holes deep and wide enough to accommodate the entire root system without bending it. However, don't plant too deep: The roots should be covered, but the crown should be right at the soil surface.
- Provide adequate space for sprawling. Set plants out 20 inches apart, and leave 4 feet between rows.
- Roots shouldn't be longer than 8 inches when plants are set out. Trim them if necessary.
- It is also possible to grow strawberries from last year's runners.
- pH should be between 5.5 and 7. If necessary, amend your soil in advance.
- Strawberry plants require 6-10 hours a day of direct sunlight, so choose your planting site accordingly.
- Tolerant of different soil types, although prefer loam. Begin working in aged manure or compost a couple months before planting.
- Planting site must be well-drained. Raised beds are a particularly good option for strawberry plants.
- Practice crop rotation for the most success. Do not plant in a site that recently had strawberries, tomatoes, peppers, or eggplant.

Care

- In the first year, pick off blossoms to discourage strawberry plants from fruiting. If not allowed to bear fruit, they will spend their food reserves on developing healthy roots. The yields will be much greater in the second year.
- Eliminate daughter plants as needed. First and second generations produce higher yields. Try to space each plant about 10 inches apart.
- Moisture is incredibly important due to shallow roots. Water adequately, about one inch per week. Strawberry plants need a lot of water when the runners and flowers are developing and again in the fall when the plants are mature.
- Keep the beds mulched to reduce water needs and weed invasion.
- Be diligent about weeding. Weed by hand, especially in the first months after planting.
- When the growing season is over, mow or cut foliage down to one inch and mulch plants about 4 inches deep with straw, pine needles or other organic material. This can be done after the first couple of frosts, or when air temps reach -6°C (20°F).
- Remove mulch in early spring, after danger of frost has passed.
- Row covers are a good option for protecting blossoms and fruit from birds.

Pests / Diseases

- Gray Mould
- Powdery Mildew
- Japanese Beetles
- Spider Mites
- Slugs

Keeping beds weed-free and using a gritty mulch can deter slugs and bugs. Spread sand over the strawberry bed to deter slugs. (This also works well for lettuce.) Pine needles also foil slug and pill-bug damage. For bigger bugs such as Japanese beetles, spray your plants with puréed garlic and neem seed oil. When birds threaten your strawberries, position balloons with scare-eyes above the beds and use reflective Mylar bird tape to deter them.

Harvest / Storage

- Fruit is ready for harvesting 4–6 weeks after blossoming.
- Harvest only fully red (ripe) berries, and pick every three days.
- Cut by the stem; do not pull the berry.
- Harvest will last up to 3 weeks. You should have an abundance of berries, depending on the variety.
- Store unwashed berries in the refrigerator for 3–5 days.
- Strawberries can be frozen whole for about 2 months.

Variants

Try planting more than one variety. Each will respond differently to conditions, and you will have a range of different fruits to enjoy.

- 'Northeaster' is best suited for the north-eastern US and south-eastern Canada. Fruit has strong flavour and aroma.
- 'Sable' is hardy to zone 3, early season, great flavour.
- 'Primetime' is a mild-flavoured, disease-resistant variety, best adapted to the Mid-Atlantic.
- 'Cardinal' is a good variety to try in the South.
- 'Camarosa' is a good variety to try on the West Coast.
- 'Tristar' is a day-neutral variety that's very well-suited for hanging baskets.

Other Tips

19 Tangerine

The tangerine (Citrus tangerina) is a group of orange-coloured citrus fruit consisting of hybrids of mandarin orange (Citrus reticulata). Tangerines are smaller and less rounded than common oranges. The taste is considered less sour, as well as sweeter and stronger, than that of an orange. Tangerines contain 85% water, 13% carbohydrates, and negligible amounts of fat and protein (table). Among micronutrients, only vitamin C is in significant content (32% of the Daily Value) in a 100 gram reference serving, with all other nutrients in low amounts. A ripe tangerine is firm to slightly soft, heavy for its size, and pebbly-skinned with no deep grooves, as well as orange in colour. The peel is very thin, with very little bitter white mesocarp, which makes them usually easier to peel and to split into segments. All of these traits are shared by mandarins generally.

Sowing Season	Northern Hemisphere (Cold Climate) ○	Northern Hemisphere (Temperate Climate) ○	Northern Hemisphere (Subtropical Climate) ○	Northern Hemisphere (Tropical Climate) ○	Southern Hemisphere (Cold Climate) ○	Southern Hemisphere (Temperate Climate) ○	Southern Hemisphere (Subtropical Climate) ○	Southern Hemisphere (Tropical Climate) ○			
Growing	Sun Exposure Full Sun	Soil Type Loamy, Well-drained	Soil pH 6.0-7.0	Bloom Time Spring	Flower Colour White	Hardiness Zones 9-11					

Introduction

Although Citrus is a subtropical genus, northern gardeners can grow lemons, oranges, and other citrus trees in containers to enjoy fresh citrus fruit. Standard-size grapefruit and orange trees can grow 18 to 22 feet tall, whereas dwarf varieties only grow 8 to 12 feet tall. Most citrus varieties are self-fertile, so only one tree is needed for fruit production. On average, fruit bearing begins when the trees are between 3 and 6 years old; however, exact timing will depend on the type of citrus (lemons, oranges, grapefruit, etc.), the cultivar, your climate, the health of the plant and its care, and other factors. Flowering is not seasonal, but occurs during warm weather and regular rainfall. Flowers and fruits may coincide.

Planting

Citrus trees should be planted in a sunny and wind-protected area. In the citrus belt (a loosely defined area stretching from southern California to Florida), trees can be planted at any time, however, spring is the best time for container-grown plants. Standard-size citrus trees should be spaced 12 to 25 feet apart and dwarf citrus trees should be set 6 to 10 feet apart. The exact distance depends on the variety. The bigger the fruit, the farther the distance. If the soil is not well-drained, plant the trees on a slight mound to prevent waterlogging. To plant citrus trees inside from seeds, remove the seeds from the desired fruit. Soak the seeds overnight in water and plant them ½ inch deep in moist potting soil. Cover the pot with a plastic bag or wrap and let it sit in a warm and sunny spot for a few weeks until the seeds start to grow. Then, remove the plastic but keep the pot near a warm and sunny window.

Care

A few weeks after planting, and for the first few years (before bearing age), feed the tree a balanced (such as 6-6-6) fertilizer. Learn more about soil amendments and preparing soil for planting. For newly bearing trees, provide nutrients to continue branch and leaf growth, but also to replace nutrients lost by fruit forming. A citrus blend is ideal. Check manufacturer's directions, ask a garden nursery, or consult your local cooperative extension as to how often and how much fertilizer to apply during each year of a tree's growth. Mulches are not recommended for citrus trees, but if trees are located in a cultivated plant bed where mulch is used, keep at least 12 inches of bare ground between the tree trunk and the mulch. Pre-emergent herbicides may be used to prevent weed seeds from germinating. Fruit thinning is unnecessary for citrus trees, as they typically experience something called the "June drop." In late spring or early summer (May or June for most of the country), citrus trees naturally drop a number of their immature fruit.

Pests / Diseases

- Aphids
- Spider Mites
- Root and Crown Rots
- Fungal Leaf Spots
- Fruit Flies
- Tristeza Virus spread by Aphids

Harvest / Storage

Depending on the climate, citrus fruits may take 6 to 8 months to ripen. Citrus fruits will not ripen off the tree, so refrain from picking them too early. The best indicator of ripeness is taste. Harvest the fruit by cutting them off with pruning shears or by pulling the fruit stalk from the tree. Undamaged citrus fruits can be stored for several weeks at cool temperatures.

Other Tips

20 Watermelon

Citrullus lanatus is a plant species in the family Cucurbitaceae, a vine-like (scrambler and trailer) flowering plant originally from Africa. It is cultivated for its fruit. The subdivision of this species into two varieties, watermelons and citron melons. The watermelon is an annual that has a prostrate or climbing habit. Stems are up to 3 m long and new growth has yellow or brown hairs. Leaves are 60 to 200 mm long and 40 to 150 mm wide. These usually have three lobes which are themselves lobed or doubly lobed. Plants have both male and female flowers on 40-mm-long hairy stalks. These are yellow, and greenish on the back. The watermelon is a large annual plant with long, weak, trailing or climbing stems which are five-angled (five-sided) and up to 3 m (10 ft) long. Young growth is densely woolly with yellowish-brown hairs which disappear as the plant ages. The leaves are large, coarse, hairy pinnately-lobed and alternate; they get stiff and rough when old. The plant has branching tendrils.

The white to yellow flowers grow singly in the leaf axils and the corolla is white or yellow inside and greenish-yellow on the outside. The flowers are unisexual, with male and female flowers occurring on the same plant (monoecious). The male flowers predominate at the beginning of the season; the female flowers, which develop later, have inferior ovaries. The styles are united into a single column. The large fruit is a kind of modified berry called a pepo with a thick rind (exocarp) and fleshy centre (mesocarp and endocarp). Wild plants have fruits up to 20 cm (8 in) in diameter, while cultivated varieties may exceed 60 cm (24 in). The rind of the fruit is mid- to dark green and usually mottled or striped, and the flesh, containing numerous pips spread throughout the inside, can be red or pink (most commonly), orange, yellow, green or white.

Sowing Season	Northern Hemisphere (Cold Climate) ○	Northern Hemisphere (Temperate Climate) ○	Northern Hemisphere (Subtropical Climate) ○	Northern Hemisphere (Tropical Climate) ○	Southern Hemisphere (Cold Climate) ○	Southern Hemisphere (Temperate Climate) ○	Southern Hemisphere (Subtropical Climate) ○	Southern Hemisphere (Tropical Climate) ○			
Growing	Sun Exposure Full Sun	Soil Type Sandy Loam	Soil pH 6.0-7.0	Bloom Time Summer	Flower Colour Yellow	Hardiness Zones 4-11					

Planting

If you live in warmer climes, you can sow seeds directly outdoors, but wait until the soil temperature warms to at least 21.1°C (70°F) to avoid poor germination. Watermelon vines are very tender and should not be transplanted until all danger of frost has passed. (To be safe, wait at least two weeks past your last frost date.) If you are in a cooler zone, start seeds indoors about a month before transplanting. Amend soil with aged manure, seaweed, and/or compost before planting. Watermelons are heavy feeders. Learn more about soil amendments and preparing soil for planting. Watermelons prefer a soil pH between 6 and 6.8. Growing the vines in raised rows, known as hills, ensures good drainage and will hold the sun's heat longer. Space the plants about 2 feet apart in a 5-foot-wide hill. If you're growing in rows, space 6 feet by 6 feet apart. Watermelons like loamy, well-drained soil. Handle them gently when you transplant. After you transplant, cover the plants with row covers to keep pests at bay. You'll remove the row covers when you see both male and female flowers on the vine.

Care

Mulching with black plastic will serve multiple purposes: it will warm the soil, hinder weed growth, and keep developing fruits clean. Watering is very important—from planting until fruit begins to form. While melon plants are growing, blooming, and setting fruit, they need 1 to 2 inches of water per week. Keep soil moist, but not waterlogged. Water at the vine's base in the morning, and try to avoid wetting the leaves and avoid overhead watering. Reduce watering once fruit are growing. Dry weather produces the sweetest melon. If you choose to fertilize (and many do), make sure it delivers more nitrogen than phosphorus and potassium. However, after flowering begins, use a fertilizer with less nitrogen. We like to use liquid seaweed. Pruning isn't necessary, but vine productivity may be improved if you do not allow lateral (side) vines to grow and stick to the main vine.

When the plant is young, just cut off the end buds as they form (before the side shoots become vines). You can also pinch off some blossoms to focus the energy on fewer melons (though it's a challenge to kill off a potential fruit). Vines produce male and female flowers separately on the same plant. They often begin producing male flowers several weeks before the females appear. Do not be concerned if the male flowers fall off. The female flowers (which have a swollen bulb at the base) will stay on the vine and bear fruit. Blossoms require pollination to set fruit, so be kind to the bees! As fruit is ripening, prevent rotting by gently lifting it and putting cardboard or straw between the fruit and the soil.

Pests / Diseases

- Aphids
- Cucumber Beetles
- Squash Vine Borer Moths
- Fusarium Wilt

Harvest / Storage

Watermelons don't sweeten after they are picked, so harvest time is important. They generally ripen over two weeks so keep your eye on them.

Tell if it's Ripe
How to tell if watermelons are ripe: Thump it. If the watermelon sounds hollow, it's ripe. Look at the colour on the top. The watermelon is ripe when there is little contrast between the stripes. Look at the colour on the bottom. A green watermelon will have a white bottom; a ripe melon will have a cream- or yellow-coloured bottom. Press on it. If the watermelon sounds like it gives a little, it's ripe. (Rhodes doesn't like this method because it can ruin the quality of the fruit.) Check the tendril. If it's green, wait. If it's half-dead, the watermelon is nearly ripe or ripe. If the tendril is fully dead, it's ripe or overripe; it's not going to get any riper, so you might as well pick! Stems should be cut with a sharp knife close to the fruit. Watermelons can be stored uncut for about 10 days. If cut, they can last in the refrigerator for about 4 days. Wrap tightly in plastic.

Variants

- 'Sugar Baby': 80 days to maturity. Produces 10-pound melons with bright red flesh. This variety of smaller fruit can be planted just 4 feet apart.
- 'Sweet Beauty': 80 days to maturity. A 2004 All-America Selection. Bears 6-pound, oblong melons with red flesh.
- 'Golden Midget': 70 days to maturity. Bears petite, yellow-skinned 3-pound melons with pink flesh. Good for Northern gardeners.

Other Tips

Watermelon is 90% water.

Basil

Sowing Season	Northern Hemisphere (Cold Climate) ○	Northern Hemisphere (Temperate Climate) ○	Northern Hemisphere (Subtropical Climate) ○	Northern Hemisphere (Tropical Climate) ○	Southern Hemisphere (Cold Climate) Sep-Feb	Southern Hemisphere (Temperate Climate) Sep-Dec	Southern Hemisphere (Subtropical Climate) Aug-Feb	Southern Hemisphere (Tropical Climate) All Year			
Sowing Guide	Sowing Depth 3mm	Row Spacing ○	Plant Spacing 25-40cm	Frost Tender / Hardy FT	Direct Sow / Raise Seeds R/D	Germination Time 7-14 Days					

Introduction

Basil is a warm-weather, fragrant herb that tastes great in Italian dishes—and let's not forget homemade pesto! Plant seeds or transplants after all danger of frost has passed and soil is warm, and it will yield an abundant harvest within weeks. Keep harvesting the leaves to keep the plant going strong. The most common type of basil is sweet basil; other types include purple basil (less sweet than common basil), lemon basil (lemon flavour), and Thai basil (liquorice flavour). Basil is easy to grow but it only grows outdoors in the summer—and only once the soil has warmed up nicely—so plan accordingly. If you're planning on making pesto, grow several plants. Otherwise one or two basil plants yields plenty.

Planting

- To get a head start, start the seeds indoors 6 weeks before the last spring frost. (See local frost dates.)
- To plant outside, wait until the soil is at least 50°F, preferably around 70°F for best growth. Don't rush basil. Without heat, the plant won't grow.
- Basil needs to be in a location that gets 6 to 8 hours of full Sun daily; soil should be moist and well-drained.
- Plant seeds/seedlings about ¼-inch deep and 10 to 12 inches apart. They should grow to about 12 to 24 inches in height. For smaller plants, plant farther apart (about 16 to 24 inches).
- During the dry periods in summer, water the plants freely.
- Remember to pinch out the flower heads as soon as they appear to make sure that the leaves will continue growing.
- If you're planning on cooking with these plants, plant in clean soil (don't use fertilizers that leave harmful residues) and grow them away from driveways and busy streets so that exhaust won't settle on the plants.
- Tomatoes make great neighbours for basil plants in the garden.

Care

Make sure that the soil is moist. Basil plants like moisture. If you live in a hot area, use mulch around the basil plants (the mulch will help keep the soil moist). After the seedlings have their first six leaves, prune to above the second set. Every time a branch has six to eight leaves, repeat pruning the branches back to their first set of leaves. After 6 weeks, pinch off the centre shoot to prevent early flowering. If flowers do grow, just cut them off. If the weather is going to be cold, be sure to harvest your basil beforehand, as the cold weather will destroy your plants.

Pests / Diseases

- Aphids
- Variety of bacterial and fungal leaf, stem, and root diseases

Harvest / Storage

Start picking the leaves of basil as soon as they are 6 to 8 inches tall. Once temperatures hit 80°F, basil will really start leafing out. Make sure to pick the leaves regularly to encourage growth throughout the summer. Even if you don't need to leaves, pick them to keep the plant going. Freeze the leaves. If you pick regularly, twelve basil plants will produce 4 to 6 cups of leaves per week. The best method for storing basil is freezing. Freezing will prevent the plant from losing any of its flavour. To quick-freeze basil, dry whole sprigs of basil and package them in airtight, resealable plastic bags, then place in the freezer. Another storage method is drying the basil (although some of the flavour will be lost). Pinch off the leaves at the stem and place them in a well-ventilated and shady area. After 3 to 4 days, if the plants are not completely dry, place them in the oven on the lowest heat setting with the door slightly open. Remember to turn the leaves (for equal drying) and check them frequently.

Variants

Cinnamon basil, to add a hint of cinnamon to a dish. Purple basil, to add some nice colour to your garden (when steeped in white vinegar, it creates a beautiful colour) Thai basil, to add a sweet liquorice flavour to a dish.

Other Tips

Basil has a lovely fragrance. Pick from the stems and put in water for a few days as you would cut flowers!

Introduction Chives are a perennial member of the onion family that sport beautiful purple flowers. Here's how to grow chives in your garden! Chives are cool-season, cold-tolerant perennials that are planted in early spring. Be mindful when planting this herb, as it will take over your garden if the flowers are left to ripen (the flowers scatter the seeds). However, this plant is easy to dig up and moved if it overwhelms your garden.

Planting

Chives prefer full sun. Soil needs to be moist, fertile, rich, and well-draining. Before planting, incorporate 4 to 6 inches of well-composted organic matter. Apply 2 to 3 tablespoons of all-purpose fertilizer (16-16-8) per square foot of planting area. Work compost and fertilizer into the soil to a depth of 6 to 8 inches. For a head start, start the seeds indoors 8 to 10 weeks before the last spring frost. (See local frost dates.) Transplants need good growth before being set in the garden. If you are growing from seed, sow as soon as the soil is workable in the spring. For the best growth, the soil should be around 60° to 70°F. Plant seeds ¼ inch deep and final plant spacing should be 4 to 6 inches apart in all directions.

Care

It is important to give chives consistent watering throughout the growing season for high yields. Moisten the soil thoroughly when watering. Use mulch to conserve moisture and keep the weeds down. For good production, sidedress with fertilizer in May and July with 1 teaspoon of 21-0-0 per square foot. Minimal care is needed for fully grown plants. After the flowers bloom, be sure to remove them so that the seeds aren't spread throughout your garden. Plants grow to be 12 to 24 inches tall and may spread a foot across. Remember to divide the plants every 3 to 4 years in the spring. Chives are much more productive if divided regularly. Allow divided plants to grow for several weeks before harvesting.

Pests / Diseases

- Bulb rots (caused by soilborne fungi)
- White Rot
- Mildew
- Rust
- Smut
- Various fungal leaf spots (such as purple blotch and gray mould)
- Onion Fly
- Thrips

Harvest / Storage

Harvest chives 30 days after you transplant or 60 days after seeding. Be sure to cut the leaves down to the base when harvesting (within 1 to 2 inches of the soil). Harvest 3 to 4 times during the first year. In subsequent years, cut plants back monthly. The chive plant will flower in May or June. (The flowers are edible.) Use chives when they're fresh or frozen (freeze the leaves in an airtight bag). Dried chives lose their flavour. Store chives in a cool place in a resealable container.

Variants

Other Tips

- In the garden, plant chives next to carrots.
- Bunches of chives hung in the home were used to drive away diseases and evil.
- Garlic chives, to add a mild garlic flavour to any dish

Introduction	In July and August, we harvest the garlic we planted last fall. Garlic produces numerous bulbs after a long growing season. In October, we'll plant garlic anew! See our tips on both planting and harvesting garlic. It's so easy to grow—and frost-tolerant, too! Beyond its intense flavour and culinary uses, "the stinking rose" is also good in the garden as an insect repellent and has been used for centuries as a home remedy.

13 Aloe Vera

The aloe vera plant is an easy, attractive succulent that makes for a great indoor companion. Aloe vera plants are useful, too, as the juice from their leaves can be used to relieve pain from scrapes and burns when applied topically. Aloe vera plants have thick, variegated leaves that fan out from the plant's central stem. Keep the aloe vera plant in a pot near a kitchen window for everyday use. Please note: Aloe vera leaves should not be ingested by humans or pets. They can cause unpleasant symptoms and may be toxic in larger quantities.

Planting

Before Planting
Select a container that's about as wide as it is deep. If your aloe plant has a stem, choose a container that is deep enough for you to plant the entire stem under the soil. A pot made from terra-cotta or a similarly porous material is recommended, as it will allow the soil to dry thoroughly between waterings and will also be heavy enough to keep the plant from tipping over. A plastic or glazed pot may also be used, though these will hold more moisture. When choosing a container, be sure to pick one that has at least one drainage hole in the bottom. This is key, as the hole will allow excess water to drain out. Use a well-draining potting mix, such as those made for cacti and succulents. A good mix should contain perlite, lava rock, coarse sand, or all three. Aloe vera plants are hardy, but a lack of proper drainage can cause rot and wilting, which is easily the most common cause of death for this plant. A layer of gravel, clay balls, or any other "drainage" material in the bottom of the pot is not necessary. This only takes up space that the roots could otherwise be using. A drainage hole is drainage enough! (Optional) To encourage your aloe to put out new roots after planting, dust the stem of the plant with a rooting hormone powder. Rooting hormone can be found at a local garden or hardware store, or online.

Planting
If your aloe plant has grown leggy, has gotten too large, or simply needs an upgrade, it's time to re-pot it. Here's how:

1	Prepare your pot. After giving the new pot a quick rinse (or a good scrub, if it's a pot you've used before) and letting it dry thoroughly, place a small piece of screen over the drainage hole; this will keep the soil from falling out the bottom and will allow water to drain properly. A doubled-up piece of paper towel or newspaper can also work in a pinch, though these will break down over time.
2	Prepare your plant. Remove the aloe vera plant from its current pot and brush away any excess dirt from the roots, being careful not to damage the roots. If your plant has any pups, remove them now. (See the "Care" section of this page for instructions on removing and potting pups.) If your plant has a very long, spindly stem that won't fit in the pot, it is possible to trim the stem off partially. Note that this is risky and could kill the plant. To trim the stem: Cut off part of the stem, leaving as much as possible on the plant. Next, take the bare plant and place it in a warm area that gets indirect light. After several days, a callous will form over the wound. At this point, continue with the repotting instructions below.
3	Plant your plant. Fill the pot about a third of the way with a well-draining potting mix, then place your plant in the soil. Continue filling in soil around the plant, bearing in mind that you should leave at least ¾ of an inch of space between the top of the soil and the rim of the pot. The bottom leaves of the aloe plant should rest just above the soil, too. Do not water after planting.
4	Ignore your plant (temporarily). After you've placed your aloe in its new pot, don't water it for at least a week. This will decrease the chance of inducing rot and give the plant time to put out new roots. Until the plant seems to be rooted and happy, keep it in a warm place that receives bright but indirect light.

Replanting
Mature aloe vera plants often produce offsets—also known as plantlets, pups, or "babies"—that can be removed to produce an entirely new plant (a clone of the mother plant, technically).
1. Find where the offsets are attached to the mother plant and separate them using pruning shears, scissors, or a sharp knife. Leave at least an inch of stem on the offset.
2. Allow the offsets to sit out of soil for several days; this lets the offset form a callous over the cut, which helps to protect it from rot. Keep the offsets in a warm location with indirect light during this time.
3. Once the offsets have formed callouses, pot them in a standard succulent potting mix. The soil should be well-draining.
4. Put the newly-potted pups in a sunny location. Wait at least a week to water and keep the soil on the dry side.

Care

Place in bright, indirect sunlight or artificial light. A western or southern window is ideal. Aloe vera does best in temperatures between 13-27°C (55-80°F). Water aloe vera plants deeply, but infrequently. To discourage rot, allow the soil to dry at least 1 to 2 inches deep between waterings. Don't let your plant sit in water. Water about every 3 weeks and even more sparingly during the winter. Use your finger to test dryness before watering. If the potting mix stays wet, the plants' roots can begin to rot. Fertilize sparingly (no more than once a month), and only in the spring and summer with a balanced houseplant formula mixed at ½ strength. Re-pot when root bound, following the instructions given in "Planting," above.

Pests / Diseases

Aloe vera plants are susceptible to common garden pests, such as mealybugs and scale. Avoid overwatering to keep these conditions from developing.

Common Diseases
● Root rot
● Soft rot
● Fungal stem rot
● Leaf rot

Harvest / Storage

To make use of the aloe vera plant's soothing properties, remove a mature leaf from the plant and cut it lengthwise. Squeeze the gel out of the leaf and apply it to your burn, or simply lay the opened leaf gel-side–down on top of the affected area.

Variants

● Tiger or Partridge-Breasted Aloe (Aloe variegata) – A compact aloe characterized by short, spiky leaves with white stripes.
● Lace Aloe (Aloe aristata) – A small plant with white-spotted, finely sawtoothed leaves.
● Blue Aloe (Aloe glauca) – A larger aloe species with silver-blue leaves.

Other Tips

Aloe vera will decorate a kitchen shelf with quiet grace while doing double duty as a self-regenerating first-aid kit. Read more about the natural health benefits of aloe vera. One of aloe's most famous uses is to soothe sunburnt skin, and it can be also used for cold sores.

Pests

Staying on Top of Pests

Keep your eyes open when you are weeding and you may be surprised by the kinds of pests you find. Look for tell-tale signs like holes in leaves, egg masses, and webs. Leaf miners tunnel between leaf layers in chard, spinach, lamb's quarters, and beet greens leaving a light green meandering trail behind. Often you don't notice them until you cook up the greens and find a lot of tiny worms.

Cutworms are one of the many critters that do their dastardly deeds at night. In the morning you'll find plants chewed off at the soil line leaving only stubs behind. Sometimes if you dig around the base of the plants you'll find a fat cutworm sleeping it off and you can remove him from the premises in any way you choose.

Another night time visitor is the slug. If large ragged holes are appearing in your hostas and petunia leaves, the slugs have been dining there. The only tip they leave are the silvery trails of dried mucus they slid out on. We've all seen green aphids on plants in the springtime, but every summer we get a crop of red aphids on our heliopsis plants. They are easy to dislodge with a strong spray of water and usually don't come back.

Flea beetles are tiny black hoppers that eat small holes in the leaves making them look like they have been hit with mini-buckshot. Their larvae, white grubs with brown heads, are 3/4 inch long - much larger than the adults. They live in the soil and eat plant roots.

Make sure to check for asparagus beetles during the summer. There are two kinds. One is black and white and appears very early in the spring. The other one is bright orange and it is active right now (mid-summer), laying eggs on the fronds which hatch into fat slimy worms that hungrily defoliate the plants. Like many beetles they tend to drop when disturbed so stick a small container of soapy water under them and shake the frond a bit and they will fall right into it. The larvae cling on tighter and have to be squished.

Female Mexican bean beetles can lay over 500 eggs. If your bean leaves are being skeletonized check the underside for clusters of yellow eggs and crush them. Handpick the beetles or knock them into a bucket of soapy water and squish or drown the spiny yellow larvae.

Colorado potato beetles will not only eat potatoes but other nightshades as well including tomatoes, eggplants, peppers, and petunias. Like the bean beetles they lay masses of yellow eggs on the undersides of the leaves. When the brick red larvae hatch they eat large amounts of foliage. By now you know the drill—handpick the adults and squish or drown them and their offspring.

Deer-Resistant Plants

Do you have problems with deer eat your garden plants? See our list of deer-resistant plants, flowers, and shrubs to keep the hungry herds away from your garden! Deer love narrow-leafed evergreens, especially arborvitae and fir, and show a particular preference for hostas, daylilies, and English ivy, according to researchers from the University of Rhode Island, who have studied white-tailed deer damage to nurseries in the Northeast. They report that the heaviest browsing occurs from October through February, when food is naturally scarce. Deer seem to prefer plants that have been fertilized to those that haven't.

Dislikes

- Not surprisingly, deer tend to stay away from poisonous plants. Daffodils, foxgloves, and poppies are common flowers that have a toxicity that deer avoid.
- Deer also turn their noses up at fragrant plants with strong scents. Herbs such as sages, ornamental salvias, and lavender, as well as flowers like peonies and bearded irises, are just "stinky" to deer.
- Would you want to eat something prickly? Neither do deer (unless they're desperate). Plants such as lamb's ear are not on their preferred menu.
- One our favourite deer-resistant perennials are bleeding hearts (Dicentra spectabilis). They are popular with us, but not deer!

Keeping in mind that the first rule in deer-proofing is that there are really no completely deer-proof plants, here is a chart with some plants that deer rarely or seldom severely damage:

● Yarrow ● Zinnia ● Monkshood ● Ageratum ● Onion ● Pine ● Snapdragon ● Horseradish ● Tarragon ● Silver Mound ● Jack-in-the-pulpit ● Wild Ginger ● Asparagus ● Aster ● Astilbe	● Common Boxwood ● Anise ● Cactus ● Pot Marigold ● Blue Mist Shrub ● Dusty Miller ● Bachelor's Buttons ● Spider Flower ● Autumn Crocus ● Larkspur ● Lily of the Valley ● Lamb's Ear ● Threadleaf Coreopsis ● Corydalis ● Broom	● Wood Fern ● Purple Coneflower ● Small Globe Thistle ● Bluebell ● Winer Aconite ● Buttercup ● Spurge ● Blue Fescue ● Crown Imperial, Fritilia ● Common Lilac ● Common Tansy ● Baby's Breath ● Strawflower ● Heliotrope ● Hyssop	● Juniper ● Lantana ● Lavender ● Statice ● Sweet Alyssum ● Snowdrops ● Horehound ● Lemon Balm ● Mint ● Bee Balm ● Forget-Me-Not ● Bayberry ● Daffodil ● Catmint ● Basil	● Poppy ● Russian Sage ● Dwarf Alberta Spruce ● Lenten / Christmas Rose ● Allegheny Serviceberry ● Snow-on-the-Mountain ● Cinquefoil ● Fragrant Sumac ● Rosemary ● Black-Eyed Susan ● Rue ● Willows ● Garden Sage ● Peony ● Germander	● Barberry ● Borage ● Butterfly Bush ● Thyme ● Daphne ● Bleeding Heart ● Common Foxglove ● Yucca ● American Holly ● Winterberry Holly ● Iris ● Arrowwood Viburnum ● Fern ● Pachysandra

Fungus Gnats

Often considered only a minor houseplant pest, fungus gnats can quickly become a major issue if an infestation gets out of hand. Here's how to identify, get rid of, and prevent fungus gnat infestations in your plants. Fungus gnats are a fruit fly–sized insect pest that primarily affects indoor houseplants. Attracted to the moisture of potting soil, adult gnats lay their eggs (up to about 200) on organic matter near the soil surface.

After about three days, the eggs hatch into larvae, which burrow into the soil to feed on fungi and decaying plant material. Two weeks after that, adult gnats emerge from the soil to repeat the process. Adults live for about one week. Fungus gnats are completely harmless to humans, since they can't bite and don't spread diseases. They can be a problem for houseplants, however, when their population explodes and their larvae starts to feed on plants' roots.

Plants Affected
- Spider Plants
- African Violets
- Peace Lilies
- Geraniums
- Wandering Jew

Fungus gnats may also spread Pythium, a group of plant pathogens that causes "damping off" in seedlings. Once you have a fungus gnat infestation, using consistent management and prevention techniques is key to ending it. Further down on this page, we've listed a few of the best ways to both get rid of adult gnats and prevent new gnats from emerging. Once you have a fungus gnat infestation, using consistent management and prevention techniques is key to ending it. Further down on this page, we've listed a few of the best ways to both get rid of adult gnats and prevent new gnats from emerging.

Size	Adult fungus gnats are tiny. Their size ranges from about 1/16 to ⅛ of an inch in length (1.5 to 3mm), which is about the same size as a fruit fly. Fungus gnat larvae may be up to ⅛ of an inch in length.
Appearance	Adult fungus gnats are a greyish-black colour and have gray or see-through wings. Their long legs and long antennae give them a mosquito-like appearance, though they are much, much smaller in size. Compared to a fruit fly, fungus gnats have a thinner body with longer legs and antennae. Larvae have a small, black head and a thin, white or see-through body.
Activity	Fungus gnats tend to spend most of their time on the soil surface of potted plants, but they may be seen flying around the outer edge of the pot or near drainage holes as well. They are not strong fliers, so they have a tendency to walk along the soil and fly only in short bursts. Their flight is erratic and they are much slower than fruit flies, acting more like mosquitoes while flying. Annoyingly, fungus gnats have a tendency to fly into people's faces and drinks, though they are completely harmless and a few well-placed swats will show them what's what.
Damage	In small numbers, fungus gnats are more of an annoyance than anything. In fact, the adult gnats don't actively harm plants nor people. If their population gets out of hand, however, the larvae may start feeding on plant roots, causing notable damage. This is especially bad for young plants, such as seedlings, which have only a few delicate roots. Fungus gnats are also capable of spreading the plant pathogen that causes damping off and the eventual death of seedlings. Fungus gnat damage will appear similar to that of any other root-related issue, such as root rot. Lower leaves may turn yellow and drop, and the plant's growth may slow down or stop completely. In particularly bad cases, wilting of the entire plant could occur, followed by the death of the plant if roots are extremely damaged.
Removal	Getting rid of fungus gnats is all about consistency. Catching the adults is fairly easy, but because the adult population comes in cycles, you need to make sure that your traps are refreshed regularly. For the best results, use a combination of the traps listed here as well as the additional preventative methods listed in the subsequent section.

Sticky Cards	These traps consist of a yellow note card covered in a sticky adhesive. They are most effective when cut into small squares and placed directly on top of the soil or attached to skewers just above the soil. Adult gnats will fly or crawl onto the card and become trapped. Fungus gnats are attracted to the colour yellow, so use the yellow sticky cards rather than the blue ones. Both can be bought at most hardware or garden stores, as well as online.
Cider-Vinegar Traps	Simple and effective, cider-vinegar traps consist of a shallow container with a small amount of apple cider vinegar, water, and liquid dish soap. Make a cider-vinegar trap: Find a shallow container—a tuna can is perfect—and fill it with equal parts water and apple cider vinegar. (The liquid should be at least ¼-inch deep.) Put a few drops of liquid dish soap into the mixture and stir gently. Place the trap near the base of the affected plant or, ideally, inside the pot on top of the soil. Check it every few days to refresh with new vinegar and water.
Diatomaceous Earth	Diatomaceous earth (DE) is an organic, abrasive powder that works well on fungus gnats. The powder sticks to the gnats, dehydrating and immobilizing them. Use "food-grade" DE, which is available at most garden and hardware stores. To use DE: Dust the soil surface with DE, especially around the inside edges of the pot and the base of the plant. DE should only be applied when the soil is dry—otherwise, it will soak up moisture and won't stick to the gnats. In our experience, using DE on top of a layer of sand and watering from the bottom of the pot has been most effective.
Flypaper	Flypaper ribbons, such as those hung in horse barns to catch outdoor flies, can also be used to catch fungus gnats. However, these traps are usually overkill for gnats and can easily get stuck to things you don't want them to stick to, such as furniture, hair, plants, and so on.
Keep Soil Dry	Fungus gnats seek out moist soil, so allowing your houseplants to dry out a bit between waterings can slow down or stop an infestation. Let the top inch or two of soil dry out before watering again, and try to go as long as possible between waterings. Gnats may be deterred from laying their eggs if the soil is dry on the surface.
Mosquito Dunks	Mosquito dunks are used to keep mosquito larvae from populating fountains, animal troughs, fish ponds, and other small bodies of water. The product consists of a dry pellet containing a type of bacteria called Bacillus thuringiensis subspecies isrealensis. This beneficial bacteria infects and kills the larvae of flying insects, including mosquitoes, fruit flies, and fungus gnats. To use mosquito dunks: Fill up a gallon jug (or watering can) with clean water and toss in a mosquito dunk. It's a good idea to break up the dunk a bit before placing it in the water, or you can wait for it to soften before breaking it apart. Let the dunk soak in the water for as long as possible (at least overnight), then remove it from the water (the dunk can be reused) and use this water for fungus gnat–infested plants. The bacteria will have leeched into the water and will now infect and kill any larvae that come into contact with it in the soil. Repeat this process every time you water your plants for at least a few months.
Sand Layer	Put a half-inch layer of coarse sand on top of your houseplant's soil to stop adult gnats from laying eggs and new gnats from emerging from the soil. Consistent coverage is key. Be sure to water from the bottom of the pot, too; otherwise the sand will just wash away.
Cover Drainage Holes	Though gnats typically remain near the tops of pots, they may find their way to the drainage holes on the underside of a pot and start laying eggs there, too. If this happens, cover the drainage holes with a piece of synthetic fabric to prevent the gnats from getting in or out of the hole, but to also let water pass through freely. Attach with tape or rubber bands.

Slugs

Slugs are very damaging garden pests that can be found throughout the country, most likely in moist and humid climates. Your garden is likely to have more slugs during a particularly rainy season. Slugs are not insects, rather, they are soft-bodied molluscs. Slugs never change, because they are members of the phylum Mollusca, along with the giant squid, the periwinkle, and the steamer clam. Unlike seagoing molluscs, the slug is equipped with a single lung. Its shell is lacking or represented only by a small plate, but it does not seem to mind.

Slugs are hermaphroditic, with each individual having both male and female reproductive organs. As you would expect, their love life is complex. The common gray garden slug dances an elaborate, hour-long nuptial waltz before mating, while other species perform acrobatic movements while hanging suspended from threads of slime.

- Most garden slugs are gray to dark brown and about one-inch long. They will hide in dark, damp places during the day.
- Many people are prompted to ask, "Where do slugs come from?" This is because they are hard to spot in the soil due to their dark colour, but also because they only feed at night and hide throughout the day. If you realize you have slug damage but can't find the slugs, you're not alone.
- Slugs will leave a slimy secretion where they have been, so even if you can't spot them, you'll know they are there. Look for slime both on plants and surrounding soil. It is easiest to see the trails of slime first thing in the morning.
- You can monitor slug activity in your garden by digging holes that are four inches wide and six inches deep. Cover these holes with a board, and then check for slugs after three days. If you see many of them, these might be the sneaky pests that are eating your plants!
- Slugs lay their eggs in moist soil or compost. Their populations can grow rapidly in cool and moist conditions.

What do slugs eat? They will feed on almost anything in the garden—look for holes and ragged edges on leaves and stems. The holes should have irregular shapes due to their file-like mouthparts. Small seedlings can be consumed entirely.

Slugs can digest tissues from most plants, but you might find them especially liking your beans, lettuce, cabbage, and tomatoes.

Removal

- You can create the perfect slug trap by laying boards or pieces of cardboard on the bare soil around your plantings. Each morning, turn the boards over and scrape the hiding garden slugs into large plastic containers. Cover and place in freezer for three hours. When frozen stiff, dump them on your compost pile.
- Place shallow dishes of beer around the garden to lure the slugs to a drunken death. Or mix water with molasses, cornmeal, flour, and baking yeast to replace the beer. These are both great slug baits that can help control your garden slug population.
- Some slugs are a bit beer-resistant and might crawl out of the dish. If you find this happening, try creating a beer trap that they can't escape from: Cut the spout end off a plastic beverage bottle just where it reaches the fattest diameter. Now, turn the pour-spout around so that it's pointing inside the bottle and fasten it with staples or duct tape. Pour a little beer into the bottle (add extra yeast, if desired) and lay it on its side in the garden.
- If necessary, get out and handpick the little rascals—a task best undertaken in the evening twilight or in the early light of dawn, before they have sought shelter from the heat of the day.

- If you need a slug repellent to keep slugs away from tender plants, circle them with wood ashes (which are also a good source of potassium for your plants), diatomaceous earth, copper sheeting, coffee grounds, pine needles, coarse sand, or crushed eggshells. These rough mulches rip up a slug's tender underside.
- Alcohol kills these pests by acting as a surfactant, or wetting agent, that can penetrate an insect's waxy coat of armour and kill on contact with the body. Isopropanol (rubbing alcohol) works fine and is easy to find, but be sure it doesn't have additives. Ethanol (grain alcohol) seems to work best. Alcohol usually comes in 70 percent strength in stores (or 95 percent strength purchased commercially). To make an insecticidal spray, mix equal parts 70 percent alcohol and water (or, if using 95 percent alcohol, mix 1 part alcohol to 1 ½ parts water).
- A spray of cold coffee can control small slugs, but it must completely drench them to be effective.
- Some plants have been shown to do well despite being around slugs. If you tend to have slugs and are having trouble getting rid of them, try planting astilbe, phlox, or mint to reduce damage.

Prevention
● It is helpful to rake your garden in early spring in order to clean up some of the moist debris that slugs love, as well as to rake away any slug eggs. Large wood chips also provide hiding areas for slugs, so try not to use them.
● Only water your garden when necessary so as to minimize the damp places in which slugs congregate.
● Slugs have many natural predators. If you have chickens or ducks, they will help by eating slugs and their eggs. Also, be sure to encourage the populations of snakes, turtles, frogs, toads, and ground beetles in your garden. The same goes for songbirds, so check out our tips on creating a bird-friendly habitat.
● Slugs experience a small shock when exposed to copper, which will make them turn back. Try making a perimeter around your plants with copper tape.

Voles

Voles drive gardeners and home owners crazy! You'll know voles by the snakelike tunnels all over your lawn. Here's advice on how to identify, prevent, and control your vole population. First off, voles are not moles! People confuse the two animals because they both tunnel through your yard. You might not have seen either critter since they're usually underground, but they look very different. Voles (Myodes) are small, stocky rodents similar to field mice. In fact, a vole might look like a mouse at first glance. In contrast, moles are NOT rodents. Moles are all nose and mouth. And they have big feet used in digging!

Voles have small rounded ears that are often hidden by their fur, small eyes, and short tails. Their fur is generally thick and light brown to gray. Two common species of voles in North America are the prairie vole and the meadow vole. Meadow voles are more widely distributed, but prairie voles are more common in prairie areas. They are very similar, and methods for controlling them are mostly the same.

Voles, similar to other rodents, have a mainly vegetarian diet. Voles mainly eat stems and blades of lawn grass—so it's usually vole tunnels that you'll see near the surface of the yard. Moles have a mainly carnivorous diet. (Moles are beneficial in many ways. They help plow the soil and eat grubs and insects!)

It's helpful to know this difference not only because it will help you identify the damage but also because a vole bait would use peanut butter whereas moles would be more interested in an insect or earthworm. If it helps, remember that their frenzied activity does subside. Vole populations cycle, and about every 3 to 5 years there will be a population boom. Mild winters with good snowfall can help to increase vole populations.

Identification	You'll know voles by the shallow snake-like tunnels that you'll see all over your lawn. The tunnels are about two inches wide and very near the surface so they can eat their favourite food, grass stems and blades. Voles are especially manic in the early springtime. Moles, on the other hand, have deeper feeding tunnels that they use as a network. They do have secondary runways that appear on your lawn's surface, however, they look more like raised ridges and have little volcano-shaped mounds. Voles leave no mounds behind.

You'll also be able to identify voles by the type of damage. Remember: It's the voles who are plant eaters.
● If you have partially eaten carrots, potatoes, or other root vegetables, you probably have a vole problem. According to one reader, "They dig under my carrots, pulling them down, and eating them. There's just a row of holes where the carrots were. Kind of amusing, like a bugs bunny cartoon. They're a real pest this year."
● Voles also eat flower bulbs from below the ground as they're near the surface.
● If you see chewed-up bark near the base of trees and shrubs, look closely. A vole's front teeth will leave ¼ inch side-by-side grooves in the wood as it gnaws away on the bark.

Prevention	Make your yard inhospitable to voles! Prevention is very important to keep vole numbers down. ● Voles like dense, heavy vegetative cover, weeds, and meadows because it provides them with protection from predators and provides nesting material. Cut back brush, mow, weed, and create a clean space. ● Remove woodpiles and hiding places for voles from near your garden, shrubs, and trees. ● Keep your lawn mowed and bushes trimmed up from the ground. ● Avoid putting dense mulch too close to trees and shrubs. ● Keep snow cleared from the base of trees and shrubs. Protect young trees by wrapping the lower trunk with a guard.

Removing Voles
● In small areas, trapping may be an effective way of reducing vole populations. Try Havahart live vole traps situated perpendicular to the widest vole runways or near the nesting sites at the base of trees and shrubs. Bait traps with peanut butter. Set baits midday to early evening when voles get more active. Reset the traps as often as necessary until you eliminate the population. Relocate voles if it's legal where you live. The key to trapping is persistence. You may want to cover the traps so that pets and children do not accidentally find them.
● Large vole populations have been effectively reduced with toxic baits. There are some pesticides available for home use. Be sure to read the label before you buy any pesticide and again before use. Vole baits should be placed inside bait stations to reduce the risk of non-target species ingesting the bait. Most pesticides recommended for voles are restricted and can only be used by Certified Pesticide Applicators.
● Some readers have suggested a variety of irritants sprinkled into vole tunnels (from natural to chemical): cayenne powder, garlic, onion, castor oil, a little nitrogen fertilizer, moth balls, and ammonia. In many cases, these ingredients can be mixed with water or soapy water and put in a spray bottle. However, you need to reapply ever time it rains.
● Repellents have mixed results and need to be reapplied after it rains. Garden stores sell fox or coyote (predator) urine which usually turns off voles. (You can also pee in your own yard!)
● Bulb control? You can discourage voles from nibbling on bulbs by adding gravel to the planting hole (surrounding the bulbs). When you plant bulbs, drench or powder them with a fungicide to keep voles at bay. Plus, check our list of rodent-proof bulbs.
● Voles in the veggie garden? These little critters aren't very good climbers. Protect plants by fencing the area with a half-inch of mesh (hardware cloth), at least 12 inches above the ground and buried 6 to 10 inches deep.

Tomato Hornworms

Big, fat, and green! Here are tips on how to identify, control, and get rid of tomato hornworms in your garden. If you've ever grown garden tomatoes, chances are you have dealt with these green caterpillar pests. They can be found in most any region of the US and can ruin your tomato crop in record time; they also feed on eggplants, peppers, and potatoes. They can blend in quite easily with the green foliage and feed non-stop, creating spotty and chewed leaves and fruit.

Tomato hornworms live according to the following life cycle:
● In late spring, large adult moths lay eggs on the undersides of foliage, which will hatch within a week.
● Caterpillar larvae will feed from 4–6 weeks before creating a cocoon for overwintering in the soil. If the weather is warm enough, larvae may only burrow for as little as 2–3 weeks.
● Moths will emerge in the spring, and will then lay eggs once again. More than one generation a year may be possible in warmer climates.

Identification

Tomato hornworms can be up to 5 inches long—which can be quite a shock when you first come across one! They do the most damage in the caterpillar, or larval, stage. They are pale green with white and black markings, plus a horn-like protrusion stemming from their rear. (Don't worry, they aren't able to sting!) The caterpillar also has eight V-shaped stripes on its green body. Tomato hornworms come from a mottled brown-gray moth.

The larvae blend in really well with the plant greenery. Just get used to a daily patrol, looking for hornworm eggs and small caterpillars. Here are some cues of infestations:
● Look closely at the TOP of your tomato leaves for dark green droppings left by the larvae feeding on the leaves. Then look at the underside of leaves and you'll find a hornworm.
● Look for stems missing some leaves and wilted leaves hanging down. You may find white cocoons and their hornworm hosts nearby.

There are a few species of hornworms that inhabit North American gardens, including tomato hornworms (Manduca quinquemaculata) and tobacco hornworms (Manduca sexta). Both species feed on common garden plants like tomatoes, potatoes, peppers, and eggplants. Here's how to tell which caterpillar is which:
● Tobacco hornworms have parallel white stripes; tomato hornworms have white V–shaped markings.
● Tobacco hornworms have black spots lining each of their stripes; tomato hornworms do not.
● Tobacco hornworms have a red "horn" on their tail end; tomato hornworms have a black horn.

If you see leaves with large holes and severe defoliation, devoured flowers, and/or scarring on fruit surfaces, you have tomato hornworms. The fruit also might be damaged by sunscald because of the reduced foliage.

Prevention

Handpicking is an excellent tactic for control if you have the time and patience, or a small garden. The caterpillars are not dangerous and cannot sting. If you are squeamish about crushing these large insects, drop them into soapy water instead (or feed them to your chickens, if you've got a flock).

If the hornworm population or the area of your garden is too large, insecticides can be a useful control. You can use the organic pesticide Bt (Bacillus thuringiensis), which is a bacterium that acts as a stomach poison on some insects (but doesn't harm other plants or animals). Please check with your local Cooperative Extension for a list of approved insecticides in your area.

● Till soil at the beginning and end of each gardening season to destroy overwintering larvae. Tillage has shown to cause up to 90% mortality.
● To keep hornworms away from your tomato plants next year, try interplanting dill or basil; marigolds are also an excellent companion plant and keep many pests away.
